Volume 1

Green Cities, Clean Waters (CSO LTCP Update) Advisory Committee
Invitation Packet

September 26, 2007

Re: Invitation to Join PWD's Green Cities – Clean Waters Advisory Committee

Dear Potential Committee Member:

The Philadelphia Water Department (PWD) is beginning a two year process to update its Combined Sewer Overflow Long Term Control Plan (CSOLTCP). To assist us with the development of strategies, public information and outreach materials regarding this plan, we are convening a public advisory committee to guide and provide input about the program and the communication strategies that will be developed to ensure successful public participation. We are hoping that you are interested in joining this committee, as the perspective that you will provide, as a representative of your organization and/or neighborhood, will be invaluable.

You are invited to participate in the first advisory committee meeting, scheduled for Tuesday, November 13, 10 a.m. to 12 p.m., at the Fairmount Water Works Interpretive Center. This meeting will focus on providing advisory committee members with a background on PWD's approach to meeting the requirements (and our own goals for our region's rivers and streams) of the National CSO Policy, a general assessment of the City's combined sewer system, and a timeline for future meetings and meeting topics. We expect that the advisory committee will meet twice a year over a two year period (although advisory committee members would certainly be welcome at all CSO Long Term Control Plan Update (LTCPU) public meetings).

I have enclosed two backgrounders – one on the LTCP and one on the LTCPU - to give you a sense of the program and the elements we will be striving to share with the public. I have also enclosed the directions to the Fairmount Water Works Interpretive Center.

Please give me a call at 215-685-4944 or e-mail me at joanne.dahme@phila.gov with questions and to confirm your attendance at the first advisory committee meeting. We look forward to working with you to make this an exciting public process.

Sincerely yours,

JOANNE DAHME
Watersheds Programs Manager

THE CSO LONG TERM CONTROL PLAN

GREEN CITIES
CLEAN WATERS

History and Background

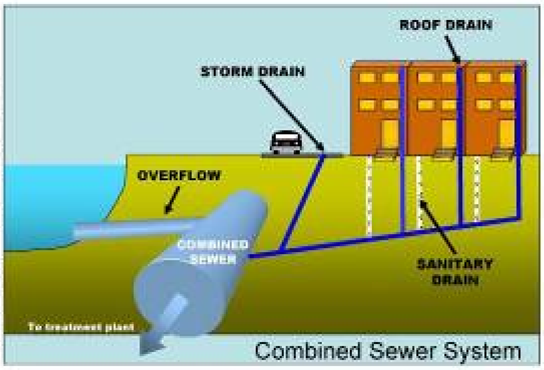
The City of Philadelphia

INTRODUCTION

Philadelphia is fortunate to have an abundance of creeks, open space, parkland and beautiful rivers. The Schuylkill and Delaware Rivers are not only scenic; they are the drinking water source for Philadelphia residents. These waterways, however, suffer from pollution from various sources, both within and outside the City limits. One such pollution source: Combined Sewer Overflows (CSOs)*.

What are Combined Sewers Overflows?

A combined sewer system is a wastewater collection system owned by a municipality which transports wastewater* from homes, businesses and industry, stormwater* from the approximately 75,000 storm drains on our streets and property roof leaders through a single-pipe system to a Water Pollution Control Plant (WPCP).



Combined Sewer System

During dry weather conditions (when it is not raining) and during very small storm events, combined sewers* can adequately transport this mixture of sanitary wastewater and stormwater to one of the City's three WPCPs for treatment.

Under heavier rainfall conditions, however, the flow in combined sewers may exceed the capacity of the pipe or treatment facility. As a result, a portion of the wastewater and stormwater may be diverted directly to a nearby stream or river so as to prevent the flooding of homes and streets. This is what is known as a Combined Sewer Overflow (CSO). During heavy rainfalls or sudden snowmelts, Philadelphia may experience these overflows in various locations throughout the City from any of its 164 permitted combined sewer outfalls. These overflows may exceed water quality standards (WQS)*, threaten aquatic life and habitat, and impair the use and enjoyment of the water body.

The definitions of words with an asterisk* can be found in the glossary at the end of this publication.

CSO outfalls in the City of Philadelphia

What is the Combined Sewer Overflow Program?

The fundamental goal of the Philadelphia Water Department's (PWD) combined sewer overflow program is to improve and preserve the water environment in the Philadelphia area and to fulfill the PWD's obligations under the Clean Water Act and the Pennsylvania Clean Streams Law by implementing technically viable, cost-effective improvements and operational changes.

The PWD's strategy to attain these goals has three primary phases: aggressive implementation of a comprehensive program for Nine Minimum Controls (NMCs); planning, design and construction of numerous capital projects that would further enhance system performance and reduce CSO volume and frequency; and a commitment of significant dollars for services and resources toward comprehensive watershed based planning and analyses that would identify additional priority actions to further improve water quality in Philadelphia area water bodies.

These three phases successively provide comprehensive programs that follow the direction of the EPA CSO Policy and its guidance documents and are consistent with the requirements of the Clean Water Act. The NMCs and the capital improvement program have resulted in implementation of the highest level of cost-effective, technology-based improvements. They have provided a substantial reduction in CSO volume and frequency and a significantly greater percentage of combined sewer flow transported and treated at the PWD's three wastewater treatment plants.

Combined Sewer Overflow at Crescentville in Philadelphia

Nine Minimum Controls (NMCs) System "Tune-Up"

In the first phase of the PWD's CSO strategy, and in compliance with its National Pollutant Discharge Elimination System (NPDES)* permits, the PWD submitted to the Pennsylvania Department of Environmental Protection (PADEP) on September 27, 1995, CSO Documentation: Implementation of Nine Minimum Controls (NMCs).

The NMCs are low-cost actions or measures that can reduce CSO discharges and their effect on receiving waters*, do not require significant engineering studies or major construction, and can be implemented in a relatively short time frame. This program ensures that our existing sewer system is operating to the best of its ability, providing a "tune-up" to the existing infrastructure.

To provide information needed for the development of the NMCs program, the PWD instituted a $6.5 million project to upgrade its comprehensive system flow monitoring network. This program provides information necessary to identify and eliminate dry weather overflows, monitor system performance and operation, and configure and calibrate computer hydraulic models needed to develop the NMCs and long-term CSO control plans.

Extensive data from the PWD's Geographic Information System (GIS), flow monitoring system, the U.S. Army Corps of Engineer's Storage, Treatment, Overflow, Runoff Model (STORM), and the EXTRAN and RUNOFF blocks of the U.S. EPA Stormwater Management Model (SWMM) were used to support each phase of the CSO program. These tools were developed to support concept engineering through implementation and post-construction monitoring. The monitoring system, models, and GIS have and will serve as the basis for planning improvements and enhancing operation of the sewerage system over the long-term.

For more details on the NMCs, please visit the U.S.EPA on-line at: http://cfpub.epa.gov/npdes/home.cfm?program_id=5.

Capital Projects
Design and Build New Combined Sewer System Components

The second phase of the PWD's CSO strategy had been focused on technology-based capital improvements to the City's sewerage system that have and will further increase its ability to store and treat combined sewer flow, reduce inflow to the system, eliminate flooding due to system surcharging, decrease CSO volumes and improve receiving water quality. The recommended capital improvement program is the result of a detailed analysis of a broad range of technology-based control alternatives. The capital improvement plan encompasses the three major areas of the City that are affected by CSOs: the Northeast, Southeast and Southwest drainage districts. Capital projects were selected by the PWD to provide significant CSO load reduction.

The total estimated cost of the selected capital improvement projects is in excess of $48 million. However, to date, current expenditures and estimates of future estimates bring this number to over $100 million. Hydraulic and hydrologic model simulations indicate that annual CSO volumes will be reduced by over two billion gallons system-wide in a typical hydrologic (average rainfall) year, upon completion of all these projects.

These significant, technology-based projects may not, in and of themselves, bring receiving waters into compliance with all water quality standards. Additional management plans, actions and projects needed to attain water quality standards will be defined through the process of watershed planning, as discussed below. However, these projects will not only reduce overall loadings, but will hopefully encourage other point* and non-point source* dischargers to implement similar technologies, over and above what their current permit mandates, while the development of a comprehensive watershed management plan proceeds.

For more details on the capital projects, please view the 2006 CSO Annual Report on-line at: http://www.phillyriverinfo.org.

Watershed Management & Watershed Partnerships - Integrated, Regional Watershed Planning & Implementation

The third component of the City's CSO strategy involves a substantial commitment by the City to conduct watershed planning to identify long term improvements throughout the watershed, including possibly additional CSO controls that will result in further improvements in water quality, and ultimately, the attainment of water quality standards. The need for this watershed initiative is rooted in the fact that insufficient physical, chemical and biological information currently exists on the nature and causes of water quality impairments, sources of pollution, and appropriate remedial measures. In addition, Philadelphia is downstream, meaning that the headwaters, some tributaries, and upper segments of our rivers and streams reside in municipalities north of Philadelphia. We do not always know the source, nor can we control stormwater runoff* or other pollutants* flowing into our streams above the city's boundaries. This creates a unique challenge in our goal to attain water quality standards, especially with respect to the effects of wet weather discharges and receiving water dynamics.

These watershed realities have led to a broader, national recognition of the need for regional, watershed-based planning and management to properly define water quality standards and goals. Therefore, the PWD has adopted a holistic approach – a watershed management approach to control pollution to rivers and streams. This approach evaluates the impacts of both point and non-point pollution sources and aims to find regional, watershed solutions to restore water quality. Because watersheds are defined by natural features and do not adhere to political boundaries, the PWD believes that watershed management is the most practical and effective way to manage pollution and improve water quality. Through PWD's watershed management plans, water quality impairments are identified and addressed via comprehensive watershed based planning, stream water quality analysis, baseline water quality monitoring and the assessment of watershed-wide pollutants. Consequently, the major sources of the impairments are explored, modeled, and defined to understand how to attain regulatory water quality standards and establish programs that will continue to monitor and ensure permanent improvements in water quality.

> A watershed refers to the land that drains stormwater (rain or melting snow) to a specific body of water, such as a river or stream.

The PWD forms partnerships with its suburban neighbors, businesses and industries, community and non-profit groups and all other watershed stakeholders to evaluate our regional watersheds and to develop an effective watershed management plan. To be successful, watershed management plans must be adopted and implemented by all participating stakeholders and their constituents.

To date, the PWD has initiated the formation of watershed partnerships in all of the City's watersheds. The combined sewer watersheds include the Darby-Cobbs Watershed Partnership, Tookany/Tacony – Frankford Watershed Partnership and Pennypack Watershed Partnership, while the separate sewer watersheds include the Poquessing Watershed Partnership and the Wissahickon Watershed Partnership. The Schuylkill Watershed is represented by the Schuylkill Action Network (SAN), a partnership of the City of Philadelphia, federal and state agencies, and local watershed groups protecting the drinking water supply in the Schuylkill River watershed. This fall, the remaining watershed partnership will be formed - the Delaware Direct Watershed Partnership.

Tacony Creek

*Glossary**

Combined Sewer Overflow (CSO)

A mixture of wastewater and runoff found in combined sewers during rainfall or snowmelt events that spills to the environment untreated. CSOs enter the environment either directly or through a storm sewer, as the result of the capacities of the interceptor sewers and/or treatment plants being exceeded.

Combined Sewer System (CSS)

A wastewater collection and treatment system where domestic and industrial wastewater is combined with storm runoff. Although such a system does provide treatment of stormwater, in practice, the systems may not be able to handle major storm flows.

Indirect Discharge

The introduction of pollutants into a municipal sewage treatment system fro any non-domestic source (i.e., any industrial or commercial facility) regulated under Section 307(b), (c), or (d) of the CWA.

Industrial Sources

Non-municipal, or industrial sources, often generate wastewater that is discharged to surface waters. The types of wastewaters generated at a facility depend on the specific activities undertaken at a particular site, and may include manufacturing or process wastewaters, cooling waters, sanitary wastewater, and stormwater runoff.

National Pollutant Discharge Elimination System (NPDES)

A provision of the Clean Water Act which prohibits discharge of pollutants into waters of the United States unless a special permit is issued by EPA, a state, or, where delegated, a tribal government on an Indian reservation.

Glossary continued

Non-Point Source

Diffuse pollution sources (ie, without a single point of origin or not introduced into a receiving stream from a specific outlet). The pollutants are generally carried off the land by storm water. Common nonpoint sources are agriculture, forestry, urban, mining, construction, dams, channels, land disposal, saltwater intrusion, and city streets.

Point Source

Any discernible, confined, and discrete conveyance, including but not limited to, any pipe, ditch, channel, tunnel, conduit, well, discrete fissure, container, rolling stock concentrated animal feeding operation (CAFO), landfill leachate collection system, vessel or other floating craft from which pollutants are or may be discharged. This term does not include return flows from irrigated agriculture or agricultural stormwater runoff.

Pollutant

Dredged spoil, solid waste, incinerator residue, filter backwash, sewage, garbage, sewage sludge, munitions, chemical wastes, biological materials, radioactive materials (except those regulated under the Atomic Energy Act of 1954, as amended (42 U.S.C. 2011 et seq.)), heat, wrecked or discarded equipment, rock, sand, cellar dirt, and industrial, municipal, and agricultural waste discharged into water [40 CFR 122.2].

Receiving Waters

All distinct bodies of water that receive runoff or wastewater discharges, such as streams, rivers, ponds, lakes, and estuaries. The "Water of the United States" as defined in 40 CFR 122.2 into which the regulated stormwater discharges.

Runoff

Water from precipitation or irrigation that flows over the ground and into bodies of water. It can contribute to soil erosion and carry harmful pollutants.

Sanitary Sewer

A pipe or conduit (sewer) intended to carry wastewater or water-borne wastes from homes, businesses, and industries to the POTW.

Sanitary Sewer Overflow (SSO)

Untreated or partially treated sewage overflows from a sanitary sewer collection system.

Stormwater

Water that accumulates on land as a result of storms, and can include runoff from urban areas such as roads and roofs.

Stormwater Discharge-Related Activities

Activities that cause, contribute to, or result in stormwater point source pollutant discharges, including excavation, site development, grading, and other surface disturbance activities; and measures to control stormwater, including the siting, construction, and operation of BMPs to control, reduce, or prevent stormwater pollution.

Wastewater

The spent or used water from a home, community, farm, or industry that contains dissolved or suspended matter. Water Pollution: The presence in water of enough harmful or objectionable material to damage the water's quality.

Water Quality Standards

State-adopted and EPA-approved ambient standards for water bodies. The standards prescribe the use of the water body and establish the water quality criteria that must be met to protect designated uses.

THE CSO LONG TERM CONTROL PLAN *UPDATE*

Clean Water Benefits and the Balanced Approach

GREEN CITIES
CLEAN WATERS

The City of Philadelphia

INTRODUCTION

The Philadelphia Water Department (PWD) wants to transform Philadelphia's urban landscape into a vibrant, green community where people want to live and work. By merging the vision of a "green city" with "clean water" we can benefit not only our watershed environment, but the region's economic health, quality of life and sustainability.

The PWD is well suited to the development and implementation of a watershed approach to Combined Sewer Overflow (CSO) control. The PWD owns and operates the City's sanitary sewers, storm sewers, combined sewers and wastewater treatment plants. In cooperation with the Philadelphia City Planning Commission, the PWD regulates stormwater management during the construction and post-construction phases of most development and redevelopment projects.

In 2007, the PWD began to revaluate its CSO Long Term Control Plan (LTCP) and capital improvements program to integrate additional projects that reduce CSO frequency and volume. The CSO Long Term Control Plan Update (LTCPU) involves the development of additional management alternatives to ensure capture and treatment of sanitary sewer system flows and the reduction of discharges from CSOs, building on the experience and progress gained from the implementation of our original CSO LTCP.

Benefits of Clean Water

The resources, amenities and socioeconomic impacts that result from the watershed management approach are endless. A "Green Cities - Clean Water" strategy will stimulate tourism, recreation, and riverfront development, along with the resulting economic benefits and jobs. Cleaner rivers create increased civic pride in the riverfront area, higher property values, and greater potential for valuable riverfront projects.

An exciting day of fishing at the annual Philly Fun Fishing Fest!

Paddlers take to their boats for the Schuylkill Regatta.

GREEN CITIES
CLEAN WATERS

THE LONG TERM CONTROL PLAN *UPDATE*

Clean Water Benefits and the Balanced Approach

Fact Sheet #2

CSO Long Term Control Plan Update (CSO LTCPU)

Philadelphia's CSO LTCPU seeks to achieve the regulatory requirements of the National CSO Control Policy through a comprehensive watershed-based approach. The Long Term Control Planning Guidance set forth by the U.S. EPA supports the implementation of a comprehensive watershed management approach and recognizes that the major advantage in using such an approach is that it identifies multiple solutions (land-water-infrastructure based) that are cost effective measures which result in site specific improvements to problems caused by the impacts of CSO and non-CSO sources of pollution on water quality.

The CSO Long Term Control
Plan Update
Falls under the
"Green Cities - Clean Waters"
Program.

The National CSO Control Policy

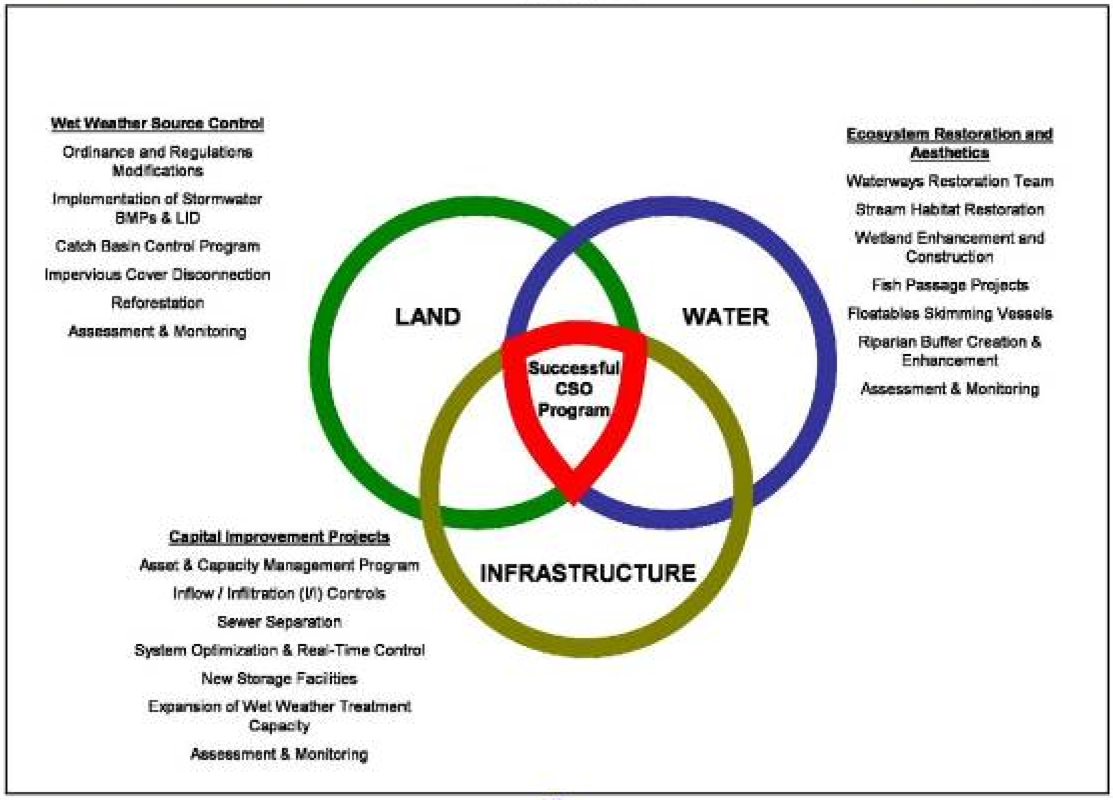
The National CSO Control Policy requires that the CSO LTCPU consist of the following nine elements:

- Characterization, monitoring, and modeling of the combined sewer system as the basis for selection and design of effective CSO controls
- A public participation process that actively involves the affected public in the decision-making to select long-term CSO controls
- Consideration of sensitive areas as the highest priority for controlling overflows
- Operational plan revisions to include agreed-upon long-term CSO controls
- Evaluation of alternatives that will enable the permittee, in consultation with the National Pollutant Discharge Elimination System (NPDES)* permitting authority, Water Quality Standards (WQS)* authority, and the public, to select CSO controls that will meet the Clean Water Act (CWA)* requirements
- Cost/performance considerations to demonstrate the relationships among a comprehensive set of reasonable control strategies
- Maximization of treatment at the existing wastewater treatment plant for wet weather flows
- An implementation schedule for CSO controls
- A post-construction compliance monitoring program adequate to verify compliance with water quality-based CWA requirements and to achieve the effectiveness of CSO controls.

A Successful CSO Program: The Balanced "Land-Water Infrastructure" Approach

The Philadelphia Water Department is committed to a balanced "land-water-infrastructure" approach to achieve its watershed management and CSO control goals. This method includes infrastructure-based approaches where appropriate, but also includes a range of land-based stormwater management techniques and the physical reconstruction of aquatic habitats, where appropriate.

The ultimate goal of PWD's approach is to restore and protect our rivers and streams including the floodplains, riparian buffers, stream channels, streambeds, wildlife, vegetation and other biomarkers that define a



healthy stream ecosystem that have been degraded as a result of urbanization within the City of Philadelphia and in the surrounding counties, while achieving full regulatory compliance in a cost-effective manner. The "Land-Water-Infrastructure" approach is made up of the following three programs, all of which enable the PWD to accomplish its goals under the CSO LTCPU.

LAND:
Wet Weather Source Control

The Wet Weather Source Control program promotes the use of Low Impact Development (LID)* and other structural and non-structural controls to reduce CSO volume through evaporation*, transpiration*, infiltration* and detained release* to the combined sewer system for treatment. The goal of our LID program, unlike past practices, is to keep stormwater runoff out of our sewer systems. One way that PWD is meeting its goals for this program is through the enactment of our recent stormwater management regulations for new development and redevelopment, established in 2006. These regulations focus on restoring a more natural balance between stormwater runoff and infiltration by requiring the capture of the first one inch of rainfall, reducing pollutant loads through infiltration and/or detention and controlling runoff rates at levels that minimize stream bank erosion. Site designers can ensure the level of stormwater management performance required through the use of a variety of land-based practices that mimic the natural environment, (e.g., redirecting runoff from impervious surfaces* to green areas, bioretention*, subsurface storage* and infiltration, green roofs, swales*, and tree canopy).

GREEN CITIES
CLEAN WATERS

THE LONG TERM CONTROL PLAN *UPDATE*

Clean Water Benefits and the Balanced Approach

Fact Sheet #2

Our planned Low Impact Development (LID) programs will include:

- Large-scale implementation of green, attractive measures to manage stormwater at the source on public land and streets to reduce demands on sewer infrastructure
- Requirements and incentives for green, attractive measures to manage stormwater at the source on private land and streets to reduce demands on sewer infrastructure
- A large-scale street tree program to improve appearance and manage stormwater at the source on City streets
- Incentives to preserve open space for use for stormwater management at the source

Infiltration garden at Buckman Heights in Portland, Oregon

Naturalized stormwater detention basin at Black Rock in Upper Providence Township

Porous parking lot at Johnson & Johnson Pharmaceutical Research and Development campus

Rain Garden at Wissahickon Creek installed as part of the Valley Green Environmental Restoration program

A rain barrel installed at a Philadelphia residence

WATER:
Ecosystem Restoration and Aesthetics

The Ecosystem Restoration and Aesthetics program focuses on projects that contribute to the improvement of the aesthetic and ecological integrity of CSO receiving waters.

Such watershed-based approaches include stream bed and bank stabilization and reconstruction, aquatic habitat creation, plunge pool removal, improvement of fish passage, and floodplain reconnection. Restoring designated uses and ultimately removing streams from the state's list of impaired waters will require the restoration of the functions of a healthy aquatic ecosystem. These functions may be impossible to restore without restoration of the physical channel and the habitat required to support them.

PWD is designing and implementing projects that will restore and/or create stream and wetland habitat through programs that focus on stream habitat restoration, wetland enhancement and construction, fish passage projects and riparian buffer creation and enhancement.

Cobbs Creek at Marshall Road

Before

The creek at Marshall Road suffered from severely eroded banks (*triangle*) and exposed infrastructure (*star*).

In Progress

After

The natural design of the creek and healthy riparian buffer provides many benefits, including improved habitat for aquatic animals.

INFRASTRUCTURE:
Capital Improvement Projects

The Capital Improvement Projects program continues to build CSO capital improvement projects that were planned during the previous CSO permit cycle in addition to new projects to continue to increase the capture and treatment of combined sewage.

These construction projects include traditional storage, conveyance, and treatment measures within the combined sewer collection and treatment system, (e.g., the installation of inflatable dams, underground sewage storage tanks, and storm relief sewers.) Similar in-system construction will continue to be considered along with land-based and water-based measures, and they may be identified as the most cost-effective and feasible solutions in some situations.

However, if used alone, infrastructure-based measures can not address the root causes of impairment in urban streams. For example, the Cobbs Creek and Tookany/Tacony-Frankford Integrated Watershed Management Plans conclude that while some water quality problems exist, the primary causes of impairment in these streams are modified flow patterns and habitat degradation resulting from the urban development of our once natural watersheds. Controlling volume and quality of stormwater runoff is key for restoring the ecosystems of our streams. The Pennsylvania Department of Environmental Protection's (PADEP) integrated impairment listings agree with these findings.

Infrastructure-based measures are typically focused on removing loads of specific pollutants in our piping systems rather than restoring natural flow conditions and habitat. Controlling stormwater runoff (before it enters the sewer system) through rain gardens, tree infiltration trenches, bioswales* and other land-based practices that recreate the natural environment, is essential for achieving healthy streams. It is for this reason that PWD's strategies include a well defined evaluation of infrastructure solutions combined with LID.

From a story in the Philadelphia *Inquirer's* "Today" Magazine, January 29, 1961. *Research credit Adam Levine.*

Additional examples of our capital improvements program include the Real Time Control Center, Water Pollution Control Plant (WPCP) Wet Weather Treatment Maximization, In-Line System Storage Projects, an Asset & Capacity Management Program, Inflow/Infiltration (I/I) Controls, Sewer Separation, and New Storage Facilities.

Additional Watershed Projects

The PWD integrated and adaptive approach has the added benefit of meeting other stakeholder water resources needs more universally. These programs and projects include: River Conservation Plans, the Watershed Information Center, Integrated Water Use Status Networks, Interpretive Signage, Interpretive Centers, Basin-Specific Stormwater Management Plans (Act 167*) and Sewage Facility Planning. For more information on the CSO LTCP, please visit: http://www.phillyriverinfo.org

The encapsulation of Mills Creek in 1883. *Research credit Adam Levine.*

*Glossary**

Act 167

The Pennsylvania Stormwater Act 167 of 1978 says that each county must prepare a stormwater management plan for each of its designated watersheds in consultation with the municipalities located within the boundaries of the watershed.

Bioretention

A vegetated depression located on the site that is designed to collect, store and infiltrate runoff. Typically includes a mix of amended soils and vegetation.

Detention System

Temporary storage of stormwater to control the rate of release, allow for infiltration and provide treatment.

Evaporation

A change of liquid to vapor form.

Impermeable

Not easily penetrated. The property of a material or soil that does not allow, or allows only with great difficulty, the movement or passage of water.

Impervious Surface

Those surfaces in the landscape that can not infiltrate rainfall, such as rooftops, pavement, sidewalks, driveways and compacted earth. Lawns with underlying soils compacted by heavy machinery are considered impervious.

Infiltration

The penetration of water through the ground surface into sub-surface soil or the penetration of water from the soil allowing for the recharge of our groundwater table and the baseflow of streams.

Low Impact Development (LID)

A design strategy with the goal of maintaining or replicating the pre-development hydrologic regime through the use of design techniques that mimic the natural environment.

National Pollutant Discharge Elimination System (NPDES)

A provision of the Clean Water Act which prohibits discharge of pollutants into waters of the United States unless a special permit is issued by EPA, a state, or, where delegated, a tribal government on an Indian reservation.

Pervious or Permeable Surfaces

Soil or other material that allows infiltration or passage of water or other liquids.

Subsurface Storage

Retaining or detaining water underground. Stored water can be released at a later time into natural waterways to reduce peak storm flows, or allowed to slowly infiltrate to recharge groundwater.

Swale / Bioswale

Open, vegetated drainage channel designed to detain, treat and/or infiltrate stormwater.

Transpiration

The process by which water vapor is lost to the atmosphere from living plants.

Water Quality Standards (WQS)

State-adopted and EPA-approved ambient standards for water bodies. The standards prescribe the use of the water body and establish the water quality criteria that must be met to protect designated uses.

GREEN CITIES
CLEAN WATERS

THE LONG TERM CONTROL PLAN *UPDATE*
Clean Water Benefits and the Balanced Approach
Fact Sheet #2

Clean Water Act (CWA)

Introduction to the Clean Water Act as given by the EPA

The Clean Water Act (CWA) is the cornerstone of surface water quality protection in the United States. (The Act does not deal directly with ground water nor with water quantity issues.) The statute employs a variety of regulatory and nonregulatory tools to sharply reduce direct pollutant discharges into waterways, finance municipal wastewater treatment facilities, and manage polluted runoff. These tools are employed to achieve the broader goal of restoring and maintaining the chemical, physical, and biological integrity of the nation's waters so that they can support "the protection and propagation of fish, shellfish, and wildlife and recreation in and on the water."

For many years following the passage of CWA in 1972, EPA, states, and Indian tribes focused mainly on the chemical aspects of the "integrity" goal. During the last decade, however, more attention has been given to physical and biological integrity. Also, in the early decades of the Act's implementation, efforts focused on regulating discharges from traditional "point source" facilities, such as municipal sewage plants and industrial facilities, with little attention paid to runoff from streets, construction sites, farms, and other "wet-weather" sources.

Starting in the late 1980s, efforts to address polluted runoff have increased significantly. For "nonpoint" runoff, voluntary programs, including cost-sharing with landowners are the key tool. For "wet weather point sources" like urban storm sewer systems and construction sites, a regulatory approach is being employed.

Evolution of CWA programs over the last decade has also included something of a shift from a program-by-program, source-by-source, pollutant-by-pollutant approach to more holistic watershed-based strategies. Under the watershed approach equal emphasis is placed on protecting healthy waters and restoring impaired ones. A full array of issues are addressed, not just those subject to CWA regulatory authority. Involvement of stakeholder groups in the development and implementation of strategies for achieving and maintaining state water quality and other environmental goals is another hallmark of this approach.

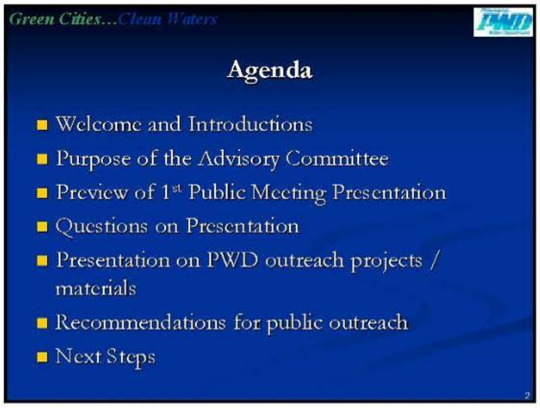
- Too much technical jargon – **Starr**
- Why does this matter to the public – **Mann**
- Slide 7 Wow (graphic with the location of 164 outfalls) – **RobbGrecco**
- Start with photos not technical stuff – **Starr**
- From the civic group side, Who will fix my problems, I don't care about the regulatory issues, talk more about the personal impacts of overflows (basement) – **Simpkins**
- Talk first about what the problems are, then go into the solutions – **Thorp**
- What is the regulatory process – who approves, EPA, who lobbies, how can each 'hood get more money – **Tran**
- Show this as an investment to our City – Get them to care – **Starr**
- Show Cost-effectiveness – **Mann**
- City incentives for green roofs on private property – **Mann**
- LTCPU – had 10 yrs to study, these are the investments made, it's an ongoing process, now it's time for a mix of solutions – **Blaustein**
- Give them clear alternatives for the future – **Blaustein**
- Adaptive Management Approach – **Neukrug**
- Tell them what we have done and what we are doing. We are standing at a fork in the road now. Tell them the story of the choices. Give them the problem and two alternative solutions. Focus on the stuff we have done. – **Starr**
- Remember the anger from affected citizens (flooding). We are walking a fine line with the citizens. Make the story clear. Cut the # of slides in half or third – **Knapp**
- SFR vs CSO – big difference of what we are on the hook to solve in the LTCPU – **Smullen**
- Show a few slides discussing SFR, but clearly state that this is not what we are talking about in the rest of the presentation., acknowledge the seriousness of the flooding issue – **Starr**
- What are the long term health risks, what are you doing about public notification – **Mann**
- Put signs up high like they did in Pittsburgh – **Blaustein**
- Do dogs drink the water? – **Neukrug**

Green Cities…Clean Waters

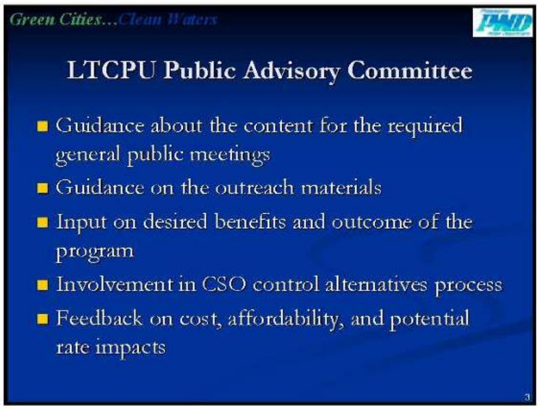
Long Term Control Plan Update

Public Advisory Committee Meeting #1
November 13th, 2007



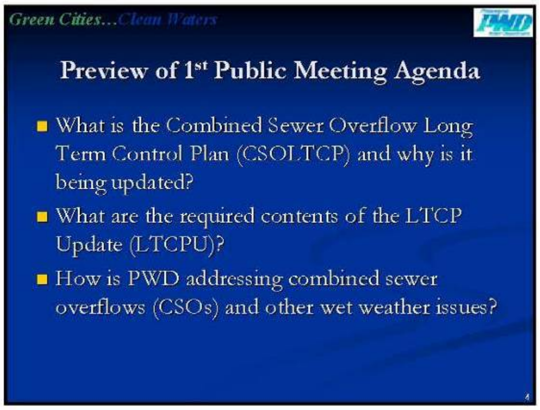
Agenda

- Welcome and Introductions
- Purpose of the Advisory Committee
- Preview of 1st Public Meeting Presentation
- Questions on Presentation
- Presentation on PWD outreach projects / materials
- Recommendations for public outreach
- Next Steps



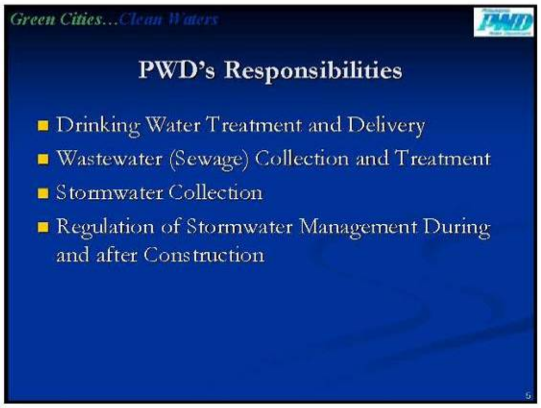
LTCPU Public Advisory Committee

- Guidance about the content for the required general public meetings
- Guidance on the outreach materials
- Input on desired benefits and outcome of the program
- Involvement in CSO control alternatives process
- Feedback on cost, affordability, and potential rate impacts



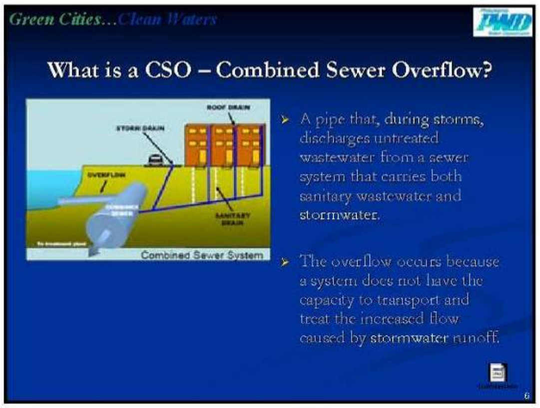
Preview of 1st Public Meeting Agenda

- What is the Combined Sewer Overflow Long Term Control Plan (CSOLTCP) and why is it being updated?
- What are the required contents of the LTCP Update (LTCPU)?
- How is PWD addressing combined sewer overflows (CSOs) and other wet weather issues?



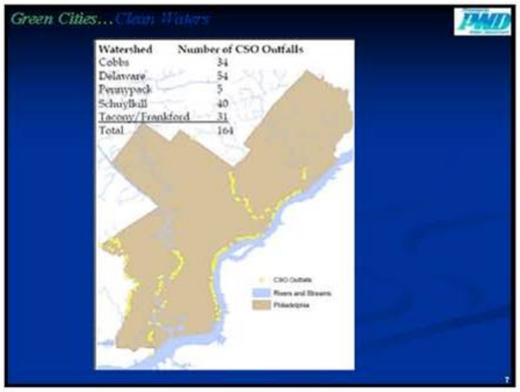
PWD's Responsibilities

- Drinking Water Treatment and Delivery
- Wastewater (Sewage) Collection and Treatment
- Stormwater Collection
- Regulation of Stormwater Management During and after Construction

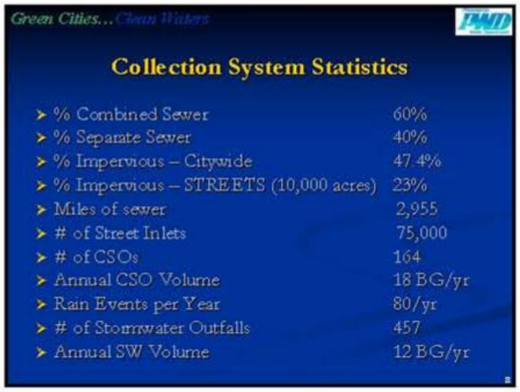


What is a CSO – Combined Sewer Overflow?

- A pipe that, during storms, discharges untreated wastewater from a sewer system that carries both sanitary wastewater and stormwater.
- The overflow occurs because a system does not have the capacity to transport and treat the increased flow caused by stormwater runoff.

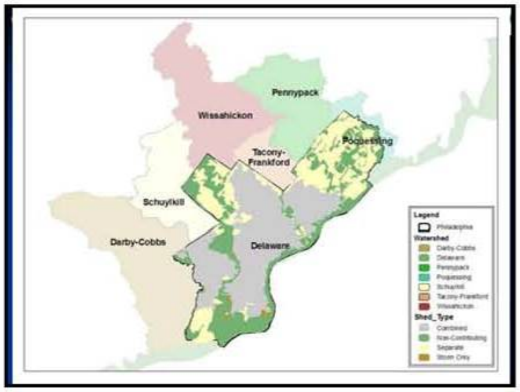


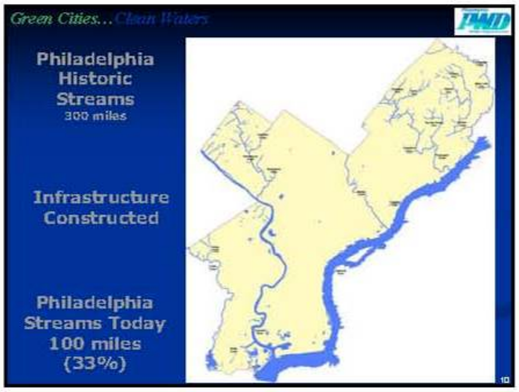
Watershed	Number of CSO Outfalls
Cobbs	34
Delaware	54
Pennypack	5
Schuylkill	40
Tacony/Frankford	31
Total	164



Collection System Statistics

% Combined Sewer	60%
% Separate Sewer	40%
% Impervious – Citywide	47.4%
% Impervious – STREETS (10,000 acres)	23%
Miles of sewer	2,955
# of Street Inlets	75,000
# of CSOs	164
Annual CSO Volume	18 BG/yr
Rain Events per Year	80/yr
# of Stormwater Outfalls	457
Annual SW Volume	12 BG/yr

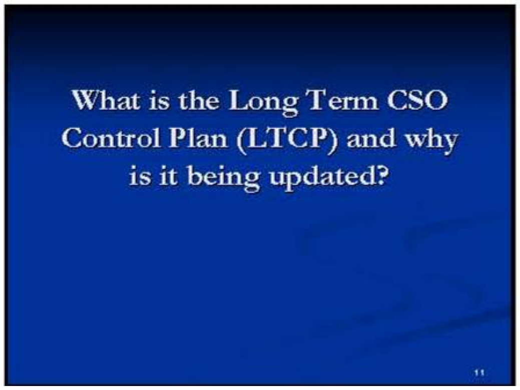




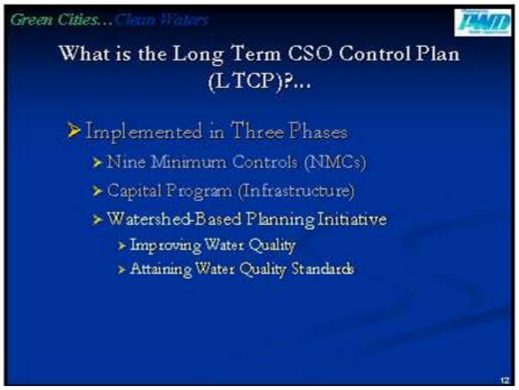
Philadelphia Historic Streams
300 miles

Infrastructure Constructed

Philadelphia Streams Today
100 miles
(33%)

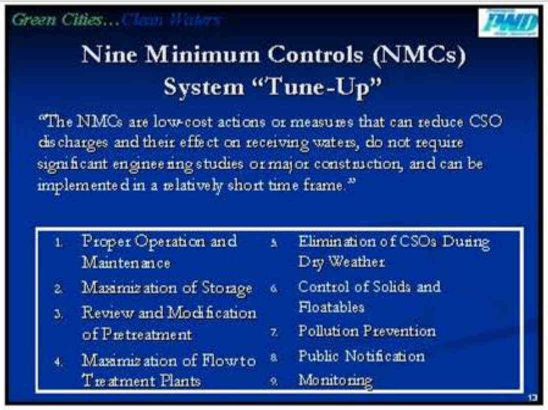


What is the Long Term CSO Control Plan (LTCP) and why is it being updated?



What is the Long Term CSO Control Plan (LTCP)?…

- Implemented in Three Phases
  - Nine Minimum Controls (NMCs)
  - Capital Program (Infrastructure)
  - Watershed-Based Planning Initiative
    - Improving Water Quality
    - Attaining Water Quality Standards

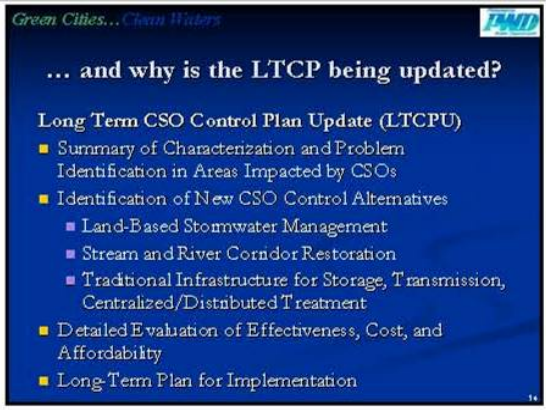


Green Cities…Clean Waters

Nine Minimum Controls (NMCs) System "Tune-Up"

"The NMCs are low-cost actions or measures that can reduce CSO discharges and their effect on receiving waters, do not require significant engineering studies or major construction, and can be implemented in a relatively short time frame."

1. Proper Operation and Maintenance
2. Maximization of Storage
3. Review and Modification of Pretreatment
4. Maximization of Flow to Treatment Plants
5. Elimination of CSOs During Dry Weather
6. Control of Solids and Floatables
7. Pollution Prevention
8. Public Notification
9. Monitoring

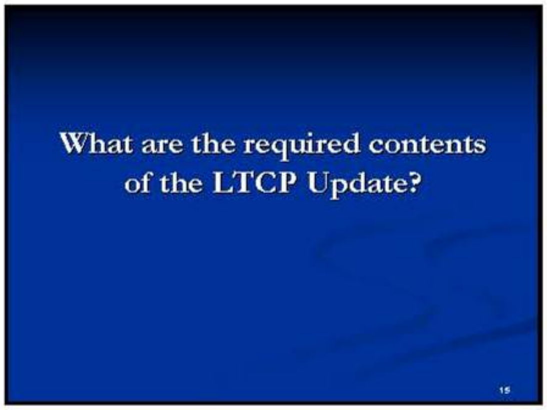


Green Cities…Clean Waters

… and why is the LTCP being updated?

Long Term CSO Control Plan Update (LTCPU)

- Summary of Characterization and Problem Identification in Areas Impacted by CSOs
- Identification of New CSO Control Alternatives
  - Land-Based Stormwater Management
  - Stream and River Corridor Restoration
  - Traditional Infrastructure for Storage, Transmission, Centralized/Distributed Treatment
- Detailed Evaluation of Effectiveness, Cost, and Affordability
- Long-Term Plan for Implementation



What are the required contents of the LTCP Update?

Green Cities…Clean Waters

Regulatory Framework: Clean Water Act and National CSO Control Policy

- Nine Minimum Controls
- Long Term CSO Control Plan
  - System Characterization
  - Public Participation
  - Consideration of Sensitive Areas
  - Evaluation of Alternatives
  - Cost/Performance Consideration
  - Operational Plan
  - Maximizing Treatment at Existing Plants
  - Implementation Schedule
  - Post-Construction Compliance Monitoring Program
  - Water Quality Standards Review

Today's Meeting

Green Cities…Clean Waters

Watershed and Water Body Characterization

Living Resources
Designated Uses
Regulatory Compliance

Stakeholder Goals
Quality of Life

Dry Weather Water Quality and Aesthetics
Stream and Stream Corridor Living Resources
Wet Weather Water Quality and Quantity

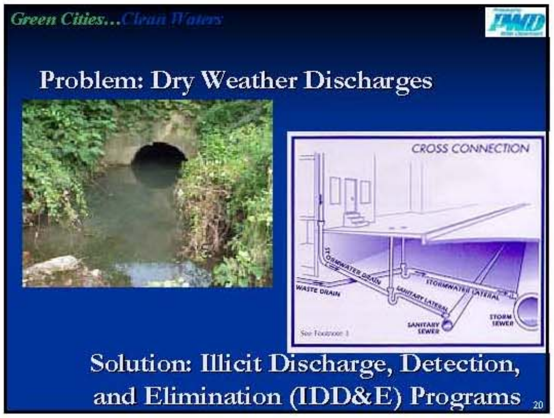
Green Cities…Clean Waters

Target A – Dry Weather Water Quality and Aesthetics

- Streams need to look good, be accessible, and become an amenity to the community
- Stream water quality during dry weather (about 60-65% of the time) should improve

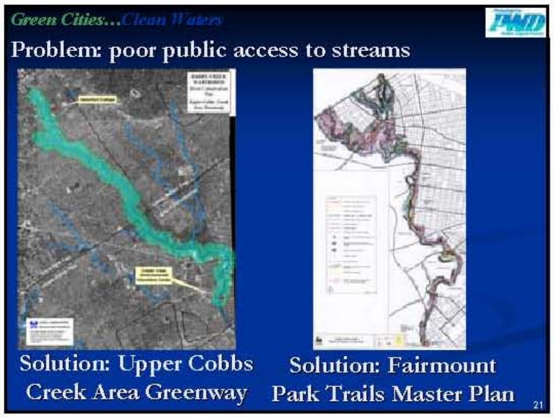
Problem: Dumping and Trash

Solution: Waterways Restoration Team - removing trash



Problem: Dry Weather Discharges

Solution: Illicit Discharge, Detection, and Elimination (IDD&E) Programs



Problem: poor public access to streams

Solution: Upper Cobbs Creek Area Greenway

Solution: Fairmount Park Trails Master Plan

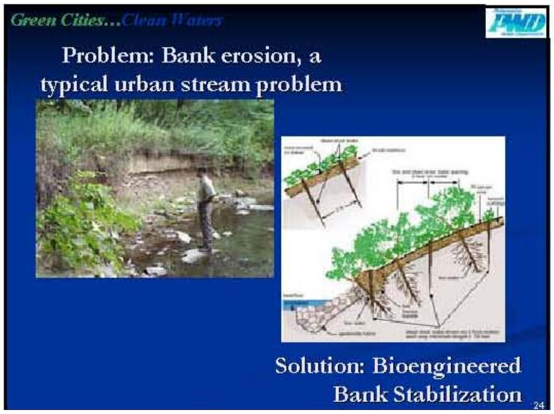
Problem: Can we increase resident awareness?

Solution: Public Education

Solution: Active Community Stewardship

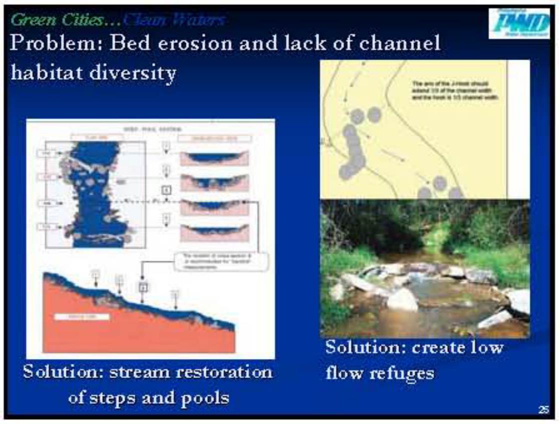
Target B – Healthy Living Resources

- Focus on improved aquatic habitat and healthy fish populations
- Stream restoration (bank, channel, riparian, corridor)
- Fish passage (fish ladders, dam modification)



Problem: Bank erosion, a typical urban stream problem

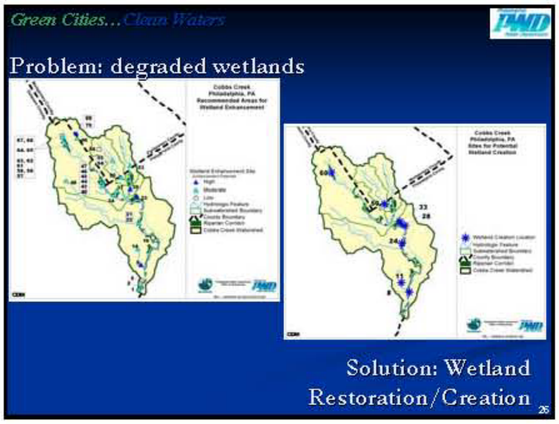
Solution: Bioengineered Bank Stabilization



Problem: Bed erosion and lack of channel habitat diversity

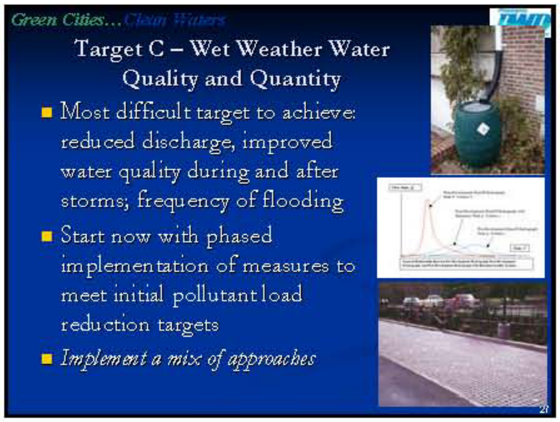
Solution: stream restoration of steps and pools

Solution: create low flow refuges



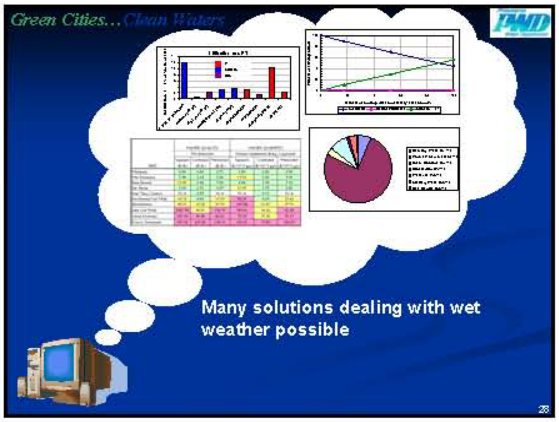
Problem: degraded wetlands

Solution: Wetland Restoration/Creation

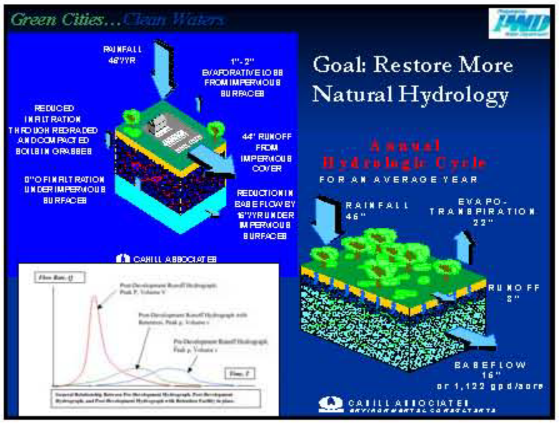


Target C – Wet Weather Water Quality and Quantity

- Most difficult target to achieve: reduced discharge, improved water quality during and after storms; frequency of flooding
- Start now with phased implementation of measures to meet initial pollutant load reduction targets
- *Implement a mix of approaches*



Many solutions dealing with wet weather possible

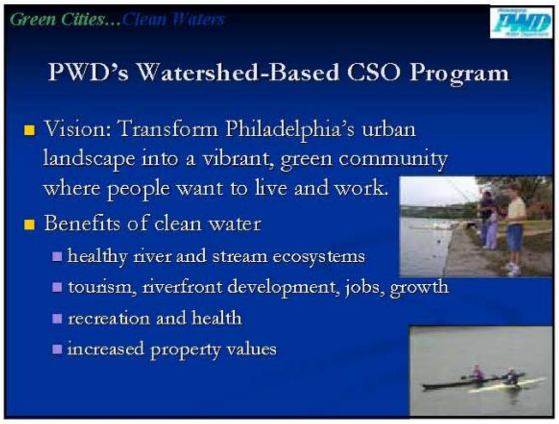


Goal: Restore More Natural Hydrology

How is PWD addressing combined sewer overflows (CSOs) and other wet weather issues?

The Old Approach – Big Tanks and Tunnels

- Are we going to build on yesterday's mistakes?
- Is this approach sustainable?
- Can we reach our environmental goals?
- Can we get a better value for limited $$$?



PWD's Watershed-Based CSO Program

- Vision: Transform Philadelphia's urban landscape into a vibrant, green community where people want to live and work.
- Benefits of clean water
  - healthy river and stream ecosystems
  - tourism, riverfront development, jobs, growth
  - recreation and health
  - increased property values

Watershed-Based CSO Program

Streambank and Habitat Restoration
Constructed Wetlands
Baseflow Augmentation
Floatables Skimming Vessels
Stream Cleanup Teams
Assessment & Monitoring

Low-Impact Development and Re-Development
Stormwater BMPs
Regional Stormwater Facilities
Riparian Buffer Creation & Enhancement
Reforestation
Green Building Technology
Water Conservation
Assessment & Monitoring

New Storage Facilities
New Treatment Capacity
Real-Time Control
Sewer Separation
Inflow / Infiltration Controls
Catch Basin Controls
In-line Netting
Swirl Concentrators
Assessment and Monitoring

INFRA

- Asset & Capacity Management Program
- Inflow / Infiltration (I/I) Controls
- Sewer Separation
- System Optimization & Real-Time Control
- New Treatment Capacity
- New Storage Facilities

Tank - Venice Island

WPCP Wet Weather Capacity Expansion

Thermal Imaging Studies

Sewer/Stream Separation - USACE Mill Creek Feasibility Study

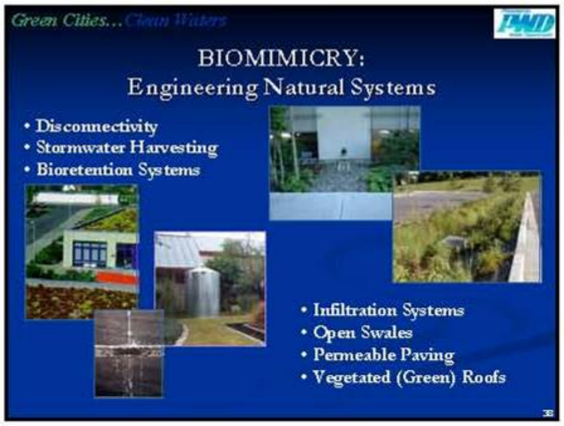
In-System Storage

Infrastructure Summary

- Necessary part of CSO mitigation
- These projects are a large part of PWD's Capital Program
- Innovative
- But…
  addresses only a small part of the environmental goal

LAND

- Implementation of Stormwater BMPs
- Low Impact Development & Redevelopment (LID)
- Catch Basin Control Program
- Impervious Cover Disconnection
- Reforestation
- Green Building Technology & Water Conservation
- New Stormwater Management Regulations



BIOMIMICRY: Engineering Natural Systems

- **Disconnectivity**
- **Stormwater Harvesting**
- **Bioretention Systems**

- **Infiltration Systems**
- **Open Swales**
- **Permeable Paving**
- **Vegetated (Green) Roofs**

Low Impact Development Program

Stomwater Detention (ex. Vacant Land Management)

Green Streets

Infiltration Trenches & Basins

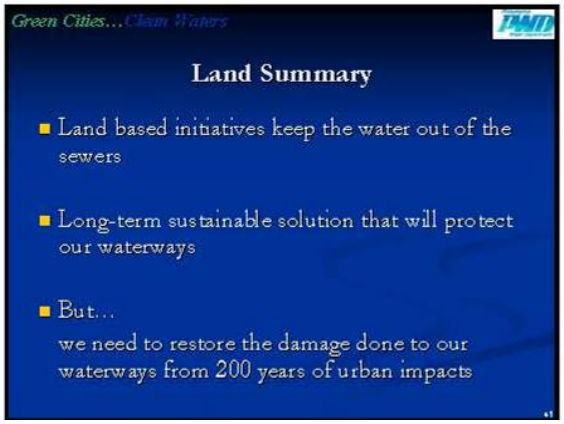
Bioretention (ex Rain Garden)

Permeable Paving

New SW Regulations

Green Roofs

Cisterns & Rain Barrels



Land Summary

- Land based initiatives keep the water out of the sewers
- Long-term sustainable solution that will protect our waterways
- But…

  we need to restore the damage done to our waterways from 200 years of urban impacts

WATER

- Waterways Restoration Team
- Stream Habitat Restoration
- Constructed Wetlands
- Fish Passage Projects
- Floatables Skimming Vessels
- Riparian Buffer Creation & Enhancement

Green Cities... Clean Waters

Future Meeting Topics

- Meeting #2 – CSO Control Options – Low Impact Development (green infrastructure) and Capital Improvements; What Other Cities Are Doing; Prototype Examples
- Meeting #3 – Alternatives Analysis and Affordability
- Meeting #4 – Review of Draft Plan

Green Cities... Clean Waters

Today's Agenda

- Welcome and Introductions
- Purpose of the Advisory Committee
- Preview of 1st Public Meeting Presentation
- Questions on Presentation
- Presentation on PWD outreach projects / materials
- Recommendations for public outreach
- Next Steps

Green Cities... Clean Waters

Today's Agenda

- Welcome and Introductions
- Purpose of the Advisory Committee
- Preview of 1st Public Meeting Presentation
- Questions on Presentation
- Presentation on PWD outreach projects / materials
- Recommendations for public outreach
- Next Steps

The fundamental goal of the Philadelphia Water Department's (PWD) combined sewer overflow program is to improve and preserve the water environment in the Philadelphia area and to fulfill the PWD's obligations under the Clean Water Act and the Pennsylvania Clean Streams Law by implementing technically viable, cost-effective improvements and operational changes.

Today's Agenda

- Welcome and Introductions
- Purpose of the Advisory Committee
- Preview of 1st Public Meeting Presentation
- Questions on Presentation
- Presentation on PWD outreach projects / materials
- Recommendations for public outreach
- Next Steps

Dwayne Myers	myersrd@cdm.com	CDM/PWD
Bill Cesanak	cesanakwe@cdm.com	CDM/PWD

Comments for February 20th Meeting

1. Take out the acronyms- don't say "CSO," say Combined sewer overflow – Sarah R.G.
2. CSO vs Separate – make the colors different. (H2O for stormwater- blue & poop brown, then combine colors)
3. Take time on CSO vs. Separate diagrams, BUT ALSO VERY IMPORTANT to point out NPS pollution with CSO effect. + pros and cons of each
4. Fix diameter of CSO & separate into 2 pipes where it comes out of house – Burke
5. After Green vs. Gray go back to sewer diagram and add green and show H2O coming out -Burke
6. Old Maps → New maps = Good (we should still treasure & preserve what we still have & bring back what is lost – Burke
7. Stream Natural vs. Urban → Different isn't visible in photos because you can't see development in 2nd pair; show aerial?
8. 4" Rain vs. 3" → impact? → MAJOR STORM! 4" over 3 hours vs. 4" over 24 hours…explain clear difference & emphasize impact – Sarah R.G.

- Average storm is ½ in – Melanie
- Snow comparison?

9. "Piping" is creek- EXPLAIN that burying creek and creek runs through pipe
10. How to get involved → go to very end again x2 & Add "next steps"- why you want to get involved & why are they here?
11. What can they do?

- Good Practices- rain barrel, explain why these practices are beneficial.

12. Vision of what their street can look like – list things like plant trees, rain barrels, you can do it, grass… etc.
13. Role of public? Do you like the idea of spending $ on green stuff? & gray stuff? Mix?
14. Additional Tables? Recycling Table, Anti Litter Campaign?
15. Stream Restoration & other green > cut out 1-2 i.e. keep Portland and Chicago.
16. Don't use toxic, use "unsanitary" & "filthy" in history section!

1. Darby Cobbs

- 34 outfalls
- 2004 wmp completed

2. Schuylkill

- 40 overflows
- Sewer water as t.s. & sewer Water Protect. Plan- completed in 2006

3. Tookany/Tacony-Frankford

- 31 in TF section
- WMP completed 2007

4. Pennypack

- Only 5 CSOs
- WMP started in 07. To be completed in 2008

5. Delaware

-54 in DE Direct
- started RCP last year
6. Poquessing
- 0 outfalls, served by separate sewer system RCP complete last year & wmp to start this fall

Imagine a
Philadelphia like
this…

CSO LTCPU Advisory Board Meeting Comments 10.08.2008

Intro Presentation

- What do we want from the public?
- Targeting the public: what is the cost to them and how will it benefit them and their children
- Explain what PWD does and how this is an additional but necessary part of their role as a water utility provider
- Emphasize recreation, quality of life, increase in property value in using green infrastructure
- Contrast green and gray more explicitly
- Big investment in infrastructure is necessary, but how do we do this?
- Slide 30- call out features or what is being shown

Characterization Presentation

- Maps- provide landmarks, parks, streets, neighborhood names for reference
- Redo Tookany/Tacony- Frankford map
- Slide 4- take out or switch with previous
- Emphasize recreation
- Connect public actions to their effect (e.g. what pour down the drain, flush the toilet- goes into sewer system)
- Homeowner Stormwater Management Manual could be referred to
- Mark green streets slides with call outs to different features

CSO Advisory Meeting 4-9-09

Slide Target C- Change RT Control to Inflatable dam
Slide Cost vs Benefit- Phrase it down
Slide RTB – make it plural
    Take out RTB and add a text saying it is underground
Slide green homes – make sure its local plants
Slide Green public facilities – Change green walls to living walls
Slide green programs – make components readable
Slide Enhanced Aquatic life – Show that it is a fish ladder
Slide Alternatives – Take out TTF CSO…
    Take out TBL
    Add pics, take out legends, Bigger Pipe instead of increased transmission
Slide Survey – Take out notes and acronyms
Slide CSO – take out CSO, spell it out
Slide Benefit – Text centered, bullets fixed, animation needs to be faster.

-City spend Billions, how does the public wants us to spend the money?
-Gray before and after photos with green before and after photos
-Explain all elements
-Pics of green components before the green program slide so the public will know what they are.
-Picture of Street overflowing
-Should we be biased towards green since were incorporating both green and gray?
-Add incentives for going green
- Fix all animations and layouts

Adv. Ct. Meeting Comments 4/9/09

-Too technical, remove "Satellite", "Transmission", "DO" or explain what it means – **Lara**
-Make it simpler – **Rachel**
-RTB slide, spell it out on 2nd slide – **Sarah**
-No acronyms at all – **Katie**
-Too much impervious language, explain it at the beginning – **Sarah**
-3 Alternatives, explain what the headings mean and how they differ – **Sarah**
-Green, Bigger pipe, mini treatment plant – **Marc**
-More neutral but discuss green benefits better –**Marc**
-List more green benefits – **Marc**
-More construction, detail so the public knows – **Rachel**
-Green Streets, components of each – **Katie**
-Explain green components thru pics – **Joan B**
-Explain how each components impact stormwater management – **Joan B.**
-Insert Stormwater slides, impervious vs pervious, stormwater runoff slides – **Joan B.**
-What is a CSO? Spell it out. – **Lara**
-Summarize slide: Cost vs Benefit, green vs gray – **Sarah**
-Overview 30 mins. New topic 2nd presentation; advertize as such – **Rachel**
-how do you want the city to tell us what you think? Be upfront. – **Marissa**
-Explain what other cities have done in our position. This is new so we need public input. – **Marissa**
-Show partnerships and others are green, so what is the additional value? – **Rachel**
-More biased go green – **Rachel**
-history of CSO slides, why not there now? – **Rachel**

Green Cities, Clean Waters Advisory Committee Meeting

August 5, 2009

The purpose of the meeting was to review the draft summary report CSO LTCP Update and to discuss how to improve outreach on the CSO LTCP Update upcoming final round of meetings.

Key comments made on draft summary report CSO LTCPU:

- "This plan is a marvelous illustration of a real world watershed approach and we plan to use it as a model for watershed planning for counties and municipalities across Pennsylvania." – Patrick Star, PEC
- "This plan addresses social justice and equity issues" [that other CSO programs do not]- Patrick Star
- "This plan really builds on the first LTCP in 1997 that laid the groundwork for the watershed approach." - David Burke, DEP
- "Biggest Public Works Project in the foreseeable future." - Joan Blaustein, Fairmount Park
- "Fairmount Park will be planting 300,000 trees to meet the GreenWorks Challenge. Their primary purpose is to improve water quality and reduce stormwater runoff." Joan
- "The Green Program allows Philadelphia residents to see what they are paying for" – Unknown

Brainstorming results on increasing public participation at final round of public meetings:

- Give away water ice
- Write Op-ed in Inquirer
- Get Inquirer to write articles
- Conduct press briefing to draw environmental bloggers
- Have ANS Urban Sustainability Forum contact promote through listserv

Public Meetings
Notifications & Media Coverage

Philadelphia
PWD
Water Department

GREEN CITIES, CLEAN WATERS PROGRAM:

COMBINED SEWER OVERFLOW LONG-TERM CONTROL PLAN PUBLIC MEETINGS

Please join the Philadelphia Water Department (PWD) for a series of public meetings on our Combined Sewer Overflow Long-Term Control Plan Update entitled "Green Cities, Clean Waters".

Learn about the City's combined sewer system, and PWD's proposed strategies for significantly reducing combined sewer overflows to our rivers and streams. Give us your feedback on these strategies that are designed to combine 'gray' solutions, such as underground infrastructure and 'green' solutions such as tree infiltration trenches.

1ST MEETING

WHEN: Wednesday, April 2 from 5:45 – 7:45 p.m.

WHERE: Port Richmond Library
(2987 Almond Street, Philadelphia, 19134)

2ND MEETING

WHEN: Thursday, April 10 from 6:00 – 8:00 p.m.

WHERE: Fels Community Center
(2407 S. Broad Street, Philadelphia, 19148)

3RD MEETING

WHEN: Thursday, April 24 from 6:00 – 8:00 p.m.

WHERE: School of the Future
(4021 Parkside Avenue, Philadelphia, 19104)

Learn how you can help protect our local sources of drinking water and help Philadelphia Go Green!

For more information, please contact Tiffany Ledesma

Philadelphia
PWD
Water Department

GREEN CITIES, CLEAN WATERS PROGRAM: COMBINED SEWER OVERFLOW LONG-TERM CONTROL PLAN PUBLIC MEETING

Please join the Philadelphia Water Department (PWD) for a public meeting on our Combined Sewer Overflow Long-Term Control Plan Update entitled: "Green Cities, Clean Waters"

This meeting is a follow-up to the previous round of meetings held last spring.

At this meeting, PWD will present the problems of the creeks and rivers, the sources of pollution and the vision behind the goals that will help transform the City.

Give us your feedback on these strategies and let your voice be heard!

WHEN: Thursday, October 23 from 5:30 – 7:30 p.m.
WHERE: Fairmount Water Works Interpretive Center
640 Waterworks Drive, Philadelphia, 19130
(behind the Philadelphia Museum of Art)

Learn how you can help protect our local sources of drinking water and help Philadelphia Go Green!

For more information, please contact Tiffany Ledesma Groll at (215) 499-3756 or visit www.phillyriverinfo.org.

Water Department

GREEN CITIES, CLEAN WATERS PROGRAM:

HEAR ABOUT THE CITY'S PLANS TO REDUCE POLLUTION AND PROTECT YOUR DRINKING WATER!

Please join the Philadelphia Water Department (PWD) for two public meetings on the Combined Sewer Overflow Long-Term Control Plan Update entitled: "Green Cities, Clean Waters"

- Hear about the vision for a greener, cleaner Philadelphia and how it affects your community;
- Find out how you can help protect your drinking water;
- Provide feedback on your future!

At the public meetings on December 4 and 10, PWD will review the sources of pollution that affect the creeks and rivers in your communities, and present its plan to transform Philadelphia into a green oasis!

Join us to hear the vision and strategies, and let your voice be heard!

1st Meeting:
WHEN: Thursday, December 4 from 5:30 – 7:30 p.m.
WHERE: Cobbs Creek Community Environmental Education Center
(700 Cobbs Creek Parkway, Philadelphia 19143)

2nd Meeting:
WHEN: Wednesday, December 10 from 6:00 – 8:00 p.m.
WHERE: Center in the Park
(5818 Germantown Avenue, Philadelphia, 19144)

For more information, please contact Tiffany Ledesma Groll at (215) 499-3756 or visit www.phillyriverinfo.org.

Give Your Views on Water Issues

Philadelphia's waterways supply essential drinking water and destinations to play, fish, relax and reconnect. That's why the Philadelphia Water Department is submitting a 20-year plan to the Environmental Protection Agency that outlines how to improve our waters and green our city. Citizens are strongly encouraged to attend a public meeting and provide important feedback to City planners.

Meetings will be held from 6 to 8 pm throughout the City. Water ice will be provided to attendees.

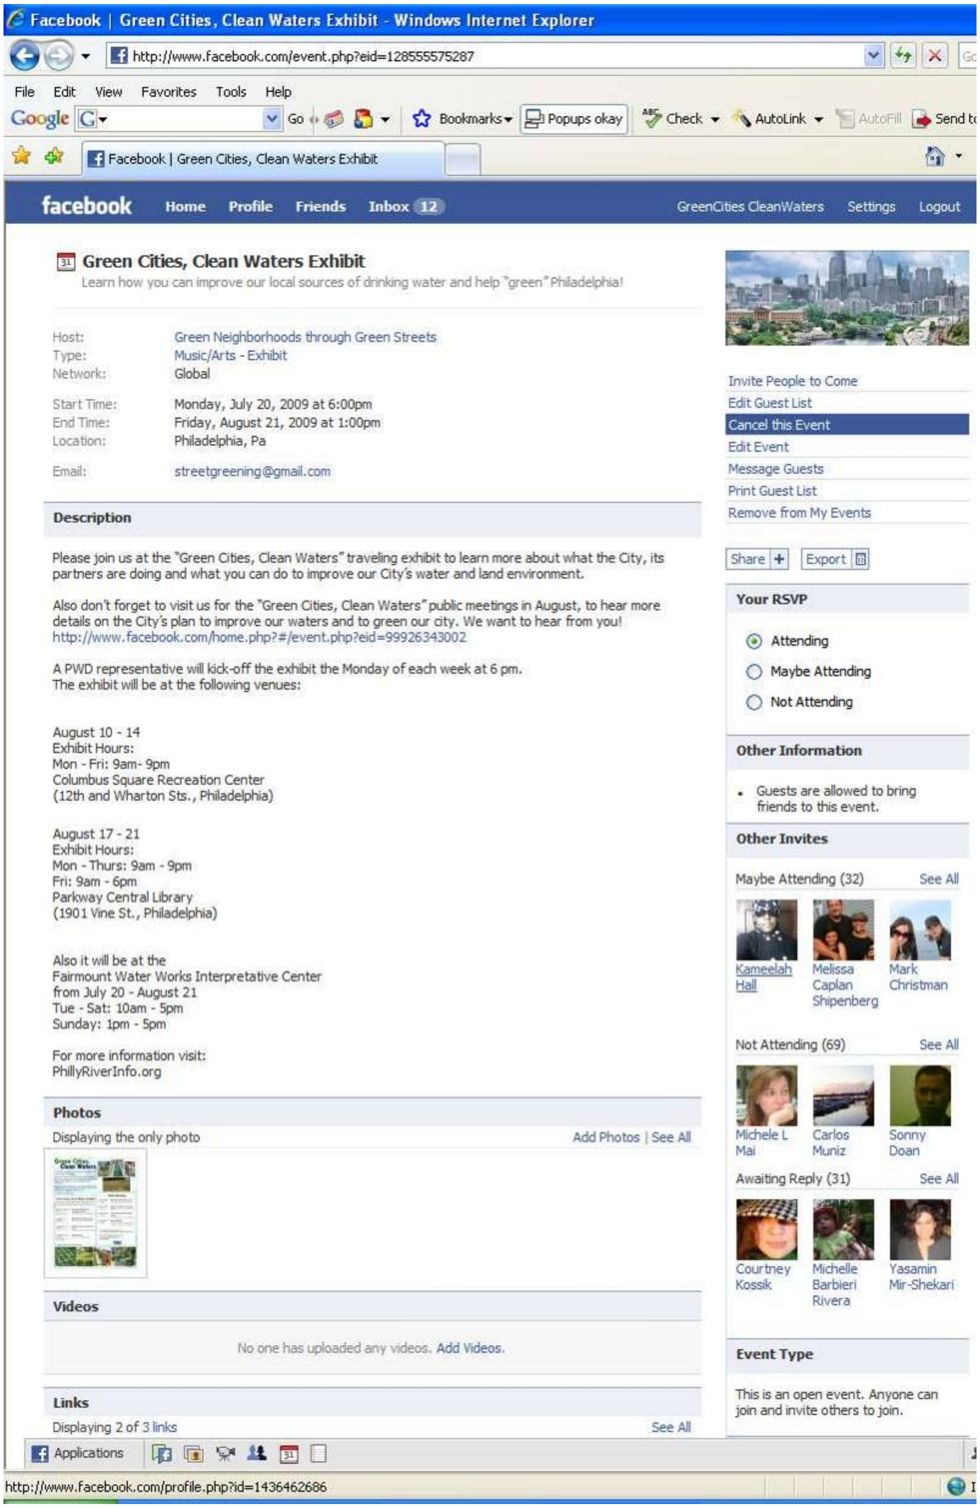
In the Northwest, the meeting will take place August 18 at Waterview Recreation Center, 5826 McMahon Street.

Other meetings will be held August 19 at the Northern Liberties Community Center, 700 North 3rd Street; August 20 at Columbus Square Recreation Center, 12th and Wharton streets; and August 25 at Mercy Hospital, 54th and Cedar streets, 7th Floor Chapel Conference Room

The Green Cities, Clean Waters program commits $1.6 billion over 20 years to capture 80 percent of the sewage and storm water that flows into the Schuylkill and Delaware Rivers and the Tacony and Cobbs creeks. A major part of the solution focuses on greening our streets, schools and public facilities.

"The program is designed to make our waterways cherished and thriving destinations, and lay the groundwork for revitalizing Philadelphia in areas of public health, recreation, housing and neighborhood values," says Joanne Dahme, Public Affairs Manager for PWD. "But we need citizens to tell us what they think before we present to the EPA on September 1."

For more information, visit www.PHILLYRIVERINFO.org/CSOLTCPU or call 215-499-3756.



Green Cities, Clean Waters Exhibit

Learn how you can improve our local sources of drinking water and help "green" Philadelphia!

Host: Green Neighborhoods through Green Streets
Type: Music/Arts - Exhibit
Network: Global

Start Time: Monday, July 20, 2009 at 6:00pm
End Time: Friday, August 21, 2009 at 1:00pm
Location: Philadelphia, Pa

Email: streetgreening@gmail.com

Description

Please join us at the "Green Cities, Clean Waters" traveling exhibit to learn more about what the City, its partners are doing and what you can do to improve our City's water and land environment.

Also don't forget to visit us for the "Green Cities, Clean Waters" public meetings in August, to hear more details on the City's plan to improve our waters and to green our city. We want to hear from you!
http://www.facebook.com/home.php?#/event.php?eid=99926343002

A PWD representative will kick-off the exhibit the Monday of each week at 6 pm.
The exhibit will be at the following venues:

August 10 - 14
Exhibit Hours:
Mon - Fri: 9am- 9pm
Columbus Square Recreation Center
(12th and Wharton Sts., Philadelphia)

August 17 - 21
Exhibit Hours:
Mon - Thurs: 9am - 9pm
Fri: 9am - 6pm
Parkway Central Library
(1901 Vine St., Philadelphia)

Also it will be at the
Fairmount Water Works Interpretative Center
from July 20 - August 21
Tue - Sat: 10am - 5pm
Sunday: 1pm - 5pm

Green Cities, Clean Waters

Public Meeting

Please join the Philadelphia Water Department (PWD) for a public meeting on the Green Cities, Clean Waters Program (Combined Sewer Overflow (CSO) Long Term Control Plan Update).

Meeting Locations and Times

Thursday, December 4th - 5:30-7:30 p.m.
Cobbs Creek Community Environmental Education Center
(700 Cobb Creek Parkway, Philadelphia)
Wednesday, December 10th - 6:00-8:00 p.m.
Center in the Park
(5818 Germantown Avenue, Philadelphia)

These meetings are a follow-up to the previous round of meetings held last spring. PWD will present the problems of the creeks and rivers, the sources of pollution and the vision behind the goals that will help transform Philadelphia into a greener city with cleaner waters.

Give us your feedback on these strategies
and let your voice be heard!

Contact Tiffany Ledesma Groll at:
ledesmagrollta@cdm.com or (215) 499-3756 with questions

PUBLIC MEETINGS

GREEN CITIES, CLEAN WATERS

Please join the Philadelphia Water Department (PWD) for a series of public meetings on our Combined Sewer Overflow Long-Term Control Plan Update, entitled "Green Cities, Clean Waters."

Learn about the City's combined sewer system, and PWD's proposed strategies for reducing combined sewer overflows to our rivers and streams. Give us your feedback on these strategies that are designed to combine 'gray' solutions, such as underground tunnels, and 'green' solutions, such as rain gardens and tree trenches.

PUBLIC MEETINGS

1st Meeting:	2nd Meeting:	3rd Meeting:
WHEN: Tuesday, June 2, 2009 6:00 – 8:00 p.m.	**WHEN:** Thursday, June 4, 2009 6:00 – 8:00 p.m.	**WHEN:** Wednesday, June 10, 2009 6:00 – 8:00 p.m.
WHERE: FELS South Philadelphia Community Center (2407 South Broad Street, Philadelphia)	**WHERE:** Waterview Recreation Center (5826 McMahon Street, Philadelphia)	**WHERE:** Northern Liberties Community Center (700 North 3rd Street, Philadelphia)

Rain Barrel Drawing: We will give away 1 *FREE* rain barrel at each public meeting!

Learn how you can help protect our local sources of drinking water and help Philadelphia Go Green!

Philadelphia PWD Water Department

South Philly review

NEWS – JUN 11, 2009

Let it seep in

by Amanda Snyder

Three local areas are already part of The Water Department's long-term plan to prevent sewers from overflowing and to make the city greener. More learned how to become part of the mix last week.

Marc Cammarata, manager of watershed planning and engineering for the Philadelphia Water Department, presented the long-term plan to lessen combined sewer overflow in the city (Staff Photo by Greg Bezanis).

PWD CSOLTCPU Public Meeting #1
Port Richmond Library
Wednesday, April 2 from 5:45 – 7:45 p.m.

Comments/Questions paraphrased:
Unknown asked: Is the I & Ramona project already installed.
Joanne Dahme responded that the project is currently in design and will go out to bid this summer.

Unknown asked: Are you going to have to have a storage tank or diversion system for every one of the 164 outfalls?
Joanne Dahme responded that we will be looking at the drainage area to each outfall to find the most cost-effective solution.

Unknown asked: Why were people in the NE so upset about the proposed tank?
Joanne Dahme responded that we should have done more outreach to explain the tank. Joanne also explained current solution.

Unknown asked: Cost comparison between Holy Family tank and new pipe solution?
Joanne Dahme responded that implementation costs were comparable; maintenance may be easier for piping solution.

Unknown asked: Are we (PWD) in talks with PENNDOT about SW for Girard interchange work?
Joanne Dahme explained our talks with PENNDOT and how we expect them to adhere to our SW regulations.

Unknown asked: With marshlands that filter SW, do they ever get clogged?
Joanne Dahme explained periodic cleaning of sedimentation fore bay.

Unknown asked: Why do we allow garbage disposals in Philly?
Joanne Dahme explained that it is part of the plumbing code. Explained that we need outreach to help people understand how their garbage disposal affects sewer system. Conversation ensued on cities that change/prohibit garbage disposals.

Unknown asked: Are grey water systems illegal in Philly?
Joanne Dahme explained meeting with L & I to allow downspout disconnects where applicable with permission from PWD. Joanne explained rain barrel program.

Unknown commented: It seems like you are going to do as much green as possible and then moving to gray.

Unknown asked: Does the National Policy require Green Projects?
Joanne Dahme responded that EPA put out a paper that recognized the green approach.

Unknown commented: Recommendation to bring in political science people to help PWD interact with the public.

PWD CSOLTCPU Public Meeting #1
FELS Center
Thursday, April 10 from 6:00 – 8:00 p.m.

Comments/Questions

Name:

Meg Malloy

Comment/Question:

"I do like the strategy."

Think its key – ex: that you show

☆ Makes it real. gives a pt in real life +

brings it home – makes it personal

I wish more people could see the photos

how bout @ FMAIC

Name:

Harry Lespee

Comment/Question:

– "Yeah I think its a great idea"

Takes a while to get the world out to the public. They are busy

– compared to the recycling program. Took a while to take hold

– Rain barrels

Partnering w/ community groups + associations help build momentum → leads to individual action

Name:

Harry Lespee

Comment/Question:

Do you keep track of how many rain barrels are ~~deploy~~e out there.

Name:

Meg Malloy

Comment/Question:

For these projects do you analyze, study, model the benefits.

Nice to show/refer to sites that show effectiveness

Green Roofs - IN PHILA
17!

①
"I like the strategy"
↳ Meg

② "I think it takes a while to get the word out to public b/c people are busy w/ their lives." (Yes - exhibit ~~this~~ at FWWIC)
↳ Penoni

"It may also be economics b/c people may not be able to afford to buy rain gardens, so work w/ communities/ associations - groups"
↳ Penoni

③ Examples are key
↳ i.e. Penn Alexander
Meg's ↳ Specifics w/ locations - that ~~it~~ hits home. People realize what's there.
(Yes - Nice to do more BMP tour)

④ - Do you monitor how many rain barrels you've distributed? - Penoni (Yes)

⑤ "W/ some of these projects, can you calculate the impact that results from projects?" - Meg
(Yes - w/ Infrastructure projects)
+ w/ green
harder to quantify but works!
look @ Porous Pavement

Comments/Questions

Name: CALVIN DAVINGER

Comment/Question:
Do you have Capital project designs now? SPECIFICALLY WETLAND PROJECT;
Marc said YES! → Columbus Square
Mill Creek Tree Trench, Mill Creek Porous Pavement,
" " Outdoor Rain Garden

Name: MRS. DAVINGER

Comment/Question:
How do you keep weeds down (with all of the green stuff) ?
We work w/ partners to help us maintain the sites, such as community groups, BUT PWD will also work O+M into place + it's not as intensive as one thinks → minimal maintenance.

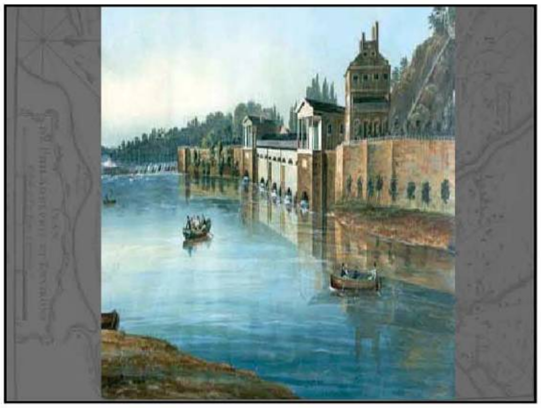
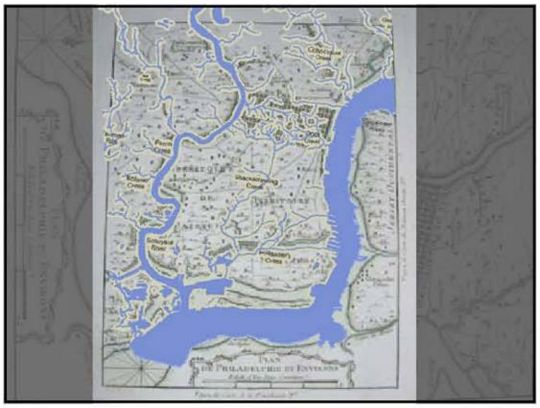
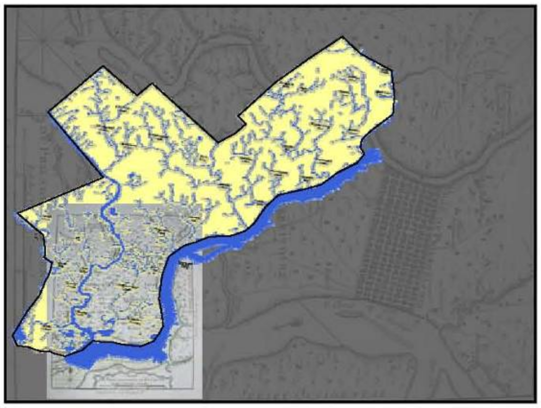
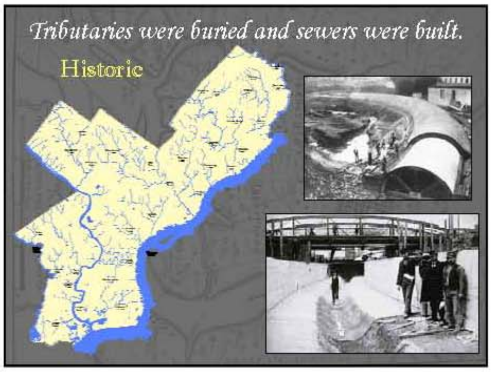
III. Securing clean water for the future
- *Updating* the combined sewer overflow long term control plan



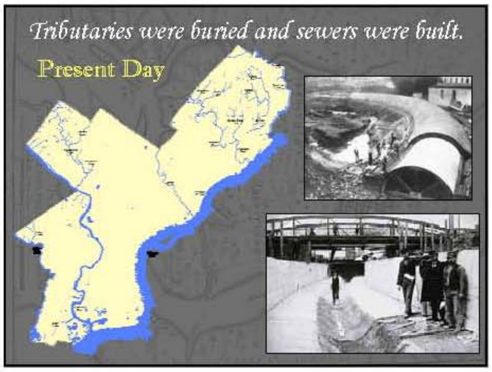






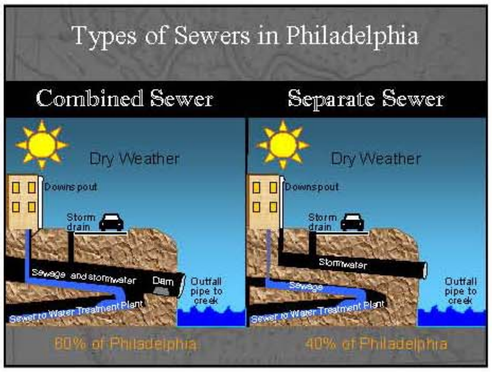
Tributaries were buried and sewers were built.

Historic



Tributaries were buried and sewers were built.

Present Day

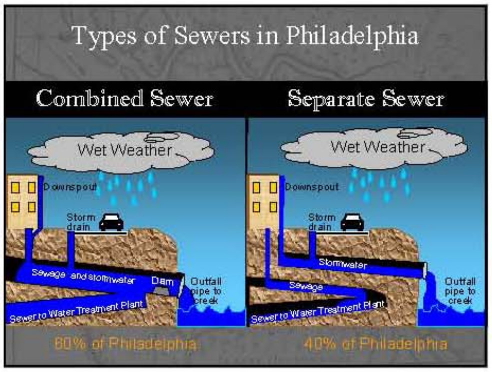


Types of Sewers in Philadelphia

Combined Sewer | **Separate Sewer**

60% of Philadelphia

40% of Philadelphia



Types of Sewers in Philadelphia

Combined Sewer | **Separate Sewer**

60% of Philadelphia

40% of Philadelphia

Stormwater

'Natural' Area

Plants and trees work to absorb stormwater

Stormwater is absorbed into the ground

'Urban' area

Water hits impervious surface and runs off

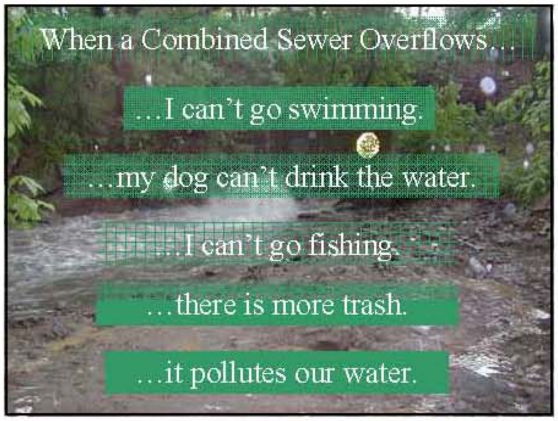
Roofs, streets, parking lots, etc.

Runoff goes into the sewers

4” rain in three hours “Natural” watershed

4” rain in 24 hours “Urban” watershed

Stormwater causes combined sewers to overflow.



When a Combined Sewer Overflows…

…I can’t go swimming.

…my dog can’t drink the water.

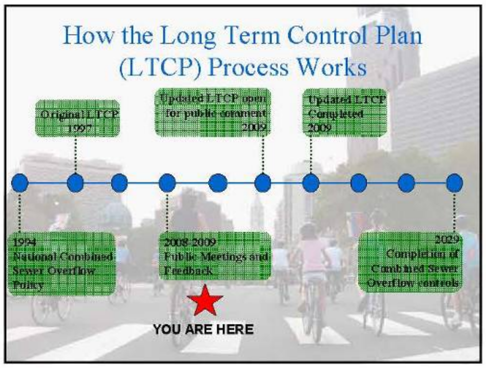
…I can’t go fishing.

…there is more trash.

…it pollutes our water.

National Combined Sewer Overflow Control Policy

Every city with Combined Sewer Overflows must create a Long Term Control Plan to clean up the water.



How the Long Term Control Plan (LTCP) Process Works

Original LTCP 1997

Updated LTCP open for public comment 2009

Updated LTCP Completed 2009

1994 National Combined Sewer Overflow Policy

2008-2009 Public Meetings and Feedback

2029 Completion of Combined Sewer Overflow controls

Public Meetings, Series #2

Philadelphia
Water Department

CSO LTCPU
Public Meeting
October 23, 2008

Agenda

1. Welcome & Introductions

2. Water Quality Characterization, Problem Analysis & Goals for Our Watersheds

3. Questions and Answers

PWD CSOLTCPU Public Meeting #2
Fairmount Water Works Interpretive Center
Thursday, October 23, 2008 from 5:30 – 7:30 p.m.

Comments/Questions
Name:

Comment/Question:
__How is PWD going to provide incentives for residential/ commercial properties to encourage greening?

Name:

Comment/Question:
__Have you (PWD) had any dialogue with the larger parcels that will be affected by the rate reallocation?

Comments/Questions
Name:

Comment/Question:
CSOcast; is it showing whether an overflow is occuring or is it measuring volume?

Name:

Comment/Question:
__Gray infrastructure- how will you model/size?

Comments/Questions
Name:

Comment/Question:
Are there tidal influences on the drinking water intake on the Delaware?

PWD CSOLTCPU
Public Meeting

PWD CSOLTCPU Public Meeting #2
Cobbs Creek Community Environmental Education Center
Thursday, December 4, 2008 from 5:30 – 7:30 p.m.

Comments/Questions

Name: Trish
"Gray infrastructure stores H_2O in tank instead of going to creek?"

Comment/Question: Joanne
Yes.

Name: Debbie Carr
"Where will there be sidewalk planters?"

Comment/Question: Joanne
1st one @ Columbus Sq., but in the future we would like to see it at all parks, city properties + others such places.

Comments/Questions

Name:

Trish

Comment/Question:

Trish Do you have literature on the success of S. grove & the treatment wetland?

Joann - yes, mainly on Total Suspended solids. It has reduced significantly so far

Name:

[redacted] Roberta Turner

Comment/Question:

What is the longevity of porous asphalt? Any models?

Joann Morris Arb. has had theirs for over 17 years & there is minimal maintenance.

Comments/Questions

Last wmn

Name:
Roberta Turner

Comment/Question:
SW Regs. are only <u>in</u> the City?

Yes, but other muni's are doing Similar programs - some even more stringent

Name: Mr. Shallcross
What is baseflow?

Comment/Question:
Marc. The amt. of water in the Stream on non-rainy days. It's not possible to replenish base flow with water not infiltrating land.

Comments/Questions

Name:
Khiet

Comment/Question:
Why catfish in pic?

Marc - B/c fish need DO, so represents importance of DO in creeks.

Name:
Roberta Turner

Comment/Question:
Any difference in bacteria from Suburbs (Montgo Co) vs. in City?
Yes, some time can be worse in suburbs...That's why we need to work with upstream neighbors through partnerships.

⑤

Comments/Questions

Name:

[illegible]

Comment/Question:
Where is the fish ladder in the photo?
Flat Rock.

Will the Fairmount fish ladder have a photographic monitor?
Yes. It will stream to FWWIC.

Name:
Jason Brady

Comment/Question: Marc –
are other cities developing plans? Are we behind?
Yes, we're behind but it's a good thing. B/c others are under consent decree, so we learn from their mistakes & develop a plan that can try to get us under a consent decree.

⑥

Comments/Questions

Name:
~~[illegible]~~ Tim Burkett

Comment/Question:
Matt ~~[illegible]~~ Phila. has a very comprehensive program, ~~[illegible]~~ [illegible] Other cities are doing programs, but not leading with green + filling in with gray.

Name:
Jason Brady

Comment/Question:
What's the price tag? Over how long?

Rough numbers - $2½-$5 Billion over 20 yrs - 30 yrs.

Comments/Questions

Name:
Mr. Shallcross

Comment/Question:
What is the tunnel system?

Marc: Pipes that are 30ft. in diameter
+ 200ft. below the ground.
Will we build tunnels?
Marc: Yes, we will have to build some.

Name:
Tim Burkett

Comment/Question:
What is the degree of imperviousness?
In Cobbs?
56% City-wide

Comments/Questions

Name: Kate Zaidan (Clean Air Council Rep.)
Will the presentation be on-line?

Comment/Question:
Joanne (PWD): Yes – phillyriverinfo.org

Name:
Peter Kurtz (Fairmont Park Commission)

Comment/Question:
Joanne (PWD): The dams are designed to prevent back-ups ???
They capture minimum amt. of rainfall. We have realtime control (computers) that know when to blow dams (inflatable) up + deflate, so they control the flow going out.

②

Comments/Questions

Name: Hal Krieger (Frnds of Monoshe)

Is the Kelly Drive Flood Relief Project a dam (in-storage) project?

Comment/Question:

Joanne (PWD): Yes. (Technical Explanation provided by Marc Cammarata)

Name: Eddie Battle (Eddie R. Battle Assoc.)

Comment/Question:

What other cities have gray projects?

Joanne (PWD): Many – Portland, Baltimore,... a lot of the older cities.

③

Comments/Questions Rev. Williams:

Name: [redacted]

Comment/Question: There is alot of digging Underground in the city. Why not do more modern projects, like watrfall-type (on surface)?

Joanne (PWD) Yes, We would like to do as much on the surface as possible. You are right on! I'll present some of these projects now = Green Approach.

Name: Rev. Williams:

[redacted]

Comment/Question:

How do you pick out sites for projects? My community would love to see a green project in our area - on Chew Ave.?

Joanne: We will work with communities soon on the greening projects, we're just not there yet. like a sidewalk planter

We will work with the Communities through the TTF Watershed Partnership.

Comments/Questions

Name:
Jerry Kaufield (Awbury Arb.)

Comment/Question:
Can you tell us how the sidewalk infiltration project works?

Joanne (PWD): (Detailed technical) explanation followed.

Name: Rev. Williams
~~Spencer Schenk~~

Comment/Question:
What do you consider an Emergency?

Joanne (PWD): These projects aren't for sites handling Emergencies. They are planning initiatives & opportunities, not Emergencies.

Spencer: What if you have flooding Emergency on your property (at storm street drain)?

We need to know about these issues immediately. Report them, so that we can address them.

Comments/Questions Margaret

Student that attends Springside School

Name: Cliveden Park "That is pretty"!

Comment/Question:

~~Spencer~~ Rev. Williams:
Along the expressway, ~~near~~ ~~[illegible]~~ (Queen Ln.) ... Are you doing anything to catch the stormwater Runoff on Park site?

Joanne: Yes, We're looking into a project to better manage the Stormwater there.

Name:

Gerry: What does it mean to get

Comment/Question: the neighborhood involved?

Joanne: Having TTF Watershed Partnership (Sarah Robb Greco) set up now ~~[illegible]~~ enables us to work + coordinate with the Communities.

Charles Parsons: Why are City Water Customers forced to pay for stormwater?

Joanne: We have a 3,000 mile collection system. We have a user fee. ~~[illegible]~~ ~~[illegible]~~

⑥

Comments/Questions

Name: Rev. Williams:

~~[illegible]~~

Comment/Question:

Whatever we do to survive, ~~we need~~ will require the support of the community. Why can't we Start with the community 1st ~ to develop the partnership? We want ~~it~~ a green project at a train station, not a park?

Joanne: That's where we want to go. Before, with pipes only, it wasn't ~~[illegible]~~ benefiting communities. Now, we're designing with communities in mind.

Name:

Comment/Question:

We're gearing up to do more grass roots projects in the very near future

?

Jo: PWD is funded solely thru water + sewer bills. We only collect enough to operate - not to make profit.

We need to sit down with other agencies to work together, like the GreenPlan brought people together.

Comments/Questions

Name:
Charles:

Comment/Question:
The stormwater permit doesn't belong to PWD, but to the City.

Joanne: The PWD is the designated agency. We hold the permit, as a utility.

Name:
Catherine Brown: How can we engage average family? How ~~get~~ them to relate to green projects?

Comment/Question:
Education should be simpler. You shouldn't have to have a degree to understand these problems.

People need to relate the everyday benefit to these projects.

Joanne: Yes, that's why we have Sarah (TTF Partnership) + we want to figure out how to get more people/communities to these meetings + getting involved. →

Catherine : There should be projects that kids have to take on to get involved in those projects.

Marc: One of the major programs that may address this issue is the Green Schools Program. Look at the student, here, that pointed out the rain garden on her school property (in the PowerPoint). That is the result of a demonstration project.

springside Student : Teachers at my school teach through watershed model, taking us to stream to learn about fish + insects, etc.

Charles : ~~The water customers are~~ PWD should go back to just taking care of the basic watr responsibilities,

Marc : When you turn your faucet on, does watr come out?

9

Comments/Questions

Name: Bridget Chadwick:

I live in Cheltenham. I think

Comment/Question: We should work/develop partnerships with DVRPC – transportation projects ~~to widen the streets~~. b/c they are impacting our environment with the widening of streets, etc. Not goo

Marc: Since our projects have multiple benefits, we will have to partner with the multiple agencies.

Name:

Comment/Question:

Charles: How much does PWD spend on cleaning storm drains? Why can't Streets do this?

Marc: We (PWD) own the infrastructure

Rev. Williams: We want (my community) ~~wants~~ greening projects in ~~o~~ my (15-block radius) community. How do we do it?

Marc: Contact Councilman + Work w/ TTF Partnership

Rev. Williams:

~~Spencer~~: Who are the stakeholders?

Marc.: Everyone - Business leaders, landholders, municipal reps, etc.

Bridget: Make a list of shovel ready projects, Like Breaking up channelized stream so

GRAY GREEN

Balance

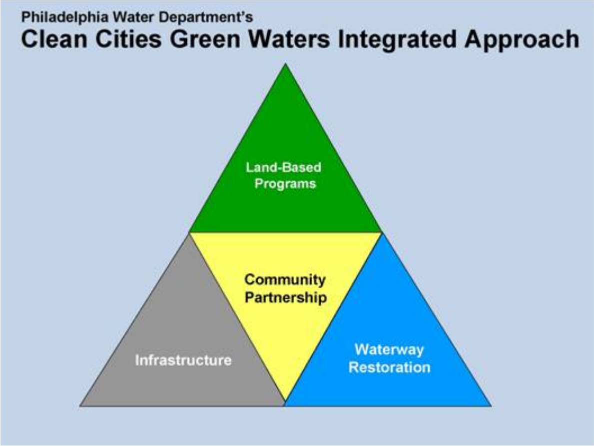
Updating the
Combined Sewer Overflow
Long Term Control Plan
will utilize **GREEN** and **GRAY**
technology.

Good Timing

Currently, many initiatives around Philadelphia share the same 'green' goals.

Mayor's Priorities

- Public Safety: Safest largest city in the country
- Education: Country's premier education city
- Jobs & Economic Development: Grows as a green city
- **Healthy & Sustainable Communities: Philly neighborhoods vibrant and livable**
- Ethics: Philly demonstrates highest standards for ethics and accountability
- Customer Service and a High Performing Government: Philly becomes a national customer service leader



Philadelphia Water Department's

Clean Cities Green Waters Integrated Approach

Community Partnerships

The primary goals of community partnership efforts include:

- Implementation projects in upstream communities
- Coordination of stormwater regulations
- Increased visibility of PWD efforts
- Stronger public stewardship
- More public education and awareness
- Strengthened political and public support for projects

Infrastructure

PWD will continue to evaluate, and where appropriate, design and implement gray infrastructure projects, such as:

- Expanding wastewater treatment capacity
- Creating new storage capacity using tanks and tunnels
- Adding floatables control through outfall netting
- Installing street catch basin controls and cleaning
- Integrating time control, inflatable dams, etc.

Waterways Restoration

PWD is implementing a waterways restoration program including:

- Restoration of stream channels and riparian habitat
- Creation or restoration of wetlands
- Elimination of impediments to fish migration
- Stream maintenance and cleanup
- Floatables control using skimming vessels

Land-based Programs

This program includes a wide variety of measures requiring or encouraging distributed storage, infiltration, and evapo-transpiration of stormwater to ease the burden on existing infrastructure, including:

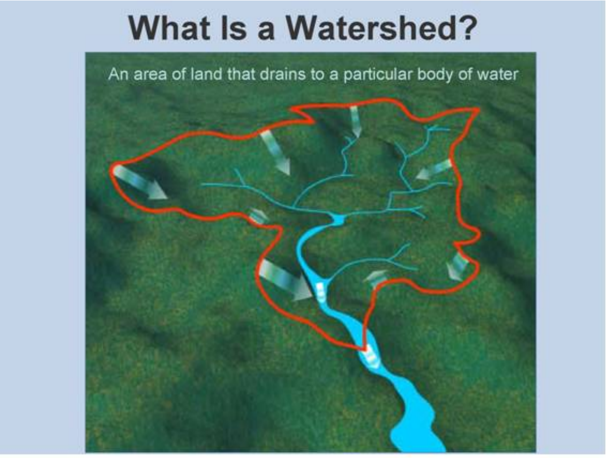
- New stormwater management regulations
- Use of low impact development
- Parcel-based stormwater billing

Together we can achieve a brighter tomorrow

Why Are We Here?

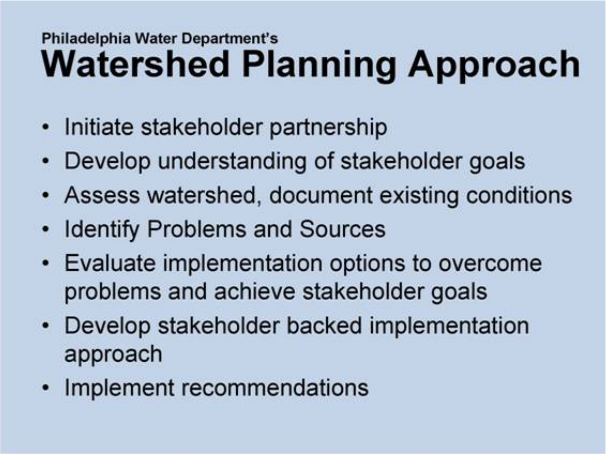
Why Are We Here?

- To gain an understanding of existing watershed problems and conditions
- To explore how the Long Term Control Plan addresses these problems and helps us realize our vision



What Is a Watershed?

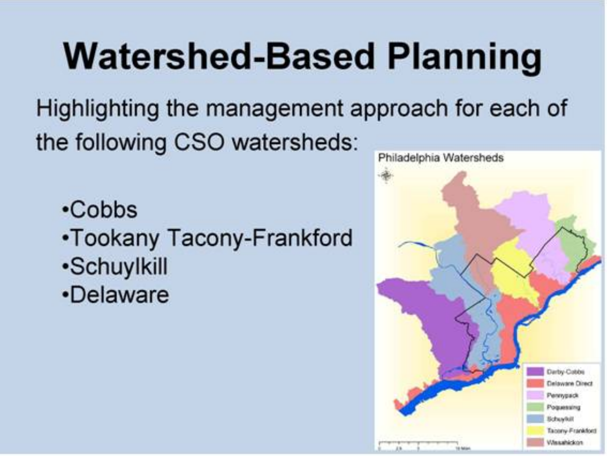
An area of land that drains to a particular body of water



Philadelphia Water Department's

Watershed Planning Approach

- Initiate stakeholder partnership
- Develop understanding of stakeholder goals
- Assess watershed, document existing conditions
- Identify Problems and Sources
- Evaluate implementation options to overcome problems and achieve stakeholder goals
- Develop stakeholder backed implementation approach
- Implement recommendations



Watershed-Based Planning

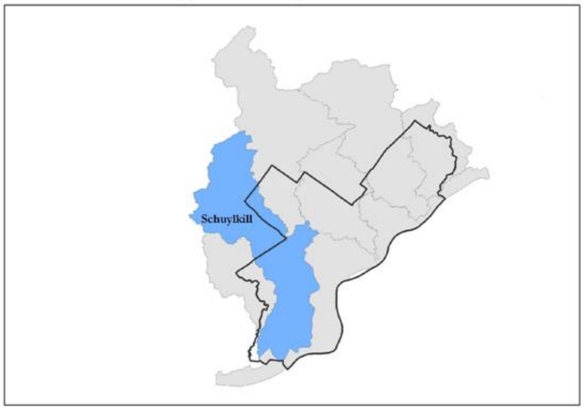
Highlighting the management approach for each of the following CSO watersheds:

•Cobbs
•Tookany Tacony-Frankford
•Schuylkill
•Delaware

Philadelphia's Regional Watersheds

Philadelphia's Regional Watersheds

Philadelphia's Regional Watersheds



Philadelphia's Regional Watersheds

PWD's Watershed Partnerships

Watershed	Partnership Active Since	Plan
Darby-Cobbs	1999	IWMP Completed 2004; Implementation underway
Tookany/Tacony-Frankford	2000	RCP completed 2004; IWMP completed 2005; Implementation underway
Schuylkill (Schuylkill Action Network)	2004	Source Water Protection Plan completed 2004; RCP completed 2001
Delaware (Direct)	2007	RCP Underway (2008); Implementation plan to follow

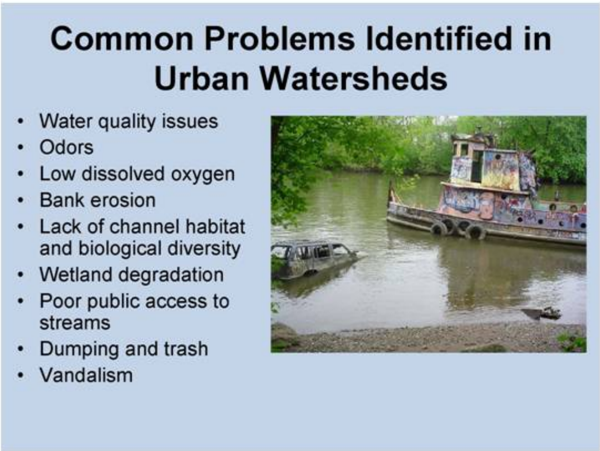
Characterization of Existing Conditions

PWD implements a detailed monitoring program in each planning shed including:

Chemical

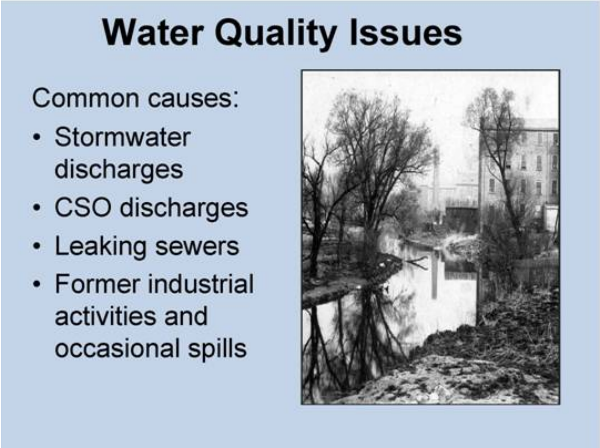
Biological

Physical



Common Problems Identified in Urban Watersheds

- Water quality issues
- Odors
- Low dissolved oxygen
- Bank erosion
- Lack of channel habitat and biological diversity
- Wetland degradation
- Poor public access to streams
- Dumping and trash
- Vandalism



Water Quality Issues

Common causes:

- Stormwater discharges
- CSO discharges
- Leaking sewers
- Former industrial activities and occasional spills

Odors

Common causes

- Cross-connections in separate sewered areas
- Leaking sewers along stream
- CSOs during storms

Low Dissolved Oxygen

Common causes/sources:

- Oxygen demanding substances
- Leaking sanitary sewers
- CSOs
- Stormwater runoff
- Lack of streamside shade
- Over-widened channels
- Loss of baseflow
- Excessive invasive plant growth

http://www.waterencyclopedia.com/images/wsel_01_img0017.jpg

Bank Erosion

Common causes:

- Lack of stormwater management upstream
- High impervious cover in watershed

Lack of Channel Habitat and Biological Diversity

Common causes:

- Lack of stormwater management upstream
- High impervious cover in watershed
- Alterations to stream channel (channelization)

Degraded Wetlands

Common causes:

- Land development
- Uncontrolled Stormwater

Poor Public Access to Streams

Common causes:

- Residential development up to stream edge
- Lack of public paths

Dumping and Trash

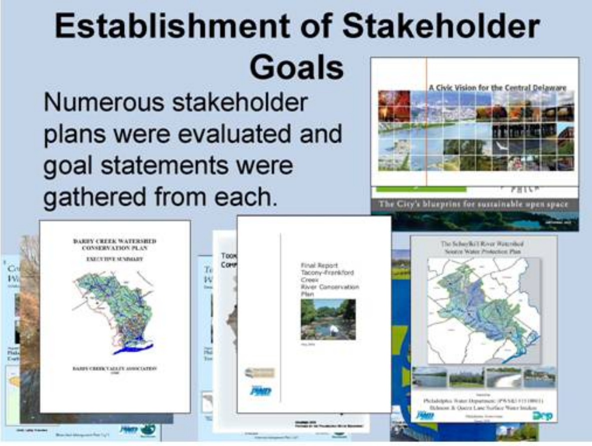
Common causes:

- Litter carried by storm flows
- Illegal dumping at vehicle access points

Vandalism

Common causes:

- Poor lighting
- Lack of public visibility and engagement
- Lack of patrolling

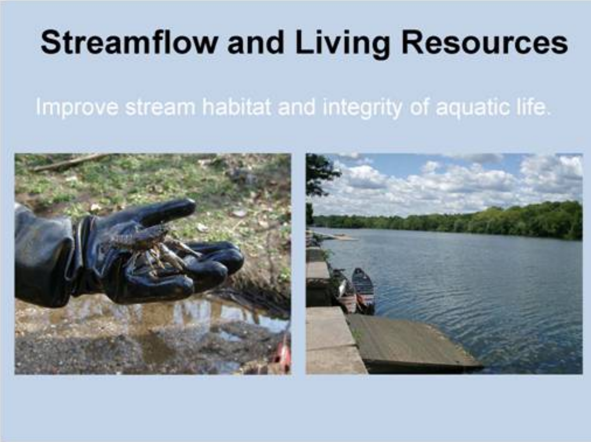


Establishment of Stakeholder Goals

Numerous stakeholder plans were evaluated and goal statements were gathered from each.

The Philadelphia Water Department's "Umbrella" Stakeholder Goals

1. Streamflow and Living Resources
2. Instream Flow Conditions
3. Water Quality and Pollutant Loads
4. Stream Corridors
5. Flooding
6. Quality of Life
7. Stewardship, Communication, and Coordination
8. Recreation



Streamflow and Living Resources

Improve stream habitat and integrity of aquatic life.

Instream Flow Conditions

Reduce the impact of urbanized flow on living resources.

Water Quality and Pollutant Loads

Improve dry and wet weather stream quality to reduce the effects on public health and aquatic life.

Stream Corridors

Protect and restore stream corridors, buffers, floodplains, and natural habitats including wetlands.

Flooding

Identify flood prone areas and decrease flooding.

Quality of Life

Enhance community environmental quality of life

Stewardship Communication and Coordination

Foster community stewardship and improve inter-governmental, state, local, and stakeholder cooperation and coordination on a watershed basis.

Next Steps

So – How do we get there?

- Visions have been outlined by various stakeholder groups
- We believe implementation of the LTCP with respect to the visions outlined by stakeholders and coupled with adequate support will enable the realization and execution of these visions.

6:00 – 8:00 p.m.

Comments/Questions

Name:

Audience Member

Comment/Question:

I like what is being proposed. But what if a street already has trees, will PWD remove the trees or build infiltration pits beneath the trees? Can this be done?

No. PWD will not remove any trees. We love trees. If a block already has a full set of trees, we'll look at other green street tools, e.g., bumpouts, that we can apply to manage the stormwater.

Name:

Audience Member

Comment/Question:

Who is paying for this?

PWD's Capital budget is funding the design and implementation of both the green and the gray, traditional projects. But it ultimately comes back to being paid by our ratepayers, our water/sewer customers. That's why it's so important to have public feedback

Comments/Questions

Name:

Audience Member

Comment/Question:

I live on Albion Street which is a very small street. Can you green a street like mine?

Small streets are certainly more challenging than wider streets, but we are still fine tuning designs that may be a better fit for streets like yours. When homeowners install a rain barrel or a flow through planter, this can help make the street a green one.

Name:

Audience Member

Comment/Question:

When this happens, how are we training the designers and contractors to build these properly and to maintain them in the future?

PWD has been designing and building stormwater demonstration projects for the past 10 years with many public and private partners, so we've gained a lot of experience. But we are still learning and we have consultants working with us to help us refine our current designs and to help us develop guidelines for long term maintenance and operation of these systems. We see green infrastructure as providing green economy jobs.

Comments/Questions

Name: Audience Member

Comment/Question:

I live on a block where nobody wanted trees. So I bought a large planter and placed it on my sidewalk. Suddenly, all my neighbors saw how nice it looks and that it stopped people from parking on the sidewalk. Now a lot of my neighbors have tem. Sometimes, people just need to see how things looks and work first to accept and want them.

Yes! That's why we are doing model neighborhood projects. Social Marketing!

Comments/Questions

Name:
Rev. Williams

Comment/Question:
PWD did a very good job restoring the creek near Adams Ave. & Rising Sun intersection.

Name:
Michael Wilcox ([illegible])

Comment/Question:
Can you tell us about Porous asphalt?

PWD: Yes, I will explain it & show you because we have a demonstration of it right outside of the building.

Comments/Questions

Name:
Rev. Williams

Comment/Question:
Could you separate sw runoff and sanitary at the end of the pipe?

PWD: You can't do it at the end of pipe. It must be at the source, unless you build a tunnel.

Name:
Rev. Williams

Comment/Question:
How does green roof work, in terms of plants surviving?

PWD: Green roofs use sedums, which are ideal for green roofs.

Comments/Questions

Name:

Rev. Williams

Comment/Question:

Is the City incorporating green design in all current bumpouts.

PWD: We're in the process of trying to convince them, (storm wtr) but we need the residents to go to City + express they want it to be green.

Name:

Brian Williams (gray)

Comment/Question:

How do you deal with mosquitoes?

PWD: Mosquitos ~~[illegible]~~ only like stagnant water. Green infrastructure ~~[illegible]~~ is designed ~~[illegible]~~ to move water ~~[illegible]~~, therefore ~~water is always moving~~ mosquitoes aren't a problem.

Michael Wilcox (Green)

Parking lot for church I work with is having problems with green b/c it is taking a long time & it is too expensive.

↳ PWD: We have to change the system (to speed it up?)

We can speak to congregations, about the greening benefits.

Green is Michael (Biz Card

9

Comments/Questions

Name:
Rev. Williams

Comment/Question:
Can you create long sidewalk planters along entire block?
PWD: Yes, you can put multiple ones in.

Name: Lisa

Comment/Question:
~~Explain~~ Do you put tree pits or actual trenches in for tree trenches?

→ PWD: Actual trenches are below ground.

⑤

Comments/Questions

Name: Lisa

girl line?

Comment/Question: What do trees do to sidewalks?

PWD: Broken laterals invite trees, not vice versa. Also If you plant trees properly, then you won't have problem.

Name: Rev. Williams

Comment/Question: I tried the new system for my roof where you paint the roof gray + now runoff just shoots right off.

PWD: That is the negative impact that roofs have.

⑥

Comments/Questions

Name:

Brian Williams gray

Comment/Question:

Kids can drown in buckets of water. Are rain barrels safe?

PWD - Yes, they have tops on top to protect children from getting inside.

Name:

Rev. Williams

Comment/Question:

Do we have to cut grasses on sidewalk?

PWD: No, we want to use native plants, so there is less maintenance.

⑦

Comments/Questions

Name:
Lisa

Comment/Question:
Are there incentive for developers to do green infrastructure?

PWD: Yes, new regs. require that they manage 1st inch of runoff, if site is going to be disturbed and is larger than 15,000 ft.^{2}

Name:
Michael Wilcox

Comment/Question:
I'm a registered plumber. I'm concerned about contamination, esp rain barrel. What are the negatives? Maybe have sticker on rain barrel that says not safe to drink water?

PWD: Contamination in SW is same at source, as at the end of pipe.

~~Maybe adding~~ Adding sticker warning is a great idea!

Rev. Williams

If I have rain barrel + move
out + new owner has problem
w/ rain barrel. Am I liable?

PWD: No!

Lisa

Since city corridors already developed,
how become green?

PWD: Convert vacant lands to urban
farms or other greening.
As streets get redeveloped, add green.
give businesses incentives.
give homes incentives.
Need to tackle in steps ~ in
pockets & areas that need redeveloping.

Rev. Williams

Wouldn't City save $ by building green, instead of paying alot for cement?

PWD - Yes, In future, we hope it will be a requirement to do green, but right now it's not cost-effective for the Streets Dept.

Rev. Williams

Why not green 30th st station? It's blight + an eyesore.

PWD - It's not cost effective at this moment for them, possibly.
We need to create the incentive for ~~the~~ property owners to do this like in the way we will bill large commercial + Industrial properties (billed based on size of property + amt. of impervious)

~~Rev. [illegible]~~

Rev. Williams

Is there such thing as too many trees on ~~a~~ block?

PWD - Yes. You need to have appropriate spacing, so roots don't overlap, etc.

Rev. Williams

Who owns the sidewalks?

PWD = You do!

PWD CSOLTCPU Public Meeting, Series #3
Northern Liberties Community Center
Thursday, June 10, 2009
6:00 – 8:00 p.m.

Comments/Questions

Name:

Erika

Comment/Question:

We have a new rain garden in our park ~ a mini - version of a wetland!
Marc - Yes!

Name:

Comment/Question:

Is street higher than sidewalk where bioswales are present?
Yes, in order to direct stormwater to the vegetation

Comments/Questions

Name:

Aberdee

Comment/Question:

Are there contractors that can do porous pavement?

PWD: Yes, there are. You can find them on-line. We need the demand to be there, so that the costs decrease + contractors want to do it.

Name:

Aberdee

Comment/Question:

How much stormwater runoff will you remove thru greening?

PWD: The 1^{st} inch of rain fall (at the very least).

③

Comments/Questions

Name:

Comment/Question:

Is it common to measure temperature thru the green projects?

Green will create more cooling than blacktop at sometimes we consider temperature differentials, depending on the project.

Name:

Comment/Question:

Do you have information on what the neighbor think, re: vegetation?

[illegible] At Saylor Grove Wetland, residents love it!

Comments/Questions

Name:
Attendee

Comment/Question:
Do native plants stay?
With control, after first two seasons,
yes + they keep invasives out.

Name:
Attendee

Comment/Question:
How does school sign up for greening?
Phila. School Dist. is a private entity +
PWD can only financially support public ~~projects~~
properties, but PWD can support
private schools with other support (e.g. grant funds
+/or license agreements/ownership rights.)

⑤

Comments/Questions

Name:
Attendee

Comment/Question:
Has anyone on city-council taken this on as a city issue (green)?
The Mayor! We are [illegible] following his green plan

Name:
Attendee

Comment/Question:
Can you green rec. center?
Yes!

⑥

Comments/Questions

Name:

Comment/Question:

Will new SW regs affect homeowners?

NO!

Only industry/commercial + huge property owners.

However, bills go down when these impacted properties start putting in green (they will get credit)!

Name:

Comment/Question:

Is there a way to incentivize residential credit?

Right now, no, but working w/ PennFuture, So that resident gets credit if put Rain barrels, etc. in.

(57)

Comments/Questions

Name:

Comment/Question:

Can we green playground + (next to Akwd) REC Center?
Yes, We have to create a demand for it!

Name:

Comment/Question:

Is general street tree planting a component?
Yes, but current tree pits are not designed to manage SW runoff. But we will pay $ to enhance tree pits.

Green Cities, Clean Waters

Summer, 2009

CSO-Control Approach Survey

The Philadelphia Water Department (PWD) believes that the best way to spend its customers' dollars to decrease Combined Sewer Overflows (CSOs) is through an approach that largely focuses on a green solution that captures stormwater on land through more natural practices, with some traditional "gray" solutions, such as new pipes and tanks to fill in the gaps where green practices can't capture the volume that we are targeting.

- Generally, do you like this strategy?

- Generally, what do you like about this strategy?

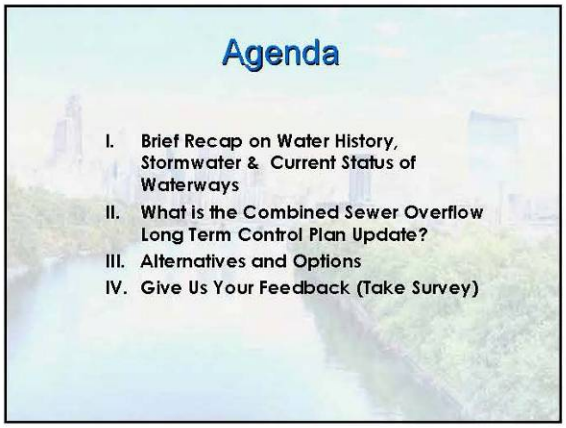
- Generally, what concerns do you have about this strategy?

- What additional information do you think would be helpful?

Green Cities, Clean Waters

The Combined Sewer Overflow Long Term Control Plan Update

Philadelphia PWD Water Department



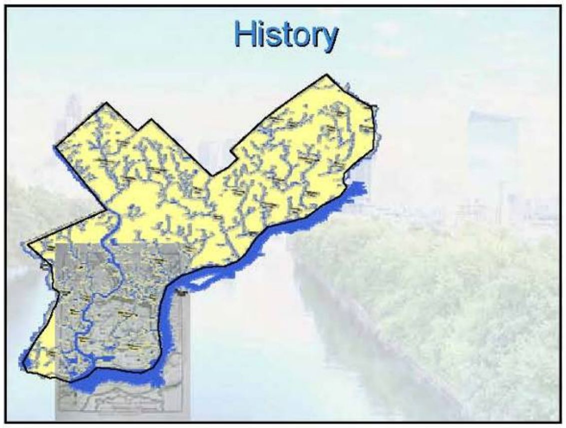
Agenda

- I. Brief Recap on Water History, Stormwater & Current Status of Waterways
- II. What is the Combined Sewer Overflow Long Term Control Plan Update?
- III. Alternatives and Options
- IV. Give Us Your Feedback (Take Survey)

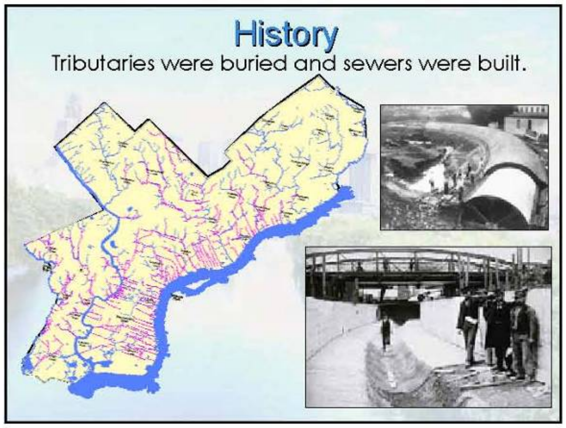
Vision

- We want a beautiful, green city with clean waters.

Image credit: PENN Praxis

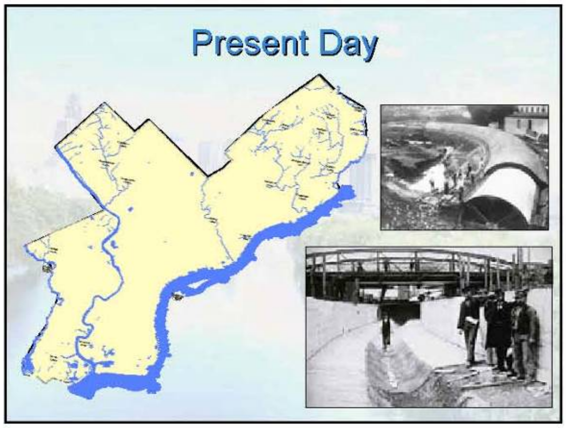


History

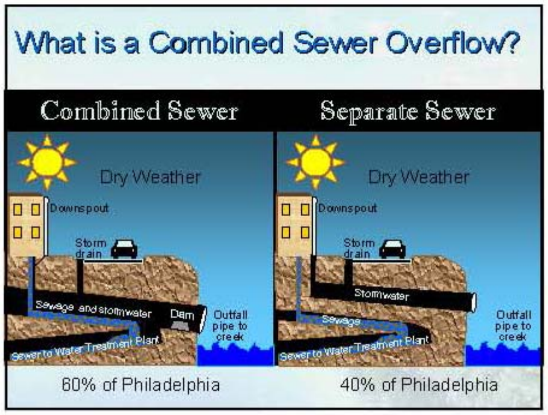


History

Tributaries were buried and sewers were built.



Present Day



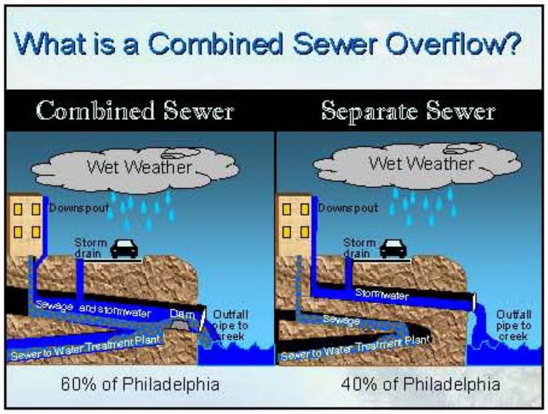
What is a Combined Sewer Overflow?

Combined Sewer

Separate Sewer

60% of Philadelphia

40% of Philadelphia



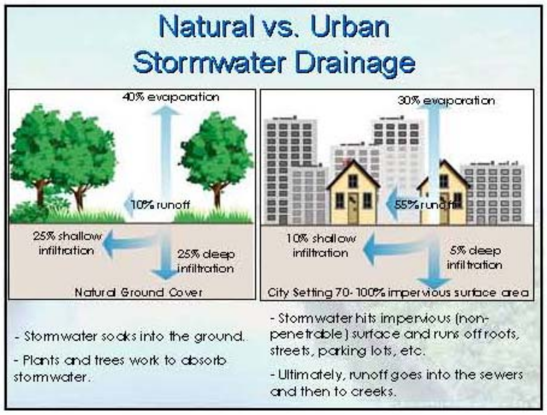
What is a Combined Sewer Overflow?

Combined Sewer

Separate Sewer

60% of Philadelphia

40% of Philadelphia



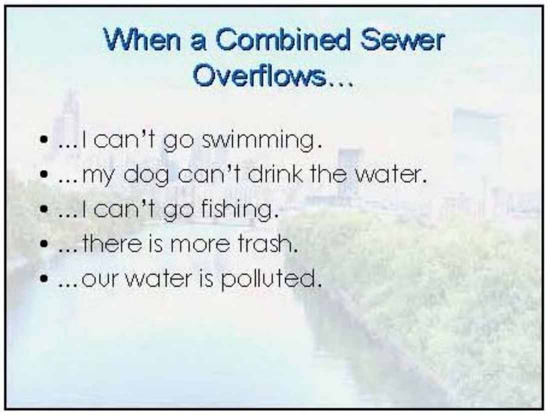
Natural vs. Urban Stormwater Drainage

- Stormwater soaks into the ground.

- Plants and trees work to absorb stormwater.

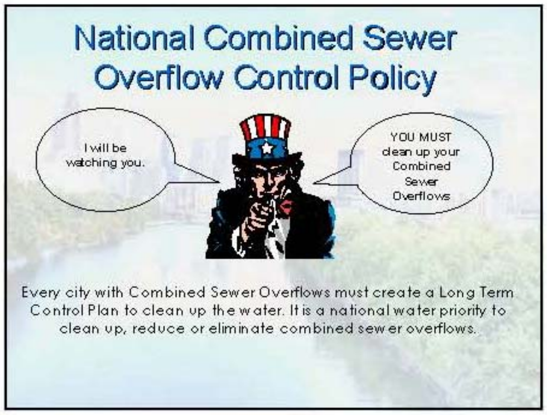
- Stormwater hits impervious (non-penetrable) surface and runs off roofs, streets, parking lots, etc.

- Ultimately, runoff goes into the sewers and then to creeks.



When a Combined Sewer Overflows…

- …I can't go swimming.
- …my dog can't drink the water.
- …I can't go fishing.
- …there is more trash.
- …our water is polluted.



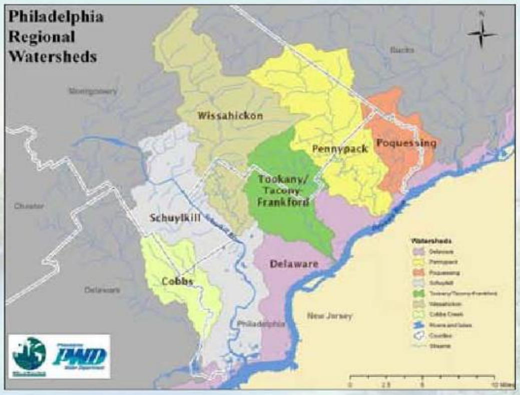
National Combined Sewer Overflow Control Policy

Every city with Combined Sewer Overflows must create a Long Term Control Plan to clean up the water. It is a national water priority to clean up, reduce or eliminate combined sewer overflows.

It's not just a Philly Problem

Philadelphia's Watershed Approach

Watershed: An area of land that drains stormwater to a common body of water



Implementation Approach

- PWD has developed "**Implementation Targets**" as means to measure progress and sustain stakeholder support through the Combined Sewer Overflow Plan over the span of 20 -30 years.
  - **Target A:** Dry Weather Water Quality and Aesthetics
  - **Target B:** Healthy Living Resources
  - **Target C: Wet Weather Water Quality**

Target A: Dry Weather Water Quality and Aesthetics

Target B: Healthy Living Resources

Boulders and plants added to provide refuge for fish and bugs

Concrete box channel remains

Target C: Wet Weather Quality

- **Requires lengthy timeline**
  - Heavily relies on Combined Sewer Overflow and Low Impact Development teams
- **Building both Green and Gray Infrastructures**
  - Inflatable Dam, Combined Sewer Overflow gates, etc.
  - Best Management Practices
    - All of our Green Program Elements
- **Adaptive Management**

Cost vs. Benefit

The Water Department is expecting to spend billions of dollars over 20 – 30 years to reduce the number of Combined Sewer Overflows that occur each year.

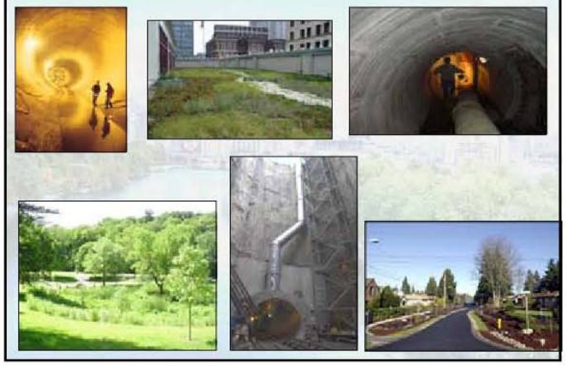
There is a level of benefit (and cost) associated with every dollar spent on building green and gray infrastructure.

PWD is working to determine a cost effective solution to improve and restore the quality of our waterways and to reduce the number of annual overflows.

What can we afford that works best?

The most cost effective & beneficial method will be the **Green Infrastructure** approach with some traditional "gray" solutions to fill in the gaps where green practices can't capture the volume that we are targeting.

Gray Infrastructure Solutions Green



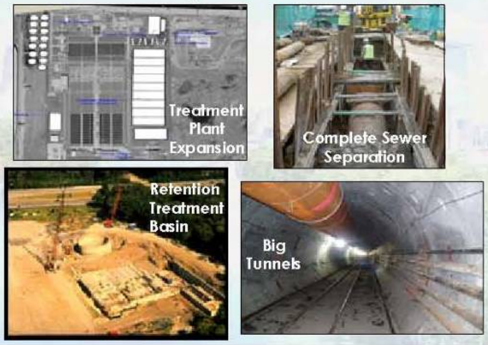
Gray – What is it?

"Gray" refers to traditional infrastructure solutions to manage stormwater.

4 Options

- Complete Sewer Separation
- Expand Treatment Facilities
- Big Tunnels/More Storage
- Retention Treatment Basins

Gray Options

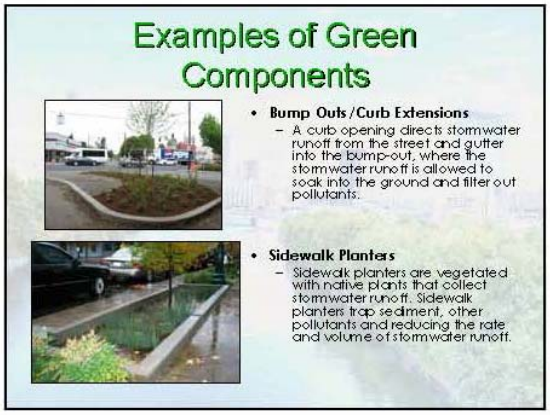


Green – What is it?

- "Green" is the use of natural and man-made technology to mimic nature's ability to deal with stormwater.
- Treats stormwater as a resource
- 10 Green Elements in our Green Program

Examples of Green Components

- **Green Roofs**
  - A green roof is a roof that is partially or completely covered with vegetation to manage stormwater runoff.
- **Porous Pavement**
  - This porous surface replaces traditional pavement, allowing stromwater runoff to infiltrate directly into the soil and receive water quality treatment.



Examples of Green Components

- **Bump Outs/Curb Extensions**
  - A curb opening directs stormwater runoff from the street and gutter into the bump-out, where the stormwater runoff is allowed to soak into the ground and filter out pollutants.
- **Sidewalk Planters**
  - Sidewalk planters are vegetated with native plants that collect stormwater runoff. Sidewalk planters trap sediment, other pollutants and reducing the rate and volume of stormwater runoff.

Examples of Green Components

- **Grass Pavers**
  - Grass pavers are porous surfaces with open areas designed to allow grass to grow within the open slots.
- **Flow-through Planters**
  - Flow-through planters are vegetated boxes with a small reservoir that receive runoff through rain drains or curb cuts.

Examples of Green Components

- **Living Wall**
  - A living wall is a vertical arrangement of plants and other vegetation.
- **Rain Barrel**
  - A Rain barrel collects and stores stormwater runoff from downspouts.

Examples of Green Components

- **Tree Trenches**
  - The trees and soil in the tree trench provide the important function of filtering out common stormwater runoff pollutants and absorbing stormwater runoff
- **Vegetated Swales**
  - Swales are designed to trap suspended solids and to reduce the flow and velocity of stormwater runoff.

Green Program

Green Streets

Components of a Green Street could include:

-Curb Openings
-Sidewalk Planters
- Street Trees
- More Landscaping
-Curb Extensions/Bump Outs
-Porous Pavement

Green Program

Green Homes

Components of a Green Home could include:

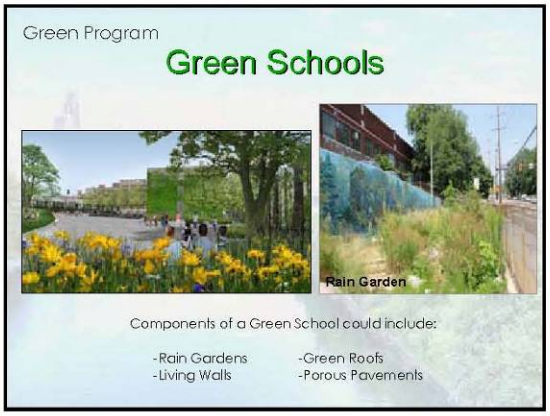
-Rain Barrels
-Rain Gardens
-Flow-through Planters
-Green Roofs
-Native Plants
-Energy Efficient Practices & Appliances

Green Program

Green Parking

Components of Green Parking could include:

- Porous Pavements
-Vegetated Swales
- Pavers



Green Program

Green Schools

Components of a Green School could include:

-Rain Gardens
-Living Walls
-Green Roofs
-Porous Pavements

Green Program

Green Public Facilities

Components can include:

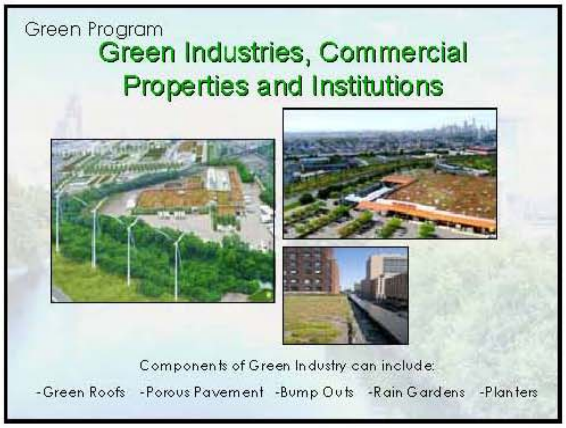
- Living Wall
- Street trees
- Rain Gardens
- Green Roofs
- Porous Pavements
- Sidewalk Planters

Green Program

Public Open Spaces

Components can include:

- Rain Gardens
-Porous Pavements
- Tree Trenches
- Vegetative Swales



Green Program

Green Industries, Commercial Properties and Institutions

Components of Green Industry can include:

-Green Roofs -Porous Pavement -Bump Outs -Rain Gardens -Planters

Green & Gray Infrastructure Costs

- **Dollars**
  - Both strategies cost money to implement.
- **Construction**
  - Both strategies require construction and the disruptions that come with it.

Green & Gray Infrastructure Costs

- **Traffic**
  - Both strategies may cause traffic (during construction).
- **Energy**
  - Both strategies consume energy.

Benefits

Gray	Green
Reduced Combined Sewer Overflows	Reduced Combined Sewer Overflows
Improved Water Quality	Improved Water Quality
More Jobs	More Jobs (Green Jobs)
	Better Air Quality & Health Benefits
	Cooling
	Reduced Heat Stress
	Reduced Carbon Footprint
	Energy Savings
	Increased Recreation
	Enhanced Aquatic Life & Terrestrial Life
	Improved Aesthetics
	Higher Property Values

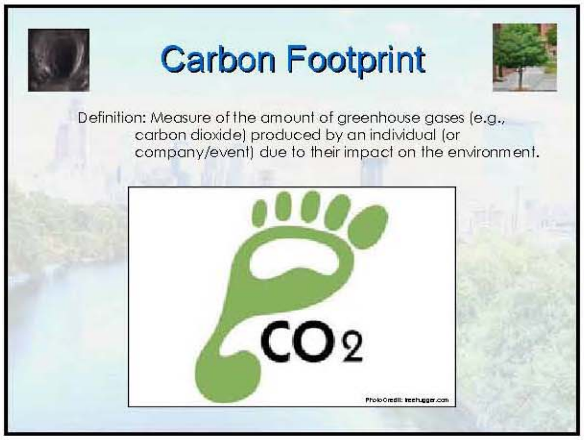
Reduced CSOs/ Improved Water Quality

Both strategies are designed to clean up, reduce or eliminate combined sewer overflows and therefore, improve water quality.

Increased Job Creation

Green technology creates more local green jobs over time compared to gray infrastructure, where big companies are hired to do the work on a short-term basis.

Air Quality & Health Benefits



Carbon Footprint

Definition: Measure of the amount of greenhouse gases (e.g., carbon dioxide) produced by an individual (or company/event) due to their impact on the environment.

Photo Credit: treehugger.com

Increased Recreation

Green parks coupled with clean water increases recreational opportunities and promotes a city of Brotherly Love.

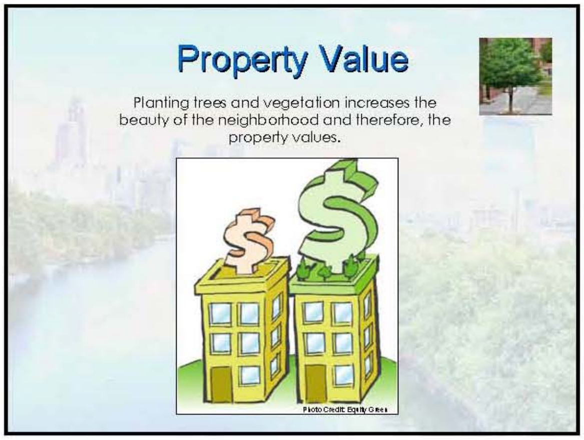
Enhanced Aquatic Life & Terrestrial Life

Improve stream habitat and integrity of aquatic and terrestrial life.

Fish Ladder

Fishing Fest

Aesthetics



Property Value

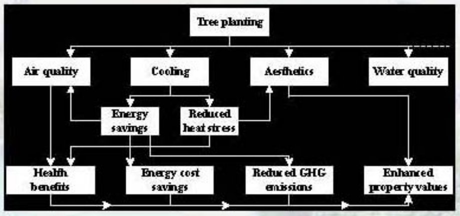
Planting trees and vegetation increases the beauty of the neighborhood and therefore, the property values.

Photo Credit: Equity Green

Economic/Environmental/Social Benefits

- Costs
- Ecological Benefits
- Recreation
- Heat Stress Mortality
- Energy Savings
- Air Quality
- Carbon Footprint
- Aesthetics
- Jobs
- Property Value

How Benefits are Linked



Alternatives Evaluation

- **Qualitative Factors Considered**
  - Public Support
  - Location
  - Construction Feasibility
  - Complexity and Difficulty of Solution
- **Maximize benefits to society – Triple Bottom Line**
- **Minimize Cost to PWD and its Customers**
- **Financing and Affordability**
- **All alternatives must meet goals**

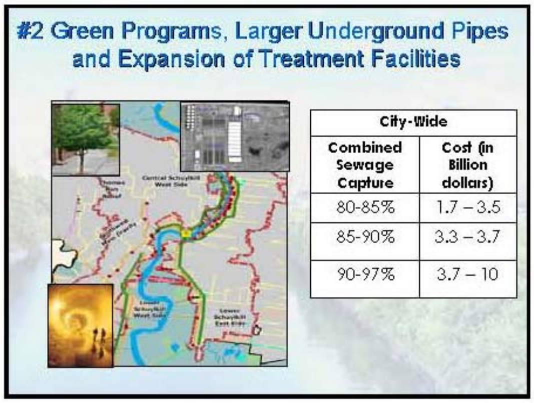
The alternatives considered to help us reach the ultimate goal of reducing CSOs…

Alternatives Evaluated

1. **Big Tunnels**
2. **Green Programs, Larger Pipes and Expansion of Treatment Facilities**
3. Green Programs, Increased Transmission , Expansion of Treatment Facilities and Retention Treatment Basins
4. **All Green**
5. Green with Smaller-Scale Gray
6. Plant Expansion, Satellite Treatment (Ballasted Floc)
7. Plant Expansion, Satellite Treatment (Swirl/Vortex)
8. Retention Treatment Basins

#1: Big Underground Tunnels

City-Wide	
Combined Sewage Capture	Cost (in Billion dollars)
80-85%	N/A
85-90%	N/A
90-97%	3.2 – 10



#2 Green Programs, Larger Underground Pipes and Expansion of Treatment Facilities

City-Wide	
Combined Sewage Capture	Cost (in Billion dollars)

Green Streets/Model Neighborhood Petition

I, Andrew Kerber as the representative for the 2500 block of Grays Ferry Avenue, submit this petition as evidence that nearly 100 percent of the residents on my block want to find out more about becoming one of the City's Green Streets (which can include trees with planters, curb bumpouts, above ground planters, and other street features that better manage rainwater runoff and improve the beauty of our block).

#	Name	Address
1	Andw Kerber	2534 Grays Ferry Ave
2	[illegible]	2527 Grays Ferry Ave.
3	[illegible]	2527 GRAYSFERRY AVE
4	Mildred J Himes	2521 Grays Ferry Ave
5	[illegible]	2519 Grays Ferry Ave
6	[illegible]	2519 Grays Ferry Ave.
7	[illegible]	2519 Grays Ferry Ave
8	Beverly Higgins	2527 Grays Ferry Ave.
9	JAMES CAMPBELL	2531 GRAYS FERRY AVE
10	Madeleine Gates	2515 Grays Ferry Ave
11	Joe Whitley	2536 Grays Ferry Ave.

Model Neighborhood

Three Typical Stormwater Management Projects

Street Tree Plantings

Street trees provide shade, improve air quality, reduce stormwater runoff, absorb noise and beautify neighborhoods. From a stormwater management perspective, trees can reduce stormwater runoff by capturing rainfall on leaves and branches. Trees can be planted in special ways to capture the flow of water from the street and sidewalk letting it soak to the soil around the tree roots, and filtering pollutants from the runoff. Other tree benefits include, improved property values and crime reduction.

Sidewalk Planters

Sidewalk planters (or rain gardens) are shallow depressions in the sidewalk, vegetated with native plants that collect stormwater runoff from the adjacent street and sidewalk, filter pollutants from the runoff and allow the runoff to soak into the ground. Stormwater runoff from the street is directed to the planter through a curb opening. Stormwater that is not absorbed by the plants and the soil overflows back out to the street and the existing storm inlet or directly into the sewer system through a pipe. Sidewalk planters/rain gardens help protect our waterways by trapping sediment, fertilizer, oil, pet waste and other pollutants and reducing the rate and volume of the stormwater runoff.

Vegetated Curb Bump Outs

Vegetated curb bump-outs are located along the curb line of the street, where the curb is bumped out into the existing parking lane of the street. A curb opening directs stormwater runoff from the street and gutter into the bump-out. The bump-out is slightly depressed and vegetated with native plants to allow stormwater runoff to pond, soak into the ground and become filtered by the plants before overflowing to the existing storm inlet. In addition to managing stormwater runoff and improving water quality, bump-outs may also slow down traffic and create safer pedestrian crossings.

WHY A MODEL NEIGHBORHOOD ?

Philadelphia Water Department (PWD) is working on a new and exciting green initiative with its partners, Fairmount Park, Citizens for Pennsylvania's Future (PennFuture), the Next Great City coalition, Pennsylvania Horticultural Society and local community groups.

Model Neighborhoods is an initiative to transform the neighborhoods of Philadelphia into model green communities that manage stormwater in innovative ways. These neighborhoods will showcase green infrastructure elements, such as street trees trenches, sidewalk planters, and bump outs/curb extensions (see middle panel for definitions). These projects help clean stormwater runoff, help slow it down and help it soak back into the ground, reducing the amount of stormwater that would otherwise travel through underground pipes to our streams and rivers.

Beyond stormwater benefits, green infrastructure projects beautify neighborhoods, improve air quality, reduce the City's temperature (urban heat island effect), and create safer, healthier communities.

HOW TO NOMINATE YOUR BLOCK?

1. Contact your local neighborhood group or civic organization to notify them of your interest. Civic partners play a key role in *Model Neighborhoods.*
2. Fill out the Green Street Petition and obtain signatures from the residents on your block.
3. Submit the petition to the Philadelphia Water Department so that your block can be considered.

* The first four blocks that sign up in each neighborhood will be considered for a green street. Others may be considered at a later date.

See contact information on the reverse side for materials.

MODEL NEIGHBORHOOD ELEMENTS

Examples of green infrastructure elements that you may see on your street, block and on other public properties:

Street Trees Trenches

Street trees trenches capture the flow of stormwater from the street and sidewalk, letting it soak into the soil. They provide shade, improve air quality, absorb noise and beautify neighborhoods.

Sidewalk Planters

Stormwater runoff from the street is directed to the planter through a curb opening. Sidewalk planters help protect our waterways by trapping pollutants and reducing stormwater runoff.

Bump Outs/Curb Extensions

A curb opening allows stormwater runoff from the street and gutter into the curb extensions, where the stormwater runoff soaks into the ground and filters out pollutants.

Rain Barrels

Rain barrels are storage containers that collect and store stormwater runoff from the downspouts.

Rain Gardens

Rain gardens are shallow depressions in the land, vegetated with native plants that filter stormwater runoff.

Porous Pavement

Porous pavement allows stormwater runoff to soak right through it, while providing the same structural support as traditional pavement.

WHERE ARE THE CURRENT MODEL NEIGHBORHOODS?

Location	*Civic Partner*
Passyunk Square	Passyunk Civic Association
Awbury/Cliveden	Tookany/Tacony-Frankford (TTF)Watershed Partnership

For more details on the above events and other future events, in addition to more information on *Model Neighborhoods*, visit:

www.PHILLYWATERSHEDS.org
Facebook Group: *Green Neighborhoods through Green Streets*

WHAT CAN HOMEOWNERS DO?

Examples of projects that homeowners can do on their properties to better manage stormwater runoff:

- Plant a tree.
- Install a rain barrel.
- Plant a rain garden.
- Install a planter (container garden).

Project Sponsors:

FREQUENTLY ASKED QUESTIONS (FAQS)

Q. Who funds *Model Neighborhoods*?

A. Primarily Philadelphia Water Department (PWD), with support from other city agencies and local nonprofit groups.

Q. Are projects on private properties considered for funding?

A. No. PWD can only implement projects in public right of ways (i.e. streets and sidewalks), however, PWD may provide technical support to private property owners. In fact, PWD is interested in evaluating residential properties in Philadelphia for rain gardens (where appropriate) and flow-through planters. Please contact us, if you are interested.

Q. Who will maintain the *Model Neighborhoods* green infrastructure projects?

A. PWD. However, PWD will rely on residents to do minor maintenance, such as litter removal and sweeping leaves.

Q. Where can the general public purchase porous asphalt?

A. Porous asphalt is only cost-effective in larger batches. PWD recommends that you contact a contractor that you would hire to install a traditional driveway and ask this contractor if he/she is willing to work with porous materials.

Green Cities, Clean Waters
MODEL NEIGHBORHOODS

Discover how a green neighborhood could be YOURS!

History

In 1682, William Penn made a treaty with the local Native American tribes under the sheltering branches of the "Treaty Elm" which stood at what is now Penn Treaty Park. Penn's vision for the city would eventually grow up around that site and include parks, gardens, open spaces and trees.

Now, more than 325 years later, Penn would be proud of his vision. There are more than 125,000 street trees in the 21st Century version of his "greene countrie towne," and they are the responsibility of Fairmount Park.

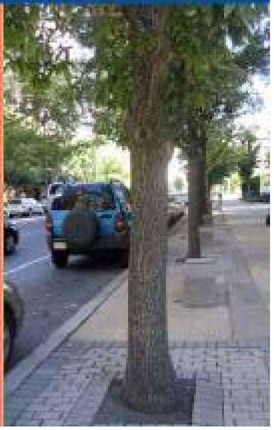
Call 911 for emergencies (fallen tree or limb is blocking a street, damaged a house, car or utility line) after normal business hours.

Fairmount Park
PHILADELPHIA'S PARK SYSTEM

PHILADELPHIA Street Trees

WWW.FAIRMOUNTPARK.ORG



What is a "Street Tree?"

Street trees are located in the strip of land between sidewalks and curbs – or in planting sites cut into sidewalks next to a curb. They range from newly planted maple trees to the mighty oak trees planted in the 1920's. Philadelphia street trees are important to our environment, they shade and beautify our neighborhoods, absorb noise, filter pollution and improve property values while keeping William Penn's vision alive.

Street trees don't have an easy life. They have to endure pests and diseases, air pollution, summer droughts and salt contamination from melting ice and snow. Damage occurs from cars, animals, bicycle chains and by advertisements stapled or nailed to their trunks.

Like any living thing, street trees need care and Fairmount Park has the authority over street trees in the City of Philadelphia. Please contact us before planting, removing, pruning or any other work on Philadelphia street trees.

A periodic visual inspection of your street trees will help keep them healthy. Examine your tree for the presence of:

- pests and insects
- stunted growth
- dead branches
- tree rot
- cavities in the trunk or branches

How You Can Help

At the request of Philadelphia property owners, Fairmount Park's Street Tree Management Division will inspect street trees and, if conditions warrant, have the tree pruned or removed for safety reasons at no cost to the homeowner.

Fairmount Park arborists will also inspect your location to determine whether it is appropriate for a new street tree. If so, the proper tree species for the site will be selected by the arborist.

Property owners are permitted to hire tree contractors* (qualified arborists) to perform work on street trees adjacent to their property. This work can include planting, pruning, minor root pruning (required for plumbing and/or masonry work), pesticide spraying, fertilization and tree removal. Contractors must apply for a permit from the Fairmount Park Street Tree Management Division prior to performing work on any street tree in Philadelphia.

* Homeowners can obtain a list of qualified tree contractors by contacting the Philadelphia Street Tree Management Division.

When street trees are no longer able to provide shade and beauty, they provide benefits to Philadelphia citizens through our organic recycling program. Free wood chips, firewood and compost are available at the Fairmount Park Recycling Center near Ford Road & Chamounix Drive in West Fairmount Park and at Park District recycling yards in Northeast, Northwest and South Philadelphia. Contact 215.683.0200 for locations.

Tree Tenders

In 1993, Fairmount Park partnered with The Pennsylvania Horticultural Society to launch the Tree Tenders project to teach general tree care skills to organized community groups and Philadelphia residents. Today, there are over 1,900 Tree Tenders from 150 different neighborhoods.

Learn how you can be a Tree Tender by visiting http://www.pennsylvaniahorticulturalsociety.org/phlgreen/tree-training.html.

Sidewalk Trees
& House Sewer Laterals

Homeowners often engage in a type of "chicken or the egg" discussion concerning the roots of their sidewalk trees and the effect of these roots on their sewer lateral – the pipe that connects the home's wastewater drainage system to the sewer in the street. You may have heard a neighbor claim that the roots of the tree in front of their house broke through their lateral pipe, causing the pipe to eventually block up so that problem-free flushing became a fond memory.

Tree roots can find their way into a sewer lateral, but normally that occurs only after the lateral has begun to deteriorate as a result of age, settlement or other factors. Most of a tree's root system is concentrated in the **top 12 – 24 inches of soil** directly beneath the concrete sidewalk. A home's sewer lateral, beneath the sidewalk slab, is an average of **six to seven feet below ground,** providing a buffer of soil and fill between the lateral and the tree.

The **brown pipe** connecting the house to the sewer in the street is the house sewer lateral. The **blue pipe** connecting the house to the street is the house water service. Note that the sewer lateral is approximately six feet below the sidewalk and that the roots of the tree are approximately two feet below the sidewalk.

When roots are adventurous enough to find their way to the lateral, it is usually a result of a crack or open joint in the pipe that allows water to escape into the surrounding soil, attracting stray tree roots.

Following are a few additional facts to set your mind at ease when contemplating your own sidewalk tree:

- **House laterals** in Philadelphia are made from **cast iron.** Pipes of this material usually last 60 – 70 years. This is based upon average Philadelphia weather (its freeze and thaw cycles), urban loads in streets (cars and trucks), the nature of sidewalk/street fill and electrical currents in the ground. Older homes, built prior to World War II, may have had terra cotta lateral pipes, which are more prone to cracking and breaking.
- **Sidewalk trees** in the City are approved by the Fairmount Park Commission to ensure that only trees that are suitable to urban environments (trees that can withstand urban challenges such as pollution and sidewalks & streets that are filled with infrastructure) are planted along city streets.
- Plumbers have the ability to **check the condition of house laterals** without digging up the pipe if they need to look for blockages caused by roots or other materials. In addition, commercially available products exist that can be poured into your toilet and flushed into your pipe, destroying any roots that may have found their way into the pipe via a crack.

Trees are Good for your House and the Environment

- A 2005 Study by the University of Pennsylvania found that trees translated into **higher property values.** The study found, for example, that planting a tree within 50 feet of a house increased its sale price by nine percent.
- Trees provide a **cooling shade** to a home in the hot summer months, decreasing the amount of energy required to cool a home and the related electric bills. Tree lined blocks can actually decrease local temperatures.
- Trees naturally **clean the air** of pollutants and create a neighborhood **noise buffer.**
- Trees improve **stormwater management,** reducing the amount of polluted stormwater runoff that normally would go directly into storm drains. The **leaves** of trees capture rain drops before they hit the ground, evaporating some of this rain water and sending it back into the air. **Tree roots** allow rainwater to filter back into the soil, recharging the often thirsty earth.

Your House Lateral and You

Property owners are responsible for the care and maintenance of their house lateral, from the point it leaves the property to its connection into the city sewer in the street. PWD has a Homeowner's Emergency Loan Program (HELP) in place to assist residents with the cost of repairing a broken sewer lateral (the average replacement cost is $3,000). If you receive a notice from PWD about a broken lateral or water service, call the number on the notice – 215-685-xxxx. For water or sewer emergencies, or for general information, call PWD's hotline at 215-685-6300.

MODEL NEIGHBORHOODS

for STAFF ONLY

Street Trees in Philadelphia

Background Information

What are some of the benefits of street trees?
Street trees provide shade from the hot rays of the sun. The temperature is always several degrees cooler under the shade of a tree! Trees muffle noise from traffic and construction, help filter dust and pollution particles from the air (the air is actually cleaner and healthier beneath and around trees!), help reduce flooding from storm water runoff, and provide habitat for wildlife. Trees give beauty and charm to neighborhoods, can increase property values by 10-15%, and can encourage local businesses.

Who owns the street trees?
The City of Philadelphia

What is a street tree?
A street tree is a tree located between the sidewalk and the curb. A tree growing in your yard is not a street tree even though its branches might be hanging over into the sidewalk or street. The Park will go out to the site to determine if it's a street tree or not.

Who is responsible for street trees?
Fairmount Park manages all street trees (as well as park trees) in the City of Philadelphia and is responsible for planting, pruning and removing street trees. Most of this work is done by arborists overseen by the Park. The Park has a separate contract for each of these three services: one for planting, a second for pruning, and a third for removal.

Who do I call to get a street tree planted?
Call Fairmount Park's *Street Tree Management Division* at **215 685-4363** or send an email to **fpc.streettree.info@phila.gov** .

How long does it take to get a street tree planted?
The wait to get your street tree planted can be one year, depending on resources. The Park plants street trees in spring and fall. Spring planting begins mid-March; fall planting begins at the end of October. The planting schedule depends on weather conditions and when the vendor can get trees. (Fairmount Park just received their 2006 **and** 2007 street tree budget in one lump and will be planting these trees in fall 2007 and spring 2008.)

Who chooses the street tree?
The resident can request a particular species, but the Park arborist who visits the site makes the final determination. There are many factors that go into choosing a street tree: the Park chooses a variety of species so that they don't create a monoculture and looks at the surroundings--are there overhead wires, telephone poles, driveways?--all of which determine what the species will be and whether the species should be large, medium, small or columnar. Check out the City of Philadelphia's recommended street tree list at www.fairmountpark.org/RecommendedTreeList.asp

Planting the street tree
A large hole, called a tree pit, is dug for the new street tree. The minimum tree pit size is 3'x3' and depends on the site conditions. After the tree is planted, the contractor mulches the tree pit area, stakes the new tree, and waters it.

What can residents do to help care for their street tree?
Residents should **water** their street trees with 15-20 gallons of water each week. One of the biggest stresses on newly planted street trees is not getting enough water. Residents can also remove weeds from the tree pit and should not plant anything (other than the tree) in the tree pit. Weeds, flowers and ground cover compete for water, nutrients and root space and can put stress on your street tree. Residents can help by being careful with car doors and bikes, which can damage the protective bark. To do anything more to your street trees, such as major pruning or removing, you must obtain a permit. Contact Fairmount Park when you observe a problem. The Pennsylvania Horticultural Society (PHS) has a program called "Tree Tenders" that provides 9 hours of training on tree biology, urban stresses, tree identification, basic pruning, root care, tree planting, and community organizing. For more information about the Tree Tenders program, call PHS at (215) 988-8844 or check out their website at www.pennsylvaniahorticulturalsociety.org.

Who do I call when there is a problem?
To report a problem with your street tree, call Fairmount Park's *Street Tree Management Division* at **215 685-4363** or send an email to **fpc.streettree.info@phila.gov** If it is after normal working hours, leave a voice mail message. The Park will send someone out within 7-10 working days to look at it. Hours are 7:00 am – 3:30 pm Monday through Friday except City holidays.

If it is an **emergency**, **call 911**. Examples of emergencies are a tree or branch falls and is blocking access to the sidewalk or street; a tree or branch falls on your roof. Someone from the Park will be dispatched through radio.

Will the Park remove a tree I don't like?
No. The Park does not take down trees because people don't like them. There has to be a valid problem for the Park to remove it. Having to rake up fallen leaves, seeds and other fruits is not considered a valid problem.

What if the tree is breaking up my sidewalk?
If a street tree is breaking up the sidewalk, the Park will come out to look at it. The Park will make a decision on a case-by-case basis according to the condition of the tree and what's going on around it. Often the solution is for the property owner to replace the paving.

Will the Park take care of a problem with a tree in my yard?
No. The Park is not responsible for trees growing in yards. Trees growing in the yard are the resident's responsibility.

What about trees growing in alleyways?
The City only responds to emergencies with trees in alleyways. Emergencies would include a tree or branch that falls and blocks the alleyway, falls on your roof, or damages your property. For emergencies with trees in your alleyway, call **215 683-0222**. The work on alleyway trees is paid for through the Mayor's Neighborhood Transformation Initiative (NTI) program and is performed by Fairmount Park arborists under the supervision of Gus Jardell.

What about trees growing through cracks in the sidewalk?
Trees growing through a crack are not street trees. Any tree growing through a crack should be pulled out. The resident can do this.

What are some of the stresses on street trees?
The biggest stress on new trees is not getting enough water. Cuts and gashes in the protective bark caused from car doors, lawn mowers, weed wackers, bicycles, and carving initials allow insects and disease to enter and can weaken and kill the tree. Insects and disease can also enter when branches get broken or torn off from climbing on trees. Salt used to melt ice on sidewalks and roads can try the leaves and roots (although the Park tries to choose salt-tolerant trees), dog feces (dog feces are high in acidity and nitrates which are harm ful to trees), pollution, harmful insects and disease.

Where does the money come from for street trees?
Money for street tree planting, care and removal comes from a variety of sources :

- Planting money comes from the Park's capital budget.
- Pruning and removal money comes from the Park's operating budget and the Managing Director's operating budget.
- City Council members have their own "discretionary" money and will sometimes allot some of this money for street trees. For example Janie Blackwell recently put money aside to do tree removals in her council district.

Tell me more about Fairmount Park's *Street Tree Management Division*
The Park's Street Tree Management Division is located at Boelson Cottage on West River Drive . The division has a total of 9 Park staff: this includes five tree inspectors who are in the field each day, two arborists, one word processing operator, and a manager (Fran Piller) who oversees the division. For management purposes, the Street Tree Management Division divides the city into 5 districts. East Park's district is district 1.

Green Neighborhoods through Green Streets Survey

Green Neighborhoods through Green Streets

The Philadelphia Water Department (PWD) would like to green our neighborhoods to better manage stormwater (rain or melting snow) runoff before it enters storm drains. This would consequently improve our quality of life. The City would like to help by planting trees, and by using other green techniques.

We appreciate your feedback on green streets. This survey will only take about 7 minutes. Time permitting please complete the entire survey of 12 questions.

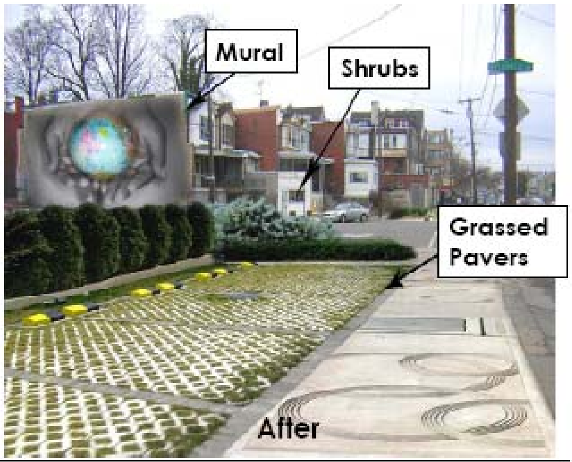
1) After viewing each set of images below, are you in favor of greening in your neighborhood?

☐ Yes

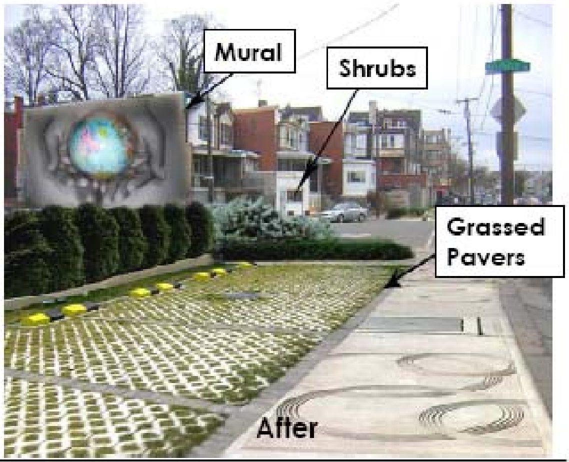
☐ No

a) What do you like about the images?

b) What don't you like about the images?



2) In your own words, please describe a "Green Street."



2) In your own words, please describe a "Green Street."

3) Using trees and plants as examples of green street features, what actions would you be willing to take to green your neighborhood? Please check all that apply.

☐ Ask for more trees/plants for your street

☐ Plant a tree/garden

☐ Maintain a tree/garden (pruning, removing litter, etc.)

☐ Advocate for more trees/plants

☐ Participate in a public meeting

☐ Educate your neighbors about trees/gardens

☐ Provide feedback

☐ Other (please specify)

4) Of the following issues, which THREE are most important to you?

☐ Safety – e.g. Traffic calming

☐ Health – e.g. Less asthma

☐ Environment – e.g. Cleaner water

☐ Streets – e.g. In safe condition

☐ Parks and playgrounds – e.g. In good condition

☐ Less or no trash and litter

☐ Less or no vandalism

☐ Leaving the world a better place for our children (the next generation)

5) If the nearby riverfront was cleaner, safer and more accessible, which recreational activities would you participate in? (Choose all that apply.)

☐ Walking/Hiking/Jogging
☐ Boating/Canoeing/Kayaking
☐ Resting/Viewing/Hanging Out
☐ Biking
☐ Birding
☐ Fishing
☐ Picnics
☐ Photography
☐ Other (please specify)

6) A: Where does the water in your neighborhood go when it rains?

☐ Nearest water treatment plant
☐ Nearest creeks and/or rivers
☐ I don't know

B: What do you call this water?

☐ Rainwater
☐ Runoff
☐ Stormwater
☐ Other (please name)__________

8) A: Are you familiar with the term watershed?

☐ Yes
☐ No

B: What watershed do you live in?

(include an "I don't know" option aside from all the watersheds)

9) Do you have any additional comments?

10) Gender

☐ Male

☐ Female

11) Age

☐ Under 18

☐ 18-25

☐ 26-34

☐ 35-45

☐ 46-54

☐ 55-64

☐ Over 64

12) Race/Ethnic Background

☐ White or Caucasian

☐ Black or African-American

☐ Latino/Hispanic

☐ Alaska Native or Native American

☐ Asian/Pacific American

☐ Prefer not to answer

☐ Other (please specify)

13) What is your zip code?

14) What is your block address (ex. 1100 Market St.)?

Thank you for taking this survey! If you would like to learn more about Philadelphia's waterways and watersheds, visit www.phillyriverinfo.org.

Start showing your support for green streets today! Forward the link to this survey to your friends and colleagues in Philadelphia.

Green Neighborhoods through Green Streets

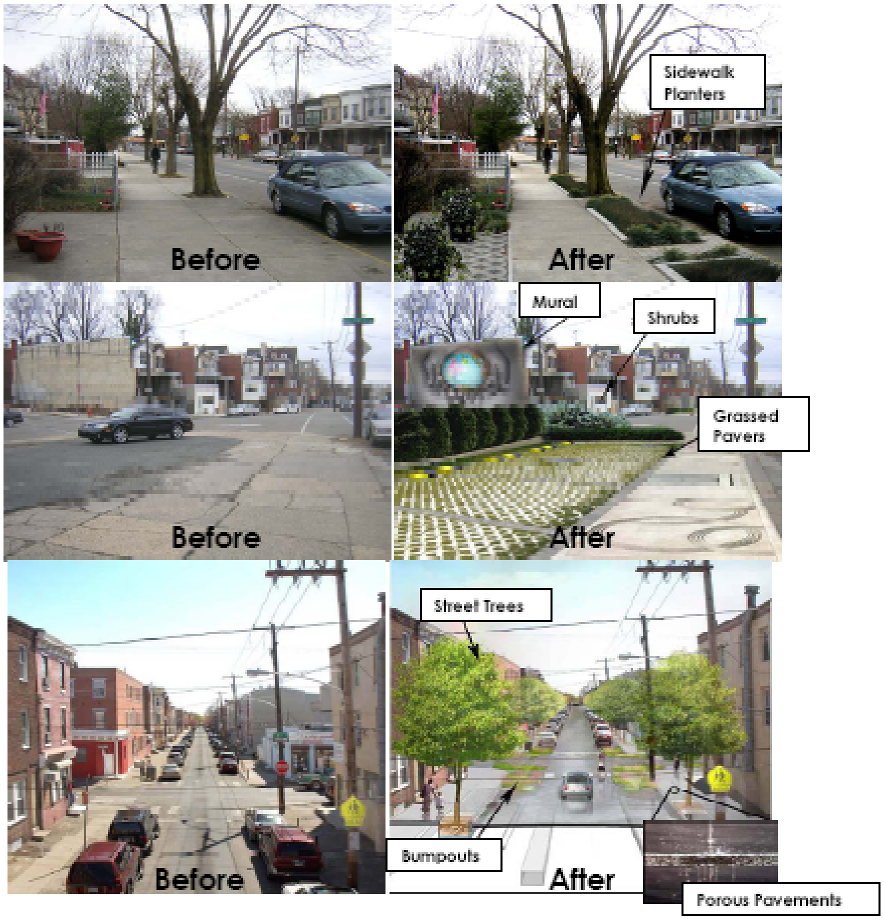
The Philadelphia Water Department (PWD) would like to green our neighborhoods to better manage stormwater (rain or melting snow) runoff before it enters storm drains. This would consequently improve our quality of life. The City would like to help by planting trees, and by using other green techniques.

<u>**We appreciate your feedback on green streets. This survey will only take less than 5 minutes.**</u>

1. After viewing each set of images below, are you in favor of greening in your neighborhood?
☐ Yes
☐ No

a) What do you like about the images?

b) What don't you like about the images?



Turn Over →

2. Using trees and plants as examples of green street features, what actions would you be willing to take to green your neighborhood? Please circle or check all that apply.

- ☐ Ask for more trees/plants for your street
- ☐ Plant a tree/garden
- ☐ Maintain a tree/garden (pruning, removing litter, etc.)
- ☐ Advocate for more trees/plants
- ☐ Participate in a public meeting
- ☐ Educate your neighbors about trees/gardens
- ☐ Provide Feedback to the Philadelphia Water Dept.

3. In your own words, please describe a "Green Street."

4. Do you have any additional comments?

5. Your Zip Code:

____

6. What is your block address (ex.1100 Market Street)?

____

Thank you for taking this survey. If you wish to learn more about green streets, please provide your contact information (name, email, phone and/or address) in the space below so that we can update you on meetings and activities. You can also check us out online at www.phillyriverinfo.org

Total number of responses: 438(online) + 297(hardcopy) = **735**

What do you like about the images?		
Responses	**Total**	%
1) I love greening	150	22.3
2) Beautiful, Attractive, etc...	100	14.9
3) I want more Trees	91	13.5
4) Safer, Friendlier, Welcoming Atmosphere	91	13.5
5) Plants and Vegetation	75	11.1
6) Environment friendly	58	8.6
7) Health and Cleanliness	54	8.0

Description:

1) They are in favor of greening.
2) Greening makes the block look aesthetically pleasing.
3) They want more trees.
4) Greening makes them feel safe in their block and creates a sense of pride in their neighborhood.
5) They want more gardens, planters, flowers and grass.
6) Greening improves air quality and takes care of runoffs.
7) Greening provides shade, cools the warm air and makes the block cleaner.

Overall: 92% responded positively (698/735)

What do you dislike (potential concerns)?		
Responses	**Total**	%
1) Nothing	226	34.7
2) Maintenance problems	148	22.7
3) Trash and Leaves	63	9.7
4) Root Damages	47	6.5
5) Before pictures	42	5.5
6) Financial costs/ taxes	29	4.1
7) Narrow Sidewalk	24	3.1

1) They like everything about greening
2) Who will prune, water and cut the trees and plants?
3) Trash and pet waste will accumulate near trees and bumpouts. Foliage is also a problem.
4) Tree roots damages sidewalk, pipes and home foundations.
5) They dislike the "before pictures."
6) Where is the money for the project and upkeep coming from? Are taxes going to rise?
7) Trees and plants might get vandalized.

Overall: 60% have potential concerns regarding greening

Describe a green street		
Responses	**Total**	%
1) A street with substantial plant life	167	25.7
2) Clean, safe and friendly neighborhood	99	15.3
3) All about greening	76	11.7
4) Deals with runoff issues	64	9.9
5) None	56	8.6
6) a street that is properly maintained	47	7.2
7) environment-friendly street	46	7.1

1) Explained a green street as having trees, plants, vegetation, garden, etc...
2) Aside from having some or none of number 1, they mentioned the positive effect it has on the morale, health and cleanliness of the neighborhood.
3) They mentioned a little bit of everything. I just decided to group them all together.
4) Aside from having some or none of number 1, they specifically mentioned that it helps deal with flooding, runoff, etc...
5) No comment
6) Aside from having some or none of number 1, they mentioned that it needs to be maintained either by the neighbors or by the city.
7) Aside from having some or none of number 1, Green helps the environment (more oxygen, cooler, etc...)

2) What are you willing to do?

	total	%
Ask for more trees/plants for your street	575	79.42
Plant a tree/garden	533	73.62
Maintain a tree/garden	516	71.27

Model Neighborhoods

Global

Basic Info

Name:	Model Neighborhoods
Category:	Common Interest - Health & Wellness
Description:	Philadelphia Water Department (PWD) is working on a new and exciting green initiative with its partners, Fairmount Park, PennFuture, Pennsylvania Horticultural Society and local civic organizations.

Model Neighborhoods is an initiative to transform the neighborhoods of Philadelphia into model green communities that manage stormwater in innovative ways. These neighborhoods will showcase green infrastructure elements, such as street trees, sidewalk planters, and bump outs/curb extensions (see middle panel for definitions). These projects help clean stormwater runoff, help slow it down and help it soak back into the ground, reducing the amount of stormwater that would otherwise travel through underground pipes to our streams and rivers.

Beyond stormwater benefits, green infrastructure projects generate other benefits too – beautifying neighborhoods, improving air quality, reducing the City's temperature (urban heat island effect), and creating safer communities, among other benefits.

Green Neighborhoods through Green Streets

Global

Basic Info

Name: Green Neighborhoods through Green Streets

Category: Common Interest - Health & Wellness

Description: The Philadelphia Water Department (PWD) would like to green our neighborhoods to better manage stormwater (rain or melting snow) runoff before it enters storm drains.

Green structures and practices have a lot of advantages. Aside from beautifying Philadelphia, these practices and structures also improve water quality and better air quality.

To better understand the benefits of greening to your community and our goals, we would like to explain why the Philadelphia Water Department (PWD) is proposing this effort.

In much of Philadelphia, as in many other large cities throughout the world, a single-pipe, "combined sewer system" is used to collect and treat both rain runoff, or "stormwater," and residential and commercial sanitary waste. However, during intense rain events, there is not enough capacity in our pipes and treatment plants to handle the volume of stormwater runoff, causing Combined Sewer Overflows (CSOs) into Philadelphia's creeks and rivers. The City will need to spend billions of dollars over the next decades to reduce these overflows.

To reduce Combined Sewer Overflows, PWD proposes to use a combination of "grey infrastructure," including building underground storage pipes and tunnels and expanding our treatment plants, and "green infrastructure." Examples of green infrastructure include curbside tree planters, rain gardens, rain barrels and green roofs. These "green" practices all use natural methods to allow stormwater runoff to soak in the ground to prevent it from reaching our sewers or slow down the runoff enough to help prevent overflows.

The PWD would like to emphasize the use of green infrastructure based on the additional social, economic and health benefits it can provide to Philadelphia neighborhoods.

In order to do that, we need your help. We believe that a truly effective greening effort would involve the cumulative participation of all of Philadelphia's neighborhoods. Our first step is to work with you to help us gauge the interest in greening through conducting a survey.

THE CSO LONG TERM CONTROL PLAN

GREEN CITIES
CLEAN WATERS

History and Background

The City of Philadelphia

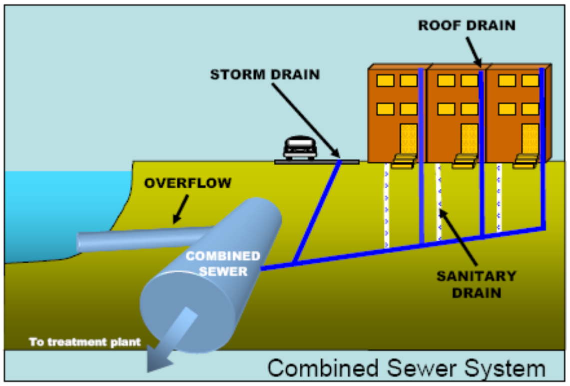
Philadelphia
PWD
Water Department

INTRODUCTION

Philadelphia is fortunate to have an abundance of creeks, open space, parkland and beautiful rivers. The Schuylkill and Delaware Rivers are not only scenic; they are the drinking water source for Philadelphia residents. These waterways, however, suffer from pollution from various sources, both within and outside the City limits. One such pollution source: Combined Sewer Overflows (CSOs).*

What are Combined Sewers Overflows?

A combined sewer system is a wastewater collection system owned by a municipality which transports wastewater* from homes, businesses and industry, stormwater* from the approximately 75,000 storm drains on our streets and property roof leaders through a single-pipe system to a Water Pollution Control Plant (WPCP).



During dry weather conditions (when it is not raining) and during very small storm events, combined sewers* can adequately transport this mixture of sanitary

to a nearby stream or river so as to prevent the flooding of homes and streets. This is what is known as a Combined Sewer Overflow (CSO).

Real-Time Control - Tacony Creek Park Storage

Infrastructure Project

Tacony-Frankford Watershed

Philadelphia Water Department

Real-Time Control - Tacony Creek Park Storage...

CSO outfall T14, a very large sewer (21' by 24'), discharges into the Tacony Creek during periods of moderate to heavier rainfall. T14 has a volume of approximately 10 million gallons and to use as much of this storage as possible, a control structure is needed in the sewer. Installation of a crest gate is proposed in order to retain flow within the sewer. This gate will reduce CSO discharges to the creek by utilizing the relief sewer for in-system storage. This control technology provides an additional margin of protection against dry weather overflows while still maintaining flood protection for upstream communities. The crest gate retains the stored flow in the relief sewer and a new connector pipe drains the stored flow to an existing nearby interceptor.

Benefits:

- The Tacony Creek will realize a consistent average annual reduction of

Fairmount Park Commission (FPC)

Philadelphia Water Department

Waterways Restoration Team...

The Philadelphia Water Department has instituted a Waterways Restoration Team (WRT), a crew dedicated to removing large trash, cars, shopping carts, and other dumped debris from the 100 miles of stream systems that define our City's neighborhoods. This crew is also restoring eroded streambanks and streambeds around outfall pipes and in tributaries as a part of PWD's goal to restore our streams while meeting Clean Water Act permit requirements. The Waterways Restoration Team is working in partnership with the Fairmount Park Commission staff and the various Friends of the Parks groups to maximize resources and the positive impacts to our communities.

Benefits:

Philadelphia Water Department

Real-Time Control - Main Relief Sewer Storage...

The Main Relief Sewer, a set of five sewers which provide flood relief to combined sewer areas in all of PWD's drainage districts, discharges to the Schuylkill River at Fairmount Park. Prior to this project, CSO was released into the river at the Main Relief Sewer outfalls. An inflatable dam was installed in the Main Relief sewer (13.5' by 13.5') with a potential storage volume of 6.2 million. This dam will reduce CSO discharges to the creek by utilizing the sewer for in-system storage. The inflatable dam retains the stored flow in the sewer and a new connecting sewer drains the stored flow to a nearby interceptor. The dam became fully operational in Fall 2006.

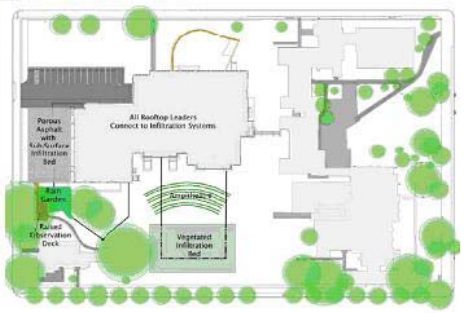
Benefits:

•The installation of the inflatable dam results in significant reductions in CSO

Penn Alexander School

Stormwater BMP Project

Multiple Watersheds



Contact: Amy Leib
215.685.6035
amy.leib@phila.gov

Status: Monitoring

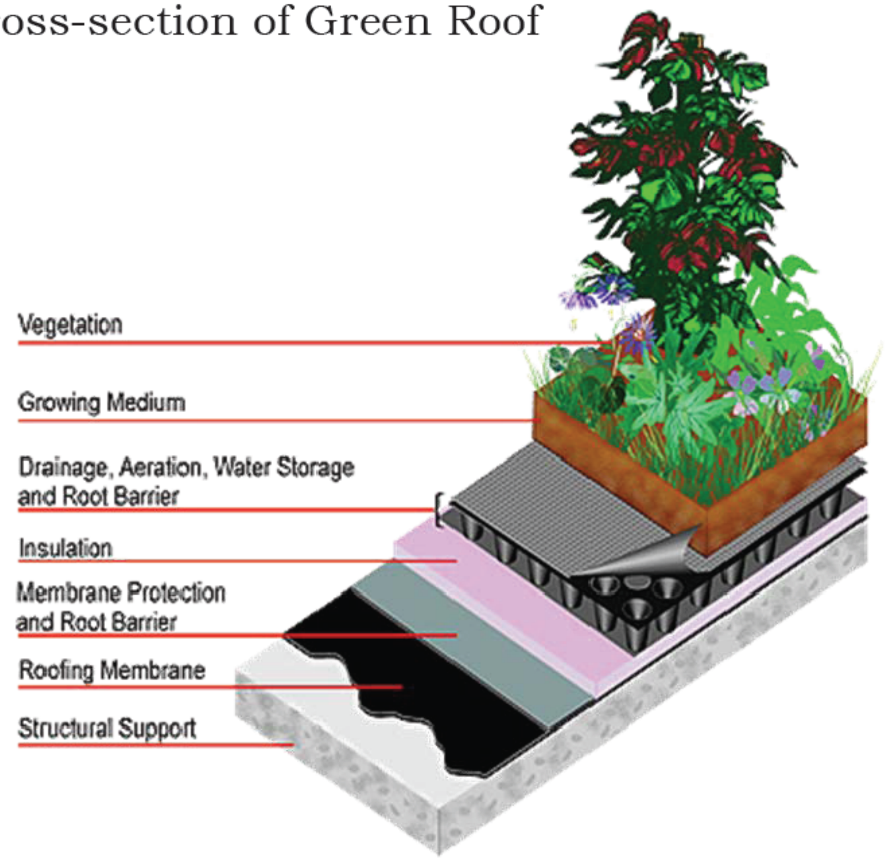
Partners:

- Pennsylvania Department of Environmental Protection (PADEP)
- University of Pennsylvania (UPENN)
- Philadelphia School District (PSD)

Penn Alexander School...

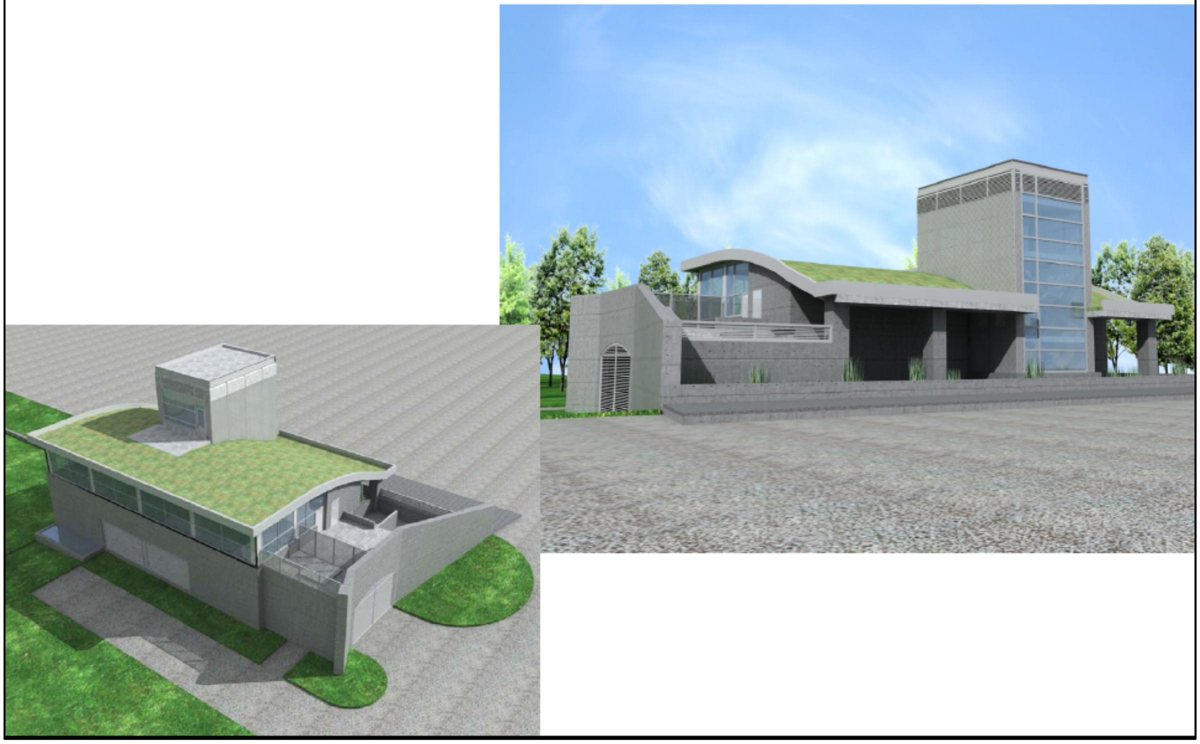
The University of Pennsylvania and the School District of Philadelphia, working in partnership with the Philadelphia Water Department Office of Watersheds, implemented an innovative storm water management project on the site of Alexander Elementary School in West Philadelphia. The school site posed significant challenges in terms of stormwater retention and soil erosion and offered significant opportunities to provide environmental education and environmental diversity to the community. Major components of the project include rooftop collection, an underground infiltration bed, porous pavement play yard, and a rain garden.

Benefits:



Cross-section of Green Roof

Venice Island Pumping Station with Green Roof

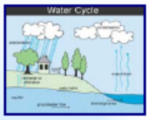


Mill Creek Playground Basketball Courts

The basketball courts at Mill Creek Playground have been built with a special type of pavement that allows rain and melted snow to pass right through it instead of running off into the sewer system. This surface is called "porous pavement." Below the pavement is a layer of stone where water is stored until it is all absorbed into the ground below. Porous pavement is best suited for parking lots, walkways, or play courts.

Effects of Stormwater

Stormwater is precipitation. In an urban environment, stormwater flows over concrete and pavement, rather than percolating through soil into ground water, like it would in a natural environment.



RAIN BARRELS

A rain barrel is a device that collects water from the downspouts which lead from the roof of a building to the ground

By storing rain water, there is a decreased impact of stormwater

Uses for Rain Barrel Water

- Watering the lawn
- Watering garden plants and flowers
- Filling a bird bath
- Washing gardening containers and tools

Stream Restoration of Cobbs Creek at Marshall Road

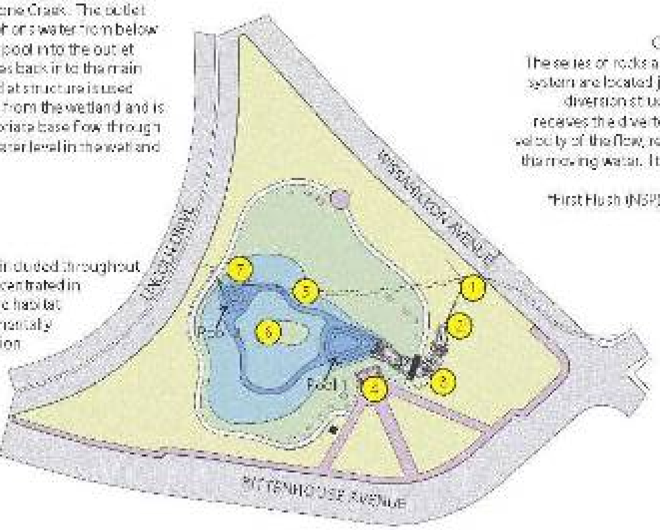
Restoration Project **Darby-Cobbs Watershed**

SAYLOR GROVE
STORMWATER WETLAND
& ITS STORMWATER MANAGEMENT FEATURES

Final Outlet/ Stormwater Diversion Chamber #2
This is the final outlet structure. It diverts the flow back into the original storm sewer after treatment before it enters the Monoshone Creek. The outlet has an 8" storm pipe that siphons water from below the surface of the collecting pool into the outlet structure. The outlet then ties back in to the main 48" stormwater line. The outlet structure is used to regulate flow discharging from the wetland and is used to maintain the appropriate base flow through the wetland system. If the water level in the wetland goes above 2 feet, it will spill into the outlet structure.
*Stream Bank Erosion, Stream Restoration

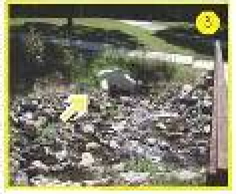
Island/Wetland Meadow
Plants, shrubs, and trees are included throughout the site, but are heavily concentrated in this area to provide a diverse habitat community in this environmentally sensitive zone. The vegetation also filters and removes pollutants from the water, slows down the velocity of the flow, and increases the uptake of water.
*Native Species, Removal of Pollution by Plants, Indicators of Water Quality (Aquatic Organisms)

Permanent Pool (Pool #1),
Channels, Collecting Pool (Pool #2)
The permanent pool is located at the base of the cascade. It removes the majority of the fine particulate matter in the stormwater wetland. The collecting pool is a smaller version of the permanent pool. It is located directly across – on the other side of the wetland where the outlet structure is located. The surrounding channels reduce the velocity of the flow.
*Water Quality Sampling



Stormwater Diversion Chamber #1:
A 48" storm sewer carries the stormwater runoff from this region and connects to a diversion chamber, which intercepts the stormwater flow and directs it to the weir (cascade) for treatment. This structure also acts as a settling chamber where it captures the metals, hydrocarbons and/or other pollutants found in the sediment carried by stormwater runoff, before it enters the wetland. If the two manholes at this site were to be removed, you could view the encapsulated stream flowing right below you into the park.
*Watersheds, Nonpoint Source Pollution (NSP), Stormwater Runoff, Cross Connections/Illicit Discharges

Cascade (Energy Dissipator System):
The series of rocks and pools that make up the cascade system are located just downstream of the stormwater diversion structure outlet (Image 3). The cascade receives the diverted stormwater and slows down the velocity of the flow, reducing the energy associated with the moving water. It also removes coarse sediment and aerates the water.
*First Flush (NSP), Water Quality and Water Quantity Issues, Energy Dissipation



Stormwater Diversion Chamber #2 Outlet:
Stormwater runoff from the Rittenhouse Avenue side of the Park is diverted into the Park as well. The outlet for this diversion chamber is also visible at the cascade. Refer to Site #1 for a description of the chamber.
*Stream Daylighting

Scenic Overlook/Site of Old Fountain:
Surface stormwater runoff from the surrounding parkland on this side of the site drains to the fountain area. There are two drains that release runoff into the wetland underneath this structure.
*Surface Stormwater Runoff

*Indicates Possible Educational Discussion Topics

BACKGROUND

Stormwater Runoff Impacts

The Monoshone Creek flows alongside Lincoln Drive, just across from Saylor Grove, through Historic RittenhouseTown. The majority of the Monoshone Creek now exists in storm sewer pipes. The creek and its tributaries were encapsulated over a century ago to allow for development of the Germantown community. When development occurs, the natural features of a landscape, such as vegetation and soil, are replaced with hard surfaces, such as pavement and buildings. These hard surfaces prevent stormwater from soaking back into the earth during a rainstorm. As a result, stormwater flows across these impenetrable surfaces, picking up all of the pollutants in its path such as oil, pesticides, fertilizers, or anything else that will float and/or dissolve in stormwater. These pollutants can be transported either directly over land into nearby water bodies or into storm drains which are connected to storm sewer pipes that discharge to streams and creeks. Polluted stormwater not only impacts the water quality of streams, but when the runoff rushes out of the stormwater pipes in great volumes and at high velocities, the form and shape of the streams also become jeopardized. Among many impacts that result from such conditions, the stream beds become scoured, erosion is accelerated, aquatic habitats are damaged, and stream banks become unstable. Stormwater is a water quantity and water quality issue, as we have seen in the Monoshone Creek.

Drinking Water Impacts

The Monoshone Creek and its surrounding sub-shed (smaller scale watershed) are located within the Philadelphia Water Department's (PWD) highest priority zone for source water (drinking water) protection — the Queen Lane and Belmont intakes. The Monoshone is a tributary to the Wissahickon Creek, which empties into the Schuylkill River, near the drinking water intake for Philadelphia's Queen Lane Water Treatment Plant. Because 24% of Philadelphia's drinking water comes from Queen Lane, the health of the entire Wissahickon Creek Watershed, including the Monoshone Creek, is critical to all who live and work in Philadelphia.

In Conclusion

At Saylor Grove, the stormwater treatment wetland will help detain (temporarily hold back) and treat the stormwater which was originally piped directly to the Monoshone Creek. This project will help reduce the quantity of stormwater entering the Monoshone at any given time and help improve the quality of the stormwater runoff as well. The Philadelphia Water Department would like to see every stream mile in the City of Philadelphia meet its designated use as a fishable and "swimmable" stream. This project is an exemplary demonstration of how the City and its partners are reaching this goal together.

SITE FACTS

- Saylor Grove Park is approximately 3.2 acres. The Saylor Grove Wetland makes up about one-third to one acre of the park.
- Saylor Grove Wetland drains approximately 156 acres of stormwater runoff from Germantown. The wetland is designed to drain the stormwater within 24 hours.
- Saylor Grove Wetland will filter a significant portion of the estimated 70 million gallons of stormwater per year.
- The wetland will remove approximately 13 tons of total suspended solids from the Monoshone Creek.
- The first 0.7 inches of every rainfall event will be sent to and treated at the wetland. According to the long-term historical record of the airport's rainfall data, 70% of all storms make up 0.7 inches or less of rainfall.
- The wetland will improve flow variability of the Monoshone Creek.
- The wetland will increase biodiversity (vegetation and animals).
- Approximately 3,000 trees, shrubs, and herbaceous plugs have been planted.

For more information on the stormwater management features, refer to the inside of this document.

Saylor Grove Stormwater Treatment Wetland Tour Guide

Stormwater Management Practices Demonstration Site

Spring 2006

Welcome to the Saylor Grove Stormwater Treatment Wetland! The Philadelphia Water Department (PWD), the Fairmount Park Commission (FPC), and its many partners like to dream big in their shared mission to protect and improve the environment. Fortunately for the Germantown section of Philadelphia, the dreaming (and hard work!) has transformed Fairmount Park's parcel of parkland — Saylor Grove — into one of Philadelphia's first stormwater treatment wetlands. The one-acre wetland, constructed in the fall of 2005, helps to slow down stormwater runoff and filter polluted stormwater from approximately 156 acres of Germantown before it enters the Monoshone Creek. A significant portion of this estimated 70 million gallons of urban stormwater runoff will be treated naturally every year! Saylor Grove not only boasts a stormwater treatment wetland, but also a new educational trail, interpretive signage, historic memorials and sculptures previously located in the park and a renovated, beautified space for all visitors to enjoy.

Why a Wetland?

Wetlands clean stormwater, replenish groundwater, reduce flooding risks, and provide habitats for wildlife. The Saylor Grove Stormwater Treatment Wetland is a highly visible project in the historic Wissahickon Watershed and was selected as a demonstration to illustrate how wetlands can successfully treat stormwater in an urban environment. In demonstrating the success of this project, we hope that similar wetland projects will be replicated throughout the City and in neighboring communities to improve water quality and to help bring back healthy streams and creeks throughout the region.

Philadelphia PWD Water Department

Office of Watersheds

CENTER IN THE PARK

Fairmount Park

Prepared for the Center in the Park (Senior Environment Corps)
by the Office of Watersheds, Philadelphia Water Department

CONSTRUCTION & SPECS

The R. E. Roy is a 39-ft, front-end loader, single hull, shallow draft, debris skimming vessel. It is powered by a main diesel engine, Caterpillar Model 3056 205 hp and a four-blade, magnesium bronzed propeller. The vessel is also equipped with a 122-gallon fuel tank, a 150 gpm, 100 psi Water Canon system, and a 5.6 yd^3 hydraulically controlled, grated bucket. Its construction began in June, 2004 and the vessel was delivered in March, 2005

THE DEDICATION

The dedication took place on July, 16, 2005 where the R. E. Roy was officially commissioned. The skimming vessel is named for Richard E. Roy, a former Water Commissioner who gave more than 30 years of gracious service to the City of Philadelphia and the Philadelphia Water Dept.

The R. E. Roy

Floatable Skimming Vessel

Commissioned July, 2005

HISTORY AND BACKGROUND

The Philadelphia Water Department Office of Watershed's (PWD OOW) vision is to unite the city with its waterways, creating a green legacy for future generations while incorporating a balance between ecology, economics and equity. PWD's Combined Sewer Overflow Long-Term Control Plan (PWD CSO LTCP), completed in 1997, highlights the need to improve public awareness of an individual's contribution to coastal aesthetics, notably in the Delaware and Schuylkill Rivers, and to improve water quality and aesthetics of surrounding parks and recreational areas. As such, the plan recommends the use of a floatables skimming vessel to remove debris from targeted reaches of the Delaware and Schuylkill Rivers. Similar waterfront enhancement programs have been very successful in New York City, Passaic Valley, NJ, Baltimore, MD, and Washington D.C.

WHY THE NEED FOR THE VESSEL?

The Schuylkill and Delaware Rivers are both undergoing a renaissance of development, ranging from hotel and entertainment centers and new housing, to the restoration of museums, greenways, gardens, and open space. The floatable skimming vessel enables the Philadelphia Water Department to monitor and remove floatables that accrue on the City of Philadelphia's waterways. In addition, it demonstrates to our citizens the value that the City of Philadelphia places on its waterways

HOW IT WORKS!

The front-end loader design allows the skimmer to utilize a grated bucket to lift floatables from the water surface into an on-board hold. The vessel collects debris in the bucket through two means. As the vessel drives through a mat of debris, the debris enters the bucket and is held by the grates as water passes through the grates. In addition, the vessel is designed to create a strong suction current that draws water through the vessel hull and the grated bucket, thus, drawing floatables into the bucket. The grated bucket is capable of holding over 3 yd^3 of material. Once the vessel returns to the dock, a crane lifts the grated bucket from the deck for disposal. The R. E. Roy is scheduled to be operated through PWD's Flow Control Unit five days per week from March through November each year, with December to February allotted for annual maintenance.

PROJECT BENEFITS

- Address water quality by collecting trash of a wide variety – identified through the qualitative assessment.
- Directly affect the interface of land and water by educating the public about where to put trash and better managing non-point source pollution in river.
- Improve and expand public access to coastal zone by drawing people to cleaner and more aesthetically pleasing rivers and providing a cleaner tourist destination point.
- Manage and protect coastal natural, historic, cultural or recreational resources.
- Provide a regional model that can serve as an example for similar projects that will address watershed management that directly impacts the Delaware Estuary by serving as a key implementation project in the abatement of trash as a result of non-point and point source pollution.

Interpreting the Green Cities, Clean Waters Vision

The Philadelphia Water Department's (PWD) "Green Cities, Clean Waters" program seeks to implement a comprehensive watershed management approach that identifies multiple solutions (land, water, and infrastructure-based) to improve and preserve the City's water environment, to create a green legacy for future generations and to incorporate a balance between ecology, economics and equity.

Our daily interaction with water provides a prime example of humans' ecological relationship with the planet – it is one of the most common yet vital interactions we have with the natural world everyday. Art, with its appeal to the senses, imagination, and intellect, provides a unique approach to explore this relationship between society and water. The jars featured in this exhibit, filled with water and teeming with life and imagery, are a reminder of how intertwined we are both locally and globally with the finite amount of water that exists on this planet.

- Bill Kelly

Please join us at the Fairmount Water Works Interpretive Center, as artist, Bill Kelly, displays an artistic interpretation of Philadelphia's "Green Cities, Clean Waters" program.

Water meets art meets water

Bill Kelly's jar art

Bill Kelly thinks about water a lot.

As an artist, he's looked at how people interact with the wilder world, and he's recently focused on water as "one of the most common but easily overlooked interactions we have with nature everyday, and one reason why it presents an ideal lens through which to explore the larger story of society's reliance upon the natural world."

He's recently finished a series of "jar art" - filled with water, plants and images - tal "remind how we are intertwined both locally and globally with the finite amount of water that exists on this planet."

A public reception is being held Thursday from 5:30 to 7:30 p.m. at the Fairmount Water Works Interpretive Center.

The exhibit will remain open through Nov. 22.

The exhibit is part of the Philadelphia Water Department's "Green Cities, Clean Waters" program.

Kelly studied photography at the Art Institute of Philadelphia and has a master's degree in fine arts from Goddard College in Vermont.

He reports in a prepared statement that after this, "I can never again nonchalantly drive over a local river, turn on my tap, or dump something down the drain without thinking of the many ways I may be impacting - and am in turn affected by - the local water cycle."

I would like to see more of Bill Kelly's jar art. Does he have a website or book of his jar art?

Green Cities, Clean Water Exhibition

"Green Cities, Clean Water," the new exhibit at the Interpretive Center combines photography, art and stormwater management practices. A team from the Office of Watersheds created the exhibit to raise awareness of its long-range plan to transform Philadelphia into a city celebrated for its clean and beautiful rivers and streams.

Bill Kelly with one of his "jars."

Known officially as the Combined Sewer Overflow Long-term Control Plan, The Philadelphia Water Department's CSOLTCP seeks to implement a comprehensive watershed management approach that identifies multiple solutions (land, water, and infrastructure-based) to improve and preserve the City's water environment, to create a green legacy for future generations and to incorporate a balance between ecology, economics and equity.

Office of Watersheds Director Joanne Dahme predicts that the Green Cities, Clean Water project will take 20 years and many millions of dollars. "Our goal is to reduce stormwater runoff as much as possible by capturing it on the surface, through gardens, green roofs, permeable building materials and other green technologies that minimize runoff. Green technology will allow us to replace today's system with smaller pipes and fewer storage tanks. And we'll keep our rivers and streams cleaner and more beautiful." For more information go to: phillyriverinfo.org

Meanwhile, the Office of Watersheds has completed several demonstration projects and offers suggestions homeowners can put into practice to reduce runoff on their properties. The exhibit juxtaposed successful public programs with small projects, such as rain barrel collection systems, wild flower meadows and permeable paving materials.

Click here to see the environmental projects underway at Springside School.

Water Department project designer Tiffany Ledesma Groll invited environmental photographer Bill Kelly to create artwork to complement the Green Cities, Clean Water exhibit. Bill brings his perspective as an individual living in urban environments and interacting with the "wild" world on a daily basis. He uses jars filled with water, photographs, and plant life to demonstrate both the finite amount of water in our world and its ubiquity in our cities and lives.

"While jars are often used to preserve, in this context the addition of a living organism suggests that what needs preservation is not a static entity which can be bottled and stored, but rather it is the purity of the natural cycle of water that must be allowed to run its course," Bill explained. "As we witness the plants make their home in a surreal aquatic environment, we are reminded of water's life-sustaining gifts to both humanity and all that grows alongside us. This work is a tribute to the miracle and challenge of making our home in what was originally dubbed a city between two rivers."

To see a slide show of Kelly's work, click here. Copies of his photos and his actual jars are available at the Fairmount Water Works Interpretive Center. A portion of the sale price will benefit the Interpretive Center.

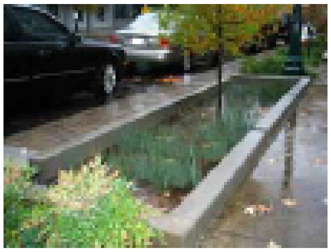
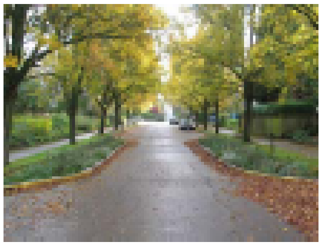
GREENING OUR STREETS

2008

URBAN WATERSHEDS
REVITALIZATION CONFERENCE





Date: Friday, October 31, 2008

Time: 8:30 a.m.— 3:30 p.m.

Location: Community College of Philadelphia

Fee: $20

Register Today: http://www.stormwaterbmp.org/conference
watersheds@pennhort.org
215-988-8772

Overview

We plan to explore what constitutes a green street, present the vision that is guiding the movement toward green streets, and provide insight into how our region can move forward by turning the vision into a reality. We will explore how to improve stormwater management on public right-of-ways, while also beautifying communities, providing economic incentives, and creating other environmental benefits and amenities. The conference will focus on demonstration projects and case studies in Philadelphia and in the nearby suburbs, as well as the work and experience of regional and national design and engineering experts.

Brought to you by: Philadelphia Water Department, Pennsylvania Horticultural Society, American Water Resources Association, Pennsylvania Environmental Council, Montgomery County Conservation District, Temple University, Villanova University, Philadelphia University, Drexel University, & Community College of Philadelphia.

2007
URBAN WATERSHEDS REVITALIZATION CONFERENCE

Please reserve **Thursday, May 3,** from **8:30 a.m. to 3:00 p.m.** for the third annual Urban Watersheds Revitalization Conference at Philadelphia University (School House Ln. & Henry Ave.) in Philadelphia.

The conference will target the urban (or mostly developed) watershed communities of south-east Pennsylvania, including the City of Philadelphia and the surrounding suburbs. The event will feature two panel discussions, a poster session and an awards ceremony for the winning projects of the Stormwater Best Management Practices (BMPs) Recognition Program. The first panel discussion will cover the theme of stormwater management regulations and requirements. The second panel discussion will be the response from the design community on the realities of implementing these regulations and requirements. The subjects addressed in the panel discussion may include the perceptions, realities and responses to the state model stormwater ordinance, National Pollutant Discharge Elimination System (NPDES) requirements, flood control minimization, stormwater rate structure reallocation, retrofit funding mechanisms and other programs and initiatives that aim to demonstrate the environmental, economic and social benefits that arise through sustainable watershed management.

FOR MORE INFORMATION

For more information and to register for the conference, please visit: **www.stormwaterbmp.org/conference**. This event is FREE, so sign up soon!

Also, please visit the Stormwater BMP Recognition Program website and nominate a local project at: www.stormwaterbmp.org.

Hi Tiffany,

The conference was fantastic for me. One of the best I've been to since I started with TTF. In particular, the panel with Joy and Gina and the PWD and Streets Dept staff was incredibly useful. I learned so much from hearing all their points of view. You guys really did a great job with the entire day.

Let's talk more.

THE CSO LONG TERM CONTROL PLAN *UPDATE*

GREEN CITIES
CLEAN WATERS

Current Status
of Our Waterways
The City of Philadelphia

Philadelphia PWD Water Department

Introduction

The Philadelphia Water Department (PWD) is charged with ensuring optional compliance with the City's federal Clean Water Act (CWA) permit. In doing so, PWD is striving to define a stormwater management program that protects and enhances our region's waterways by managing stormwater in a way that significantly reduces the need for infrastructure (pipes). PWD believes that money spent on stormwater management and the attainment of CWA goals should also represent money spent to improve the natural resources of the City and to enhance the community. In 2007, PWD began to reevaluate its Combined Sewer Overflow (CSO) Long Term Control Plan (LTCP) and capital improvements program to integrate additional projects that will reduce CSO frequency and volume. The CSO Long Term Control Plan Update (LTCPU) involves the development of additional management alternatives to ensure capture and treatment of combined sewer system flows and the reduction of discharges from CSOs by building on the experience and progress gained from the implementation of our original CSO LTCP.

The US EPA's Guidance for Long Term Control Plan Development outlines a number of specific tasks for municipalities to undertake while developing their own LTCP, including what is called a "System Characterization." A system characterization includes a detailed assessment of current conditions of the combined sewer system and receiving waters. To accomplish this task, PWD initiated a detailed monitoring program that includes chemical, biological and physical assessments to characterize the current state of the watershed and identify existing problems and their sources. PWD characterized both CSO and non-CSO sources of pollution within each watershed, in order to better understand all causes of water quality impairment. Technical Memorandums, Reports, Plans and Documents for each of our watersheds are available on the City's Watershed Information Center website at www.phillyriverinfo.org

This fact sheet includes a summary of existing conditions for the Cobbs, Tookany/Tacony-Frankford, Schuylkill and Delaware Watersheds; potential solutions for addressing problems identified through the System Characterization will be presented in a forthcoming fact sheet – winter 2009.

PWD's Monitoring and Assessment Programs for System Characterization:

PWD's monitoring and assessment program includes the collection and organization of both existing and new data on surface water hydrology and quality, wastewater collection and treatment, stormwater control, land use, stream habitat and biological conditions, and historic and cultural resources in order to gain an understanding of what data already exists and where there may be gaps worth filling. Data are collected from various agencies and organizations in a variety of forms, ranging from reports to databases and Geographic Information System (GIS) files. To supplement existing data, PWD's Office of Watersheds (OOW) conducted an extensive sampling and monitoring program to characterize the conditions of each watershed.

Schuylkill and Delaware Rivers. The Delaware River Basin Commission (DRBC) and PWD have collected water quality data from sampling locations within the Delaware and Schuylkill Rivers. Additionally, the U.S. Geological Survey (USGS) had recorded historic baseline water quality data that can now be compared with the data collected by DRBC. This comparison allows for a more comprehensive analysis of water quality and the impacts of urbanization over the past 10 years.

Cobbs and Tookany/Tacony-Frankford Creeks. A Comprehensive Characterization Report (CCR) has been developed for both the Cobbs and Tookany/Tacony-Frankford Watersheds. CCRs form the scientific basis for the creation of an Integrated Watershed Management Plan. A CCR includes physical, chemical and biological assessments of a watershed and incorporates land use, geology, soils, hydrology, water quality, ecology, and pollutant loads related information about a watershed. PWD carried out a comprehensive sampling and monitoring program in the Darby-Cobbs watershed between 1999 and 2002 and in the Tookany/Tacony-Frankford between 2002 and 2004.

The definitions of words with an asterisk* can be found in the glossary at the end of this publication.

Watershed Planning Process

PWD's Integrated Watershed Management Planning (IWMP) process is based on a carefully developed approach to meeting the challenges of watershed management in an urban setting. PWD developed their concept of regional watershed management planning recognizing that, as the downstream most entity in each of the watersheds leading to the City of Philadelphia, they could not make sustainable improvements to the waterways without support from upstream partners. The planning process also incorporates the best of existing municipal and conservation planning efforts (including River Conservation Plans, Open Space Plans, municipal Comprehensive Plans, etc.) as well as regulatory requirements and stakeholder goals. Its focus is on attaining priority environmental goals in a phased approach, making use of the consolidated goals of the numerous existing programs that directly or indirectly require watershed planning. These plans are built upon a solid, scientific foundation composed of water quality monitoring (wet and dry weather), macroinvertebrate and fish bioassessments, physical stream surveys (FGM) and computer simulated modeling programs for stormwater flows and pollutant loading.

An integrated watershed management plan is a long-term road map designed to achieve healthy communities and restore natural resources. An integrated plan embraces the laws designed to save our streams, preserve the streams' ecology, and enhance the parkland and riparian buffers that shelter these streams. The plan will also reach out to include the best of municipal and conservation planning efforts, which strive to ensure that growth within the watershed occurs with particular attention to the impacts on the environment. Most importantly, the plan will incorporate the goals of a diversity of people who live, work, and dream in all areas of the watershed.

Watershed Partnerships:
Stakeholder support is critical to the success of a regional planning initiative. A diversity of stakeholder perspectives must be involved with the development of each stage in the planning process in order to ensure that the plan is representative of stakeholder interests. This stakeholder buy-in is most critical to ensuring ultimate implementation of the plan. Recognizing this, PWD has helped to develop stakeholder watershed partnerships for each watershed that drains to the City of Philadelphia.
The ultimate goal is to cultivate a partnership committed to implementing the plan once completed.

Characterization of Existing Conditions in Philadelphia's Watersheds

Philadelphia, which is being called "The Next Great City," faces new and exciting challenges in every aspect of city planning. Having to restore the natural resources of the waterways, as well as prevent further damage to the creeks and rivers is a tall order for such a rapidly growing and constantly changing City, but Philadelphia is embracing this challenge and leading the way with its integrated watershed management planning approach.

Philadelphia's urban watersheds suffer from many problems within the City limits. Many of these problems stem from the highly urbanized settings surrounding the waterways and have a direct correlation to the actions of the public and land management practices in the region.

During wet weather (when it is raining), our consequences on the environment are evident when bacteria (from human waste and other sources) ends up in our waterways through both combined and stormwater outfalls. This type of problem creates an environment which is not conducive to swimming, nor to any other form of primary contact with the water.

An additional problem in our waterways includes fluctuations in dissolved oxygen (oxygen in the water) levels, which have been observed in all of our urban creeks. These changes can adversely affect the health of the fish in our streams.

Furthermore, very high flows are common in our streams during larger storm events. During these events, the streamside vegetation along the creek banks begin to disappear, leading to erosion of the stream banks contributing to additional sediment in the water and habitat loss. High volume streamflows erode the stream banks and stream bottoms, and in many locations, this results in exposed PWD sewer infrastructure.

PWD and its partners are working hard to reverse the adverse impacts on our streams. As such, stream restoration projects, outreach to large property owners and the implementation of a variety of innovative stormwater management practices, such as green roof installations, are only a few examples of the steps that we are taking, as a City, towards the ultimate goal of transforming Philadelphia into a leading "green city" with "clean waters."

Cobbs Creek

Cobbs Creek drains approximately 23 miles over portions of 10 municipalities and the City of Philadelphia, ultimately discharging into the Darby Creek. The designated uses for the non-tidal suburban portion of Cobbs Creek include all the state-wide uses including: Migratory Fishes, Warm Water Fishes, Potable Water Supply, Industrial Water Supply, Livestock, Water Supply, Wildlife Water Supply, Irrigation, Boating, Fishing, Water Contact Sports, Aesthetics, plus the addition of Migratory Fishes (25 PA§ 93.9e).

Completed Plans and Watershed Assessments

A number of assessments and planning initiatives have been completed within this watershed area, each illuminating problems, potential problem sources as well as recommended solutions. PWD carried out a comprehensive sampling and monitoring program in the Darby-Cobbs Watershed between 1999 and 2002. PWD's sampling revealed some *good news* – very few (only five) of the Pennsylvania State Water Quality Criteria revealed exceedances of in dry weather conditions and thirteen during wet weather conditions. A total of 29 criteria were used to test these parameters. Also, during the biological assessment — 44 different species of fish were identified. And, as the Integrated Watershed Management Plan is implemented in this watershed, these numbers will only improve!

Among those evaluated by the CSO LTCPU process are:

- Cobbs Creek Wetland Assessment – 2000 and 2006
- Darby-Cobbs Comprehensive Characterization Report – 2004
- Geomorphologic Survey – Level II for Cobbs Creek – 2003
- Streamside Infrastructure Assessment – 2002
- Cobbs Creek Integrated Watershed Management Plan – 2004
- Darby-Cobbs River Conservation Plan – 2005
- The Darby-Cobbs Act 167 Stormwater Management Plan – 2005

Partnerships

In 1999, the Philadelphia Water Department initiated the Darby-Cobbs Watershed Partnership in an effort to engage residents, businesses, and government, as neighbors and stewards of the watershed. Since then, the Partnership has been active in developing a vision for the watershed and guiding and supporting subsequent planning activities within the watershed.

The mission as established by the Darby-Cobbs Watershed Partnership is *"To improve the environmental health and safe enjoyment of the Darby-Cobbs watershed by sharing resources through cooperation of the residents and other stakeholders in the watershed. The goals of the initiative are to protect, enhance, and restore the beneficial uses of the Darby-Cobbs waterways and riparian areas."*

Current Conditions	
Erosion, Sediment Accumulation, Flow Variety	• Stream bank erosion • Storm discharges • Channel modification • Hydromodification and combined sewer overflow
Wetlands	• 43 wetlands have been identified within the watershed (many impaired) • 10 wetland creation/enhancement opportunities have been identified • Invasive Species programs in place
Healthy Riparian Habitat	• Water diverted from land to waterways • Land Development/encroachment • Invasive Species Programs in place • Streamside tree plantings underway
In-stream Habitat and Biological Impairment	• Over-widening/Erosion • Loss of natural curves/Habitat alteration • Loss of floodplain • Loss of stream/floodplain connection • Loss/degradation of aquatic habitat • Severe water flow fluctuations • Point and non-point source (NPS) pollution from urban development
Sewer Odors	• Suspected sewer leaks during dry weather • Cross-connected sewer lines • CSOs*
Trash and Dumping	• Trash from stormwater discharge • Deliberate disposal of debris in the creeks • Careless behavior
Water Quality Concerns	• Sediment** • Bacteria*** • Dissolved Oxygen****

*Combined Sewer Overflow (CSO) number in Cobbs Creek: 34

**Sediment—symptom of erosion and habitat loss caused by high flows

***Bacteria—levels are higher during and soon after wet weather when CSO's and stormwater outfalls are discharging to the stream

****Dissolved Oxygen— Stormwater and CSO discharges, treated discharges, septic systems, lack of shade, invasive plant growth, natural sources, plunge pools and other poorly mixed areas

Tookany/Tacony-Frankford Creek

The Tookany/Tacony-Frankford (TTF) Watershed drains 29 square miles of Philadelphia and Montgomery County. The creek is referred to as the Tookany Creek until it enters Philadelphia at Cheltenham Avenue; then as the Tacony Creek until the confluence with the historic Wingohocking Creek in Juniata Park; and finally the section of the stream from Juniata Park to the Delaware River is referred to as the Frankford Creek. Municipalities within this watershed drainage area include Cheltenham Township, Abington Township, Jenkintown Borough, Rockledge Borough, Springfield Township and the City of Philadelphia.

Completed Plans and Watershed Assessments

A number of assessments and planning initiatives have been completed within this watershed area, each illuminating problems, potential sources as well as recommended solutions. From 2000 through 2004, PWD has collected water quality data for sampling locations in the Tookany/Tacony-Frankford Watershed. Sample results were compared to relevant PA DEP general water quality criteria to provide an initial impression of which parameters might need further investigation. Applicable relevant standards include water uses to support a potable water supply, recreation and fish consumption, human health, and aquatic life to support warm water fishes. PWD's sampling revealed some *good news* – very few (only nine) of the Pennsylvania State Water Quality Criteria revealed exceedances of in dry weather conditions and eighteen during wet weather conditions. A total of 46 criteria were used to test these parameters. Also, during the biological assessment — 17 different species of fish were identified. And, as the Integrated Watershed Management Plan is implemented in this watershed, these numbers will only improve!

Among those evaluated by LTCPU process are:

- TTF Creek Wetland Assessment – 2006
- Fluvial Geomorphologic Assessment of the TTF – 2006
- TTF Streamside infrastructure Assessment – 2005
- TTF Integrated watershed Management Plan – 2006
- Tacony-Frankford River Conservation Plan – 2005
- The TTF Act 167 Stormwater Management Plan – 2008

Partnerships

TTF Partnership is a consortium of proactive environmental groups, community groups, municipalities, government agencies, businesses, residents, and other watershed stakeholders who have an interest in improving their watershed.

The goals of the partnership are to protect, enhance, and restore the beneficial uses of the waterways and riparian areas. Through watershed management we can mitigate the adverse physical, biological, and chemical impacts of land uses as surface and ground waters are transported throughout the watershed to the waterways.

The mission of the TTF Partnership is *"To increase public understanding of the importance of a clean and healthy watershed; to instill a sense of appreciation and stewardship among residents for the natural environment; and to improve and enhance our parks, streams, and surrounding communities in the Tookany/Tacony-Frankford watershed.*

Current Conditions	
Erosion, Sediment Accumulation, Flow Variety	Stream bank erosion Storm discharges Channel modification Hydromodification and combined sewer overflow
Wetlands	24 wetlands have been identified within the watershed (many impaired) 26 wetland enhancement opportunities have been identified Invasive Species programs in place
Healthy Riparian Habitat	Water diverted from land to waterways Land Development/encroachment Invasive Species Programs in place Streamside tree plantings underway
In-stream Habitat and Biological Impairment	Over-widening/Erosion Loss of natural curves/Habitat alteration Loss of floodplain Loss of stream/floodplain connection Loss/degradation of aquatic habitat Severe water flow fluctuations Point and non-point source (NPS) pollution from urban development
Sewer Odors	Suspected sewer leaks during dry weather Cross-connected sewer lines CSOs*
Trash and Dumping	Trash from stormwater discharge Deliberate disposal of debris in the creeks Careless behavior
Water Quality Concerns	Sediment** Bacteria*** Dissolved Oxygen****

*Combined Sewer Overflow (CSO) number in TTF Creek: 31

**Sediment—symptom of erosion and habitat loss caused by high flows

***Bacteria—levels are higher during and soon after wet weather when CSO's and stormwater outfalls are discharging to the stream

****Dissolved Oxygen— Stormwater and CSO discharges, treated discharges, septic systems, lack of shade, invasive plant growth, natural sources, plunge pools and other poorly mixed areas

Tookany/Tacony-Frankford Creek

The Tookany/Tacony-Frankford (TTF) Watershed drains 29 square miles of Philadelphia and Montgomery County. The creek is referred to as the Tookany Creek until it enters Philadelphia at Cheltenham Avenue; then as the Tacony Creek until the confluence with the historic Wingohocking Creek in Juniata Park; and finally the section of the stream from Juniata Park to the Delaware River is referred to as the Frankford Creek. Municipalities within this watershed drainage area include Cheltenham Township, Abington Township, Jenkintown Borough, Rockledge Borough, Springfield Township and the City of Philadelphia.

Completed Plans and Watershed Assessments

A number of assessments and planning initiatives have been completed within this watershed area, each illuminating problems, potential sources as well as recommended solutions. From 2000 through 2004, PWD has collected water quality data for sampling locations in the Tookany/Tacony-Frankford Watershed. Sample results were compared to relevant PA DEP general water quality criteria to provide an initial impression of which parameters might need further investigation. - TTF Integrated watershed Management Plan – 2006
- Tacony-Frankford River Conservation Plan – 2005
- The TTF Act 167 Stormwater Management Plan – 2008

Partnerships

TTF Partnership is a consortium of proactive environmental groups, community groups, municipalities, government agencies, businesses, residents, and other watershed stakeholders who have an interest in improving their watershed.

The goals of the partnership are to protect, enhance, and restore the beneficial uses of the waterways and riparian areas. Through watershed management we can mitigate the adverse physical, biological, and chemical impacts of land uses as surface and ground waters are transported throughout the watershed to the waterways.

The mission of the TTF Partnership is *"To increase public understanding of the importance of a clean and healthy watershed; to instill a sense of appreciation and stewardship among residents for the natural environment; and to improve and enhance our parks, streams, and surrounding communities in the Tookany/Tacony-Frankford watershed.*

Current Conditions	
Erosion, Sediment Accumulation, Flow Variety	• Stream bank erosion • Storm discharges • Channel modification • Hydromodification and combined sewer overflow
Wetlands	• 24 wetlands have been identified within the watershed (many impaired) • 26 wetland enhancement opportunities have been identified • Invasive Species programs in place
Healthy Riparian Habitat	• Water diverted from land to waterways • Land Development/encroachment • Invasive Species Programs in place • Streamside tree plantings underway
In-stream Habitat and Biological Impairment	• Over-widening/Erosion • Loss of natural curves/Habitat alteration • Loss of floodplain • Loss of stream/floodplain connection • Loss/degradation of aquatic habitat • Severe water flow fluctuations • Point and non-point source (NPS) pollution from urban development
Sewer Odors	• Suspected sewer leaks during dry weather • Cross-connected sewer lines • CSOs*
Trash and Dumping	• Trash from stormwater discharge • Deliberate disposal of debris in the creeks • Careless behavior
Water Quality Concerns	• Sediment** • Bacteria*** • Dissolved Oxygen****

*Combined Sewer Overflow (CSO) number in TTF Creek: 31

**Sediment—symptom of erosion and habitat loss caused by high flows

***Bacteria—levels are higher during and soon after wet weather when CSO's and stormwater outfalls are discharging to the stream

****Dissolved Oxygen— Stormwater and CSO discharges, treated discharges, septic systems, lack of shade, invasive plant growth, natural sources, plunge pools and other poorly mixed areas

Delaware River

(Delaware Direct)

The Delaware Direct Watershed, located entirely in Philadelphia and draining approximately 84 square miles, is highly urbanized and discharges directly to the Delaware River. As an urban watershed, this area has rich complexities and multiple dimensions-diverse land use and communities, Center City, a formerly industrial Delaware waterfront, and a mix of neighborhoods and communities, reflecting a wide range of stakeholders, concerns and interests. Yet, there are many planning projects underway, many people gathering around the river and many groundbreaking events and projects taking place at this very moment in Philadelphia. As a result, the plans and teams behind these projects are aiding in the reconnection of the people and the City of Philadelphia to its waterway, making the streams and parks in our communities valuable assets to our citizens and joining PWD and partners in our protection efforts.

Completed Plans and Watershed Assessments

A number of assessments and planning initiatives have been completed within this watershed area, each illuminating problems, potential sources as well as recommended solutions. Dissolved Oxygen levels have increased significantly over the last three decades, enabling shad to more freely though the tidal zone of the Delaware River and into the freshwater zone in Philadelphia, as they make their way to the Fairmount Fish Ladder in the Schuylkill River. Where the shad were once limited by a lack of oxygen, they are returning to migrate up the Delaware River - a valuable indicator of improving environmental conditions!

Among those evaluated by the CSO LTCPU process are:

- Delaware Direct River Conservation Plan—2009
- Delaware River Source Water Protection Plan—2007
- Delaware Estuary Program's State of the Estuary Report—2008
- GreenPlan Philadelphia – 2008
- North Delaware Riverfront Master Plan – 2001
- Central Delaware Riverfront Planning Process – 2008
- Northern Liberties Waterfront Plan – 2007
- Philadelphia Navy Yard Master Plan
- Delaware River Basin Commission Boat Run Data
- USGS Gage Stations

Partnerships

The Delaware Direct Watershed Partnership was formed in 2007 to support the River Conservation Planning process for the Delaware Direct River Conservation Plan. A myriad of stakeholders are involved– non-profits, state and local government, in addition to community representatives.

Current Conditions	
Erosion, Sediment Accumulation, Flow Variety	•Stream bank erosion •Storm discharges •Channel modification •Hydromodification and combined sewer overflow
Wetlands	•Several wetland creation/enhancement opportunities have been identified
Healthy Riparian Habitat	•Water diverted from land to waterways •Land Development/encroachment •Invasive Species Programs in place •Streamside tree plantings underway
In-stream Habitat and Biological Impairment	•Loss of flood plain •Loss of stream/floodplain connection •Loss/degradation of aquatic habitat •Point and non-point source (NPS) pollution from urban development
Sewer Odors	•Suspected sewer leaks during dry weather •Cross-connected sewer lines •CSOs*
Trash and Dumping	•Trash from stormwater discharge •Deliberate disposal of debris in the creeks •Careless behavior
Water Quality Concerns	•Sediment** •Bacteria*** •Dissolved Oxygen****

*Combined Sewer Overflow (CSO) number in Delaware River: 54

**Sediment—symptom of erosion and habitat loss caused by high flows

***Bacteria—levels are higher during and soon after wet weather when CSO's and stormwater outfalls are discharging to the stream

****Dissolved Oxygen— Stormwater and CSO discharges, treated discharges, septic systems, lack of shade, invasive plant growth, natural sources, plunge pools and other poorly mixed areas

Philadelphia Water Department

Internet Resources

PhillyRiverInfo

http://www.phillyriverinfo.org/

On this website, you will find general information on Philadelphia's watersheds as well as upcoming watershed-related events. Check this site often to find out what is going on in your watershed!

Green Cities, Clean Waters (LTCPU)

http://www.phillyriverinfo.org/csoltcpu/

An offshoot of PhillyRiverInfo, this websites focuses on the Green Cities, Clean Waters Program (Combined Sewer Overflow Long Term Control Plan Update). Here you can read about details of the plan and learn about the basics of a combined sewer system.

CSOCast

http://www.phillywatersheds.org/csocast/

NEW! This website is PWD's latest effort to show the overflow status of the City's 164 Combined Sewer Outfalls. CSO Cast indicates whether CSOs are occurring or are suspected to have occurred within the last 24 hours. It is updated twice daily with information from PWD's extensive sewer monitoring network.

RiverCast

http://www.phillyrivercast.org/

The Philly RiverCast is a forecast of water quality that predicts potential levels of pathogens in the Schuylkill River between Flat Rock Dam and Fairmount Dam (i.e., between Manayunk and Boathouse Row). Visit this site to find out the daily RiverCast prediction and to learn more about water quality.

Rain Barrel Program

http://www.phillywatersheds.org/rainbarrel/)

The Philadelphia Water Department is providing rain barrels to residents of Philadelphia's watersheds free of charge, in order to promote the reduction of stormwater flows to our sewer system and creeks. To receive a rain barrel, you must attend a rain barrel workshop to be educated on the installation and use of the rain barrel. Rain barrel workshops are held in locations around the city throughout the year. Check this website to see when a workshop is being held in your watershed.

Philadelphia PWD Water Department

THE CSO LONG TERM CONTROL PLAN *UPDATE*

GREEN CITIES
CLEAN WATERS

Clean Water Benefits and the Balanced Approach

The City of Philadelphia

Combined Sewer Overflow (CSO)

A wastewater collection system that transports wastewater from homes, businesses, industry, and stormwater from storm drains on our city streets through a single-pipe system to a Water Pollution Control Plant. Under heavy rainfall conditions the flow in the combined sewers may exceed the capacity of the pipe or treatment facility. As a result, a portion of the wastewater and stormwater may be diverted directly to a nearby stream or river to prevent the flooding of homes and streets.

National Pollutant Discharge Elimination System (NPDES)

A provision of the Clean Water Act which prohibits discharge of pollutants into waters of the United States unless a special permit is issued by EPA, a state, or, where delegated, a tribal government on an Indian reservation.

Non-Point Source

Diffuse pollution sources (i.e., without a single point of origin or not introduced into a receiving stream from a specific outlet). The pollutants are generally carried off the land by stormwater. In Philadelphia, examples include stream bank erosion and construction.

Point Source

A stationary location or fixed facility from which pollutants are discharged; any single identifiable source of pollution; e.g. a pipe, ditch, ship, ore pit, factory smokestack. Municipal sewer systems are regulated as point sources.

Pollutant

Generally, any substance introduced into the environment that adversely affects the usefulness of a resource of the health of humans, animals, or ecosystems.

Receiving Waters

A river, lake, ocean, stream or other watercourse into which wastewater or treated effluent is discharged.

Runoff

That part of precipitation, snow melt, or irrigation water that runs off the land into streams or other surface-water.

Sanitary Sewer

Underground pipes that carry only domestic or industrial waste, not storm water.

Sanitary Sewer Overflow (SSO)

Untreated or partially treated sewage overflows from a sanitary sewer collection system.
Definition from Philadelphia Water Department

Stormwater

The water that runs off surfaces such as rooftops, paved streets, highways and parking lots. It can also come from hard grassy surfaces like lawns, play fields, and from graveled roads and parking lots. *Definition from King County, Water and Land Resources Division.*

Wastewater

The spent or used water from a home, community, farm, or industry that contains dissolved or suspended matter.

Water Pollution

The presence in water of enough harmful or objectionable material to damage the water's quality.

Water Quality Standards (WQS)

Water quality standards are provisions of state or federal law which consist of a designated use or uses for the waters of the United States, water quality criteria to protect the most sensitive uses for such waters, and an antidegradation policy and implementation procedures to protect water quality. Water quality standards are established to protect the public health or welfare, enhance the quality of water and serve the purposes of the CWA.

CSO: Public Notification Means You're in the Know

Stormwater Best Management Practices Awards

What is a WATERSHED?

A watershed is the land surrounding a system of rivers (or streams or creeks), or a particular river, that, when it rains, sheds the runoff into that waterway. Everything you do impacts your watershed. Runoff from garden fertilizers, hazardous substances like used motor oil, and trash dumped into one area of a river bank can pollute water many miles downstream. Protecting and preserving our watersheds helps protect our water resources.

The watersheds that drain directly to Philadelphia are: Darby Cobbs Watershed, Schuylkill Watershed, Wissahickon Watershed, Delaware Watershed, Pennypack Watershed, Tookany/Tacony-Frankford Watershed and Poquessing Watershed.

Combined Sewer Overflow (CSO) Public Notification Signage Program

What is a Combined Sewer Overflow (CSO)?

A combined sewer system transports sanitary wastewater (from homes, businesses and industry), stormwater from the storm drains on our streets and stormwater from property downspouts through a single-pipe to a Water Pollution Control Plant (treatment plant).

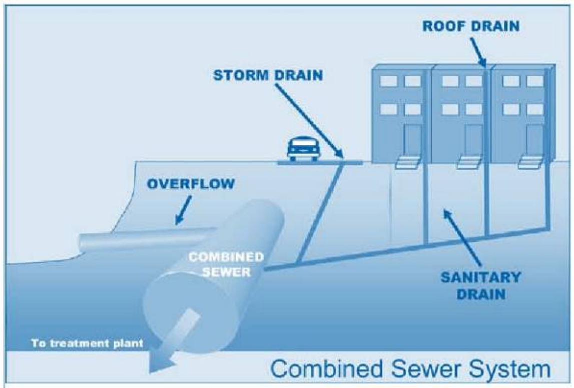
Under heavier rainfall conditions, however, the flow in combined sewers may exceed the capacity of the pipe or treatment facility. As a result, a portion of the wastewater and stormwater may be sent directly to a nearby stream or river to prevent the flooding of homes and streets. This is what is known as a Combined Sewer Overflow.

During heavy rainfalls or sudden snowmelts, Philadelphia may experience these overflows in various locations throughout the City. These overflows may exceed water quality standards, threaten aquatic life and its habitat, and impair the use and enjoyment of the water body.

What is the goal of the Combined Sewer Overflow (CSO) Public Notification Program?

The goal of the Philadelphia Water Department's (PWD) CSO program is to improve and preserve the water environment in the Philadelphia area.

The goal of the CSO Public Notification Program is to educate the public on CSOs using a variety of methods that will reach different segments of the population. One method that we are implementing is the CSO Public Notification Signage Program. This program informs the public of the potential hazards of primary contact with creeks and rivers during combined sewer overflow events.



Combined Sewer System

What is the goal of the Signage Program?

PWD is striving to educate citizens about water quality conditions in our rivers and streams during and after a rain storm.

In 2005, PWD initiated its pilot signage program and installed signs at stream and river locations with good public access. The goal of the pilot program is to gauge the effectiveness of signage as compared to other public outreach efforts. PWD is concerned about primary contact with the water (skin contact) in CSO areas during or immediately after a rain event. The signs warn the public to avoid fishing, use of PWCs (Personal Water Crafts, such as jet-skis or wave runners), wading and particularly swimming. CSOs contain bacteria and pathogens that could make someone sick if they swallow water or eat fish that have come in contact with CSOs. The public should not go in the water, near the CSOs, for 48 hours after a heavy rain event.

The signs are in English and Spanish. PWD recognizes that there are many native-Spanish speakers that use our parks and waterways for recreation, as well as other non-English native speakers.

The signs also include the Philadelphia Water Department Hotline – 215-685-6300. PWD should be contacted if there is flow coming from the outfall during dry weather (when it is not raining).

Frequently Asked Questions (FAQs)

Can I swim in the water near a CSO?

Swimming and bathing are not permitted in the City's rivers and streams due to risks of drowning, injury from submerged objects, strong currents, and other hazards. An additional risk to the public is ingesting tainted water from an overflow as untreated sewage contains bacteria. Women of child-bearing age, children, the elderly, and persons with compromised immune systems are at an even higher risk of getting sick.

Is it safe for my dog to drink the water near a CSO?

PWD recommends that your dog not drink the water after a rainstorm. Despite their superior sense of smell, dogs are known to get "up close and personal" with things that might seem gross to you, or stop to take a drink out of a muddy puddle. If this really concerns you, consider carrying plenty of drinking water and a "packable" drinking bowl for your dog. Dogs that are offered plenty of water in this manner may be less likely to drink out of the creek.

Can I eat the fish?

The Pennsylvania Fish and Boat Commission and Pennsylvania Department of Environmental Protection have jointly issued a statewide "blanket" consumption advisory recommending no more than one meal (up to 8oz) per week of recreationally caught fish, including hatchery-raised stocked trout.

Mercury and PCBs can be harmful to humans, and all fish, whether wild-caught or farm-raised, will contain some level of these contaminants. Women of child-bearing age, children, elderly, and persons with compromised immune systems may wish to limit their consumption of fish. If you still plan to consume the fish, please follow the cooking and cleaning directions for eating skinned and trimmed fish. These instructions, along with other information, may be found at http://www.depweb.state.pa.us.

Stormwater Best Management Practices (BMP) Recognition Program

On May 3, 2007, the Stormwater Best Management Practices (BMP) Recognition Program announced the exemplary and innovative stormwater management projects that were recognized for helping to transform the health of our watersheds in the region. The event took place at the third annual Urban Watersheds Revitalization Conference, held at the Kanbar Center at Philadelphia University.

The Stormwater BMP Recognition Program is sponsored by the Philadelphia Water Department, American Water Resources Association (AWRA), Montgomery County Conservation District, Villanova University, and the Department of Environmental Protection (Coastal Zone Management).

Please visit the website for more information and to submit an application: http://www.stormwaterBMP.org.

Green Cities – Clean Waters

Tookany/Tacony-Frankford Creek

Protecting and Preserving Our Waterways

The Philadelphia Water Department (PWD) is always working to protect your water resources. This includes managing the stormwater that comes with heavy rain or snow falls. We are working on ways to control stormwater that also help our waterways. Our plan to do this is called a "Long Term Control Plan," or LTCP.

Part of our plan includes studying at our combined sewer system and the rivers and streams. This means we now know how our system is working, and where we can make changes to help it work better.

What is a Combined Sewer Overflow (CSO)?

A combined sewer system brings wastewater from homes, businesses and industry, and stormwater from the storm drains on our streets through a single-pipe system to a Water Pollution Control Plant (treatment plant).

Under heavier rainfall conditions, the flow in combined sewers may be more than the pipe or treatment plant can handle. This means that some of the wastewater and stormwater may flow directly to a nearby stream or river to prevent the flooding of homes and streets. This is what is known as a Combined Sewer Overflow.

What is a Watershed?

A watershed is the land surrounding a system of rivers (or streams or creeks), or a particular river, that, when it rains, sheds the runoff into that waterway.

Everything you do impacts your watershed. Runoff from garden fertilizers, hazardous substances like used motor oil, and trash dumped into one area of a river bank, can pollute water many miles downstream. Protecting and preserving our watersheds helps protect our water resources.

The watersheds that drain directly to Philadelphia are: Darby Cobbs Watershed, Schuylkill Watershed, Wissahickon Watershed, Delaware Watershed, Pennypack Watershed, Tookany/Tacony-Frankford Watershed and Poquessing Watershed.

Green City – Clean Water

We want to make Philadelphia's urban landscape into a vibrant, green community where people want to live and work.

Philadelphia can be a green city with clean water -- and benefit economically at the same time. We can help our watershed as well as our region's economic health, quality of life and sustainability.

PWD has the knowledge and experience for creating and managing a watershed approach to Combined Sewer Overflow (CSO) control. We own and operate the City's sanitary sewers, storm sewers, combined sewers and wastewater treatment plants. We work in cooperation with the Philadelphia City Planning Commission to help local builders and developers include stormwater management in many of their projects.

In 2007, PWD began to review its CSO Long Term Control Plan (LTCP) and capital improvements program. We want to make sure our capital improvement projects control CSOs.

For our CSO Long Term Control Plan Update (LTCPU), we have developed new ways to handle sanitary sewer system flows. We have also been successful in reducing CSOs.

Over the past few years, we have gathered thousands of facts about the Schuylkill and Delaware Rivers, as well as the Cobbs and Tookany/Tacony-Frankford Creeks. We have information about their water quality, aquatic wildlife, history, land use, cultural resources, and more.

Watersheds and Waterways

We work with many local partners, including educational and environmental groups, township and other governments, and volunteer organizations. These partnerships are very important in the work we do to protect our waterways. The partnerships work together to write a plan to improve the water resources in each watershed.

Using a watershed approach means we look at more than just Philadelphia's city boundaries. Rivers and streams don't stop at those boundaries, so we don't either.

Some waterways are already damaged – erosion, trash-dumping, and neglect can mean polluted water or even further erosion. We are working to clean up damaged waterways. This will protect the land nearby, and let us enjoy recreational activities on or near the waterways.

Philadelphia PWD Water Department

WATER Wheel

The Tookany/Tacony-Frankford Creek Plan

Looking at The Tookany/Tacony-Frankford Watershed

The Tookany/Tacony-Frankford Creek Watershed is in Philadelphia and Montgomery counties, and is 29 square miles in size. From 2000 to 2004, PWD collected water data for the watershed to look at the health of the water and the land.

We then compared our findings with 46 standards set by the Pennsylvania Department of Environmental Protection. These standards tell us if the water can be used for drinking, and recreational uses, and if the water is clean enough for human health and aquatic life.

Our results were positive, but we did find some areas where we want to improve, and we developed our Watershed Management Plan.

Some of the issues we are now working on include: stream bank erosion, loss of floodplain, pollution from urban development, suspected sewer leaks, and trash and debris dumping.

We have identified the wetlands that need help the most, and developed a list of 26 projects to improve the health of these areas. We are also planting trees to help control erosion, and removing some invasive plants and aquatic life that harm our natural wildlife.

Glossary

Here are definitions of some of the terms we use when talking about water.

Sanitary Sewer

Underground pipes that carry only domestic or industrial waste, not stormwater. *Definition from the U.S. Environmental Protection Agency (EPA).*

Sanitary Sewer Overflow (SSO)

Untreated or partially treated sewage overflows from a sanitary sewer collection system. *Definition from Philadelphia Water Department.*

Stormwater

The water that runs off surfaces such as rooftops, paved streets, highways and parking lots. It can also come from hard, grassy surfaces like lawns, play fields, and from graveled roads and parking lots. *Definition from King County, Water and Land Resources Division.*

Wastewater

The spent or used water from a home, community, farm, or industry that contains dissolved or suspended matter. *Definition from EPA.*

Water Pollution

The presence in water of enough harmful or objectionable material to damage the water's quality. *Definition from EPA.*

Philadelphia **PWD** Water Department

The Combined Sewer Overflow Program: A Long Term Control Plan For Our Rivers

Introduction

Philadelphia is blessed with an abundance of creeks, open space, park land and beautiful rivers. The Schuylkill and Delaware Rivers are not only scenic; they are the drinking water source for Philadelphia residents. These waterways, however, suffer from pollution from various sources, both within and outside of the City limits. One such pollution source: Combined Sewer Overflows (CSOs).

What are Combined Sewer Overflows?

A combined sewer system is a wastewater collection system which transports sanitary wastewater (from homes, businesses and industry), stormwater from the storm drains on our streets (approximately 75,000 of them) and stormwater from property rain leaders - through a single-pipe system to a Water Pollution Control Plant (WPCP).

During dry weather conditions (when it is not raining) and during very small storm events, combined sewers can adequately transport this mixture of sanitary wastewater and stormwater to one of the City's three water pollution control plants for treatment.

Under heavier rainfall conditions, however, the flow in combined sewers may exceed the capacity of the pipe or treatment facility. As a result, a portion of the wastewater and stormwater may be diverted directly to a nearby stream or river to prevent the flooding of homes and streets. This is what is known as a Combined Sewer Overflow.

During heavy rainfalls or sudden snowmelts, Philadelphia may experience these overflows in various locations throughout the City from any of its 164 permitted combined sewer outfalls. These overflows may exceed water quality standards (WQS), threaten aquatic life and its habitat, and impair the use and enjoyment of the water body.

What is the Goal of PWD's Combined Sewer Overflow Program?

The goal of the Philadelphia Water Department's (PWD) combined sewer overflow program is to improve and preserve the water environment in the Philadelphia area and implement technically viable, cost-effective improvements and operational changes. PWD has taken a three-pronged approach:

1. Nine Minimum Controls (NMC) – System "Tune-Up"

The first component of the PWD CSO strategy involves the Nine Minimum Controls (NMCs). The NMCs are low-cost actions or measures that can reduce CSO discharges and their effect on receiving waters, do not require significant engineering studies or major construction, and can be implemented in a relatively short time frame. This program ensures that our existing sewer system is operating to the best of its ability, providing a "tune-up" to the existing infrastructure.

For more details on the NMCs, please visit the U.S.EPA on-line at: http://cfpub.epa.gov/npdes/home.cfm?program_id=5.

2. Capital Projects – Design and Build New Combined Sewer System Components

The second component of the PWD CSO strategy involves technology-based capital improvements to the City's sewer system. This program requires significant engineering, design and construction to improve the performance of the combined sewer system. This program has and will continue to increase the capacity of the City's combined sewer system, reduce infiltration into the system, decrease the volume of overflows and improve stream water quality.

A watershed refers to the land that drains stormwater (rain or melting snow) to a specific body of water, such as a river or stream.

3. Watershed Management and Watershed Partnerships

The watershed approach evaluates the impacts of both point and non-point pollution sources and aims to find regional, watershed solutions to restore water quality. Because watersheds are defined by natural features and do not adhere to political boundaries, PWD believes that watershed management is the most practical and effective way to manage pollution and improve water quality.

The PWD forms partnerships with its suburban neighbors, businesses and industries, community and non-profit groups and other stakeholders to evaluate the region's watersheds and to develop an effective watershed management plan. To be successful, watershed management plans must be adopted and implemented by all participating stakeholders and their constituents.

To date, PWD has initiated the formation of watershed partnerships in all of the City's watersheds. The combined sewer watersheds include the Darby-Cobbs Watershed Partnership, Tookany/Tacony – Frankford Watershed Partnership and Pennypack Watershed Partnership, while the separate sewer watersheds include the Poquessing Watershed Partnership and the Wissahickon Watershed Partnership. The Schuylkill Watershed is represented by the Schuylkill Action Network (SAN), a partnership of the City of Philadelphia, federal and state agencies, and local watershed groups protecting the drinking water supply in the Schuylkill River Watershed. This fall, the Delaware Direct Watershed Partnership will be formed.

If you are interested in joining a partnership or for further information on the PWD watershed management planning projects, visit: http://www.phillyriverinfo.org.

Green Cities – Clean Waters: Combined Sewer Overflow Long Term Control Plan Update

Crescentville CSO

The CSO Long Term Control Plan Update is also known as the "Green Cities – Clean Waters Program."

Introduction

In 2007, PWD began to reevaluate its combined sewer overflow program and capital improvements program to integrate additional projects that reduce CSO frequency and volume. As a result, the CSO Long Term Control Plan Update (LTCPU) was created. It involves the development of management alternatives that ensure capture and treatment of sanitary sewer system flows and CSO reductions.

PWD is committed to a balanced "Land-Water-Infrastructure" approach to achieve its watershed management and CSO control goals. This method includes infrastructure-based approaches, where appropriate, but also includes a range of land-based stormwater management techniques and the physical reconstruction of aquatic habitats, where appropriate.

The "Land-Water-Infrastructure" approach is made up of three programs:

LAND: Wet Weather Source Control

The Wet Weather Source Control program promotes the use of Low Impact Development (LID) and other structural and non-structural controls to reduce CSO volume through evaporation, transpiration, infiltration and detained release to the combined system for treatment, such as an extensive street tree program, green roofs and rain gardens. This program also requires post-construction stormwater controls on land development and redevelopment in the combined sewer area to achieve CSO reductions.

WATER: Ecosystem Restoration and Aesthetics

The Ecosystem Restoration and Aesthetics program focuses on projects that contribute to the improvement of the aesthetic and ecological integrity of CSO receiving waters. Such water-based approaches include stream bed and bank stabilization and reconstruction, aquatic habitat creation, plunge pool removal, improvement of fish passage, and floodplain reconnection.

INFRASTRUCTURE: Capital Improvement Projects

The Capital Improvement Projects program continues to implement CSO capital improvement projects that were planned during the previous combined sewer overflow program in addition to new projects to increase the capture and treatment of combined sewage. Examples of such projects include the work of the Waterways Restoration Team, Stream Habitat Restoration, Wetland Enhancement and Construction, Fish Passage Projects and Riparian Buffer Creation and Enhancement.

GLOSSARY

Runoff refers to water from rain or melting snow or irrigation that flows over the ground and into the nearest body of water. It can contribute to soil erosion and carry harmful pollutants.

Point source pollution refers to any discernible, confined, and discrete conveyance, such as a pipe, tunnel or ditch, from which pollutants are or may be discharged.

Nonpoint source (NPS) pollution, unlike pollution from industrial and sewage treatment plants, comes from many diffuse sources. NPS pollution is caused by rainfall or snowmelt moving over and through the ground. As the runoff moves, it picks up and carries away natural and human-made pollutants, such as lawn fertilizers, oil and dog waste, finally depositing them into the nearby creeks and rivers.

Receiving Waters: All distinct bodies of water that receive runoff or wastewater discharges, such as streams, rivers, ponds, lakes, and estuaries.

Water Quality Standards (WQS) are state-adopted and EPA-approved standards for water bodies. The standards prescribe the use of the water body and establish the water quality criteria that must be met to protect designated uses.

Philadelphia PWD Water Department

annual Drinking Water Quality Report

This report is being mailed to you as a requirement of the federal Safe Drinking Water Act. NOTE: Industrial and commercial customers, including hospitals, medical centers, and health clinics, please forward this report to your Environmental Compliance Manager.

Philadelphia's water is safe and healthy to drink for most people. For people with special health concerns, please see the information on page two.

PWD's Public Water System Identification #PA1510001

This report is available online at http://www.phila.gov/water

The Philadelphia Water Department

The Philadelphia Water Department (PWD) is pleased to present our annual Water Quality Report. This report, published in April 2008, includes water quality information for the 2007 calendar year.

The good news is – your tap water is top quality. Our Water Quality Report provides our customers with a summary of where Philadelphia's drinking water comes from, how it is treated and the results of water quality monitoring performed by us on a daily basis.

The U.S. Environmental Protection Agency (EPA) requires all water utilities to produce and distribute water quality reports on an annual basis.

We have consistently performed better than all drinking water standards developed by the EPA to protect public health.

How do we do this? We use proven treatment practices at our water treatment plants and we participate in groundbreaking research while keeping water rates among the lowest in the region.

Para obtener una copia del informe en Español sobre los resultados más recientes de la calidad del agua publicado por el Departamento de Agua de Philadelphia, llame al 215-685-6300.

People With Special Health Concerns

Some people may be more vulnerable to contaminants in drinking water than the general population. Immuno-compromised persons, such as persons with cancer undergoing chemotherapy, persons who have undergone organ transplants, people with HIV/AIDS and other immune system disorders, some elderly and infants can be particularly at risk from infections. These people should seek advice about drinking water from their health care providers.

Environmental Protection Agency/Centers for Disease Control (CDC) guidelines on appropriate means to lessen the risk of infection by Cryptosporidium and other microbial contaminants are available from the Safe Drinking Water Hotline: 800-426-4791.

Our standards are the highest: our drinking water consistently performs better than all drinking water standards developed by the EPA to protect public health.

Where does Philadelphia's drinking water come from?

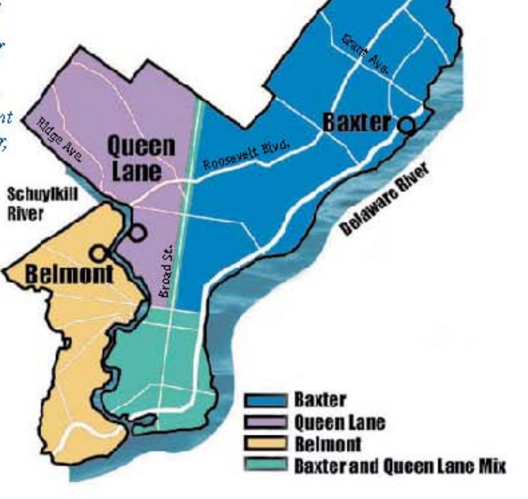
Philadelphia is located in the Delaware River Watershed, which begins in New York State and extends 330 miles south to the mouth of the Delaware Bay. The Schuylkill River is part of the Delaware River Watershed.

Map Courtesy of the Delaware River Basin Commission. Delaware River Basin Commission Map Collection.

The water that we treat comes from the Schuylkill and Delaware rivers. Rivers are surface water supplies. Philadelphia does not use groundwater. Each river contributes approximately one-half of the City's overall supply. We produce approximately 256 million gallons of high-quality drinking water for our customers on a daily basis.

PWD has three water treatment plants that process untreated river water. The Queen Lane Plant is located in East Falls and its water comes from the Schuylkill River. Its intake is located along Kelly Drive. The Belmont Plant is located in Wynnefield and its water also comes from the Schuylkill River. Its intake is located along Martin Luther King, Jr. Drive (formerly West River Drive). The Baxter Plant is located in Torresdale and its water comes from the Delaware River. Its intake is located at the plant on the Delaware River.

Depending on where you live, you receive drinking water from one of the city's three water treatment plants– Baxter, Belmont, or Queen Lane.



Safeguarding the water you drink.

At their sources, the Delaware and Schuylkill Rivers are generally clean rivers. But as the rivers flow downstream, they pick up contaminants from many sources – stormwater runoff washes pollutants on the land into the rivers, and communities and industries discharge used water back into the rivers. Today, the City enjoys watersheds that are cleaner and healthier than they have been in well over a century. Although we have seen a dramatic improvement in the water quality of the City's two major rivers since the passage of the federal Clean Water Act in the early 1970s, there is still more work that needs to be done to protect our drinking water sources from pollution.

In order to ensure that tap water is safe to drink, the Environmental Protection Agency has regulations that limit the amount of certain contaminants in water provided by water suppliers. The Food and Drug Administration establishes limits for contaminants in bottled water that must provide the same protection for public health.

Drinking water, including bottled water, may reasonably be expected to contain at least small amounts of some contaminants. The presence of contaminants does not necessarily indicate that water poses a health risk. More information about contaminants and potential health effects can be obtained by calling the Environmental Protection Agency's Safe Drinking Water Hotline (800-426-4791) or from their website (http://www.epa.gov/safewater).

How do drinking water sources become polluted?

Across the nation, sources of drinking water (both tap water and bottled water) include rivers, lakes, streams, ponds, reservoirs, springs and wells. As water (such as rain and melting snow) travels over the surface of the land or through the ground, it dissolves naturally-occurring minerals and, in some cases, radioactive material, and can pick up substances resulting from the presence of animals or from human activity.

Contaminants that may be present in source water include:

- Microbial contaminants, such as viruses and bacteria, which may come from sewage treatment plants, septic systems, agricultural livestock operations and wildlife.

- Inorganic contaminants, such as salts and metals, which can be naturally-occurring or result from urban stormwater runoff, industrial or domestic wastewater discharges, oil and gas production, mining or farming.

- Pesticides and herbicides, which may come from a variety of sources such as agriculture, urban stormwater runoff and residential uses.

- Organic chemical contaminants, including synthetic and volatile organic chemicals, which are byproducts of industrial processes and petroleum production. They can also come from gas stations, urban stormwater runoff (from streets and parking lots) and septic systems.

- Radioactive contaminants, which can be naturally-occurring or be the result of oil and gas production and mining activities.

Why is chlorine used to disinfect the drinking water?

State and federal laws require the disinfection of all public water supplies. EPA and health agencies recognize that using chlorine is the most effective way to protect public health from disease-causing organisms that can be found in rivers and streams. However, chlorine can chemically react with natural materials in rivers to form disinfection byproducts, such as trihalomethanes.

We have been adjusting our treatment process over the years to reduce this chemical reaction. But we also ensure that the treated water that is distributed through the City's water mains to your homes has a "chlorine residual." This residual continues to protect your water against bacteria and other organisms on its journey to your home tap.

We now use sodium hypochlorite, a safer form of chlorine similar to household bleach, to disinfect the water at our treatment plants.

What do we look for?

Under Primary and Secondary Safe Drinking Water Regulations, EPA and Pennsylvania DEP require drinking water utilities to monitor about 100 regulatory parameters. These regulatory parameters are defined with their maximum contaminant level (MCL) and maximum contaminant level goal (MCLG) under federal rules such as: Total Coliform Rule, Surface Water Treatment Rule, Disinfectants and Disinfection Byproducts Rule, Lead and Copper Rule, Radionuclides Rule. We monitored for the regulatory parameters listed below. Tables on page 8 and page 9 summarize monitoring results for parameters found at detectable levels. Please see a glossary of terms and abbreviations on page 9.

Inorganic Chemicals:

Antimony, arsenic, barium, beryllium, cadmium, chromium, copper, cyanide free, fluoride, lead, mercury, nitrate, nitrite, selenium, and thallium.

Synthetic Organic Chemicals:

Alachlor, atrazine, benzo(a)pyrene, carbofuran, chlordane, dibromochloropropane, di(2-ethylhexyl) adipate, di(2 ethylhexyl) phthalate, endothall, ethylene dibromide, hexachlorocyclopentadiene, lindane, methoxychlor, oxamyl, pentachlorophenol, picloram, and simazine.

Volatile Organic Chemicals:

Benzene, carbon tetrachloride, o-dichlorobenzene, p-dichlorobenzene, 1,2-dichloroethane, 1-1 dichloroethylene, cis-1,2-dichloroethylene, trans-1,2-dichloroethylene, dichloromethane, 1,2-dichloropropane, ethylbenzene, monochlorobenzene, styrene, tetrachloroethylene, toluene, 1,2,4-trichlorobenzene, 1,1,1-trichloroethane, 1,1,2-trichloroethane, trichloroethylene, and total xylenes.

Appealing to Your Senses

We also test for aluminum, chloride, color, iron, manganese, pH, sulfate, total dissolved solids, and zinc to ensure that tap water meets all water quality taste and odor guidelines so that your water looks, tastes, and smells the way it should.

Additional Testing

We periodically test for the following contaminants, even though the Pennsylvania Department of Environmental Protection (PADEP) does not require us to do so: nitrite, asbestos, dalapon, dinoseb, dioxin, diquat, endrin, glyphosate, hexachlorobenzene, 2,4-D, PCBs, toxaphene, 2,4,5-TP, heptachlor, heptachlor epoxide, and vinyl chloride. No significant levels of any of the above contaminants have been found in Philadelphia's drinking water.

Lead in drinking water

It is important to minimize the intake of lead from dust inhalation, food, and water. Children are particularly susceptible to the health effects of lead poisoning. Lead is most commonly found in dust, paint and contaminated soil. To a lesser extent, lead can also occur in tap water. Components of plumbing may have lead in them. You may be surprised to learn that brass fixtures, valves and faucets contain lead. Many homes still have leaded solder that was once used to join copper pipe together. Some homes in Philadelphia still have lead service lines and, when disturbed, these lines can contribute to lead in tap water. It is the homeowner's responsibility to maintain, repair and replace the service lines.

Our primary role in helping you minimize your intake of lead is to reduce the corrosive effects of tap water on materials that contain lead. Water is corrosive and encourages the dissolving of lead from these materials. The Philadelphia Water Department has a permit with PADEP for operating under optimized corrosion control. Under this permit, we maintain the pH of water between 6.8 and 7.8. We also maintain the amount of the corrosion inhibitor, zinc orthophosphate, at greater than 0.12 mg/L (0.12 ppm) as phosphorus. These conditions minimize lead leaching from plumbing materials.

Currently, every three years the Philadelphia Water Department tests for tap water lead at more than 50 representative taps of vulnerable homes in the city. We do this according to the requirement of the EPA's Lead and Copper Rule. The testing results are used to determine if our corrosion control treatment technique is working, so that water has minimum potential for lead to leach from plumbing materials. So far, our test results show that our treatment techniques keep lead levels to a minimum.

However, this could change in any year because Philadelphia is required to meet other regulations for tap water quality. Sometimes these water quality changes can affect the corrosion potential of the water. If such a change were to occur, the Philadelphia Water Department would notify its customers of the change while it works to return to minimum corrosion conditions again. Water utilities all over the country are in the same position as Philadelphia, trying to balance all of the regulatory requirements and changes at one time so that their customers receive the best quality water possible. We are committed to reducing the corrosive effects of plumbing and lead levels in water. Additional information is available from the Environmental Protection Agency's Safe Drinking Water Hotline at 800-426-4791.

Research and Monitoring:

Cryptosporidium and Giardia

Cryptosporidium and *Giardia* are microscopic organisms found in surface water throughout the U.S. In 2007, we conducted 36 tests on our treated drinking water. None of the samples were positive for *Giardia* or *Cryptosporidium*.

When ingested, *Cryptosporidium* and *Giardia* can result in diarrhea, fever, nausea and abdominal cramps. However, these are also symptoms of many intestinal diseases caused by bacteria, viruses or parasites. Most healthy individuals can overcome such illnesses within a few weeks. However, immuno-compromised people are at a greater risk of developing a life-threatening illness. We encourage immuno-compromised individuals to consult their doctor regarding appropriate precautions to take to avoid infection. *Cryptosporidium* and *Giardia* must be ingested to cause disease, and it may be spread through means other than drinking water.

The Philadelphia Water Department is one of the nation's leaders in *Cryptosporidium* research and was one of the first utilities in the U.S. to monitor for the organism. We are also working closely with the Philadelphia Department of Public Health to ensure that our tap water is free of pathogens that can be found in rivers. In addition to routinely monitoring for *Cryptosporidium*, we are involved in an innovative project with Lehigh University to identify the sources of *Cryptosporidium* in our watersheds. As part of the project, we collect water samples upstream of our drinking water intakes. We isolate the *Cryptosporidium* oocysts, and conduct DNA analyses to determine whether the oocysts originate from human sources or from other species such as dogs, cats, deer, geese, cows, horses, etc. By identifying the sources of *Cryptosporidium* in the watershed, we are taking a proactive approach in improving the river water quality.

Pharmaceuticals in Drinking Water

Since 2004, the Philadelphia Water Department has participated in national research and monitoring of pharmaceuticals in drinking water. The technology to detect pharmaceuticals in water is very recent and only a few laboratories in the nation have this capability. The Philadelphia Water Department has been working with them.

Nationwide, pharmaceuticals get into drinking water because people now take more pharmaceuticals than ever, both prescription and over the counter. Only a small portion of these pharmaceuticals is absorbed in the body. The rest is passed through the body, eventually making its way into our nations's rivers and streams which are our drinking water sources. The levels we have found are in extremely low concentrations. For example, a person would need to drink eight glasses of water a day for more than 40,000 years to obtain the equivalent of a single child's dose (80 mg) of Tylenol. There is currently no indication that such extremely low concentrations pose any public health risk. The Philadelphia Water Department will continue to stay abreast of this issue to ensure the safety of our drinking water and the protection of our watersheds.

You can help keep unused pharmaceuticals out of the water supply by paying attention to how you dispose of unused medications. Look for take-back programs that may be established near you, either through pharmacies, or through household hazardous waste collection programs. For more information, please visit: www.phila.gov/water/Pharmaceuticals_in_D.html.

Partnership for Safe Water

Employees of the Philadelphia Water Department's three water treatment plants have earned six consecutive Director's Awards for maintaining an elite status in the Partnership for Safe Water. This award is presented to utilities across the country which meet or go beyond the water quality goals established by the Partnership for Safe Water.

Dating back to 1996, the Philadelphia Water Department was one of the first utilities to join this unique partnership between the drinking water industry and the EPA to make voluntary improvements in the nation's drinking water quality. This program was designed to be much more rigorous than the requirements of State and federal laws.

The turbidity of Philadelphia's water is 80 percent less than the maximum amount allowed by State and federal regulations, and it is 40 percent less than the Partnership's voluntary goal of 0.1 ntu.

The Partnership for Safe Water established a turbidity goal of less than 0.10 ntu (at all times tested). Today, all three of our water treatment plants continue to lower their ntu levels, achieving a total annual average of 0.06 ntu.

Through our participation in this program, we have surveyed our treatment plants, treatment processes, operating and maintenance procedures, and management oversight practices to learn how we can improve our water system. We have already made many of the improvements, and we will continue to apply others. These improvements have helped to enhance our water system's ability to prevent *Cryptosporidium, Giardia,* and other microbial contaminants from entering the water we treat.

drinking water treatment

Philadelphia PWD Water Department

How Do We Treat the Water So That You May Drink It?

Like the majority of water utilities in the U.S., we use a multi-step treatment process at all three of our drinking water treatment plants. This Water Treatment Process diagram provides a brief description of drinking water treatment in Philadelphia.

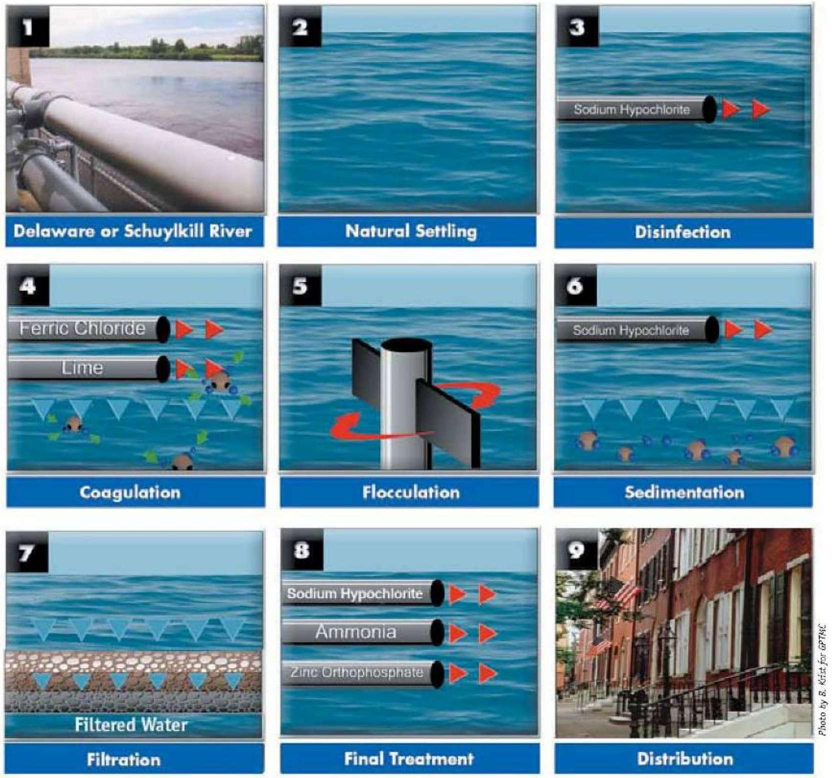


Photo by B. Krist for GPTMC

1. The River
The source of the water is from either the Delaware or Schuylkill River.

2. Natural Settling
After it has been pumped from the river, water is stored in reservoirs or basins for about 24 hours, to allow sediments to settle.

3. Disinfection
Sodium hypochlorite, a chemical compound containing chlorine, is added to kill disease-causing organisms.

4. Coagulation
The river water is "coagulated." Chemicals are added to the water to cause smaller particles in water to join together. This makes them heavier so that they will settle to the bottom of the basin.

5. Flocculation
The water is mixed gently to make sure the added chemicals are well blended and react with all of the smaller particles. The particles combine to form "floc" which settle to the bottom of the basin.

6. Sedimentation
The newly joined particles or "floc" settle by gravity and are removed from the bottom of the mixing tanks. More sodium hypochlorite may be added.

7. Filtration
The water flows by gravity through filters of sand and crushed coal, which remove very small particles that might never settle by gravity.

8. Final Treatment
Fluoride is added to help prevent tooth decay. Zinc orthophosphate is added to minimize rusting of metal pipes by the water. More sodium hypochlorite may be added. Ammonia is added to reduce the flavor of chlorine and to help the sodium hypochlorite to persist in the water while it travels through the water main system, or to remain active in the water all the way to our customers' faucets.

9. Distribution
The treated water is distributed through nearly 3,300 miles of water mains to 480,000 households in Philadelphia.

2007 DRINKING WATER QUALITY

METALS - *Tested at Customers' Taps - Testing is done every 3 years. Most recent tests were done in 2005.*

	EPA's Action Level for representative sampling of customer homes	Ideal Goal (EPA's MCLG)	90% of PWD customers' homes were less than	No. of homes considered to have elevated levels	Source

Treatment Technique One Year Average	Baxter WTP One Year Average	Belmont WTP One Year Average	Queen Lane WTP One Year Average	Source
Must be greater than or equal to 1	1.38	1.50	1.61	Naturally present in the environment.

BACTERIA IN TAP WATER

NOTE: One of the samples with Total Coliforms tested positive for E. coli.

	Level Allowed (EPA's MCL)	Ideal Goal (EPA's MCLG)	Highest Monthly Results	Source
Total Coliform Bacteria	Presence of coliform bacteria in 5% or less of more than 360 monthly samples	0	Highest % of positive samples: 0.22%	Naturally present in the environment.

OTHER CHEMICALS IN TAP WATER – PWD monitors annually although we are only required to report every nine years

	Highest Level Allowed (EPA's MCL)	Ideal Goal (EPA's MCLG)	Highest Result	Range of Test Results for the Year	Source
Nitrate	10 ppm	10 ppm	4.9 ppm	0.75 - 4.9 ppm	Fertilizer runoff, sewage
Barium	2 ppm	2 ppm	0.04 ppm	0.03 - 0.04 ppm	Metal refineries or natural deposits
Cyanide	0.2 ppm	0.2 ppm	0.06 ppm	0.05 - 0.06 ppm	Discharge from steel/metals, plastics and fertilizer factories

CLARITY CHARACTERISTICS – Tested at Water Treatment Plants

Turbidity (measure of clarity)	Baxter WTP	Belmont WTP	Queen Lane WTP	Source
Treatment Technique Requirement	95% of samples must be at or below 0.30 ntu	95% of samples must be at or below 0.30 ntu	95% of samples must be at or below 0.30 ntu	Soil runoff, river sediment
Highest Single Value for the year	0.085 ntu	0.098 ntu	0.093 ntu	Soil runoff, river sediment

NOTE: PWD achieved turbidity limits 100% at all times tested.

		Baxter WTP	Belmont WTP	Queen Lane WTP
Hardness (as Calcium Carbonate)	Annual Average *parts per million or grains per gallon*	86 ppm or 5 gpg	156 ppm or 9 gpg	153 ppm or 9 gpg
	Annual Minimum *parts per million or grains per gallon*	60 ppm or 4 gpg	120 ppm or 7 gpg	66 ppm or 4 gpg
	Annual Maximum *parts per million or grains per gallon*	99 ppm or 6 gpg	202 ppm or 12 gpg	217 ppm or 13 gpg
Alkalinity (as Calcium Carbonate)	Annual Average	40 ppm	69 ppm	67 ppm
	Annual Minimum	22 ppm	44 ppm	44 ppm
	Annual Maximum	60 ppm	108 ppm	95 ppm

SODIUM IN TAP WATER

Chemical	Baxter WTP One Year Average	Belmont WTP One Year Average	Queen Lane WTP One Year Average
Sodium	19 ppm or 4 mg per 8 oz. glass of water Range of individual test results: 14 - 28 ppm or 3 - 7 mg per 8 oz. glass of water	40 ppm or 9 mg per 8 oz. glass of water Range of individual test results: 25 - 61 ppm or 6 - 15 mg per 8 oz. glass of water	36 ppm or 9 mg per 8 oz. glass of water Range of individual test results: 17 - 53 ppm or 4 - 13 mg per 8 oz. glass of water

NOTE: We conducted monitoring for sodium throughout the year, although federal regulations do not require it.

TOTAL CHLORINE RESIDUAL – over 400 samples collected throughout the city every month

Total Chlorine in Tap Water	EPA Maximum Residual Disinfectant Level	One Year Average	Range of Highest Levels Detected at Taps
Chloramine	4.0 ppm	1.64 ppm	2.48 - 2.88 ppm

RADIOACTIVE CONTAMINANTS

Radioactive Contaminants	Highest Level Allowed (EPA's MCL)	Ideal Goal (EPA's MCLG)	Highest Result	Range of Test Results for the Year	Source
Alpha	15 pCi/L	none	3.7 pCi/L	0 - 3.7	Erosion of natural deposits of certain radioactive minerals.
Combined Radium 226 & 228	5 pCi/L	none	3.2 pCi/L	0 - 3.2	Erosion of natural deposits of certain radioactive minerals.

During the period of 2005, we conducted initial monitoring for a revised radionuclides regulation. We performed quarterly analysis of water treatment plant effluents for gross alpha, radium 226, radium 228, and uranium. Three out of twelve samples had detectable levels of radium 228, and one out of twelve samples had a detectable level of gross alpha. All detected values were below one-half of the MCL. Radium 226 and uranium were not detected in our water.

VOLATILE AND SYNTHETIC ORGANIC CHEMICALS (VOC and SOC)

Chemical	Highest Level Allowed (EPA's MCL)	Ideal Goal (EPA's MCLG)	Highest Result	Range of Test Results	Source
Atrazine	3 ppb	3 ppb	0.06 ppb	0.0 - 0.06 ppb	Runoff from herbicide used on row crops.
Simazine	4 ppb	4 ppb	0.12 ppb	0.0 - 0.12 ppb	Runoff from herbicide used on row crops.
Carbofuran	40 ppb	40 ppb	2.0 ppb	0.0 - 2.0 ppb	Leaching of soil fumigant used on rice and alfalfa.
Dichloromethane	5 ppb	0 ppb	0.6 ppb	0.0 - 0.6 ppb	Discharge from drug and chemical factories.

Listed on pages eight and nine are our Drinking Water Quality Results for 2007. All results are better than the recommended federal levels designed to protect public health. We are pleased to report that we did not have any drinking water violations for 2007. In keeping with our long-standing unblemished record, we continue to be free of violations since the Safe Drinking Water Act was implemented in 1974.

By reporting these results in the tables above, we are meeting a requirement of the EPA. Please see the glossary for definitions of abbreviations used in the tables.

Some contaminants may pose a health risk at certain levels. Others, such as turbidity, have no health effects. For information about potential risks, please visit our website (http://www.phila.gov/water), or call us at 215-685-6300. We will be happy to mail them to you.

GLOSSARY

Action Level: The concentration of a contaminant which, if exceeded, triggers treatment or other requirements that a water system must follow. The action level is not based on one sample; instead, it is based on many samples.

Alkalinity: A measure of the water's ability to resist changes in the pH level and a good indicator of overall water quality. Although there is no health risk from alkalinity, we monitor it to check our treatment process.

E. coli (Escherichia coli): A type of coliform bacteria that are associated with human and animal fecal waste.

GPG – Grains Per Gallon: A unit of water hardness. One grain per gallon is equal to 17.1 parts per million.

MCL - Maximum Contaminant Level: The highest level of a contaminant that is allowed in drinking water. MCLs are set as close to the MCLGs as feasible using the best available treatment technology.

MCLG - Maximum Contaminant Level Goal: The level of a contaminant in drinking water below which there is no known or expected risk to health. MCLGs allow for a margin of safety.

mg/L - Milligrams per liter: One milligram per liter is equal to one part per million.

ntu - nephelometric turbidity units: Turbidity is measured with an instrument called a nephelometer. Measurements are given in nephelometric turbidity units.

pCi/L - Picocuries per liter (a measure of radioactivity).

ppb - part per billion: One part per billion is equivalent to one green apple in a barrel with 999,999,999 red apples.

ppm - part per million: One part per million is equivalent to one green apple in a barrel with 999,999 red apples.

SOC – Synthetic Organic Chemical: Organic compounds, such as pesticides and herbicides, that are commercially made.

Total Coliform: Coliforms are bacteria that are naturally present in the environment and are used as an indicator that other potentially harmful bacteria may be present.

THAAs -Total Haloacetic Acids: A group of chemicals called disinfection byproducts, which form during chlorination.

TOC - Total Organic Carbons: A measure of the carbon content of organic matter. The measure provides an indication of how much organic material in the water could potentially react with chlorine to form THAAs and TTHMs.

TTHMs - Total Trihalomethanes: A group of chemicals called disinfection byproducts, which form during chlorination. TTHMs form when natural organic matter in the rivers, such as leaves and algae, decompose and combine chemically with the chlorine added for disinfection. Levels of TTHMs vary seasonally.

Treatment Technique: A required process intended to reduce the level of a contaminant in drinking water.

Turbidity: A measure of the clarity of water related to its particle content. Turbidity serves as an indicator for the effectiveness of the water treatment process. Low turbidity measurements, such as ours, show how we remove particles that cannot be seen by the human eye.

VOC – Volatile Organic Chemical: Organic compounds that include gases and volatile liquids.

WTP: Water Treatment Plant

How do we protect our water supplies from pollution?

We carefully safeguard our urban water supply through a variety of initiatives focused on protecting and improving the quality of our rivers and streams. We conduct research into new and emerging issues in water quality science, implement projects to directly enhance and improve water quality, operate and maintain an early warning system to alert our treatment plants of oil spills and other in-stream events that could impact our water supply, partner with other organizations and agencies throughout our watersheds that are also committed to improving source water quality, and continuously monitor the quality and health of our rivers and streams.

Plans Underway to Protect our Rivers and Streams

During the past several years, we completed Source Water Assessments and Protection Plans for the Delaware and Schuylkill rivers. The Source Water Assessments were completed between 1999 and 2002 and identified the major water quality concerns for the Schuylkill and Delaware rivers. The Schuylkill and Delaware River Protection Plans, completed between 2005 and 2007, took the results of the assessments and developed strategies for addressing the water quality challenges identified in the assessments. We are also involved in research to understand the impact of climate change and global warming on the water supply and conduct experimental research to understand the impact of small concentrations of everyday products, such as caffeine and pharmaceuticals, on the water environment.

For information about the quality of our region's rivers and streams, call the Pennsylvania Department of Environmental Protection at 484-250-5900 or check their website (http://www.dep.state.pa.us).

Schuylkill Action Network (SAN)

In 2004, the Schuylkill Action Network received a grant from the Environmental Protection Agency to fund projects which were identified during the Schuylkill River Source Water Assessment. This grant was one of only 13 awarded nationally that year.

Land use has a major influence on how the quality of our rivers and streams are impacted by stormwater runoff. Some lands, such as forested land or land surrounding high quality streams and reservoirs, are particularly important for drinking water protection. In 2006 and 2007, the SAN Watershed Land Protection Collaborative mapped and prioritized land in the Schuylkill Watershed based on the importance of the land for drinking water protection, and the likelihood of that land being developed. A strategy was then developed to share the results of the prioritization with land use planning and zoning agencies throughout the watershed to make sure future land use decisions consider the impacts of such decisions on drinking water supply.

Schuylkill and Delaware River Source Water Protection Plans

The Schuylkill and Delaware River Source Water Protection Plans provide a comprehensive framework for implementing a watershed-wide effort to improve source water quality. The Plans prioritize real and potential sources of contamination to Philadelphia's raw water supply, and outlines several approaches to reducing them.

One major component of the Schuylkill Plan, completed in 2005, is a build-out scenario of the Schuylkill River Watershed that looks at the possible impacts of significant development in the watershed on source water quality. Under current zoning, low-density housing could increase drastically as agricultural and forested lands are developed. This scenario helped us to see the importance of land preservation for source water protection, and has led to the development of a tool which prioritized land for protection based on its importance for preserving or improving water quality.

The Delaware River Plan, completed in 2007, brought to the forefront the need for the ongoing protection of our Baxter drinking water intake from salt intrusion from the Delaware Bay. To date, we have had ample protection from salt intrusion due to the large quantity of fresh water coming down the Delaware River. Now with the new Flexible Flow Management Plan, which was enacted for the Delaware River in October of 2007, we need to conduct extensive modeling of this plan. Along with project changes in flow characteristics from global warming, climate change, sea level rise, and population changes, this plan will make sure we continue to provide adequate protection of Baxter's intake from salt intrusion well into the future.

SAN FACTS & FIGURES

SAN Mission:
Protecting and restoring the Schuylkill River as a premiere regional:
- Drinking water source
- Recreational resource
- Natural habitat for fish and wildlife

122: Number of SAN organizations in 2007

SAN Members
- Citizens
- Universities
- Water suppliers
- Non-profits
- Funders
- Corporations
- Federal, state and local governments

Major Pollution Threats to Schuylkill River
- Agriculture
- Abandoned mine drainage
- Urban and suburban stormwater runoff
- Faulty sewer systems

The SAN provides:
- Central coordination of restoration and protection efforts for the entire Schuylkill River
- Consensus-based plans for the watershed built on sound science, data, and stakeholder input

$1.15 million: EPA Targeted Watershed Program Grant Award (2005-2009)
- 50 projects reducing the impact of agriculture, abandoned mine drainage (AMD), and stormwater on the quality of the Schuylkill River.

Agriculture: SAN Agriculture Projects are designed to treat excessive loadings of nutrients and contaminiated stormwater runoff. As of 2007:
- 32,000 feet of streambank fencing has been installed
- 6,000 feet of streambank plantings have been completed
- 15 Conservation Plans accomplished

Abandoned Mine Drainage: The upper watershed is impacted by polluted water seeping from abandoned coal mines that discharge iron, manganese, and aluminum to the Schuylkill River. To date:
- 5 AMD projects have been implemented, treating 21 million gallons per day of contaminated flow

Stormwater:
- Ranked all detention basins in the Wissahickon Creek watershed for the potential to be modified to enhance groundwater recharge and water quality treatment of stormwater runoff

Providing Early Warning Protection

Since 2004, we have led the development and implementation of the Early Warning System for the Schuylkill and lower Delaware Rivers. This system is an integrated communication and water quality monitoring network that supports the identification, notification and analysis of source water quality events such as chemical spills and other potential hazards.

The system's goal is to provide advance warning of potential source water contamination to water suppliers. Funded in part by a $775,000 grant from the Pennsylvania Department of Environmental Protection, the system provides water suppliers on both rivers with essential information to make critical treatment and pumping decisions in response to spills and accidents that can have a detrimental impact on the rivers. The Schuylkill and Delaware system is comprised of a partnership of water suppliers, industries with water intakes, and government agencies. The system also includes a web-based centralized database for water quality and event information, a telephone notification system, and a network of real–time water quality monitors located throughout the two watersheds.

Delaware Valley Early Warning System serves
- Over 3 million people
- Philadelphia, Camden and Trenton Metro areas
- 12 water utilities, 23 water treatment plants in Pennsylvania
- 5 water utilities, 5 water treatment plants in New Jersey

Since the system was fully deployed in January of 2005, 100 events have been entered into the system, ranging from a 100-million-gallon fly-ash spill on the Delaware and a cyanide discharge in the Wissahickon Creek, to flood warnings and sewage discharges. In each of these cases, the improved awareness, communication, and coordination provided by the system was valuable to our response.

RiverCast

More than 100,000 people use the Schuylkill River at Fairmount Dam ("boathouse row") for recreational activities every year. The amount and scope of river use seem to increase annually. As recreation increases, so does public concern about river water quality. In response to this concern, we developed RiverCast: the first and only bacteria forecasting system in the United States created for recreational activities. Similar to a weather forecast, RiverCast is an internet-based system that provides the public with hourly updates of expected concentrations of fecal coliform bacteria in the Schuylkill River.

RiverCast uses a color rating system to indicate bacteria levels. Each color rating is linked with guidelines for recreational activity (see below). The bacteria ranges used to determine the color ratings, along with the below activity guidelines, are based on draft EPA regulations for recreational waters.

GREEN

Bacteria	Types of Activities	RiverCast
Low level	**jet skiing, kayaking swimming, sculling**	**recommendation: suitable**

YELLOW

Bacteria	Types of Activities	RiverCast
Level elevated	**jet skiing, kayaking swimming, sculling**	**recommendation: may not be suitable**

RED

Bacteria	Types of Activities	RiverCast
Level high	**jet skiing, kayaking swimming, sculling**	**recommendation: not suitable**

The website has been visited over 100,000 times and has been used for the planning of major water recreational events such as triathlons and regattas. Visit RiverCast at www.phillyrivercast.org.

Source Water Assessments

The Pennsylvania Department of Environmental Protection has been conducting assessments of all potentially significant sources of contamination to all public drinking water sources. The Philadelphia Water Department has prepared assessments to support local and State efforts to protect the quality of Philadelphia's drinking water sources.

Funded in part by a grant from the Pennsylvania Department of Environmental Protection, we partnered with Aqua America (formerly Philadelphia Suburban Water Company) and the Pennsylvania American Water Company to perform a source water assessment of water intakes along the Schuylkill and its tributaries.

The assessment detailed major issues within the watershed that threaten the quality of the drinking water supply. The river is a major source of drinking water for the public served by these three water utilities. In addition, the Philadelphia Water Department conducted an assessment for seven surface water intakes along the tidal section of the Delaware River.

This summary is for water supply areas for the Philadelphia Water Department's Baxter, Belmont, and Queen Lane water treatment plants. It assesses the raw (untreated river) water only.

For water quality information on our treated "tap" water, please see the charts on pages 8 and 9 of this report.

If you would like to receive a copy of the source water assessment summaries, or would like to know how to get involved in protecting your water supply or watershed, please call the Philadelphia Water Department at 215-685-6300, visit our website at www.phila.gov/ water, or see Table 2 on page 14.

Baxter Water Treatment Plant

This plant, located in the Torresdale section of Philadelphia, provides treated water that comes from the Delaware River. Through the Delaware River Protection Plan, we revisited the findings of our source water assessment report and identified population growth and land cover change in the Delaware River watershed; as well as the impact of sea level rise, global warming, and changes in flow management on the vulnerability of our Baxter intake to salt intrusion; as the activities of greatest concern for our water supply on the Delaware.

Historically, we have developed and maintained emergency response plans to address transportation accidents and spills along the Delaware River that could potentially impact the water supply, since it is a working river with barges, railroads, and many other transportation activities on or adjacent to it. We now have an automated early warning system which has greatly enhanced our emergency preparedness and response. Through our award-winning Source Water Protection Program, we also work with upstream partners such as watershed organizations, regulatory agencies, planning commissions, municipalities, and water suppliers to prevent declines in water quality throughout the entire 13,000 square-mile watershed to keep our water supply as clean as possible. Our Delaware River Protection Plan outlines our many strategies for protecting and enhancing the quality of the Delaware River as a source of drinking water for future generations.

Belmont and Queen Lane Water Treatment Plants

These plants provide treated water that comes from the Schuylkill River in Fairmount Park. Through a source water assessment report, the State drinking water program has found that our water supply is potentially most susceptible to challenges caused by discharges of treated and untreated sewage upstream, polluted runoff from urban areas and agricultural lands, transportation accidents and spills, and abandoned mine drainage. Most of these potential sources are located watershed-wide, but abandoned mine drainage originates over 100 miles upriver near the source of the Schuylkill River in Schuylkill County. Much closer to Philadelphia, the Wissahickon Creek requires special protection from potential sources of pollution due to its impact on source water quality at the Queen Lane intake.

Historically, we have developed and maintained emergency response plans to address accidents and spills that could potentially impact the water supply. We now have an automated early warning system which has greatly enhanced our emergency preparedness and response. Through our award-winning Source Water Protection Program, we also work with upstream partners such as watershed organizations, regulatory agencies, planning commissions, municipalities, and water suppliers to prevent declines in water quality throughout the entire 2,000 square-mile watershed to keep our water supply as clean as possible. Our Schuylkill River Protection Plan outlines our many strategies for protecting and enhancing the quality of the Schuylkill River as a source of drinking water for future generations.

We welcome your ideas and opinions

We participate in nearly 200 public and community events a year, including presentations made at schools, ongoing educational programs, and other environmental celebrations.

We offer ways for individuals, families, students, seniors, community groups and others to participate in learning about protecting water.

We greatly benefit from our citizens advisory council, which has been working with us over the last few years to improve our communications with our customers. Citizens representing business and industry, education, environmental advocacy, senior citizens, regulatory agencies, and civic and community groups have assisted us in developing public information about a variety of topics, including drinking water quality and stormwater pollution prevention.

Interested citizens are welcome to attend our Water Quality Education Citizens Advisory Council meetings. Call our Hotline at 215-685-6300 to confirm the meeting dates, times and locations.

Getting Involved

If you would like to help protect your water supply or watershed, please call the Philadelphia Water Department at 215-685-6300, visit our website at www.phila.gov/water, or see Table 2 on page 14.

How to contact us

You can write to us at:
Philadelphia Water Department
ARAMark Tower
1101 Market Street, 3rd Floor
Philadelphia, PA 19107-2994

You can call our Customer Information Hotline at 215-685-6300.

Explore Water in Our World at the Fairmount Water Works Interpretive Center!

Our Fairmount Water Works Interpretive Center is where the water environment comes alive! The Fairmount Water Works stopped pumping water in 1909, but it now has an exciting new life housing the Interpretive Center's exhibits and theater. Activity abounds in the galleries, on the deck, and by the river as school children, families, and other visitors explore the water right outside our window.

Our exhibits and programs serve the entire Philadelphia region; the Interpretive Center has been recognized by the Pennsylvania Department of Environmental Protection as the Delaware River Basin's official Watershed Education Center.

Did you know that you can drink the same water that dinosaurs drank? Come to our Interpretive Center where you can pilot a helicopter up the Delaware River, make it rain, peak inside a 48-inch water main, visit Pollutionopolis, and more! Our adult programs include lectures and seminars from nationally and internationally known scientists and writers. We offer something for everyone.

The Interpretive Center is located at 640 Water Works Drive, below the Art Museum. Our hours are Tuesday through Saturday, 10:00 am to 5:00 pm, and Sunday from 1:00 pm to 5:00 pm. We are closed on Mondays and city holidays. Admission is free. The Center is ADA accessible. To schedule classroom tours, check out the Center's Saturday Family Programs and other environmental education events at the Center, visit our website: www.fairmountwaterworks.org.

Interesting facts about Philadelphia's water

Hardness

Hardness defines the quantity of minerals such as calcium and magnesium in water. These minerals react with soap to form insoluble precipitates and can affect common household chores such as cooking and washing. Philadelphia's water is considered "medium" hard. Hardness also affects other water qualities such as its corrosiveness, with naturally soft water being more corrosive.

Cloudy Water

Aeration is the process which takes place when the water flowing from your tap into your glass appears cloudy. This temporary condition is a result of dissolved air being released from the water and being temporarily suspended in the water in your glass. This most commonly happens in the winter time when the cold water in the water mains is warmed up quickly in household plumbing, thereby encouraging the dissolved air to come out of the water.

Temperature

The temperature of both the Schuylkill and Delaware rivers varies seasonally from approximately 32° to 82° F. The Water Department does not treat the water for temperature.

Clean water begins and ends with you

Always recycle or dispose of unwanted household hazardous wastes properly. Don't pour motor oil, antifreeze or other toxic materials down storm drains. Water that enters our storm drains often flows directly to our local streams and rivers. So, don't pollute! Recycle these household hazardous materials safely and help protect our waterways. Also, don't flush paint thinners, insect sprays, herbicides and other harmful chemicals down the sink. Contact the Streets Department to get a schedule of their Household Hazardous Materials Drop-off Events where you can dispose of these materials safely without polluting your drinking water supply.

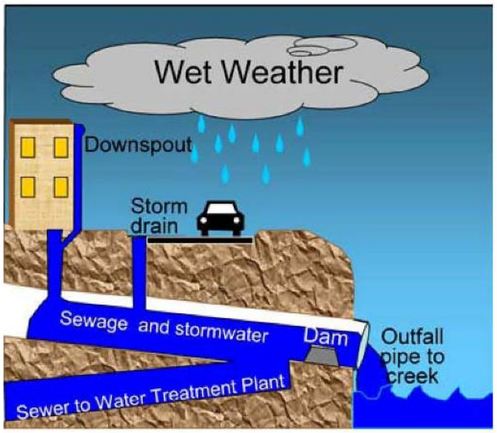
S:	Storm drain marking
T:	Water quality testing

Philadelphia PWD Water Department

WATER Wheel

“Green Cities — Clean Waters Program”

Green Cities/2008



What is a Combined Sewer Overflow (CSO)?

A combined sewer system transports sewage (from homes, businesses and industry), stormwater from the storm drains on our streets and stormwater from property rain leaders through a single underground pipe to a Water Pollution Control Plant (treatment plant).

Under heavier rainfall conditions, however, the flow of the sewage and stormwater in combined sewers may exceed the capacity of the pipe or treatment facility. As a result, a portion of the sewage and stormwater may be sent directly to a nearby stream or river to prevent the flooding of homes and streets. This is what is known as a Combined Sewer Overflow.

The Vision for Our Creeks & Our City

Imagine a Philadelphia where you can walk along any creek in the City and find yourself surrounded by wildflowers under a shady canopy, listening to birds chirp, watching butterflies and dragonflies flutter by and where you can rest and fish peacefully in clean waters. This is the vision the Philadelphia Water Department (PWD) has for the future of Philadelphia – for a greener city with cleaner waters.

PWD believes that this vision can become a reality through PWD’s “Green Cities-Clean Waters Program.” This program is also referred to as the Combined Sewer Overflow (CSO) Long Term Control Plan. It is a plan that will help us reduce combined sewer overflows and clean up our waters – the plan that will help us transform Philadelphia into a more desirable place to live, work and play.

The Warning on Our Creeks

Combined Sewer Overflows (CSOs) are not just a Philadelphia problem. They are an old problem in cities throughout the country, where combined sewer outfalls are present. CSOs discharge a mix of sewage and stormwater during rainstorms, resulting in swimming and fishing advisories and habitat destruction. Therefore, it is important that the public avoid contact with the waters in our creeks and rivers during and immediately following rain events.

The History behind Those Pipes

Philadelphia was once a city of water (see Map 1 on the next page) – where hundreds of creeks flowed through the city. It was because of these creeks and rivers that industry flourished. However, as Philadelphia grew, so did the pollution. Waste from slaughterhouses, used dye, trash and sewage – all were discharged to our rivers and creeks. It was standard practice in the 18th and 19th centuries to use creeks as sewers.

At one point, the creeks and rivers were so filthy that they became a health hazard. Thousands of Philadelphians died from disease. The creeks also became an obstacle to development. Eventually, they were driven underground, their streambeds replaced with the sewers that now contain them. By the late nineteenth century, many of the creeks had disappeared – the map of the city’s surface streams was disturbingly blank (see Map 2 on the next page).

(continued on next page)

Philadelphia PWD Water Department

WATER Wheel

"Green Cities—Clean Waters"

(continued from previous page)

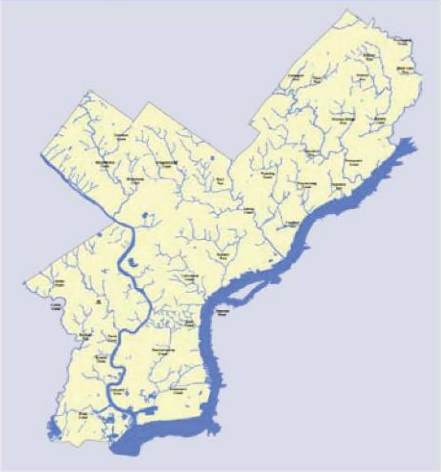
However, by the twentieth century, City leaders realized the benefits of preserving our remaining streams and creating watershed parks (East and West Parks, Wissahickon, Cobbs, Tacony, Pennyack). But for many of those streams, it was too late.

In addition, the 1972 Clean Water Act required utilities to significantly reduce pollution from its treatment facilities, combined sewers and storms. As a result, the creeks and rivers in the City are cleaner now than they have been in half a century.

Over the next 20 years, we will build upon this progress, implementing a mix of new infrastructure, green land practices, stream restoration and community involvement. Through the "Green Cities-Clean Waters Program," and with your support, we will transform Philadelphia into a place where all want to live, work and play. The creeks will become a place where we can find respite in the City; where we can walk amongst wildflowers, listen to the songs of birds, and fish in clean waters again.

For more information and to learn how you can help support the Green Cities-Clean Waters Program, please visit our website: http://www.phillyriverinfo.org.

Map 1: Historic Streams



Map 2: Today's Streams

Clip out and fold this information and carry it in your wallet, so you can report flows.

No Swimming at Any Time in Philadelphia Creeks.
Sewers May Overflow.
During and immediately after rain, polluted water may flow from pipes.

To protect your health, do not come in contact with rivers and streams during and immediately after rain events.

For information on how to protect our waterways, visit: www.phillyriverinfo.org.

Please report flows from pipes during dry weather to PWD's hotline: 215-685-6300.

Philadelphia Water Department (PWD)

Cortelo, doblelo y guardelo en tu billetero, para que puedes reporter desbordamientos.

No Nades en Ningun Tiempo en las Quebradas de Filadelfia. Puede Ocurrir Desbordamiento de Aguas Negras.

Durante e imediatamente después de llover, las aguas contaminadas pueden fluir por tubería.

Para proteger su salud, evite el contacto con ríos y quebradas durante e imediatamente después de llover.

Para información sobre como proteger nuestros cuerpos de agua visite: www.phillyriverinfo.org.

Favor de reportar cualquier desbordamiento (durante tiempos secos) a la línea directa de PWD: 215-685-6300.

Faith-Based Initiatives

Philadelphia
PWD
Water Department

June 17, 2009

Reverend Luis Cortés
Nueva Esperanza
4261 North 5th Street
Philadelphia, PA 19140

Dear Reverend Cortés,

Peace and blessings to you and Nueva Esperanza!

As the Associate Director of the Mayor's Office for Faith Based Initiatives and the Director of the Philadelphia Water Department's Office of Watersheds, we are pleased to inform you that we feel encouraged by all of the recent city initiatives to foster neighborhood stewardship of our environment. Just this month, the Mayor released GreenWorks Philadelphia, his vision for making Philadelphia the most sustainable city in the country by 2015. As people of faith know, a sustainable city is a safe and beautiful city.

The Mayor's Office for Faith Based Initiatives has been working with the Philadelphia Water Department to consider activities that will compliment the neighborhood and fulfill important environmental objectives that would serve the municipal, economic, health and spiritual needs of the City's residents. In the spirit of hope and community, we are writing to request a one hour meeting with you to begin a dialogue with Nueva Esperanza towards establishing a partnership to beautify and green the surrounding neighborhoods.

Here are a few ideas for how we might be able to work together:

- City beautification (clean-ups, planting gardens, greening sidewalks and streets)
- Establishing living memorials (commemorative trees and gardens)
- Surveying worshipers' attitudes about green streets

For more detailed background information, we have attached a separate fact sheet. Also, please feel free to contact Mr. Gerald Bright, Aquatic Biologist, with the Philadelphia Water Department – 267-339-1826. Mr. Bright will follow up with you on our behalf to schedule a meeting. Thank you for your consideration to partner with us.

Sincerely,

Minister Malcolm T. Byrd
Associate Director
Mayor's Office of Faith-Based Initiatives

Sincerely,

Howard Neukrug
Director, Office of Watersheds
Philadelphia Water Department

Faith Community Greening Partnership Facts

The Philadelphia Water Department (PWD), in partnership with the Mayor's Office of Faith-Based Initiatives (MOFI), is beginning dialogues and partnerships with Philadelphia's religious institutions, faith- inspired organizations, and neighborhoods towards further beautifying and greening of city neighborhoods through the planting of more vegetation on sidewalks and streets.

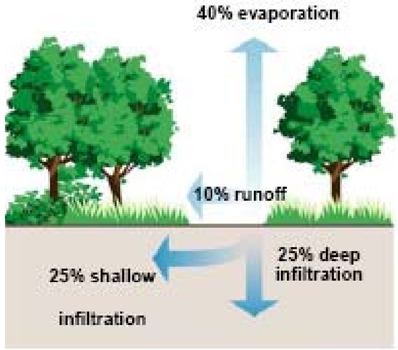
Below are illustrations of pre- and post-development conditions, the City's combined sewer system and examples of grey and green infrastructure. The federal government mandates that the City manage its stormwater runoff in order to minimize impacts to local streams. PWD wants to use as much green (vegetation) as possible to minimize this runoff. Greening will reduce combined sewer overflows, while beautifying communities, and improving air quality, in addition to providing other benefits to Philadelphia and its residents.

MOFI and PWD believe that faith leaders and their congregations understand that stewardship of our land and water is both a civic responsibility and a spiritual obligation.

We would like to gauge the interest of local congregations in greening, through conducting an environmental awareness survey. PWD will provide the surveys, background materials and staff to distribute the surveys and answer questions. Additionally, we can collaborate on formulating the message about this effort to specific congregations.

For more information, visit www.phillyriverinfo.org or contact Gerald W. Bright, Aquatic Biologist and Project Liaison, at 267-339-1826 or Gerald.Bright@phila.gov.

Pre-development



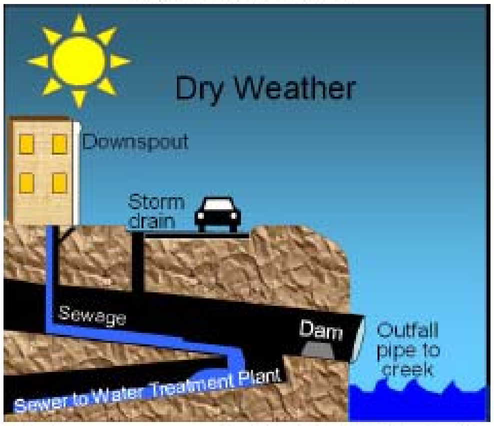
Prior to development, vegetation (trees and plants) enables stormwater (rain or melting snow) to soak into the ground, replenish groundwater and foster tree and plant growth, thereby supporting healthy living streams and rivers.

Post-development

As a city develops, we replace vegetation with built surfaces, such as rooftops, streets, and parking lots, causing stormwater to run off of these impenetrable surfaces, traveling to the nearest storm drains, which connect to underground sewer pipes.

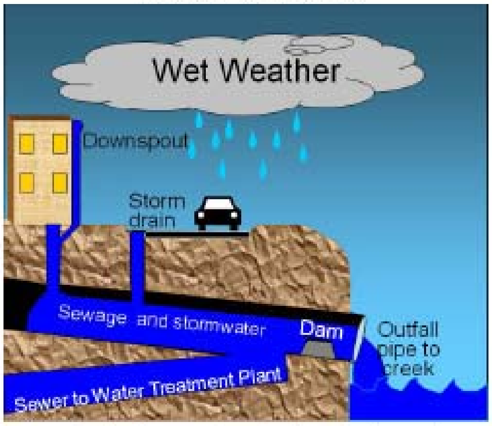
Faith Community Greening Partnership Facts

Combined Sewer System



We built sewer systems to collect the rainfall that flowed off of these built surfaces and to divert it away from our neighborhoods. In much of Philadelphia, as in many other large cities throughout the world, a single-pipe, "combined sewer system," is used to collect and treat both rain runoff, or "stormwater," and residential and commercial sanitary waste.

Combined Sewer System

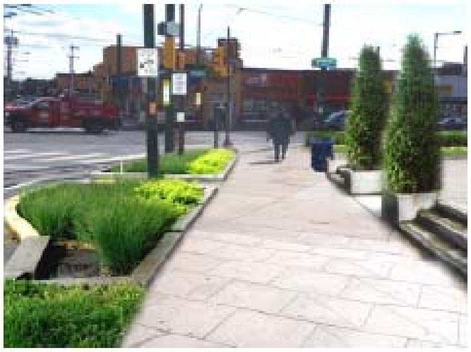


However, during intense rain events, there is not enough capacity in our pipes and treatment plants to handle the volume of stormwater runoff, causing Combined Sewer Overflows (CSOs) into Philadelphia's creeks and rivers.

Grey Infrastructure

To reduce CSOs, PWD proposes to use a combination of "grey infrastructure," including building underground storage pipes and tunnels and expanding our treatment plants, and "green infrastructure."

Green Infrastructure



Examples of "green infrastructure," include curbside tree planters, rain gardens, rain barrels and green roofs. These "green" practices all use natural methods to allow stormwater runoff to soak in the ground to prevent it from reaching our sewers and/or to slow down the runoff enough to help prevent CSOs. Green streets are safe streets that clean and beautiful our city.

Triple Bottom Line Analysis

Updated: September 1, 2009

PWD "GREEN CITY – CLEAN WATER" PROGRAM
Summary of Triple Bottom Line Analysis

Introduction

The vision outlined in "Greenworks Philadelphia" sets an ambitious agenda to transform Philadelphia into the "greenest city in America", taking advantage of Philadelphia's considerable assets such as walkable neighborhoods and mass transit, and reversing years of population and infrastructure decline. This will take a transformation in the way city agencies work together, and will need to align city government, non-governmental organizations and residents in a joint effort towards achieving a common goal of a more livable, sustainable city that reduces its energy needs, improves the economic condition of its citizens, and manages its natural resources to the greatest extent possible.

PWD's "Green City – Clean Water" program integrates management of Philadelphia's watersheds into this larger context. It is designed to provide many benefits beyond the reduction of combined sewer overflows, so that every dollar spent provides a maximum return in benefits to the public and the environment. To fully understand the economic, environmental, and social benefits of the program, PWD has undertaken a Triple Bottom Line analysis. The results of this analysis are summarized below.

Green Infrastructure and How it Works

Green stormwater infrastructure, as defined by PWD, includes a range of soil-water-plant systems that intercept stormwater, infiltrate a fraction of it into the ground, evaporate a portion of it into the air, and in some cases release a portion of it slowly back into the sewer system where it can ultimately be treated at a wastewater treatment plant. Examples include bioretention planters in sidewalks and parking lots, roof leaders that run off into lawns, green roofs, and rain gardens. These practices manage rain where it falls in a way similar to a natural system such as a forest or a meadow. An important concept used throughout this document is the concept of "greened area". The greened area in a watershed is the percentage of urban land area "served" by green stormwater infrastructure. This area includes the area of the stormwater facility itself, plus the area draining to it.

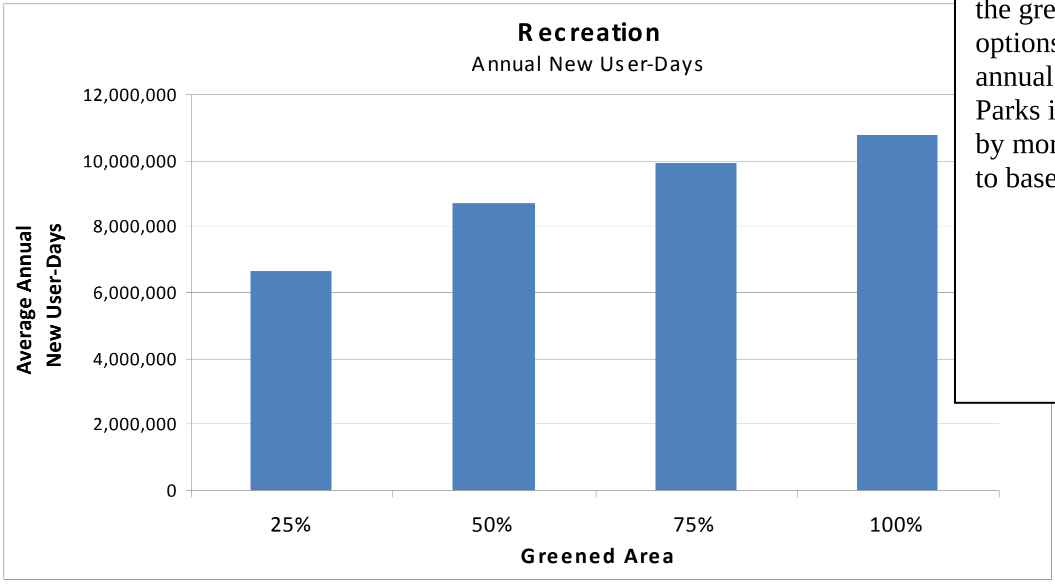
PWD's definition of green infrastructure also includes restoration of physical habitats in stream channels, along stream corridors, and on riverfronts. These practices are important to the larger approach because without them, the damage done to ecosystems by two centuries of urbanization will not be undone. Restoration of stream habitats and riverfronts can also be combined with efforts to improve public access and amenities along the water corridors.

Green Infrastructure Enhances Recreation and Restores Ecosystems

Green Infrastructure Enhances Recreation

Throughout the Fairmount Park system, residents enjoy recreation along Philadelphia's stream corridors and waterfronts, but some areas do not live up to their full potential. Improved access, appearance, and opportunities in these areas will make them more desirable destinations for the public. Recreation also will be more desirable along newly greened neighborhood streets and public places.

At full implementation of the green infrastructure options, the number of annual visits to Fairmount Parks is expected to increase by more than 6% compared to baseline conditions.



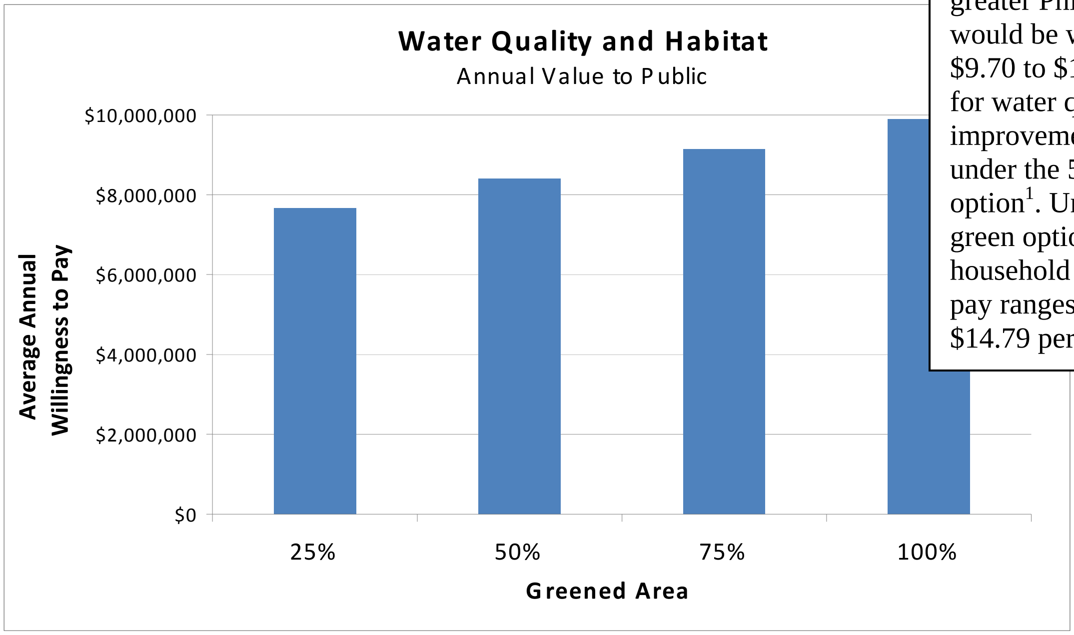
<u>Recreation: Methods and Sources</u>
The team established a baseline for the number of visitors to Philadelphia's parks today, based on reports prepared for the Philadelphia Parks Alliance and the Fairmount Park Commission, and input from park staff. With improvements to underused areas along stream corridors and riverfronts, the team estimated that these areas could be brought up to a level of use more similar to the park system as a whole. Recreation along newly greened streets and public places was linked to the area greened in each watershed. Environmental economists are able to estimate monetary values for recreation activities using "direct use" values from the academic literature and government agencies. These values estimate what a typical user pays or would be willing to pay to take part in that activity. For this study, the team was able to draw upon Philadelphia-specific direct-use values for different recreational activities, as published in a report prepared by the Trust for Public Lands (2008): *How Much Value Does the City of Philadelphia Receive from its Park and Recreation System?*.

Selected References: Trust for Public Lands, 2008; Tidal Schuykill River Master Plan, 2003

Green Infrastructure Restores Ecosystems

Green infrastructure improves ecosystems in two ways. First, by restoring a water cycle more similar to a natural watershed, green infrastructure allows rain to soak into the ground and return to streams slowly. This provides a natural water quality filter and limits erosion of stream channels caused by high flows, both of which benefit aquatic species. Second, PWD's green infrastructure approach includes physical restoration of stream channels and streamside lands, including wetlands, to restore habitat needed for healthy ecosystems.

Households within the greater Philadelphia region would be willing to pay \$9.70 to \$15.54 per year for water quality improvements expected under the 50% green option[1]. Under the 25% green option, estimated household willingness-to-pay ranges from \$8.89 to \$14.79 per year.



<u>Ecosystem Restoration: Methods and Sources</u>
Water quality and ecosystem health are difficult to value economically. However, human beings clearly value clean water and healthy ecosystems both for themselves and for future generations. Environmental economists refer to this as a "nonuse" or "nonmarket" value and have a number of tools for estimating these values in monetary terms. For this study, these values were monetized based on a large body of academic literature where households were surveyed to determine how much they would be willing to pay to improve water quality or habitat by a defined amount. Values also were derived from a large body of literature on the economic value of wetlands.

Selected References: Van Houtven et al., 2007; Woodward and Wui, 2001; Borisova-Kidder, 2006

1

---

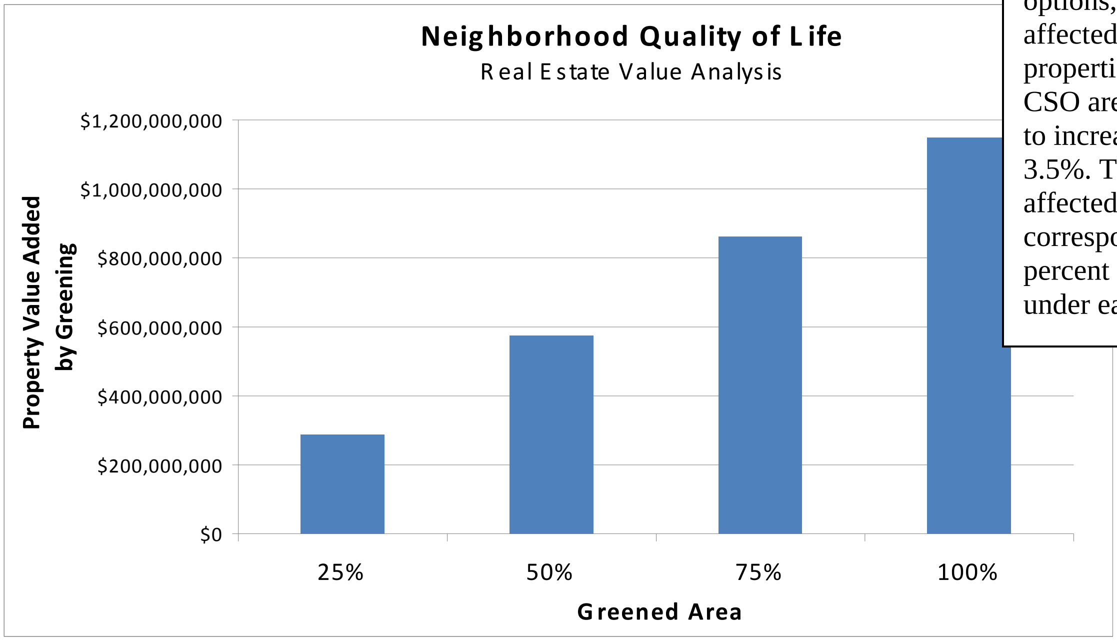
[1] Analysis assumes households outside of Philadelphia County, but within the greater Philadelphia metropolitan area, would be willing to pay for water quality improvements in the Schuylkill and Delaware Rivers due to the regional importance of these rivers. This assumption is based on the findings of several studies demonstrating a willingness-to-pay for improved resources despite the respondent's physical distance from the resource.

Green Infrastructure Improves Neighborhoods

Green Infrastructure Improves Community Quality of Life

Trees and parks are an important part of the recipe that together can make an urban neighborhood into an inviting, exciting place to live, work and play. Residents clearly recognize and value this quality of life effect of urban vegetation, and yet it is difficult to assign it an economic value. One way to estimate a value is to study property values in areas that are close to parks and greenery.

Under the various green options, the values of affected residential properties within PWD's CSO area are expected to increase by about 3.5%. The number of affected properties corresponds to the percent of greened area under each option.



<u>Quality of Life: Methods and Sources</u>

There is a rich body of academic literature showing that property values are higher when trees and other vegetation are present in urban neighborhoods, including some Philadelphia-specific studies. The study team combined estimates from this literature, data on current Philadelphia home values, and proposed increases in "greened area" to estimate these benefits under the greened area CSO options.

It is important to note that the study team evaluated increases in the value of residential properties only. However, commercial, industrial and institutional property values would also likely increase.

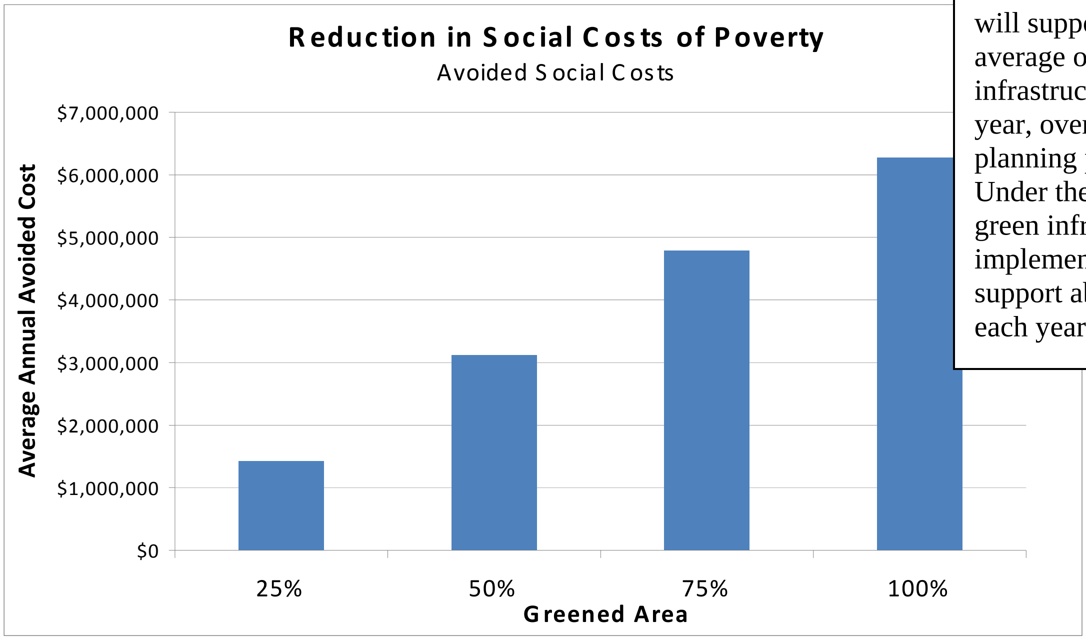
Green Infrastructure Jobs Reduce the Social Cost of Poverty

Governments at all levels incur significant costs in coping with poverty, and Philadelphia is no exception. Green infrastructure creates jobs which require no prior experience and are therefore suitable for individuals who might be otherwise unemployed and living in poverty. These new jobs create a benefit to society in reduced poverty-related costs, in addition to the wages paid to the individual workers. The stabilizing and transforming effects of green infrastructure in neighborhoods further reinforce and support the benefits of providing employment to a population that is outside the labor force. Green infrastructure is not by itself the solution to poverty, but it is a valuable tool in the toolbox of poverty reduction.



The 50% green option will support an average of 380 green infrastructure jobs per year, over the 40-year planning period. Under the 25% option, green infrastructure implementation will support about 170 jobs each year.

<u>Poverty Reduction: Methods and Sources</u>

Based on a number of local and national studies, economists have estimated that the cost of poverty related outlays in Philadelphia divided by the number of adults living in poverty ranges from about $15,000 to $45,000 per year. These studies are based on estimates of spending by all levels of government on assistance programs and avoidable crime and health impacts (e.g. it costs $30,000 per year to keep a person in jail in Philadelphia). Many of the study estimates include documented increased costs of seemingly unrelated city services due to poverty. Some of the lower estimates of total social cost are missing a number of these cost elements, thus, the higher estimates seem more plausible.

Based on these various studies, This study assumes an avoided social cost of $10,000 per new green infrastructure job created. This study also assumes that three-quarters of these new jobs would require no experience and thus provide the benefits of hiring unemployed adults living in poverty, and reducing poverty expenditures.

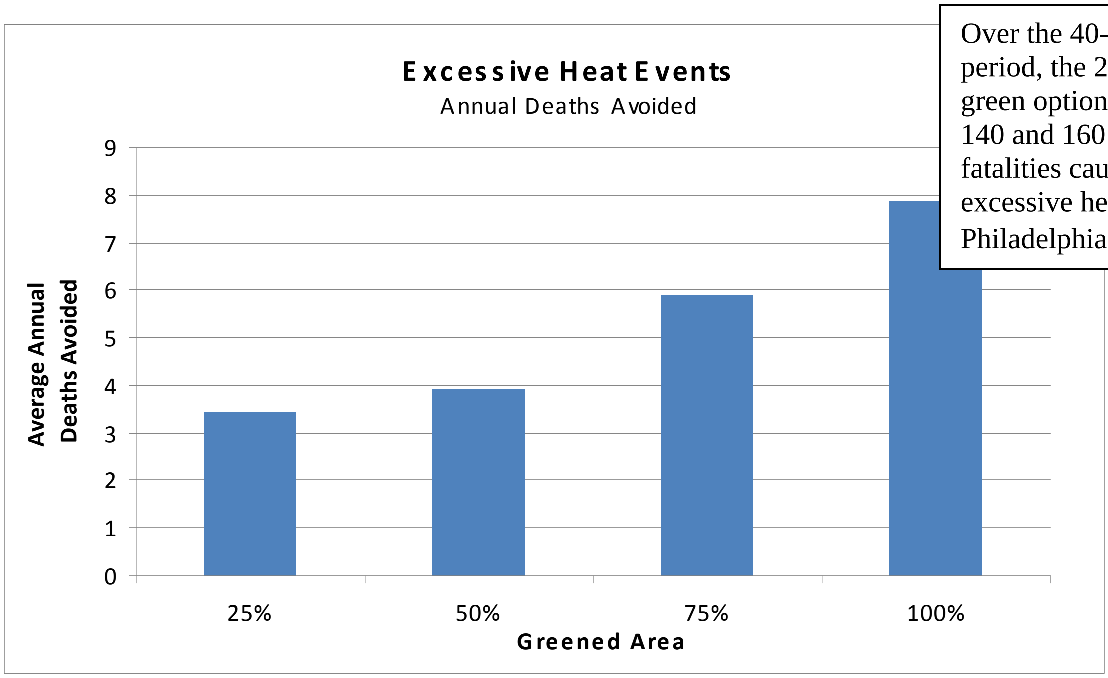
Green Infrastructure Improves Public Health

Green Infrastructure Reduces Effects of Excessive Heat

Heat waves are a fixture of summers in Philadelphia, including some severe enough that they have resulted in over 100 premature deaths (for example, the summer of 1993). These events may be more frequent and severe in the future due to climate change. Green infrastructure (for example, trees, green roofs, and bioretention sidewalks) reduces the severity of extreme heat events in three ways - by creating shade, by reducing the amount of heat absorbing pavement and rooftops, and by emitting water vapor – all of which cool hot air. This cooling effect will be sufficient to actually reduce heat stress-related fatalities in the city during extreme heat wave events.



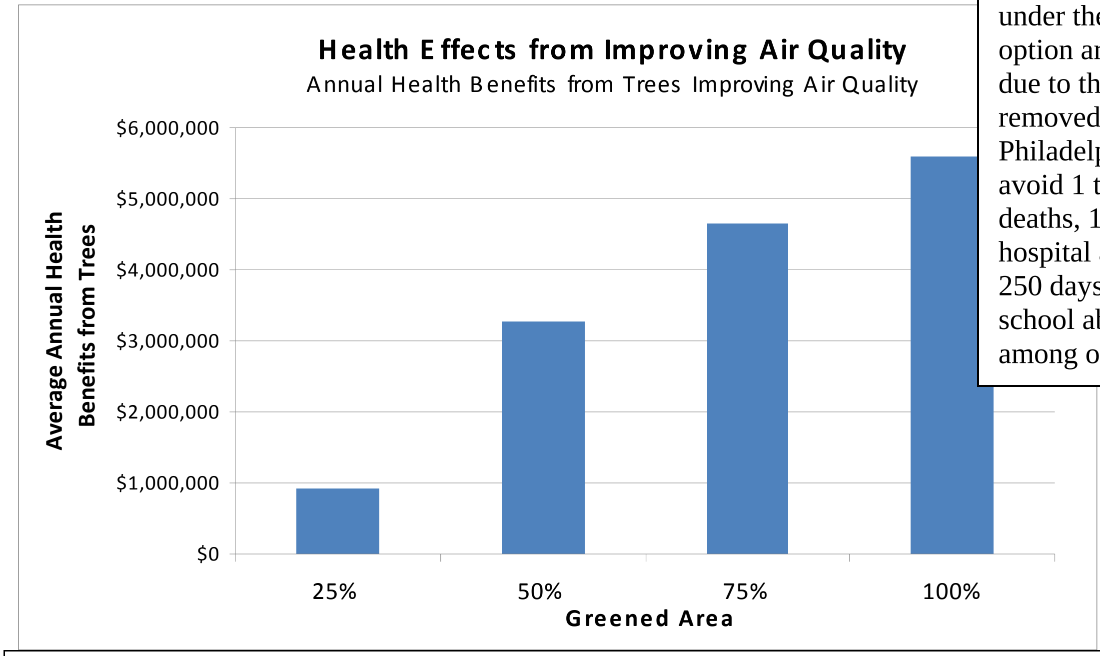
Over the 40-year planning period, the 25% and 50% green options will result in 140 and 160 fewer fatalities caused by excessive heats events in Philadelphia, respectively.

<u>Excessive Heat: Methods and Sources</u>
Extreme heat events in Philadelphia have been studied extensively by the Philadelphia Health Department, the federal Centers for Disease Control, the U.S. Environmental Protection Agency (USEPA) and others. The study team used results of several of these studies that quantified the reduction in temperature that results from significant increases in urban vegetated acreage. The study team incorporated these results into the city's existing methodology for quantifying excess heat mortality to evaluate human deaths avoided under the different green CSO options. The value of avoided heat-related deaths was then monetized based on standard methods routinely used by U.S. EPA in regulatory impact assessments..

Selected References: CDC, 1994; Hudischewskyj et al., 2001; Kalkstein and Sheridan, 2003

Green Infrastructure Improves Air Quality

Like many major cities in the United States, EPA currently classifies the Philadelphia metropolitan area as exceeding federal air quality standards for both ozone (smog) and fine particles (soot). Known health impacts of these air pollutants include premature death, hospitalization for respiratory diseases, heart attacks, and lost work and school days. Green infrastructure will improve Philadelphia's air quality in two ways – by reducing emissions of pollutants (such as SO_2) and by removing ozone and particulates from the air. Reductions in energy and vehicle use will reduce emissions of pollutants. Once in the air, some ozone and particles are taken into the leaves of trees as they "breathe." Leaves also trap additional fine particulates, which then wash off in the rain or fall with the autumn leaf drop.



When the trees planted under the 50% green option are fully grown, due to the air pollution removed by trees, Philadelphia County will avoid 1 to 2 premature deaths, 1 heart attack, 3 hospital admissions and 250 days of work loss or school absence each year, among other health effects.

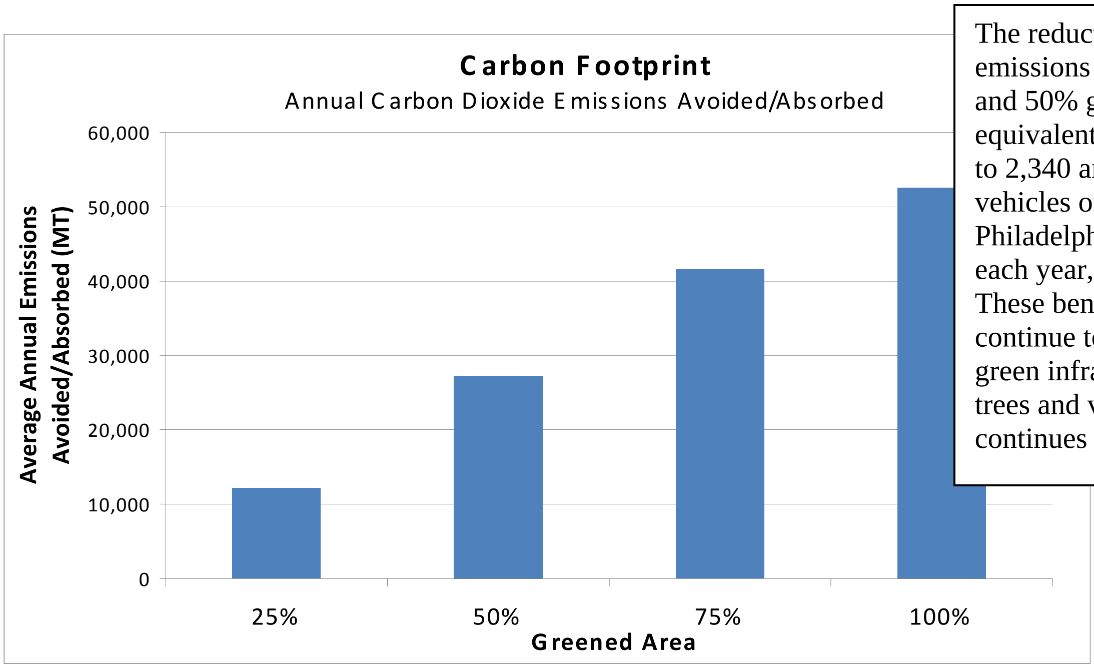
Air Quality: Methods and Sources

The U.S. Forest Service estimated air concentration removal rates associated with the urban forest in Philadelphia. The study team combined these pollutant removal rates with the projected number of new trees under the various green infrastructure scenarios. The study team then used BenMAP, USEPA's air quality benefits model, to estimate corresponding health impacts using current and projected Philadelphia air quality levels . USEPA also provides the standard methods used to value the economic impact of these avoided health effects. Additional air pollution related impacts associated with changes in emissions from energy production and vehicles are discussed in more detail in the energy and carbon section.

Selected References: USDA, 2007; U.S. EPA, 2008a; U.S. EPA, 2008b

Green Infrastructure Saves Energy and Offsets Climate Change

Green infrastructure reduces energy use, fuel use, and carbon emissions in two ways. First, the cooling effects of trees and plants shade and insulate buildings from wide temperature swings, decreasing the energy needed for heating and cooling. Second, rain is managed where it falls in systems of soil and plants, reducing the energy needed for traditional systems to store, pipe, and treat it. Growing trees also act as carbon “sinks”, absorbing carbon dioxide from the air and incorporating it into their branches and trunks.



The reduction in carbon emissions under the 25% and 50% green options, is equivalent to taking close to 2,340 and 5,250 vehicles off of Philadelphia roadways each year, respectively. These benefits will continue to accrue as the green infrastructure (e.g. trees and vegetation) continues to grow.

Energy and Climate Change: Methods and Sources

The team estimated energy savings, pollutant emission reductions, and carbon emission reductions from trees and plants using a study published by the U.S. Forest Service. Emissions related to energy production in Pennsylvania are published by the Energy Information Administration. The cost of carbon emissions to society is an area of active debate, but in the study the team used an estimate provided by the Intergovernmental Panel on Climate Change. Estimates of carbon emissions and sinks also considered construction, traffic delays caused by construction, and the manufacturing and transport of concrete.

Executive Summary

Objectives

The City of Philadelphia Water Department (PWD) is considering a wide array of options for controlling Combined Sewer Overflow (CSO) events in its four relevant watershed areas. The options range from traditional infrastructure-based approaches (e.g., storage tunnels) to more innovative “green infrastructure” approaches based largely on Low Impact Development (LID) elements (e.g., tree planting, permeable pavement, green roofs).

PWD is especially interested in gaining a more complete understanding of the Triple Bottom Line (TBL) implications of the green and traditional infrastructure approaches in terms of their respective ability to provide environmental, social, public health, and other values. Accordingly, this report provides a TBL-oriented benefit-cost assessment of the CSO control alternatives under consideration by PWD. The focus here is on the benefits and external costs of the alternatives. Ultimately, the TBL benefit results from this report, and the engineering cost information from Camp, Dresser and McKee (CDM), will be combined to provide insights as to the estimated net benefits of the alternatives.

Key Findings

The key finding of this TBL assessment is that the LID-based green infrastructure approaches provide a wide array of important environmental and social benefits to the community, and that these benefits are not generally provided by the more traditional alternatives. Tables S.1 and S.2 provide a summary of the numeric findings for two of the CSO control options under consideration: the 50% LID, or green infrastructure option [meaning runoff from 50% of impervious surface in the City of Philadelphia (the City) is managed through green infrastructure], and the 30’ Tunnel option (a system of storage tunnels with an effective diameter of 30 ft, serving all watersheds). These options were chosen to demonstrate the difference in net benefits between green and traditional infrastructure. The reporting of these results is not intended to indicate that a final PWD decision will be based on these two alternatives.

The results shown below reflect benefits (and external costs) accrued over the 40-year study period (from 2010 to 2049). Table S.1 describes the outcomes in terms of the physical outcomes obtained, and the second table provides the estimated monetary value for these outcomes, in present value terms.

Table S.1. City-wide natural unit benefits of key CSO options: Cumulative through 2049[a]

Benefit categories	50% LID option	30' Tunnel option[b]
Additional creekside recreational user days	247,524,281	
Additional non-creekside recreational user days	101,738,547	
Reduction in number of heat-related fatalities	196	
Annual willingness to pay (WTP) per household for water quality and aquatic habitat improvements[c]	\$9.70–\$15.54	\$5.63–\$8.59
Wetlands created or restored (acres)	193	
Green collar jobs (job years)	15,266	
Change in particulate matter ($PM_{2.5}$) due to increased trees ($\mu g/m^3$)	0.01569	
Change in seasonal ozone due to increased trees (ppb)	0.04248	
Electricity savings due to cooling effect of trees (kWh)	369,739,725	
Natural gas savings due to cooling effect of trees (kBtu)	599,199,846	
Fuel used (vehicles for construction and operation and maintenance) (gallons)	493,387	1,132,409
Sulfur dioxide (SO_2) emissions (metric tons)	(1,530)[d]	1,452
Nitrogen oxides (NO_x) emissions (metric tons)	(38)	6,356,083
Carbon dioxide (CO_2) emissions (metric tons)	(1,091,433)	347,970
Vehicle delay from construction and maintenance (hours of delay)	346,883	796,597

a. The 50% LID and 30' Tunnel options were chosen as example alternatives to illustrate the differences between green and traditional infrastructure approaches. This does not imply that a final decision has been made by PWD regarding the implementation of these options.

b. 28' Tunnel option in Delaware River Watershed.

c. WTP per household in Philadelphia, MA, including Bucks, Chester, Delaware, Montgomery, and Philadelphia counties.

d. Parentheses indicate negative values.

Relevant TBL Benefit Categories

A summary of the key benefit (and external costs) categories included in this TBL assessment is provided below. Most of these benefits accrue only with the LID-oriented green infrastructure options, and not under the traditional infrastructure alternatives.

Recreation. Under the LID-based options, streamside recreational opportunities will be increased as a result of stream restoration and riparian buffer improvements. Recreation will also improve in non-creekside parts of the City due to the general increase in vegetated and treed acreage in the City. These recreational benefits are not anticipated under the traditional infrastructure approaches.

Table S.2. City-wide present value benefits of key CSO options: Cumulative through 2049 (2009 million USD)

Benefit categories	50% LID option	30' Tunnel option[a]
Increased recreational opportunities	$524.5	
Improved aesthetics/property value (50%)	$574.7	
Reduction in heat stress mortality	$1,057.6	
Water quality/aquatic habitat enhancement	$336.4	$189.0
Wetland services	$1.6	
Social costs avoided by green collar jobs	$124.9	
Air quality improvements from trees	$131.0	
Energy savings/usage	$33.7	$(2.5)
Reduced (increased) damage from SO_2 and NO_x emissions	$46.3	$(45.2)
Reduced (increased) damage from CO_2 emissions	$21.2	$(5.9)
Disruption costs from construction and maintenance	$(5.6)	$(13.4)
Total	**$2,846.4**	**$122.0**

a. 28' Tunnel option in Delaware River Watershed.

Increased Community Aesthetics, Reflected in Higher Property Values. Trees and plants improve urban aesthetics and community livability and studies show that property values are higher when trees and other vegetation are present.

Heat Stress Reduction. Green infrastructure (trees, green roofs, and bio-retention areas) creates shade, reduces the amount of heat absorbing materials and emits water vapor – all of which cool hot air. This cooling effect will be sufficient to reduce heat stress-related fatalities in the City during extreme heat wave events.

Water Quality and Aquatic Ecosystem Improvements. The traditional infrastructure options (e.g., plant expansions, tunnels) are aimed at reducing the number of overflow episodes, but do little to directly improve the physical riparian area environment (i.e., riparian and aquatic ecosystems and habitat areas) or otherwise enhance living resources in many of the City's watershed environments. In contrast, the LID options, in conjunction with the related watershed restoration efforts, are expected to generate important improvements to these living natural resources.

Wetland Creation and Enhancement. The watershed restoration and related efforts, as associated with the LID options, are expected to create or enhance over 190 acres of wetlands in the relevant watersheds. These added and enhanced wetland acres will provide a range of services in the urban area watersheds.

Poverty Reduction from Local Green Jobs. Specialized labor is required for construction of conventional stormwater management solutions (e.g., boring, tunneling). Such skilled laborers might typically be already employed in the construction field. Green infrastructure creates the opportunity to hire local unskilled – and otherwise unemployed – laborers for landscaping and restoration activities. Thus the benefits of providing these local green jobs include the avoided costs of social services that the City would otherwise provide on behalf of the same people if they remained unemployed.

Energy Savings and Carbon Footprint Reduction. Green space helps lower ambient temperatures and, when incorporated on and around buildings, helps shade and insulate buildings from wide temperature swings, decreasing the energy needed for heating and cooling. In addition, diverting stormwater from wastewater collection, conveyance, and treatment systems reduces the amount of energy needed to pump and treat the water. Reduced energy demands in buildings, and increased carbon sequestration by added vegetation, result in a lower carbon footprint (reduced CO_2 emissions).

Air Quality Improvement. Trees and vegetation also improve air quality by filtering some airborne pollutants (e.g., particulate matter and ozone). Likewise, reduced energy consumption results in decreased emissions (e.g., SO_2 and NO_x) from power generation facilities. These air quality improvements can reduce the incidence and severity of respiratory illness.

Construction- and Maintenance-Related Disruption. All of the CSO options will result in some level of disruption due to construction and/or program activities. Social costs of disruption can include traffic delays, limited access to places of business, increased noise and pollution, and other inconveniences. Under all of the CSO alternatives, construction activities will likely result in occasional delays and increased travel times for passenger and commercial vehicle travelers in Philadelphia; however the level of disruption will be considerably less for the LID options than many of the traditional infrastructure alternatives.

1. Introduction

1.1 Background

There are numerous ways of managing stormwater runoff and combined sewer overflow (CSO) events in urban areas. These include traditional engineering approaches that rely largely on physical infrastructure such as large-scale concrete collection and storage systems (e.g., excavating and building large diameter tunnels), and pumping collected stormwater to wastewater treatment plants for treatment and discharge. Alternatively, there are more "natural" and environmentally friendly approaches that rely more on "green infrastructure," or Low Impact Development (LID) techniques, to help divert, store, and promote infiltration of stormwaters so that they help restore and enhance natural systems rather than overload traditional wastewater collection and treatment facilities. There are various possible levels and combinations of the traditional and green approaches that can be considered.

Both the traditional and green infrastructure approaches to stormwater and CSO management can be very expensive to retrofit within older urban areas (e.g., costing several billion dollars for a city like Philadelphia). Both approaches can also generate important environmental, social, and other benefits to local watersheds and urban-area communities. However, the green infrastructure, LID-oriented approaches may generate a broader and more valuable array of environmental, public health, and social benefits than do traditional CSO control strategies. In order to gain a clearer appreciation of which option (or mix of approaches) may be most valuable to a community, it is important to assess the types and levels of benefits associated with the alternative approaches. These benefits can then be compared to the costs of each option, so that community leaders can discern which approach will yield the largest net benefit to the community (where net benefits refer to present value benefits minus present value costs).

1.2 Objectives

The Philadelphia Water Department (PWD) currently is giving serious consideration to a wide array of options for controlling CSO events. PWD is especially interested in gaining a more complete understanding of the Triple Bottom Line (TBL) implications of green infrastructure approaches, and of more traditional approaches, in terms of their respective environmental, social, and other values. PWD, in concert with its engineering support contractor – Camp, Dresser and McKee (CDM) – retained Stratus Consulting to evaluate the benefits and external costs (i.e., costs beyond engineering cost estimates for building and operating the various control options) associated with a number of alternative approaches for controlling CSO events in the City of Philadelphia (the City).

Accordingly, this report provides a TBL-oriented benefit-cost assessment of the CSO control alternatives under consideration by PWD. The focus here is on the benefits and external costs of the alternatives. CDM is developing a separate report to describe the engineering design and performance aspects – and engineering cost estimates – for the alternatives. Ultimately, the TBL benefit results from this report, and the engineering cost information from CDM, will be combined to provide insights as to the estimated net benefits of the alternatives.

Throughout this report, we refer to the green infrastructure CSO control options as LID-based approaches. We categorize the different options based on different levels of implementation (e.g., the 50% LID option would manage runoff from 50% of impervious surfaces in Philadelphia through green infrastructure). Green infrastructure and LID are used interchangeably throughout the following chapters and appendices.

We also refer to the traditional infrastructure options according to different levels of implementation. For example, throughout the report we draw upon the "30' Tunnel" option as an example alternative. This option includes a system of storage tunnels serving all watersheds with an effective diameter of 30 ft. Alternative tunneling options (e.g., 15', 20', 25', and 35' options), are also being evaluated by PWD and the impacts of all alternatives are examined here.

1.3 Report Organization

This report is structured as follows:

- First, this main portion of the report provides a brief overview of the four PWD watershed areas addressed by the policy options, as well as abbreviated descriptions of the 16 CSO control options being considered for each area. More detailed descriptions of the watersheds and CSO control options are provided in the main body of the PWD Long Term CSO Control Plan Update (LTCPU).
- Second, a general description is provided of the data and methods used to conduct our TBL-oriented benefit-cost assessment of the alternatives. Also provided is an overview of the types of benefits and external costs we address within this assessment.
- Third, more detailed descriptions are offered of the estimated levels of benefits (and external costs) for each major benefit-cost category. An overview of the methods, data, and limitations associated with these estimates is also provided. (Detailed category-specific appendices, described below, furnish additional detail on the methods, data, findings, and limitations of the analysis for each type of benefit or external cost).

- Fourth, summaries are provided of the benefit estimates for two of the prominent CSO control options under consideration, aggregated across the four watershed areas. These summaries thus provide a city-wide overview of the physical and economic magnitude of benefits (and external costs) for two highlighted CSO control alternatives. The two highlighted CSO control options are the LID-50% option (reflecting a green infrastructure approach), and the 30' Tunnel option (reflecting a more traditional infrastructure approach).
- Fifth, a suite of detailed tables are provided that indicate watershed-specific estimates for each benefit and external cost category, for each CSO control option evaluated.
- Sixth, the key uncertainties inherent in this type of TBL-oriented benefit-cost analysis are discussed, and the results of several sensitivity analyses are provided to provide insights as to the level of stability of the estimates to alternative input values and assumptions.

The main body of this report is then followed by a series of detailed technical appendices – one for each benefit or external cost category assessed. These appendices describe the methods, data, findings, and caveats relevant to each endpoint, and also contain relevant reference citations. The appendices correspond to the following categories of assessed impacts:

- Appendix A: Recreational use and values (both creekside and non-creekside)
- Appendix B: Property values, as enhanced by the LID options
- Appendix C: Heat stress and related premature fatalities avoided
- Appendix D: Water quality and aquatic habitat enhancements and values
- Appendix E: Wetland enhancement and creation
- Appendix F: Poverty reduction benefits of local green infrastructure jobs
- Appendix G: Energy usage and related changes in carbon and other emissions
- Appendix H: Air quality pollutant removal from added vegetation
- Appendix I: Construction- and maintenance-related disruption impacts.

2. Relevant Watersheds and CSO Control Options

PWD's CSO program area covers about 40,500 acres (63 square miles) within the City. The boundaries of the CSO area fall within the watersheds of Tacony-Frankford Creek, Cobbs Creek, the Lower Schuylkill River, and the tidal portion of the Delaware River (Delaware Direct Watershed). The City's CSO program is managed on a watershed-basis and our analysis of CSO control options includes the evaluation of management alternatives in each of the four CSO watersheds.

The following sections provide a brief description of each CSO watershed and outlines the different CSO control options being considered by PWD.

2.1 Philadelphia's CSO Watersheds

The Tookany/Tacony-Frankford Watershed

The Tookany/Tacony-Frankford Watershed encompasses approximately 20,000 acres, or 29 square miles, within the north central portion of Philadelphia County and the southeastern portion of Montgomery County. The creek is referred to as Tookany Creek until it enters Philadelphia County at Cheltenham Avenue. It is then called Tacony Creek from the Montgomery County border until it meets with the historical Wingohocking Creek in Juniata Park. The section of stream from Juniata Park to the Delaware River is referred to as Frankford Creek.

The hydrology of the Tacony-Frankford system is highly modified. Most of the tributary system of Tacony Creek has been converted into sewers. Below what is now Juniata Park, the Tacony joins with buried tributaries to form Frankford Creek. In order to deal with flooding associated with large influxes of stormwater, the Frankford Creek was channelized and straightened in concrete a number of years ago. The concrete channel prevents interaction between Frankford Creek and the groundwater system and eliminates streambed habitat needed to support aquatic life. The area surrounding Frankford Creek is highly industrialized and much of the creek is inaccessible.

The Philadelphia County portion of the watershed accounts for about 62% (12,200 acres) of total watershed land area, and PWD's CSO program area covers almost all of this. The population within this part of the watershed is approximately 285,000, which results in an average population density of about 23 persons per acre. There are about 6.3 miles of stream along Tacony-Frankford Creek targeted for improvements under the different CSO control options (mainstem creek).

Cobbs Creek Watershed

Cobbs Creek is a subwatershed of the larger Darby-Cobbs Watershed, which encompasses approximately 80 square miles of land that drain to the mouth of Darby Creek or below, to its confluence with the Delaware Estuary. Cobbs Creek drains approximately 14,500 acres or 27% of the total Darby-Cobbs Watershed area. The upper portions and headwaters of Cobbs Creek, including East and West Branch Indian Creek, contain portions of Philadelphia, Montgomery, and Delaware Counties. The lower portion of Cobbs Creek Watershed, including the lower mainstem and Naylors Run, drain parts of Philadelphia and Delaware Counties. Cobbs Creek discharges to Darby Creek.

The Philadelphia County portion of the Cobbs Creek Watershed is about 3,600 acres, and falls almost entirely within PWD's CSO program area. This area encompasses about 11.5 miles of stream, including about 8.2 miles of mainstem creek and 3.3 miles of major tributaries. The population of the Philadelphia County portion of the watershed is about 107,000 (U.S. Census Bureau, 2000), which yields a population density of almost 30 persons per acre. Similar to the Tacony-Frankford Watershed, Cobbs Creek is very urbanized and its hydrologic system has been highly modified.

Lower Schuylkill River Watershed

The Schuylkill River Watershed includes portions of 11 counties, and encompasses an area of approximately 2,000 square miles. The river travels approximately 130 miles from its headwaters at Tuscarora Springs in Schuylkill County to its mouth at the Delaware River in Philadelphia. The Schuylkill River is the largest tributary to the Delaware River and is a major contributor to the Delaware Estuary.

The Philadelphia County portion of the Schuylkill River Watershed is approximately 23,000 acres. About half of this area falls within PWD's CSO area, which includes the tidal portion of the Schuylkill River, or the approximately 7 miles of river upstream of the confluence with the Delaware River.

Much of the land outside of the Schuylkill River CSO area is characterized by large open space areas and recreational amenities (e.g., East and West Fairmount Parks and Boathouse row). However, in the lower portion of the watershed, which coincides with the CSO boundaries, there is a significant amount of industrial land uses.

Within the CSO area, there are numerous active and inactive rail lines directly adjacent to the river, including the large and active East Side Yard for CSX Transportation Corporation (CSXT). Several major road corridors also run adjacent to and through the river, including I-95, I-76 (Schuylkill Expressway), I-676, Route 291/Passyunk Avenue, Grays Ferry Avenue, University Avenue, South Street, Walnut Street, Chestnut Street, and Market Street.

The population of the Philadelphia County portion of the Lower Schuylkill River Watershed is about 353,000 (U.S. Census Bureau, 2000), which yields a population density of about 16 persons per acre, on average. The majority of residents (about 82%) live within the CSO area, where population density is almost 30 persons per acre.

Lower Delaware River (Delaware Direct Watershed)

The 300-mile long Delaware River winds its way through four states on the eastern coast of the United States, encompassing 42 counties and 838 municipalities. The river serves a variety of important residential, commercial, and industrial functions, including fishing, transportation, power cooling, and recreational purposes. The river also serves as an important source of drinking water for PWD and other utilities in the regions through which it passes.

The Delaware Direct Watershed encompasses the lower 20 miles of the Delaware River, before it discharges to the ocean. The watershed is located entirely within the City. About 70% of total land area in the watershed falls within PWD's CSO boundaries, which includes the tidal portion of the Delaware River, or about 15.6 stream miles.

The population of the Delaware Direct Watershed is approximately 500,000 and close to 99% of residents live within the CSO area. Like all the CSO watersheds, this area is highly urbanized, however, it does not support the level of industrial activity as seen within the Schuylkill River CSO area. Residential and commercial uses account for about 63% of total land uses in the watershed, while industrial uses account for close to 9%.

2.2 CSO Control Options

For each watershed, PWD has developed a suite of CSO control options based on four primary approaches, including:

- Low-Impact Development
- Tunneling
- Transmission, Plant Expansion and Treatment
- Transmission and Satellite Treatment.

LID (green infrastructure approaches)

For each watershed, PWD has developed a range of LID CSO control options (e.g., 25, 50, 75, and 100% of runoff from impervious surfaces managed through green infrastructure), representing different levels of implementation. The LID approach focuses on restoring a more natural balance between stormwater runoff and infiltration, reducing pollutant loads, and controlling runoff rates at levels that minimize stream bank erosion. A variety of controls are incorporated into the different LID options, including disconnection of impervious cover, bioretention, subsurface storage and infiltration, green roofs, swales, and tree canopy. Land-based measures are a key part of this approach because they provide benefits to the community beyond water quality improvement (e.g., recreational opportunities, improved aesthetics, and increased home values).

The LID options also include a variety of water-based approaches to CSO control, including bed and bank stabilization and reconstruction, aquatic habitat creation, plunge pool removal, improvement of fish passage, and floodplain reconnection. The ultimate goal of this component of the LID program is to restore designated uses and ultimately remove CSO streams from the state’s list of impaired waters. Similar to the land-based approaches described above, stream restoration will provide a number of benefits beyond water quality improvement.

Traditional Infrastructure-based Management Measures

The Tunneling, Transmission, Plant Expansion and Treatment, and Transmission and Satellite Treatment options for CSO control include traditional storage, conveyance, and treatment measures within the collection and treatment system. For each watershed, PWD has developed a number of variations based on these three infrastructure-based approaches. For example, in each watershed, a range of different Tunneling options is currently being evaluated, along with a range of options for both Satellite Treatment and Plant Expansion.

The traditional infrastructure-based measures have two main drawbacks. First, as noted above, the LID-oriented measures provide several important environmental, social, and public health benefits to the community beyond water quality improvement. Traditional infrastructure-based measures typically do not provide these benefits.

Second, traditional infrastructure-based measures may not address the root causes of impairment in Philadelphia’s urban streams, where the primary causes of impairment are modified flow patterns and habitat degradation. Infrastructure-based measures are typically focused on removing loads of specific pollutants rather than restoring natural flow conditions and habitat. As such, they may assist in meeting some specific water quality parameters (e.g., reducing the number of overflow events), but do not necessarily support or enhance/restore the living resources (i.e., the aquatic and riparian ecosystems) of the watersheds.

To obtain maximum benefits and CSO control, PWD is currently considering many of the traditional infrastructure options (particularly the Plant Expansion options), in combination with LID measures. Traditional infrastructure options are expected to play an important role in developing cost-effective and feasible solutions. For more detailed information on the suite of CSO management options currently being considered by PWD, see LTCPU.

3. General Methodology and Data

3.1 Overview of the TBL Approach

The TBL approach reflects the fact that society and its enterprises – including the institutions that work specifically in the public interest (e.g., water and wastewater utilities) – typically are engaged in activities intended to provide the greatest total value to the communities they serve. These values extend well beyond the traditional financial bottom line that portrays only cash flows (i.e., revenues and expenditures) of a standard financial analysis. PWD and similar utilities that serve the public interest also need to consider their stewardship and other responsibilities, and to thus account for how they may generate values that contribute towards the "social" and "environmental" bottom lines. Hence, a more complete and meaningful accounting of PWD activities needs to provide a TBL perspective that reflects all three bottom lines: financial, social, and environmental.

In many ways, this TBL perspective is very similar to how an economist would define a comprehensive benefit-cost analysis that attempts to account for the full range of internal and external costs and benefits of an activity (project, or program), including nonmarket outcomes. The TBL approach provides an organizing framework within which the broad array of benefits and costs can be portrayed and communicated. This TBL approach should include both those outcomes that can be quantified and reasonably well monetized in dollar terms, as well as outcomes that are less amenable to reliable valuation and instead require qualitative discussion.

Accordingly, this TBL assessment of the benefits and external costs of the various relevant CSO control options for Philadelphia relies to a large extent on the tools and methods deployed by natural resource economists to estimate market and nonmarket values for a broad array of relevant environmental and social impacts. The sections below, and the more technically-oriented appendices, provide additional detail for the broad range of impacts that are assessed in this TBL evaluation of the PWD's CSO control options.

3.2 Key Inputs to the TBL Analysis

As noted above, the TBL analysis evaluates CSO control options that have been defined by PWD and CDM. Accordingly, most of the key physical inputs to our analyses (e.g., number and general location of trees planted, the number of stream miles impacted, the types of vehicles used on various construction and maintenance activities, power requirements associated with construction, the timing of various project activities) were provided by CDM.

3.3 General Overview of Methods and Key Assumptions

Key assumptions and basic methodological approaches used for the overall TBL analysis are detailed below. Assumptions and methods associated with each specific benefit and external cost category are discussed in the subsequent section.

External costs and benefits. As part of our analysis, we evaluate the "external" or ancillary costs and benefits associated with each of the CSO options (i.e., costs that are not included in traditional engineering estimates of the expense to build and operate facilities). External costs include, for example, time spent and fuel lost in construction-related traffic delays, and air quality impacts associated with construction and implementation activities (including the carbon footprint of concrete requirements under the traditional infrastructure alternatives). Under the LID alternatives, many of the air quality and energy impacts result in ancillary benefits in the form of carbon sequestration, air pollutant removal, and energy savings due to the cooling effect and other impacts provided by adding trees and other vegetation.

General methods for quantifying and/or valuing outcomes. The benefit and external cost estimates are derived from standard approaches as developed and used by environmental impact and valuation professionals and organizations. Many of the key methods, models and data are developed and deployed routinely by the U.S. Environmental Protection Agency (EPA) and other relevant federal agencies. For example, the air quality impacts of added trees is based on a model developed and applied by the U.S. Forest Service for Philadelphia. The resulting estimates of projected changes in ambient air quality (i.e., ozone and particulate matter concentrations) is then analyzed using EPA's Environmental Benefits Mapping and Analysis Program (BenMAP), which estimates reductions in health risks and associated monetary values for the given change in ambient air quality. Similar reliance on well established federal and other models, methods, and data underlie most of the key benefit estimates derived in this study.

Time path for realizing benefits. Results presented below represent the discounted sum of annual values over the 40-year planning horizon (2010–2049). For each benefit and cost category, we applied a time path over which the different benefits and costs accrue. Our timelines are based on implementation, construction, and maintenance schedules provided by CDM, as well as on a tree growth model that applies to benefits dependent on the number of additional trees to be planted in the watershed. For example, the benefits associated with air pollutant removal from trees will not be fully realized in the first year of project implementation. Our analysis takes into account the percentage of trees planted each year as well as the rate at which the trees grow and mature (assumed here to be 20-years after they are planted).

Present value estimates. Our monetary results are in present value terms [2009 U.S. dollars (USD)] and are based on an inflation rate of 4% and a nominal discount rate of 4.875% applied over the 40-year planning horizon. Later in this report, we present the results of sensitivity analyses that were conducted to evaluate the impact of using alternative escalation and discount rates.

Additivity versus double-counting. The benefits presented below are additive, meaning they can be added together to generate a total value. However, the results of the property value analysis are likely to include some overlap and double-counting of benefits measured under several of the other benefit categories. For example, the anticipated energy savings enjoyed at tree-shaded properties are likely to be capitalized into the property values for those residences (depending on the extent to which current and prospective owners take anticipated energy costs into account when valuing properties). Likewise, enhanced greenspace-related recreational opportunities in the neighborhood are also likely to be capitalized (at least in part) in property values. At the same time, the property value analysis does reflect some unique values that are not embodied in the other estimated categories (e.g., aesthetics). Thus, the interpretation of the property value estimates needs to be carefully considered. For the purposes of this analysis, we include 50% of the estimated property value benefits to avoid this potential double-counting.

Omissions, biases, and uncertainties. Analyses of social and environmental benefits invariably require the use of assumptions and approaches (e.g., benefits transfer) that interject uncertainty about the accuracy or comprehensiveness of the empirical results. Throughout our analysis, and as detailed in the appendices, we have attempted to be explicit and reasonable about what assumptions and approaches we are adopting. We also provide summaries in each appendix of the key omissions, biases, and uncertainties (OBUs) that we believe are embedded in our work, and describe how the results of the analysis would likely have been impacted (e.g., whether benefits would have increased, decreased, or changed in an uncertain direction) if the omission or data limitation had been avoidable.

Sensitivity analyses. In conjunction with the OBU issues, we conducted several sensitivity analyses to explore how changing some of the key assumptions would impact our findings. The results of these sensitivity analyses are summarized in Chapter 6 (and are also described in relevant appendices).

4. The Benefits and External Costs of PWD's CSO Control Options

The TBL analysis of benefits and external costs is organized according to a series of benefit categories. The general approach and results for each category are described below. Considerable additional detail can be found in the associated appendices. It is important to note that not all options generate every type of benefit described below. Likewise, some options create external costs (negative benefits, such as added energy consumption and carbon emissions) within some of the categories.

4.1 Recreational Use and Values (creekside and non-creekside)

The green infrastructure, or LID-based, options include stream restoration and riparian buffer improvements, which will result in an anticipated increase in creekside (i.e., near stream) recreational opportunities in green areas along and adjacent to the impacted waters. Most of this added activity is anticipated for land-based, near water activities such as jogging, biking, walking, picnicking, and so forth. Little or no increases are expected in in-stream recreation (direct water contact or angling is not anticipated or encouraged in some relevant watershed areas).

Under the LID options, recreational opportunities will also improve in non-creekside areas, due to the general increase in vegetated and treed acreage in the relevant portions of the City. These non-creekside recreational benefits also are included in the analysis.

The more traditional infrastructure approaches (e.g., tunnels) are not expected to generate any appreciable changes in these types of recreational levels or values. While these approaches are aimed at reducing CSO overflow events – which will yield some water quality improvement – these options do not result in improved streamside or urban landscape conditions. Thus, there are no projected recreational benefits estimated for these options.

Total recreational benefits associated with improvements made under the LID options are a function of the additional recreational trips ("user days") taken as a result of these improvements, and the benefit (or direct use value) derived from each trip. To estimate additional recreational use and associated direct use benefits, we relied on a recent report prepared for the Philadelphia Parks Alliance by the Trust for Public Lands. The 2008 report, *How Much Value Does the City of Philadelphia Receive from its Park and Recreation System?* (Parks Report), provides visitation data and direct use values for a variety of recreational uses and activities at

Philadelphia's parks. We tailored these data to individual watersheds based on conversations with park staff, detailed watershed and park management plans, and on-site visits

Based on these methods and data, we estimate an increase of nearly 350 million outings over the 40-year period (i.e., 2010–2049) for the 50% LID option. Over 70% of these outings are for near-stream activities, and the balance are non-creekside. The monetized present value of these added activities over the 40-year period amounts to over $520 million (these and all other dollar values described in this report are in 2009 USD, unless otherwise noted). Additional detail is provided in Appendix A.

4.2 Enhanced Aesthetics (reflected in residential property values)

Trees and plants improve urban aesthetics and community livability, and several empirical studies show that property values are higher when trees and other vegetation are present in urban neighborhoods. Applying a benefits transfer approach to interpret the relevant body of LID-related published hedonic valuation literature, coupled with neighborhood-specific baseline property values, we derive an estimated aggregate increase in property values for each LID option and impacted city area. The literature used includes a Philadelphia-specific study published by Wachter and Wong (2006).

For the 50% LID option applied city-wide to all four watershed areas, the estimated value of enhanced residential property values amounts to over $1.1 billion. We reduce this by 50% to avoid potential double-counting with several of the other benefit categories, since our objective here is to capture aesthetics-related benefits only. The resulting $575 million in present value benefits only accounts for residential properties; enhanced values for nonresidential properties are not included in this analysis. Additional detail is provided in Appendix B.

4.3 Heat Stress-Related Premature Fatalities Avoided

The City has endured several excessive heat events (EHEs), with numerous documented cases of premature fatality attributed to heat stress in some summer periods (e.g., over 100 premature fatalities attributed to heat stress in the EHEs of 1993). The episodes have been studied extensively by the City, the federal Centers for Disease Control (CDC), and EPA.

Green infrastructure (trees, green roofs, and bio-retention areas) – such as would be implemented under the LID-oriented options – creates shade, reduces the amount of heat absorbing materials and emits water vapor – all of which cool hot air and reduce the urban heat island (UHI) effect. This cooling effect will be sufficient to actually reduce heat stress-related fatalities in the City during extreme heat wave events.

Applying the standard methods developed and applied for relevant federal agencies, our analysis (supported by Dr. Larry Kalkstein and his associates) links increases in vegetated areas to potential reductions in summer temperatures and, ultimately, to projected cases of heat stress fatalities avoided. City-wide, we estimate 196 premature fatalities avoided over the 40-year project planning horizon, for the 50% LID option.

Standard EPA methods and values (i.e., value of statistical life, VSL, estimates) were then used to monetize these reductions in premature fatalities. For the 50% LID option, the present value of the reduced risk of premature fatality from heat stress amounts to nearly $1.1 billion. This estimate does not include the avoided medical costs and reduced suffering of morbidity impacts (i.e., the costs associated with those individuals who would otherwise suffer adversity from heat stress, but would not be projected to die from the impact). As such, the omission of morbidity events means that our premature mortality-oriented estimates are probably a lower-bound of the total public health benefit attributable to the LID options. Additional detail is provided in Appendix C.

4.4 Water Quality and Aquatic Habitat Enhancements and Values

A core objective of any CSO control option is to improve water quality and aquatic ecosystems in the impacted watersheds. The traditional infrastructure options (e.g., plant expansions, tunnels) are aimed at reducing the number of overflow episodes, but do little to directly improve the physical riparian area environment (i.e., riparian and aquatic ecosystems and habitat areas) or otherwise enhance living resources in many of the City's watershed environments. In contrast, the LID options, in conjunction with the related watershed restoration efforts, are expected to generate improvements to these natural resources.

To estimate the value of these improvements, a benefits transfer approach was applied, drawing on a meta analysis of nonuse value estimates associated with different potential baseline levels and improvements in water quality. A primary objective of this meta-analysis was to develop a tool (regression model), based on existing (primary) studies, that could be used to predict what individual households would be willing to pay for improvements in water quality to a specified level. Using the regression tool, we were able to apply information related to the Philadelphia CSO control options (e.g., demographic data and expected water quality/habitat improvements under each option) to estimate total willingness to pay (WTP) for water quality improvements.

Due to differences in demographics and location (distance from the resource), we separately evaluated WTP for households within Philadelphia and nearby households outside of the City. The households outside of Philadelphia included in this analysis fall within the greater Philadelphia Metropolitan Area (MA; including Bucks, Chester, Delaware and Montgomery counties).

The results for the 50% LID option indicate an estimated annual WTP of approximately $10 to $15 per household per year, when the water quality and related habitat enhancements are fully realized. Over the 40-year analysis period, this amounts to an estimated city-wide value of over $330 million. Additional detail is provided in Appendix D.

4.5 Wetland Enhancement and Creation

Under the LID options, watershed restoration and related efforts are expected to create or enhance over 190 acres of wetlands in the relevant watersheds. We monetized these added and enhanced wetland acres according to the range of services they are expected to provide in the urban area watersheds, using a benefits transfer approach based on the relevant published literature of wetland values.

For the 50% LID option, these added wetland acres and related services are estimated to provide over $1.6 million in added value city-wide, in present value terms, over the 40-year project planning period. Additional detail is provided in Appendix E.

4.6 Poverty Reduction Benefits of Local Green Infrastructure Jobs

Jobs associated with large civil works projects, such as CSO control options, are not typically counted within an economically sound benefit-cost analysis. This is because the labor retained in such projects typically would be gainfully employed in other ventures (private or public investments), meaning that there typically is a *transfer* of employment across potential activities rather than a real net gain in jobs. Therefore, in this analysis of PWD's CSO control options, we are not counting jobs under any of the options as new employment creation benefits.

However, there are some relevant considerations to be taken into account for some of the CSO control options. Specifically, there are likely to be social benefits (e.g., avoided social costs) when jobs can be steered to local citizens who are typically unemployed (or under-employed) due to a lack of education and training and other social circumstances.

Specialized labor is required for construction of conventional stormwater management solutions (e.g., boring, tunneling). Such skilled laborers might typically be already employed in the construction field. In contrast, green infrastructure projects, as embodied in the LID options, creates the opportunity to hire unskilled – and otherwise unemployed – laborers for landscaping and restoration activities. Thus the benefits of providing these green jobs include the avoided costs of social services that the City would provide on behalf of the same people if they remained unemployed. These "green infrastructure jobs" therefore have the unique capability to provide not just employment, but a crucial stepping stone to help people escape from poverty. The benefits of providing "green infrastructure jobs" include the avoided costs of social services that the City would provide on behalf of the same unskilled people if they remained unemployed, outside the workforce, and trapped in poverty.

For the 50% LID option, we project over 15,000 job years will be created for low-skilled local workers, over the 40-year period, across the four watershed areas. Based on the avoided costs of social services linked to these added job years, we estimate a present value benefit of nearly $125 million. For addition detail, see Appendix F.

4.7 Energy Use and Related Changes in Carbon and Other Emissions

Green space helps lower ambient temperatures and, when incorporated on and around buildings, helps shade and insulate buildings from wide temperature swings, decreasing the energy needed for heating and cooling. In addition, diverting stormwater from wastewater collection, conveyance and treatment systems reduces the amount of energy needed to pump and treat the water, which in turn reduces emissions of greenhouse gases (GHG, including carbon dioxide, CO_2) and other air pollutants (e.g., sulfur dioxide, SO_2, and nitrogen oxides, NO_x) from power plants. Reduced energy demands in buildings, and increased carbon sequestration by added vegetation, also result in a lower carbon footprint (reduced CO_2 emissions).

Our analysis calculates the amount of energy consumption added (or reduced) by the various CSO control options, and calculates the value of the added energy costs (or the energy cost savings), at current energy prices. The energy use levels include, for example, the home energy cost savings provided by the shading offered by trees added under the LID options. Also included is the increased consumption of motor fuel associated with construction-related vehicle traffic delays imposed by any of the options. Some CSO control options generate net energy savings (i.e., the LID options), and others result in a net increase in energy use and costs (e.g., the tunnel options). It is important to note that our analysis includes only those energy costs that are external to engineering cost estimates. The cost of fuel used by construction and maintenance vehicles, and electricity costs associated with excavation and other construction activities are reflected in the cost estimates developed by CDM.

In addition to the direct expense of added energy consumed (or savings from use of less energy), we also assess the level of CO_2 emissions added (or reduced or sequestered) by each option. Thus, for example, the LID options reduce CO_2 emissions at power plants by providing energy savings at shaded homes, plus the added trees sequester some CO_2 as well. These reductions more than offset the added emissions associated with implementation-related activities, such as added vehicle fuel use during the installation of green infrastructure. The net savings in emissions are valued using a "social cost of carbon" estimate derived from the Intergovernmental

Panel on Climate Change (IPCC) of the climate change damages contributed by each metric ton (MT) of CO_2 equivalent (CO_2e) emitted. The value used is $12/MT.

In contrast, traditional infrastructure options tend to increase net CO_2 emissions, because they require extensive excavation activity and concrete, and also required added energy use in pumping and treating the collected and stored stormwaters. Again, the direct cost of the energy used in constructing and operating the traditional infrastructure approaches are not included in our cost estimates, because they are internal costs that are reflected in the capital and operation and maintenance (O&M) costs developed for each of those CSO control options (i.e., the energy cost is included in the engineering cost estimates provided by CDM). However, in our work, we do include the external costs associated with the added energy use required by these options.

Finally, the changes in energy use also change the amount of SO_2 and NO_x emitted from power plants. These changes in emissions are estimated based on region-specific data from EPA, and assigned monetary values based on EPA methods that reflect the average health benefit (or cost) associated with each ton of emission reduced (or added).

For the 50% LID option, our analysis indicates a net energy savings over the 40-year planning period of nearly 370 million kilowatt hours (kWh) of electricity and nearly 600 million British thermal units (Btus) of natural gas. The 50% LID option will result in close to 0.5 million gallons of "wasted" motor fuel consumed by vehicles delayed by construction activities. Emissions reductions over that period include over 1,500 MT of $SO_{2,}$ 1.1 million MT of CO_2, and a small reduction in NO_x emissions of 38 MT.

The monetized present value of these changes from the 50% LID option amount to nearly $34 million for energy savings, over $21 million for reduced CO_2 emissions, and over $46 million for reduced net damages from SO_2 and NO_x emissions. For additional detail, see Appendix G.

4.8 Air Quality Pollutant Removal from Added Vegetation

Trees and vegetation improve air quality by filtering some airborne pollutants (particulate matter and ozone). Likewise, reduced energy consumption results in decreased emissions (SO_2 and NO_x) from power generation facilities (as described and evaluated in the previous section). These air quality improvements can reduce the incidence and severity of respiratory illness.

To evaluate the air quality impacts of added trees, we used a model developed by the U.S. Forest Service, for application in Philadelphia. We analyzed the resulting estimates of projected changes in ambient air quality (i.e., ozone and particulate matter concentrations) using software developed by the EPA to calculate the avoided health effects from the contribution of trees to reducing ozone and $PM_{2.5}$ concentrations, and to estimate the economic value of the avoided health effects. EPA's BenMAP (Ver. 3.0.15), was used to conduct this analysis.

The avoidable air pollution-related health effects estimated in this analysis are:

- Premature mortality (from ozone and $PM_{2.5}$)
- Onset of irreversible chronic bronchitis ($PM_{2.5}$)
- Heart attacks (non-fatal acute myocardial infarctions) ($PM_{2.5}$)
- Hospital admissions (non-fatal) for respiratory and cardiovascular conditions (from ozone and $PM_{2.5}$)
- Emergency room visits for asthma (from ozone and $PM_{2.5}$)
- Respiratory symptoms (days of illness) (from ozone and $PM_{2.5}$)
- Work loss days ($PM_{2.5}$) and school absence (ozone).

The quantified estimates are then monetized using standard EPA dollar values for each applicable adverse health endpoint.

For the 50% LID option, applied across the four watershed areas, we estimate that after full implementation and tree maturation, the health effects avoided will include between 1 and 2.4 premature fatalities avoided per year, 1.2 heart attacks avoided per year, and over 700 cases of other respiratory illness days avoided per year. The present value of the associated monetized benefits is over $130 million over the 40-year period. Additional detail is provided in Appendix H.

4.9 Construction- and Maintenance-Related Disruption Impacts

All of the CSO options will result in some level of disruption due to construction and program activities. Social costs of disruption can include traffic delays, limited access to places of business, increased noise and pollution, and other inconveniences. Under all of the CSO alternatives, construction activities will likely result in occasional delays and increased travel times for passenger and commercial vehicle travelers in Philadelphia. Travel time delays can be caused by:

- General traffic slowdowns associated with an increase in the number of trucks and construction equipment on the road
- Slowdowns from trucks entering and exiting construction or landscaping sites
- Lane or road closures associated with construction in the roadway or road right-of-way.

In addition to the value of "lost" time spent in traffic, construction-related delays can result in increased costs associated with additional fuel used by vehicles as a result of slower speeds and occasional vehicle stops and idling.

Using standard methods and data for estimating traffic delays and associated fuel use and time loss, we estimated the 40-year present value of these external costs for each CSO control option. City-wide, the present value of these external costs for the 50% LID option is $5.6 million, and for the 30' Tunnel option, it is more than 200 times larger, at over $13.4 billion. Additional detail is provided in Appendix I.

5. Summary of Results

The following sections summarize the benefits and external costs of the CSO control options currently being considered by PWD. We first present the results of our analysis on a City-wide basis, highlighting the benefits and costs across the CSO watersheds. More detailed tables, providing benefits and costs in each watershed by category, are provided at the end of this chapter.

Again, it is important to note that throughout the following sections, we refer to the green infrastructure CSO control options as LID-based approaches. We categorize the different options based on different levels of implementation (e.g., the 50% LID option would manage runoff from 50% of impervious surfaces in Philadelphia through green infrastructure). Green infrastructure and LID are used interchangeably throughout the next chapter and appendices.

We also refer to the traditional infrastructure options according to different levels of implementation. For example, throughout the report we draw upon the "30' Tunnel" option as an example alternative. This option includes a system of storage tunnels serving all watersheds with an effective diameter of 30 ft. Alternative tunneling options (e.g., 15', 20', 25', and 35' options), are also being evaluated by PWD and the impacts of all alternatives are examined here.

5.1 Benefits of LID CSO Control Options

Figure 5.1 presents the total net benefits (defined here as benefits minus the external costs of construction disruption) for the LID CSO control options over the 40-year project evaluation period. City-wide, total present value benefits range from about $1,935 million (2009 USD) under the 25% LID option to more than $4,466 million under the 100% LID option.

The relative make up of total benefits by watershed is consistent across LID options. As shown in Figure 5.1, the Tacony-Frankford Creek Watershed accounts for about 20 to 22% of total benefits under each option. Cobbs Creek makes up about 8 to 11%, while the Schuylkill and Delaware River Watersheds account for about 25 to 27% and 42 to 44% of total net benefits, respectively.

Figure 5.2 shows the breakdown of total City-wide benefits by benefit category for the 50% LID option. As shown, reduced heat-stress fatalities, increased property values, and increased recreational opportunities make up the majority of total benefits. These categories account for 37, 20, and 18% of total benefits, respectively.

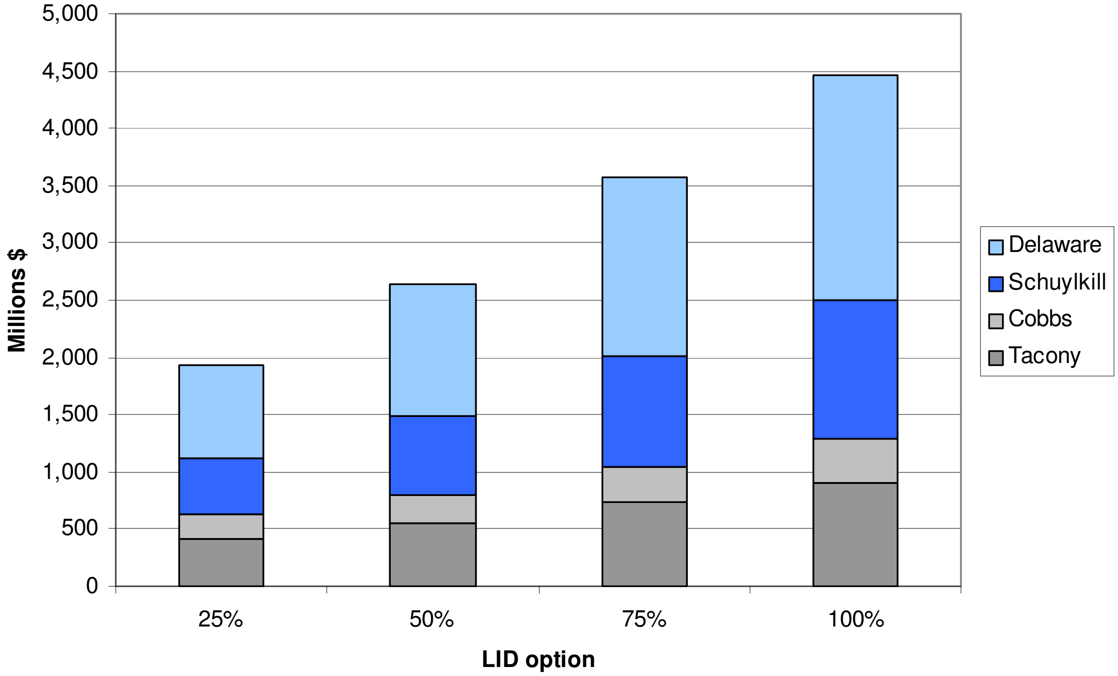

Figure 5.1. City-wide net benefits for LID options by watershed.

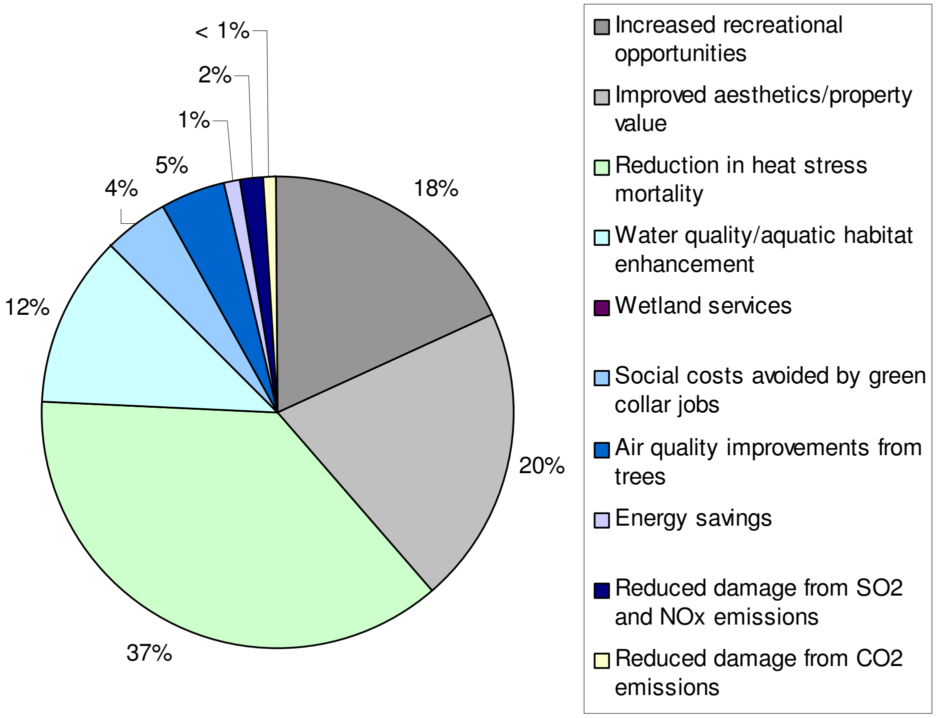

Figure 5.2. Shares of City-wide present value benefits of key CSO options: Cumulative through 2049.

The benefits associated with improved water quality and aquatic habitat also account for a substantial portion of total benefits (12%), while net energy savings, reduced NO_x and SO_2 emissions, and carbon sequestration all account for less than 2%. “Green jobs” and air quality improvements due to pollutant removal from trees, both account for about 5% of total benefits. The percent breakdown of benefit categories shown in Figure 5.2 is consistent across the LID options.

5.2 Benefits and External Costs of Example CSO Options

To show a more direct comparison of benefits and external costs of the different CSO control options, Figure 5.3 provides City-wide estimates for the LID and tunneling CSO Control options. These options were chosen to demonstrate the difference in net benefits between green and traditional infrastructure. The reporting of these results is not intended to indicate that a final PWD decision will be based on these two alternatives.

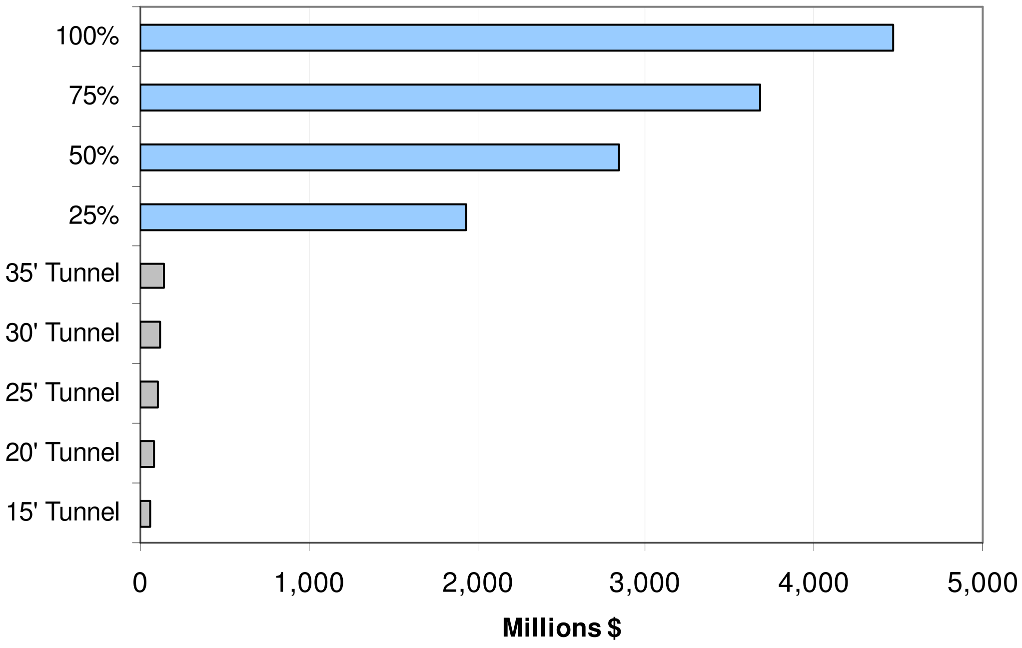

Figure 5.3. City-wide present value benefits/external costs of the LID and tunneling CSO control options, over 40-year project period (2009 USD).

As shown in Figure 5.3, on a City-wide basis, the net external costs of the tunneling options ranges from about $61.6 million under the 15’ Tunneling option, to more than $140 million under the 35’ Tunneling option. This compares to the range of net present value benefits for the LID options of $1,935 million to $4,466 million, as reported in Section 5.1 above.

Table 5.1 shows City-wide estimates for total net benefits (benefits minus external costs) of the 50% LID and 30’ Tunnel options over the 40-year project period. This comparison is intended to provide a bit more detail into the break down of the individual options. The ratio of the external costs of the tunneling options to the net benefits of the LID options varies considerably by watershed. Section 5.3 provides a comparison of the costs and benefits of these different options for each watershed.

As discussed earlier in this report, the physical unit measures associated with the monetary values presented above are an important component of our discussion of total benefits. For the LID options, for example, physical unit measures include the number of lives saved as a result of reduced heat stress, the number of new recreational visitor days, and the energy and carbon savings associated with increased vegetated area, among others.

Table 5.2 presents City-wide estimates for the physical unit measures associated with the 50% LID and 30’ Tunneling options. The measures shown below can be directly tied to the monetary values provided in Table 5.1.

5.3 Detailed Results by Watershed

The following tables provide detailed results for the CSO control options being evaluated in each of the CSO watersheds. Tables 5.3–5.6 show the present value estimates (2009 USD) for each benefit/external cost category, while Tables 5.7–5.10 provide the physical unit measures associated with these values. Finally, for comparison purposes, Figures 5.4–5.7 provide a visual depiction of the present value net benefits/external costs for the tunneling versus LID options within each watershed. The tables and figures included in the following pages include options in the Delaware River Watershed.

Table 5.1. City-wide present value benefits of key CSO options: Cumulative through 2049 (2009 million USD)

Benefit categories	50% LID option	30' Tunnel option[a]
Increased recreational opportunities	$524.5	
Improved aesthetics/property value (50%)	$574.7	
Reduction in heat stress mortality	$1,057.6	
Water quality/aquatic habitat enhancement	$336.4	$189.0
Wetland services	$1.6	
Social costs avoided by green collar jobs	$124.9	
Air quality improvements from trees	$131.0	
Energy savings/usage	$33.7	$(2.5)
Reduced (increased) damage from SO_2 and NO_x emissions	$46.3	$(45.2)
Reduced (increased) damage from CO_2 emissions	$21.2	$(5.9)
Disruption costs from construction and maintenance	$(5.6)[b]	$(13.4)
Total	**$2,846.4**	**$122.0**

a. 28' Tunnel option in Delaware River Watershed.
b. Parentheses indicate negative values.

Table 5.2. City-wide natural unit benefits of key CSO options: Cumulative through 2049

Benefit categories	50% LID option	30' Tunnel option[a]
Additional creekside recreational user days	247,524,281	
Additional non-creekside recreational user days	101,738,547	
Reduction in number of heat-related fatalities	196	
Annual WTP per household for water quality and aquatic habitat improvements[b]	$9.70–$15.54	$5.63–$8.59
Wetlands created or restored (acres)	193	
Green collar jobs (job years)	15,266	
Change in particulate matter ($PM_{2.5}$) due to increased trees ($\mu g/m^3$)	0.01569	
Change in seasonal ozone due to increased trees (ppb)	0.04248	
Electricity savings due to cooling effect of trees (kWh)	369,739,725	
Natural gas savings due to cooling effect of trees (kBtu)	599,199,846	
Fuel used (vehicles for construction and O&M) (gallons)	493,387	1,132,409
SO_2 emissions (metric tons)	(1,530)	1,452
NO_x emissions (metric tons)	(38)	6,356,083
CO_2 emissions (metric tons)	(1,091,433)	347,970
Vehicle delay from construction and maintenance (hours of delay)	346,883	796,597

a. 28' Tunnel option in Delaware River Watershed.
b. WTP per household in Philadelphia, MA, including Bucks, Chester, Delaware, Montgomery, and Philadelphia counties.

Table 5.3. Present value benefits of key CSO options in Tacony-Frankford Watershed: Cumulative through 2049 (2009 million USD)

Benefit categories	50% LID option	30' Tunnel option[a]
Increased recreational opportunities	$161.2	
Improved aesthetics/property value (50%)	$85.0	
Reduction in heat stress mortality	$249.9	
Water quality/aquatic habitat enhancement	$23.7	$13.3
Wetland services	$0.3	
Social costs avoided by green collar jobs	$27.0	
Air quality improvements from trees	$28.3	
Energy savings/usage	$7.3	$(0.4)
Reduced (increased) damage from SO_2 and NO_x emissions	$10.0	$(8.8)

6. Key Uncertainties and Sensitivity Analyses

As detailed in the appendices of this report, there are a number of uncertainties (e.g., discount rate, social cost of carbon) and potential sources of variability (e.g., changes in energy costs) surrounding our analysis. To explore the impacts of these uncertainties on our overall results, we implemented a series of sensitivity analyses. The results of these analyses are discussed below.

Sensitivity analysis involves systematically changing the value of a key input or variable to see how it affects the outcome of the analysis. The change in results shows how sensitive the project outcome is to changes in individual factors. Sensitivity analysis is often performed by varying a particular input by equal amounts greater to and less than the current value (e.g., +/- 50%). The ultimate purpose of sensitivity analysis is to understand which assumptions are important to the choice of a particular policy or project option, and what those assumptions would have to be to change the decision on which option to pursue.

As part of the sensitivity analysis, we have explored the effect of a number of key assumptions on our overall results, including:

- ***Discount rate***. It is common practice to perform a sensitivity analysis on the discount rate used to determine the present value of costs and benefits. We therefore evaluated the benefits and external costs of the CSO options under alternative discount rate scenarios. Under the first scenario, we raised the nominal discount rate to 6.5%, (up from 4.875% in the current analysis) to reflect a 2.5% real discount rate, given the cost escalator (i.e., general inflation rate) of 4%. As a second scenario, we lowered the real discount rate to 0% (because of intergenerational equity aspects associated with the LID options). This entails lowering the nominal discount rate to 4% (i.e., setting discount rate to same value as the price escalator). Table 6.1 shows the results of this analysis for the 50% LID and 30' Tunnel options.

  As shown in Table 6.1, under the 50% LID option, net benefits decrease by 27% city-wide when the discount rate is increased to 6.5% (i.e., future benefits are "discounted" at a higher rate). Under the 4% discount rate scenario, benefits increase by about 21% city-wide from the baseline analysis (where the discount rate is equal to 4.875%).

  Under the 30' Tunneling option, relative impacts are larger and more varied across watersheds. For example, in the Tacony-Frankford Watershed, increasing the discount rate to 6.5% results in a 66% decrease in net benefits. In dollar terms, this represents a decrease of about $550,000. The large percentage decrease is due to the relatively low net benefits associated with this option in the Tacony-Frankford Watershed. City-wide, net benefits decrease by 34% and increase by 27% under the 6.5% and 4% discount rate scenarios, respectively.

Table 6.1. Sensitivity analysis: Discount rates

	Present value net benefits (millions, 2009 USD)			% change from baseline estimate*	
Discount rate	**4.875%**	**6.5%**	**4.0%**	**6.5%**	**4.0%**
50% LID option					
Tacony	$596.0	$416.2	$737.0	-30%	24%
Cobbs	$270.0	$185.6	$335.7	-31%	24%
Schuylkill	$748.9	$551.9	$903.8	-26%	21%
Delaware	$1,231.6	$895.1	$1,495.4	-27%	21%
City-wide	$2,846.4	$2,048.7	$3,471.9	-27%	21%
30' Tunnel option					
Tacony	$0.8	$0.3	$1.3	-66%	59%
Cobbs	$6.5	$3.7	$8.7	-42%	34%
Schuylkill	$28.5	$18.9	$36.0	-34%	26%
Delaware	$86.2	$57.2	$108.6	-34%	26%
City-wide	$122.0	$80.1	$154.6	-34%	27%

- ***Social cost of carbon***. There is currently quite a debate among experts and in the literature regarding the true social cost of carbon. For our analysis, we assume a cost of $12 per ton (MT), as reported by the IPCC. To evaluate how an increase in the social cost of carbon would impact our results for the different CSO control options, we conducted a sensitivity analysis comparing benefits and external costs with a higher social cost of carbon of $48 versus the IPCC's average of $12. The $48 per ton is about half of the high-level estimates reported by the IPCC (which include values of $85 to $98 per MT). Table 6.2 shows the results of this analysis for the 50% LID and 30' Tunnel options. More detailed results are included in Appendix G of this report.

  As shown below, changing the social cost of carbon does not significantly impact the net benefits of the 50% LID option on a percentage basis. This is because the benefits associated with carbon sequestration and reduced emissions make up a very small component of the total net benefits (e.g., < 1% under the 50% LID option). In dollar terms, the change in net benefits under the 50% LID option amounts to more than $63 million.

Under the 30' Tunnel option, the impact of an increased social cost of carbon has a much larger relative effect on overall results. City-wide, net benefits decrease by about 15% with an increase in the social cost of carbon from $12/MT to $48 MT. In dollar terms, this change amounts to about $18 million.

Table 6.2. Sensitivity analysis: Social cost of carbon

	Present value net benefits (millions, 2009 USD)		
Social cost of carbon	$12/MT	$48/MT	% change from baseline estimate
50% LID option			
Tacony	$596.0	$609.7	2.30%
Cobbs	$270.0	$274.3	1.62%
Schuylkill	$748.9	$763.6	1.97%
Delaware	$1,231.6	$1,262.3	2.50%
City-wide	$2,846.4	$2,910.0	2.23%
30' Tunnel option			
Tacony	$0.8	$(2.5)	(400.25)%
Cobbs	$6.5	$3.5	(45.54)%
Schuylkill	$28.5	$23.4	(18.06)%
Delaware	$86.2	$79.9	(7.35)%
City-wide	$122.0	$104.3	(14.53)%

- ***Electricity prices***. Electricity and other fossil fuel-based energy prices are expected to increase if a federal climate policy is introduced. Energy prices can also increase in the future due to a number of other factors (as evident by the price volatility seen in recent years). For our analysis, we assume a conservative estimate of $0.10 per kWh of electricity. This assumption affects the benefits associated with electricity savings under the LID CSO control options (electricity costs associated with power use within any CSO control option are not included in our analysis, because they are included in engineering cost estimates).

  To evaluate the impact of our assumption for the current rate of electricity, we conducted a sensitivity analysis that doubled this rate (e.g., up to $0.20 per kWh). The analysis shows that the rate of electricity has a very small impact on net benefits of the LID options. In all cases, net benefits increased by close to 1% as a result of the additional savings that would occur with higher electricity rates.

- ***WTP for water quality improvements***. As reported in Appendix D, we conducted a sensitivity analysis to evaluate how WTP per household fluctuates in response to changes in baseline water quality and the level of water quality/habitat improvement (as defined by the WQ_{10}). The results of this sensitivity analysis (reported in Appendix D) indicate that within the reasonable range of assumptions related to these variables, WTP per household does not vary appreciably as these input values change, but seem to follow a reasonable progression. WTP is more sensitive to the actual improvement in water quality as opposed to the baseline index value used in the analysis.

A. Recreational Use and Values

The LID CSO control options currently being evaluated by PWD would provide (and enhance) recreational amenities within PWD's CSO watersheds. The LID options include a substantial increase in vegetated acreage (including "treed" acreage) throughout the City. Much of this "green" acreage would be in the form of trees planted along streets in residential areas or will be planted in areas that are currently vacant or abandoned. This "greening" of Philadelphia would increase enjoyment and participation in neighborhood activities such as walking, biking or jogging on sidewalks, bench sitting, and/or other general outdoor recreation.

In addition, under all of the LID options, PWD would implement a stream restoration program intended to improve aquatic habitat in affected water bodies. The program is focused on physical in-stream improvements (primarily within the main stem water body associated with each watershed), as well as on improvement and expansion of riparian areas. In some watersheds, this would include improving riparian lands located within Fairmount Park and/or other open space areas. Activities in these areas might include trail construction and restoration, removal of invasive species, and other activities that would improve access along streams and rivers within the combined sewer area. In other areas, access to water bodies would be improved through key land and trail connections, enhancing recreational use in these areas.

The following sections outline Stratus Consulting's methodology for estimating the benefits associated with the increased recreational opportunities that will be available under the LID options for CSO control. Estimates of total benefits within each watershed are also provided. As described below, this analysis addresses "direct use" benefits only. Nonuse values associated with increased recreational opportunities are addressed in a subsequent analysis (see Appendix D).

A.1 General Methodology

To estimate total benefits of increased recreational activity under the LID options, we separately evaluated the benefits derived from improvements made as part of the stream restoration program (which are planned for implementation under all of the LID options) and those associated with a general increase in vegetated acreage throughout the CSO watersheds. For the purposes of this analysis, we refer to these benefits as "creekside" and "non-creekside" benefits, respectively.

The following sections describe the general methodology used to evaluate creekside and non-creekside recreational benefits. Subsequent sections provide more detailed descriptions of how our analyses were tailored to each watershed.

A.1.1 Recreational use

As a first step to our analyses, we estimated the additional recreational use expected to occur under the different LID options in each watershed. To do this, we relied heavily on a recent report prepared for the Philadelphia Parks Alliance by the Trust for Public Lands. The 2008 report, *How Much Value Does the City of Philadelphia Receive from its Park and Recreation System?* (Parks Report), provides visitation data for a variety of recreational uses and activities at Philadelphia's parks.[1]

The Parks Report provides data for visitation to parks in Philadelphia in general, and does not report recreational use at individual parks. We therefore used a per-acre estimate (number of visits per acre of Philadelphia park land) to evaluate potential changes in recreational activity under the different LID options in each watershed. We tailored these per-acre estimates to individual watersheds based on conversations with park staff, detailed watershed and park management plans, and on-site visits. We also made assumptions related to per-acre recreational use in non-park areas (e.g., on residential streets). Assumptions related to per-acre use in each watershed are described in detail in subsequent sections.

Finally, the recreational use values reported in the Parks Report are for Philadelphia residents only. Our estimates therefore do not include recreational use (or benefits) for non-Philadelphia residents.

A.1.2 Direct use values

The total recreational benefits associated with improvements made under the LID options are a function of the additional recreational trips ("user days") taken as a result of these improvements, and the benefit (or direct use value) derived from each trip.

Because recreational activities are not traded in the market (i.e., there is no fee for participation), it can be difficult to establish the direct use values associated with them. However, economists have developed a number of techniques for valuing "non-market" goods and resources, such as recreation. For example, economists have often determined the value of a recreational experience based on the consumer's WTP for the recreational experience in the private marketplace.

---

1. The number of park visits reported in the Parks Report were determined via a professionally conducted telephone survey of 600 Philadelphia residents. (The random-digit-dialed survey had an accuracy level of plus or minus 4%.) Residents were asked to answer for themselves; for those adults with children under the age of 18, a representative proportion were also asked to respond for one of their children.

For this analysis, we were able to rely on direct use values for specific recreational activities, as reported in the Parks Report. The model used to quantify these values is based on the "Unit Day Value" method as documented in Water Resources Council recreation valuation procedures by the U.S. Army Corps of Engineers. The Unit Day Value model counts park visits by specific activity, and assigns each activity a dollar value, based on WTP for park activities. For example, playing in a playground is worth $3.50 each time to each user. Running, walking, or rollerblading on a park trail is worth $4.00. For a more detailed description of how direct use values were calculated, see the Parks Report.

A.2 Non-creekside Recreation

To estimate benefits associated with a general increase in vegetated acreage (including treed acreage), we relied on inputs from CDM regarding the planned increase in vegetated acreage under the LID options for each watershed. We modified the number of vegetated acres provided by CDM to reflect only those acres that would result in additional or enhanced recreational activity. For example, we subtracted out the estimated number of acres expected to be planted in green roofs (also an input provided by CDM).

In addition to accounting for green roofs, we also subtracted the number of vegetated acres estimated for implementation in parking lots. To do this, we assumed that the vegetated acreage would be distributed based on the current pattern of impervious surface area in each watershed. For example, in the Tacony-Frankford Watershed, approximately 17% of impervious area (not including roofs) can be attributed to parking lots. We therefore assumed that 17% of the vegetated acreage planned under each alternative would be planted in parking lots. Thus, after accounting for green roofs, 17% of the remaining vegetated acreage planned for the Tacony-Frankford Watershed would not result in recreational benefits.

For the Schuylkill River Watershed, we also subtracted the number of acres identified in the Schuylkill River Master Plan (EDAW, 2003) as being available for recreational development (150 acres). This area was evaluated as part of the creekside recreational analysis. We assumed a similar area, on a per-stream mile basis, would be available for recreational development along the Delaware River and accounted for this in our analysis.

Table A.1 shows the planned increase in vegetated acreage assumed to result in recreational benefits for the LID CSO options in each watershed.

Table A.1. Planned increase in vegetated acreage assumed to result in recreational benefits under the LID options

	Tacony-Frankford	Cobbs Creek	Schuylkill	Delaware
25% LID	231	87	126	236
50% LID	822	312	832	1,715
75% LID	1,169	445	1,247	2,584
100% LID	1,404	534	1,528	3,171

Our next step was to estimate the number of recreational visits, or "user days," per acre for specific recreational activities that would occur as a result of the increases in vegetated acreage. We used visitation data for specific activities (e.g., walking the dog, walking on sidewalks/trails, and picnicking or bench sitting) from the Parks Report as the basis for this estimate. We then assumed that on a per-acre basis, the vegetated acreage planted under the LID options would support about 10% of the recreational activity seen at an average park in Philadelphia.

Table A.2 presents the annual additional recreational activity (in terms of "user days") under the LID CSO options in each watershed, assuming full program implementation. Table A.3 shows total additional recreational user days over the 40-year project evaluation period. The estimates shown in Table A.3 take into account the LID implementation timeline provided by CDM.

Table A.2. Additional non-creekside recreational user days under LID CSO control options each year (at full program implementation)

	Tacony-Frankford	Cobbs Creek	Schuylkill	Delaware
25% LID	310,000	117,300	169,200	317,300
50% LID	1,104,100	419,500	1,117,600	2,304,100
75% LID	1,571,300	597,500	1,676,300	3,472,900
100% LID	1,886,700	717,000	2,053,400	4,261,400

Table A.3. Additional non-creekside recreational user days under LID CSO control options over 40-year project period

	Tacony-Frankford	Cobbs Creek	Schuylkill	Delaware
25% LID	6,376,780	2,413,061	3,481,727	6,528,626
50% LID	22,714,215	8,629,946	22,991,914	47,402,472
75% LID	32,326,746	12,292,929	34,486,588	71,448,114
100% LID	38,815,401	14,751,738	42,245,022	87,670,535

A.2.1 Direct use value of additional recreational visits

To estimate the monetary value of additional recreational activity, we applied direct use values from the Parks Report for the recreational activities described above. We used 50% of the direct-use values reported in the Parks Report to account for differences in the value of recreational activities in parks versus non-park areas (i.e., walking on a sidewalk).

To estimate total benefits over the 40-year project life, we scaled annual benefits based on the LID implementation timelines provided by CDM. Table A.4 shows the present value benefits associated with non-creekside recreational activity expected to occur under the LID CSO options in each watershed.

Table A.4. Direct-use benefits associated with non-creekside recreational visits under LID CSO control options (present value estimates for 40-year project period)

	Tacony-Frankford	Cobbs Creek	Schuylkill	Delaware
25% LID	$4,499,952	$1,702,843	$2,456,977	$4,684,956
50% LID	$16,028,916	$6,089,960	$16,224,881	$34,016,111
75% LID	$22,812,265	$8,674,846	$24,336,416	$51,271,313
100% LID	$27,391,164	$10,409,972	$29,811,370	$62,912,556

A.3 Creekside Recreation

The following sections describe Stratus Consulting's approach for estimating recreational benefits associated with the stream restoration component of the LID CSO options. For this evaluation, we adapted our methodology to account for differences in current and expected changes in recreational use in each watershed. Further, the stream restoration program is assumed to be implemented under all of the LID alternatives, therefore total benefits are the same at each level of LID (25–100%).

Our methodology and assumptions are based on an extensive review of watershed and park management/master plans (documented at the end of this appendix), on-site visits with PWD staff, and discussions with Fairmount Park representatives.

A.3.1 Tacony-Frankford Watershed

Tacony Creek Park, a unit of the Fairmount Park System, accounts for the majority of creekside recreational lands in the Tacony-Frankford Watershed. The park consists of 302 acres of land (including Juniata Park Golf Course) that form a narrow corridor of park along Tacony Creek from the Montgomery/Philadelphia County border through Juniata Park. The park offers 2.5 miles of creekside trails and is reportedly used by residents for picnicking, running, walking, and fishing. Although an illegal activity, people do swim in the Tacony Creek Park section of the creek. Unsanctioned uses of the park include all terrain vehicle (ATV) use, dumping, graffiti, and drug activity.

Below Juniata Park Golf Course, the Tacony joins with now buried tributaries to form Frankford Creek. In order to deal with flooding and large influxes of stormwater, Frankford Creek has been completely channelized in concrete. The concrete channel prevents interaction between Frankford Creek and the groundwater system and eliminates streambed habitat needed to support aquatic life. The area surrounding Frankford Creek is highly industrialized and much of the creek is inaccessible.

Stream restoration activities in the Tacony-Frankford Watershed are focused on in-stream restoration and riparian area improvements along the 2.6 miles of stream through Tacony Creek Park and the 3.5 miles of Frankford Creek (south of Juniata Park through to the Frankford's confluence with the Delaware River). Major improvements related to recreational use include trail construction and restoration, expanded riparian areas, and improved access to the Tacony-Frankford main stem. Implementation of the Frankford Creek Greenway (as described in the Frankford Greenway Master Plan) is expected to include 3.1+ miles of trail and a number of recreational amenities.

Baseline recreational use

We first established a baseline estimate for current recreational activity in Tacony Creek Park. We limited the baseline to activity within the park because it is currently the only area in the Philadelphia County portion of the watershed that provides direct access to the main stem creek.

Our baseline estimate of recreational activity relies on survey data from the Tacony-Frankford River Conservation Plan (RCP), and qualitative descriptions from Fairmount Park Staff and the Tacony Creek Park Natural Lands Restoration Master Plan. We also used the Parks Report to help determine the mix of recreational activities occurring in the park.

The RCP survey reports stream-related recreational activity for the entire watershed (including tributaries). We therefore used geographic information systems (GIS) land use data to estimate the percentage of creek-related recreational activity that occurs along the Tacony main stem in Tacony Creek Park. We estimate that Tacony Creek Park currently supports about 70% of total creek-related recreation in the watershed. The remaining 30% is assumed to occur in tributaries and other areas of the watershed not relevant to our analysis.

Table A.5 shows the inputs and data sources used to establish a baseline estimate for recreational use along the creek. As shown below, the majority of residents in the Tacony-Frankford Watershed report that they rarely, if ever, spend recreational time along the creek. Conversations with park staff also indicate that this park gets very little use.

Table A.5. Assumptions and inputs used to establish baseline recreational use along Tacony-Frankford Creek

		Data source
General inputs		
2007 watershed population (Philadelphia County portion)	285,405	EPA BenMap 2007; Tacony-Frankford Integrated Watershed Management Plan (IWMP)
Percent of population less than 18 years old	26%	2000 Census
Recreational activities along the creek		
Percent of watershed residents under the age of 18 that recreate along the creek	12%	Tacony-Frankford RCP survey data as reported in the Tacony-Frankford IWMP
Percent of watershed residents over the age of 18 that recreate along the creek	39%	Tacony-Frankford RCP survey data as reported in the Tacony-Frankford IWMP
Average number of visits per year (both groups)	3	Tacony-Frankford RCP survey data as reported in the Tacony-Frankford IWMP
Mix of recreational activities		
Walk along creek	53%	Tacony-Frankford RCP survey data as reported in the Tacony-Frankford IWMP
Other non-contact activities	38%	Tacony-Frankford RCP survey data as reported in the Tacony-Frankford IWMP; Parks Report
Fishing	8%	Tacony-Frankford RCP survey data as reported in the Tacony-Frankford IWMP

Based on the assumptions and inputs shown above, we estimate that Tacony-Frankford Creek supports approximately 192,320 recreational visits to the creek each year. This amounts to about $406,000 in annual direct-use benefits.

Additional recreational visits under LID options

To estimate total creekside recreational benefits in the Tacony-Frankford Watershed, we separately evaluate recreational use under the LID CSO control options in the following locations:

- Tacony Creek Park
- Juniata Creek Golf Course
- The planned Frankford Creek Greenway.

Tacony Creek Park. As a first step to our analysis of recreational activity in Tacony Creek Park, we calculated the average number of per-acre visits to all Philadelphia parks for specific activities expected to occur in Tacony Creek Park. These activities include:

- Visits to playgrounds and tot lots
- Picnicking or bench-sitting
- Walking on trails
- Walking dog in park
- Birdwatching/nature
- Bicycling on trails
- Running on park trails
- Fishing.

We then assumed that under the LID/stream restoration improvements, Tacony Creek Park would likely support about 40% of the per-acre visitation experienced at an average park in Philadelphia. To estimate total visitation to the park, we therefore applied 40% of the average number of recreational visits per acre of park land in Philadelphia to the 174 acres of Tacony Park (excluding Juniata Park Golf Course). Our 40% assumption is based on the relative "local" nature of the park (e.g., compared to the regional appeal of East and West Fairmount parks), surrounding neighborhood demographics, and discussions with Fairmount Park representatives.

Based on these assumptions, we estimate that approximately 2.1 million people would visit Tacony Park each year under the LID options (at full program implementation). This includes the baseline estimate of individuals who already visit the park, as well as visits from individuals who would have visited a park elsewhere in Philadelphia if the improvements along Tacony Creek had not taken place. These factors are accounted for in our estimate of total benefits, as described below.

Juniata Park Golf Course. We based our estimate of additional visits to Juniata Park Golf Course on data reported in the *Juniata Park Golf Course Land Use and Feasibility Study* (EDAW, 2008). This report indicates that odors associated with CSO events in Tacony Creek are one of many limiting factors for increasing visitation to the course.

EDAW reports that there are currently about 11,350 rounds of golf played at Juniata Park each year (2007 estimate). This compares to an average of 28,375 rounds reported for other public courses in Philadelphia, or 40% of average use. We assume that under the LID options, use might increase to about 50% of the average use at other courses, or to 14,190 rounds of golf (an additional 2,800 rounds).

Based on an average of 3 golfers per round, we estimate that as a result of the CSO improvements, approximately 8,500 individuals will golf at Juniata Park Golf Course that otherwise would not have. This includes individuals who would have golfed elsewhere in the City (and are therefore not included in the overall benefit estimates reported below).

We use a conservative estimate for increase in use of the course as a result of CSO improvements because the park is plagued by non-CSO related problems such as graffiti and vandalism. In addition, Juniata Park is smaller than many other public courses and does not have the same historic or regional appeal as some of the other more well-used courses (e.g., Cobbs Creek Golf Course).

Frankford Creek Greenway. The planned Frankford Creek Greenway is a massive public works project that would include 3.1+ miles of trail construction along Frankford Creek and would restore much of Frankford Creek to its natural stream bottom. To estimate the number of visits to the new greenway, we relied on the same methodology described above for our analysis of increased use at Tacony Creek Park.

We first estimated the total area (acres) of the greenway, based on 3.5 stream miles and an assumed greenway width from the stream zone. Based on our assumptions, we estimate that the greenway would be approximately 190 acres. We then estimated per-acre visitation for activities expected to occur along the greenway.

With the exception of fishing and playgrounds/tot lots, the activities within the greenway were assumed to be the same as those included in the Tacony Creek Park analysis. We did not include fishing as a specific recreational activity because the concrete walls on the side of the stream channel are assumed to prevent direct contact with the stream. Additionally, it is unclear whether playgrounds and tot lots would be included as part of the greenway (they were not described in the Frankford Greenway Master Plan). As with the Tacony Creek Park analysis, we assumed that the Frankford Greenway would support about 40% of the recreational use of an average park in Philadelphia, on a per-acre basis.

Based on these inputs, we estimate that more than 1.9 million individuals will visit the greenway each year, once it is fully constructed.

Total additional recreational visits. We assume that under the LID options, approximately 70% of the recreational visits reported above would be "new" visits, meaning they would not have occurred if the LID stream restoration program had not been implemented. This assumption implies that the remaining 30% of recreational visits would have occurred at parks or golf courses elsewhere in the City if the LID improvements had not taken place. Although there is a marginal benefit associated with these visits (otherwise individuals would continue to visit the other parks), these benefits are not included in our analysis.

Table A.6 provides a summary of total additional recreational visits in the Tacony-Frankford Watershed under the LID options. The number of additional visits is reported on an annual basis (assuming full program implementation) as well as in terms of total visits over the 40-year project period. Total visits over the project period were determined based on the stream restoration implementation timeline provided by CDM.

Table A.6. Summary of total additional recreational visits in the Tacony-Frankford Watershed under LID options

Additional visits to Tacony Creek Park under LID options (minus baseline)	1,934,000
Visits to Frankford Greenway	1,910,000
Additional (person) visits to Juniata Park Golf Course	8,500
Percent of visits that are new recreational visits	70%
Additional annual recreational user days s	2,696,800
Additional recreational user days over 40-year project period	80,527,887

Direct use value of additional recreational visits

To estimate the monetary value of additional creekside recreational visits under the LID CSO control options, we applied direct-use values from the Parks Report, weighted by specific recreational activity. Based on these values, we estimate that the increased recreational activity will result in approximately $6.1 million each year (2009 USD), at full program implementation. This amounts to more than $145 million in direct use benefits over the 40-year project period, in present value terms (2009 USD). Present value estimates were determined based on the stream restoration implementation timeline provided by CDM.

A.3.2 Cobbs Creek Watershed

Cobbs Creek Park, located on the western edge of Philadelphia, accounts for the majority of recreational/park land in the Cobbs Creek Watershed. The Park's 220 acres encompass nearly 13 miles of stream that eventually drain to the Delaware River. The main stem, which is 8.2 miles, accounts for the majority of total stream length. The remaining stream length is made up of tributaries such as Indian Creek, and smaller, un-named streams.

For the purposes of this analysis, we focus solely on recreational use along the Cobbs Creek mainstem, as this will be the focus of PWD's stream restoration program. All improvements along the creek are expected occur within Cobbs Creek Park, which borders the creek throughout most of the CSO area. No additional recreational amenities are planned (i.e., nothing similar to the Frankford Creek Greenway). Stream restoration program activities are expected to result in improved water quality, restored and expanded trails, and improved access to the creek via expanded riparian areas.

To estimate recreational use along Cobbs Creek, we employed a methodology similar to the methodology used for our analysis of the Tacony-Frankford Watershed. Our methodology and results are described below.

Baseline recreational use

In the absence of data for current recreational use at Cobbs Creek Park, we relied on the per-acre baseline use established for Tacony Creek Park. We applied this baseline estimate to the 220 acres of Cobbs Creek Park, assuming that per-acre use is about 15% higher at Cobbs Creek Park than at Tacony Creek Park. This assumption was based on on-site visits and qualitative descriptions of each park. Based on our per-acre use application (with the 15% adjustment), we estimate that currently, Cobbs Creek Park supports about 280,000 visits each year.

Additional recreational visits to Cobbs Creek under the LID options

Similar to our analysis of recreational benefits in Tacony Creek Park, we calculated the average number of per-acre visits to all Philadelphia parks for specific activities expected to occur in the park under the LID options. We assumed the same mix of recreational activities for Cobbs Creek as we did for Tacony Creek Park.

We applied the per-acre estimates for specific recreational activities to Cobbs Creek Park and assumed that under the LID/stream restoration improvements, Cobbs Creek Park would likely support about 40% of the per-acre visitation experienced at an average park in Philadelphia. This assumption is based on the relative “local” nature of the park (e.g., compared to the regional appeal of East and West Fairmount parks), surrounding neighborhood demographics, and discussions with Fairmount Park representatives.

Based on these assumptions, we estimate that approximately 2.7 million people would visit Cobbs Creek Park each year under the LID options (at full program implementation). This includes the baseline estimate of individuals who already visit the park, as well as visits from individuals who would have visited a park elsewhere in Philadelphia if the improvements along Cobbs Creek had not taken place.

To estimate the number of additional visits under the LID options, we subtract out the baseline visits and assume that about 70% of the total visits are *new* visits (rather than visits that would otherwise have taken place at other city parks). Based on these assumptions, we estimate that improvements under the LID options will result in approximately 1.7 million additional visits each year, at full program implementation. This amounts to an additional 50.5 million visits over the 40-year project period, based on the implementation timeline provided by CDM.

Direct use value of additional recreational visits

To estimate the monetary value associated with these increased visits, we applied direct-use values from the Parks Report, weighted by specific recreational activity. We estimate that improvements under the LID options will result in approximately $3.9 million recreation-related benefits each year, at full program implementation. This amounts to $94 million in present value benefits (2009 USD) over the 40-year project period.

A.3.3 Schuylkill River Watershed

Our analysis of recreational benefits in the Schuylkill River Watershed relies on the information and data reported in the Tidal Schuylkill River Master Plan (EDAW, 2003). The study area of the Master Plan includes the eight-mile stretch of the tidal Schuylkill River (and adjacent land) from the Fairmount dam to the Delaware River. This area consists of a significant amount of industrial land uses that are adjacent to residential, open space, institutional, and other public uses such as the Philadelphia International Airport.

There are numerous active and inactive rail lines in the area, including the large and active East Side Yard for CSXT. Several major road corridors also run adjacent to and through the study area including I-95, I-76 (Schuylkill Expressway), I-676, Route 291/Passyunk Avenue, Grays Ferry Avenue, University Avenue, South Street, Walnut Street, Chestnut Street, and Market Street.

Land use data reveal that over half of the Master Plan study area (54.75%) is currently devoted to manufacturing, utilities, parking, and transportation (rail and street rights-of-way). Another 29% of land is categorized as wooded, vacant, or water (water associated with industrial uses, not the river and canals). Only 2.52% is currently categorized as recreation and 2.81% as residential of all types.

The Master Plan proposes a number of major public investments in the revitalization of the tidal Schuylkill River. These investments include greenway and trail improvements, including neighborhood linkages to the river and "streetscapes," as well as infrastructure improvements. Based on the Master Plan's full implementation, the potential development program for the study area could include the development of:

- Over 3,270 residential units
- Over 1,600,000 square feet of retail uses
- Over 11,300 square feet of restaurants
- Over 1,000,000 square feet of office space
- Over 2,000,000 square feet of flex/industrial space
- Over 100,000 square feet of cultural facilities

- Over 150 acres of new green space and park land
- Over 8 miles of new multi-purpose trails
- Marinas and boat storage for about 400 boats.

Improvements made as part of the LID CSO control options in the Lower Schuylkill River will play a role in the implementation of the Tidal Schuylkill River Master Plan. For our analysis of recreational benefits, we focus on the development opportunities described above that can be directly tied to LID CSO control implementation. Based on our understanding of the LID options, this includes the implementation of 150 "creekside" acres of new open space and park land, including trails and streetscape improvements, and the opportunities for new marinas and boat storage. The benefits associated with these improvements are described in the following sections.

Additional recreational visits associated with new green space

To evaluate recreational benefits, we first estimate per-acre visitation for specific recreational activities associated with the additional open space and park land, based on the Parks Report. We then assume that recreational areas in the Lower Schuylkill River would support about 60% of the use of an average Philadelphia Park. This is higher than the 40% estimate used for the Tacony and Cobbs Creek parks due to the park's more regional nature. However, due to the abundance of recreational opportunities just upstream of the CSO area (e.g., East and West Fairmount parks, Boathouse Row) and the heavy industrial nature of the area, this area will likely see less use than many other parks in the region.

Additionally, we also assume that only about 50% of recreational visits to the Lower Schuylkill open space areas will be "new" visits (i.e., visits would not have taken place at another park in the region). This is also based on the abundance of recreational opportunities located just upstream of the Schuylkill CSO area.

Based on these assumptions, we estimate that the improvements identified in the Schuylkill River Master Plan (associated with green space, trails, and pedestrian linkages only) will amount to about 1.3 million new recreational visits per year, assuming full program implementation. This amounts to about 40.2 million new visits over the 40-year project period, taking into account the stream restoration implementation timeline provided by CDM. Our analysis assumes no baseline level of visitation to this area due to its highly industrial nature and current land uses.

Additional recreational visits for boating and fishing

In addition to the benefits associated with new green space, the Master Plan identifies opportunities for the development of marinas and boat storage for about 400 boats. We include this in our analysis of recreational benefits because it can be directly tied to improvements in water quality as well as the implementation of aesthetic and recreational amenities (e.g., additional open space) under the LID CSO control options.

To estimate the number of new trips to the Lower Schuylkill River for fishing and boating, we rely on original survey data from the Parks Report, provided by the Trust for Public Lands.[2] We used these data to determine the number of average trips per year taken by Philadelphians who engage in fishing and/or boating. We then assume an average of 3 people per boat/fish trip and that about 60% of the trips taken on the Lower Schuylkill River would be "new trips" (i.e., would not have taken place elsewhere). Based on these assumptions, we estimate an additional 4,400 trips each year at full program implementation. This amounts to about 131,600 trips over the 40-year project period.

Direct use value of additional recreational visits

Similar to our analysis of Tacony and Cobbs Creek watersheds, we used direct-use values for specific recreational activities from the Parks Report to determine total benefits. Based on these values, we estimate the annual value of new recreational visits resulting from the implementation of 150 acres of open space, including trails and pedestrian linkages to the river, to be about $3.1 million (2009 USD) at full program implementation. Based on the implementation timeline provided by CDM, this amounts to more than $73.4 million in present value benefits (2009 USD) over the 40-year project period. Increased participation in boating and fishing in the Lower Schuylkill will provide an additional $19,172 in annual direct-use benefits, or a total of $460,000 in present value benefits over the 40-year project period.

A.3.4 Delaware River Watershed

In absence of specific data for the Delaware River Watershed, we assume that on a per-stream mile basis, the LID CSO control options for the Delaware River will include the same amount of open/green space area as planned for the Schuylkill River.

As noted above, there are about 150 acres (or about 21 acres per stream-mile) of open/green space planned for the Lower Schuylkill area, which encompasses about 8.7 miles of river. Applying this to the 15.6 miles of the Delaware River within PWD's CSO area, we estimate there will be about 341 acres of new open/green space under the LID CSO options. Similar to the Schuylkill Watershed, this additional acreage is separate from the vegetated acreage planned for areas throughout the watershed, as reported in the section on "non-creekside" recreational

---

2. The raw survey data is unweighted and does not account for differences in demographic characteristics of the study population and the population of Philadelphia County.

benefits. For our evaluation of non-creekside benefits, we subtracted out the open/green space acreage planned for the area along the river.

We used the same methodology as described for the Schuylkill River to estimate the recreational benefits associated with this new area. Based on this methodology, we estimate that implementation of the stream restoration program under the LID CSO control options will result in about 2.6 million additional creekside recreational visits each year, at full program implementation. This amounts to about 76.1 million visits over the 40-year project period, taking into account the project implementation timeline.

In terms of direct use benefits, additional recreational visits to the Delaware River will result in an annual benefit of $5.8 million (2009 USD), at full program implementation. Over the 40-year project period, this amounts to $139 million in present value benefits (2009 USD).

A.4 Summary of Results

Tables A.7 and A.8 provide a summary of total recreational benefits associated with the LID CSO control options. Table A.7 shows the additional number of recreational visits and the direct-use benefits, in present value terms, associated with additional non-creekside recreation. Table A.8 shows the same results for the creekside recreational analysis.

Table A.7. Summary of additional recreational visits under the LID CSO control options, over the 40-year project period

	Tacony	Cobbs	Schuylkill	Delaware
Non-creekside recreation				
25% LID	6,376,780	2,413,061	3,481,727	6,528,626
50% LID	22,714,215	8,629,946	22,991,914	47,402,472
75% LID	32,326,746	12,292,929	34,486,588	71,448,114
100% LID	38,815,401	14,751,738	42,245,022	87,670,535
Creekside recreation[a]	80,527,887	50,478,407	40,371,870	76,146,118

a. Applies to all LID options.

Table A.8. Summary of monetized recreational benefits under the LID CSO control options, over the 40-year project period (present value[a])

	Tacony	**Cobbs**	**Schuylkill**	**Delaware**
Non-creekside recreation				
25% LID	$4,499,951	$1,702,843	$2,456,977	$$4,684,956
50% LID	$16,028,916	$6,089,960	$16,224,881	$34,016,111
75% LID	$22,812,264	$8,674,846	$24,336,416	$51,271,313
100% LID	$27,391,163	$10,409,972	$29,811,370	$62,912,556
Creekside recreation[b]	$145,154,937	$94,100,602	$73,900,681	$138,970,735

a. Present value estimates presented in 2009 USD, assuming a 4% inflation rate and 4.875% discount rate.
b. Applies to all LID options.

A.5 Omissions, Biases, and Uncertainties

To estimate the total recreational benefits under the LID alternatives, it was necessary to make a number of assumptions in the absence of specific data. In addition, a number of data omissions and uncertainties surrounding the analysis have been identified throughout this report. Table A.9 provides a summary of these assumptions and uncertainties and their likely impact on our estimation of recreational benefits.

Table A.9. Omissions, biases, and uncertainties

Assumption/methodology	**Likely impact on net benefits[a]**	**Comment/explanation**
Only "new" visits are included in the analysis	-	Our analysis only includes visits that would not have occurred elsewhere if the LID improvements had not been implemented. However, there is a marginal benefit associated with the trips that would have occurred in another location (or the individuals would continue to make trips to this location under the LID alternatives). Given the relatively low direct-use values, the exclusion of these benefits does not likely make a significant impact on overall benefits. Further, the percentage of total visits that are "new" is based on qualitative discussions and on-site visits. A degree of uncertainty surrounds these assumptions.

Table A.9. Omissions, biases, and uncertainties (cont.)

Assumption/methodology	Likely impact on net benefits[a]	Comment/explanation
Non-Philadelphia residents are not included in the analysis	+/++	The Parks Report includes park visitation data for Philadelphia residents only. Non-Philadelphia residents are therefore not included in our analysis due to lack of data on how often they visit Philadelphia Parks. Inclusion of these visitors would increase overall benefits, most likely in the Schuylkill and Delaware River watersheds, which have a more regional appeal.
Direct use values do not take into account the quality of the recreational experience	U	If the quality of recreational visits to CSO watersheds is higher (or lower) than for visits to an average park in Philadelphia, users might experience a higher (or lower) value per outing. Locational factors (e.g., proximity to existing parks or neighborhood demographics) may also affect the quality of the recreational experience.
The direct-use values used in this analysis are low compared to similar studies	+	The direct use values in the Parks Report are relatively low. However, in Philadelphia, recreational values are not expected to amount to as much as those in more remote areas. In the City, most people do not have to travel far to reach the parks, and residents spend a shorter time recreating once they get to the park. Further, based on qualitative descriptions of parks in the watershed, the quality of the experience seems to be lower than in other areas used in many valuation studies.
Analysis relies on average per-acre visitation estimates for all parks in Philadelphia	U-	Our analysis assumes that parks/recreational land in CSO watersheds support a certain percentage of recreational use of an average park in Philadelphia on a per-acre basis. This is based on on-site visits, review of park master plans, and discussions with park staff. Increasing/decreasing this assumption would impact net benefits. Locational factors (e.g., proximity to existing parks or neighborhood demographics) and the amount of contiguous land in improved areas may also affect per-acre use.
On-the ground implementation	U	There is a large degree of uncertainty surrounding planned activities under the LID options (e.g., location in the watershed) and how these activities will affect recreational use. It is therefore difficult to estimate the benefits associated with them. Our estimates are intended to provide an approximation of total benefits, based on our understanding of program implementation and the best available data for current recreational activity in Philadelphia.

a. Indicating how addressing the assumption or overcoming the omission would probably impact the analysis, using the following key: + would likely increase net benefits; ++ would increase net benefits significantly; U direction of change in net benefit is uncertain; - would diminish net benefits; -- would diminish net benefits significantly.

B. Property Values, as Enhanced by the LID Options

B.1 Summary

Residential property value benefits are calculated for properties within the four watersheds relevant to this analysis: Cobbs Creek, Delaware Direct, Lower Schuylkill River, and Tacony-Frankford Creek. Specifically, benefits are quantified separately for properties within PWD's combined sewer area and those outside of the area; and the analysis is limited to the City. Benefits to properties outside of the combined sewer area and within the Lower Schuylkill River Watershed are excluded from the analysis because this area already has a considerable amount of LID, including East and West Fairmount Parks, and we do not anticipate any significant additional benefits to properties in this area. An estimate is provided for each of the other seven geographic areas using a range of benefits found in the literature. These estimates are meant to account for benefits that accrue to property owners from implementation of the LID options, or a significant aspect of the LID options (e.g., trees), that are unique from other benefit estimates presented in this report. Estimates of property value benefits from the green infrastructure LID options are summarized in Tables B.1 through B.4. Details on the derivation of these estimates are presented below.

B.2 Data and Methods

Estimates are calculated using neighborhood-level property count and price data from the Philadelphia "NIS neighborhoodBase," a database of spatial and numerical data maintained by the University of Pennsylvania's Cartographic Modeling Lab (CML, 2005). The total number of properties within a watershed (both within and outside of the combined sewer area) is compiled using GIS data obtained on neighborhood boundaries, watershed boundaries, and combined sewer area boundaries. The neighborhood data contain census housing unit counts, which are used to aggregate counts over several neighborhoods within a given watershed.

Using 2007 median sales price data from the NIS neighborhoodBase, a weighted average market value is derived for properties sold within a given geographic area of interest (e.g., within the combined sewer area for a given watershed). Each neighborhood has a portion of the total properties sold for a given geographic area in 2007. Multiplying each of these neighborhood proportions by its median sales price for 2007 and summing over all neighborhoods, we derive a weighted average market value. Using the median selling price data helps to mitigate sensitivity to extreme selling prices, since only a fraction of properties sell within a given year. Moreover, if a certain type of property sold more heavily in 2007, relative to a historical baseline of sales by property type (e.g., condominiums vs. single family homes), the median will be less sensitive to this. It is for these reasons that median selling price is favored over the mean.

Table B.1. Summary of residential property value benefits from 25% LID program elements (2009 USD)

	Within combined sewer area	Outside combined sewer area	Total
Total residential properties	503,882	48,544	552,426
Weighted average median sales price	$128,307	$152,920	$130,470
Estimated total market value of affected residential properties	$16,162,924,000	$1,855,841,000	$18,018,765,000
Low-end estimate of one-time increase in residential property value for 25% LID	$161,629,000	$2,941,000	$164,570,000
Average estimate of one-time increase in residential property value for 25% LID	$282,851,000	$5,146,000	$287,997,000
High-end estimate of one-time increase in residential property value for 25% LID	$404,073,000	$7,352,000	$411,425,000

Table B.2. Summary of residential property value benefits from 50% LID program elements (2009 USD)

	Within combined sewer area	Outside combined sewer area	Total
Total residential properties	503,882	48,544	552,426
Weighted average median sales price	$128,307	$152,920	$130,470
Estimated total market value of affected residential properties	$32,325,848,000	$3,711,682,000	$36,037,530,000
Low-end estimate of one-time increase in residential property value for 50% LID	$323,258,000	$5,881,000	$329,140,000
Average estimate of one-time increase in residential property value for 50% LID	$565,702,000	$10,292,000	$575,995,000
High-end estimate of one-time increase in residential property value for 50% LID	$808,146,000	$14,703,000	$822,850,000

Table B.3. Summary of residential property value benefits from 75% LID program elements (2009 USD)

	Within combined sewer area	Outside combined sewer area	Total
Total residential properties	503,882	48,544	552,426
Weighted average median sales price	$128,307	$152,920	$130,470
Estimated total market value of affected residential properties	$48,488,771,000	$5,567,523,000	$54,056,294,000
Low-end estimate of one-time increase in residential property value for 75% LID	$484,888,000	$8,822,000	$493,710,000
Average estimate of one-time increase in residential property value for 75% LID	$848,554,000	$15,438,000	$863,992,000
High-end estimate of one-time increase in residential property value for 75% LID	$1,212,219,000	$22,055,000	$1,234,274,000

Table B.4. Summary of residential property value benefits from 100% LID program elements (2009 USD)

	Within combined sewer area	Outside combined sewer area	Total
Total residential properties	503,882	48,544	552,426
Weighted average median sales price	$128,307	$152,920	$130,470
Estimated total market value of affected residential properties	$64,651,695,000	$7,423,364,000	$72,075,059,000
Low-end estimate of one-time increase in residential property value for 25% LID	$646,517,000	$11,763,000	$658,280,000
Average estimate of one-time increase in residential property value for 25% LID	$1,131,405,000	$20,585,000	$1,151,989,000
High-end estimate of one-time increase in residential property value for 25% LID	$1,616,292,000	$29,407,000	$1,645,699,000

The literature suggests a range of benefits from green storm water infrastructure, or LID, from 0% to 7%. This implies the average property value will increase anywhere from 0% to 7% due to LID additions to the surrounding landscape. A further discussion of the literature is provided later in this appendix. For the calculations below, we tighten this range to 2–5% for properties within the combined sewer area, with a mean increase of 3.5%, given that most of the studies provide estimates within this inner range.

In the absence of spatial data that outline the specific location and magnitude of LID installments, we calculate total market value of affected residential properties under four LID scenarios: 25%, 50%, 75%, and 100% LID coverage. Under the 50% scenario, for example, the total market value of affected residential properties for a given area is calculated as 50% of the total number of properties in that area times its weighted average median selling price.

Given that LID will be implemented within the combined sewer area, properties in the near vicinity of these changes will capitalize the greatest benefit (i.e., those properties within the combined sewer area). However, properties outside the combined sewer area will arguably accrue some benefit, though perhaps at a diminished rate. A number of studies reflect this “decay” in benefit as distance from the amenity increases (see Correll et al., 1978; Tyrvainen and Miettinen, 2000; Morancho, 2003; Wachter and Wong, 2006). For properties outside the combined sewer area, we adjust the benefit estimates range downward from 2%–5% to 1%–2.5%. This downward adjustment reflects the decay of benefits as indicated by the literature. Calculations for properties both within and outside the combined sewer area assume benefits accrue uniformly among affected properties.

Property value estimates from the literature encompass a wide range of benefits associated with LID. Many of these are not distinct from other benefits presented in this report (e.g., anticipated energy cost savings are likely to be capitalized, to some extent, in the increased property values of tree-shaded properties). In theory, changes in property values should reflect associated differences in air quality, water quality, energy usage (often relating to heat stress), flood control, and perhaps other benefits (particularly those qualitative in nature). For example, a property in an area with good air quality should sell for a higher amount relative to another property in an area with low air quality, all else equal. Thus, to simply add property value benefits with the benefits from improved air quality would be double-counting. This applies to most benefit categories in this report. Therefore, only a portion of the literature estimates should be considered unique from other benefits in this report, such as those stemming from aesthetic improvements. To account for this, we adjust estimates from the literature downward by 50% to arrive at a range of 1–2.5% for properties within the combined sewer area and 0.5–1.25% for properties outside the combined sewer area.

Tables B.1 through B.4 show the projected benefits under the four LID scenarios, within and outside of the combined sewer area. Under each scenario, the total market value of affected properties is multiplied by the endpoints of the corresponding benefit estimates range, along with the mean. This yields aggregated benefit estimates for increases in property values. For example, the estimated average benefits for properties within the combined sewer area under the 50% LID scenario is a one-time increase of $565.7 million.

Total property value benefits range, on average, from \$282.9 million to \$1.13 billion for properties within the combined sewer area and between \$5.1 and \$20.6 million for properties outside the combined sewer area, depending on the LID scenario. This leads to a total estimate of average benefits ranging from \$288.0 million for 25% LID to \$1.15 billion for 100% LID.[1]

B.3 Literature Used in the Benefits Transfer

The "benefits transfer" methodology is used to calculate the above estimates. Due to the high costs of carrying out original research, primarily in terms of time, existing estimates for property benefits associated with LID or specific aspects of LID are applied to the Philadelphia context. As Sample et al. (2003) and Powell et al. (2005) point out, more research is needed in quantifying the benefits of LID; therefore, the pool of studies from which to choose is somewhat small. However, a number of studies were reviewed and six studies were selected as good candidates for a benefits transfer, given their similar context and scope. All six studies estimate a bundle of benefits associated with trees/LID/green storm water management in general. These studies are summarized in Table B.5. A brief summary is offered for each study, along with the estimate itself.

Table B.5. Studies used in benefits transfer

Study	Summary of study	Estimate (% increase in value)
Ward et al. (2008)	Estimates effect of LID on adjacent properties relative to those farther away, in King County (Seattle), WA.	3.5–5.0%
Shultz and Schmitz (2008)	Proxies LID effects by looking at differentials for neighborhoods with clustered open spaces and greenways, etc., in Omaha, NE.	Greenways: 1.1–2.7%; clustered open space: 0.7–1.1%
McPherson et al. (2006)	References an uncited study that looks at the differentials between properties with ample trees vs. none or few trees (few details).	3–7%
Wachter and Wong (2006)	Estimates the effect of tree plantings on property values for select neighborhoods in Philadelphia.	2% (intrinsic value of trees)
Anderson and Cordell (1988)	Uses sales data from Athens-Clarke County (GA) to estimate the value of trees on residential property. Looks at differences between houses with five or more front yard trees and those that have fewer.	3.5–4.5%
Braden and Johnston (2003)	Uses meta-analysis of studies to estimate several benefit categories related to on-site storm water retention (green approach/LID) for managing storm water.	0–5%

---

[1] Watershed-specific estimates are provided in Section B.4.

B.4 Watershed-Specific Results

The tables that follow (Tables B.6 through B.12) show the property value results, by watershed and LID option. The benefit estimates reported here reflect the 50% reduction in increased property values described above, so as to focus on the aesthetic value of improvements provided by the added vegetation (i.e., reflecting a conservative approach to precluding possible double counting of energy savings and other benefits that might be embedded within the property value estimates).

Table B.6. Summary table of estimates (within combined sewer area; Tacony-Frankford Creek Watershed)

LID option (% increase)	Low % increase	High % increase
25%	$22,160,000.00	$55,399,000.00
50%	$44,319,000.00	$110,798,000.00
75%	$66,479,000.00	$166,197,000.00
100%	$88,639,000.00	$221,596,000.00

Table B.7. Summary table of estimates (within combined sewer area; Cobbs Creek Watershed)

LID option (% increase)	Low % increase	High % increase
25%	$7,010,000	$17,525,000
50%	$14,020,000	$35,049,000
75%	$21,030,000	$52,574,000
100%	$28,040,000	$70,099,000

Table B.8. Summary table of estimates (within combined sewer area; Delaware Direct Watershed)

LID option (% increase)	Low % increase	High % increase
25%	$77,123,000	$192,808,000
50%	$154,246,000	$385,615,000
75%	$231,369,000	$578,423,000
100%	$308,492,000	$771,230,000

Table B.9. Summary table of estimates (within combined sewer area; Lower Schuylkill River Watershed)

LID option (% increase)	Low % increase	High % increase
25%	$55,337,000	$138,342,000
50%	$110,673,000	$276,683,000
75%	$166,010,000	$415,025,000
100%	$221,347,000	$553,367,000

Table B.10. Summary table of estimates (outside combined sewer area; Tacony-Frankford Creek Watershed)

LID option (% increase)	Low % increase	High % increase
25%	$2,133,000	$5,333,000
50%	$4,266,000	$10,666,000
75%	$6,399,000	$15,998,000
100%	$8,532,000	$21,331,000

Table B.11. Summary table of estimates (outside combined sewer area; Cobbs Creek Watershed)

LID option (% increase)	Low % increase	High % increase
25%	$81,000	$203,000
50%	$162,000	$406,000
75%	$244,000	$609,000
100%	$325,000	$812,000

Table B.12. Summary table of estimates (outside combined sewer area; Delaware Direct Watershed)

LID option (% increase)	Low % increase	High % increase
25%	$726,000	$1,816,000
50%	$1,453,000	$3,632,000
75%	$2,179,000	$5,447,000
100%	$2,905,000	$7,263,000

B.5 Omissions, Biases, and Uncertainties

To estimate property value benefits under the LID alternatives, it was necessary to make a number of assumptions in the absence of specific data. In addition, a number of data omissions and uncertainties surrounding the analysis have been identified throughout this report. Table B.13 provides a summary of these assumptions and uncertainties and their likely impact on our estimation of property value benefits.

Table B.13. Omissions, biases, and uncertainties

Assumption/ methodology	Likely impact on net benefits[a]	Comment/explanation
Focuses only on residential properties	++	Property values for commercial, industrial, and other non-residential properties are excluded from the analysis. Including the benefits to these properties would increase net benefits.
Based on benefits transfer approach, using range of 2–5%	U	The literature provides estimates for increases in residential property values from 0–7% due to LID implementation. We narrow this range to 2–5%. A Philadelphia-specific study, Wachter and Wong (2006), estimates the benefits to residential properties from tree plantings at 2%. Estimates used in this benefits transfer are assumed to be, on average, for a similar population and scale. Studies were chosen with these considerations.
Estimates are based on marginal changes to land market	U	Estimates used in the benefits transfer are based largely on hedonic analyses, which reflect benefits associated with marginal changes in a land market. We assume the aggregation of benefits over multiple properties around the City is a marginal change.
Reducing property value benefits to reflect potential double-counting	U	To avoid double-counting, we adjust property value benefits downward by 50%. This adjustment is ad hoc, but is used to estimate unique benefits to residential properties that are not estimated in other parts of the report. For example, enhanced aesthetics is a unique benefit, while reduced heat stress is not.
Number of affected properties	U	The number of residencies impacted depends on the LID option for which benefits are calculated. These range from 25%–100% as presented in Tables B.1–B.4.
Affected properties accrue benefits uniformly	U	All affected properties are assumed to accrue benefits uniformly. Considerations for baseline conditions or precise locations of LID implementations could not be made reliably in the absence of better data.

Table B.13. Omissions, biases, and uncertainties (cont.)

Assumption/ methodology	Likely impact on net benefits	Comment/explanation
Average property price is the weighted average of median prices from the affected neighborhoods	U, but small	The average property price for a given geographic area (used to derive total market value for that area) is calculated by taking the sales price for each neighborhood and multiplying by the share of residential properties sold within those neighborhoods, summing over all neighborhoods.

a. Indicating how addressing the assumption or overcoming the omission would probably impact the analysis, using the following key: + would probably increase net benefits; ++ would increase net benefits significantly; U direction of change in net benefit is uncertain; - would diminish net benefits; -- would diminish net benefits significantly.

C. Heat Stress and Related Premature Fatalities Avoided

This appendix describes the methodology used to evaluate the benefits associated with the reduction in EHEs and heat-related fatalities under the LID CSO control options currently being considered by the PWD. Results of our analysis are also provided.

C.1 Introduction

EHEs have a well documented history of adverse public health impacts. Relatively recent demonstrations of this heat-health relationship include the loss of roughly 15,000 lives in France during the 2003 European EHE (Koppe et al., 2004; Valleron and Mendil, 2004) and over 700 deaths in Chicago, Illinois, in a July 1995 EHE (Kaiser et al., 2007). In addition to causing increased mortality, EHEs have also been associated with a range of morbidity impacts including increased emergency room use (NOAA, 1995) and hospitalizations (Semenza et al., 1999).

Philadelphia has its own tragic history of adverse public health impacts from EHEs. Notably, in 1991 and 1993, the county coroner determined EHEs were responsible for over 20 and 100 deaths, respectively (CDC, 1994; U.S. EPA, 2006). These findings drew significant attention to the heat-health relationship in Philadelphia and resulted in a number of formal responses including:

- The establishment of Philadelphia's Heat Task Force to help develop and implement EHE notification and response plans.
- Interest from the City in developing a meteorological warning system to predict when threatening conditions were expected. This ultimately led to the development of Philadelphia's Heat Watch Warning System, which predicts daily mortality increases based on forecast weather conditions (Kalkstein et al., 1996).

Concern about the heat-health issue continued to build and drive research from the late 1980s through the 1990s. A similar pattern developed with respect to examining how the urban environment can increase the severity and/or duration of residents' exposure to elevated temperatures. These associated health concerns, combined with interest in reducing the electrical demand within urban areas, helped spur research into what is commonly known as UHI issues, particularly the potential for different mitigation actions (U.S. EPA, 2008a). Within this field, one studied UHI mitigation strategy involves increasing the reflectiveness (i.e., albedo) of urban surfaces and/or increasing the acreage of urban vegetation (e.g., Hudischewskyj et al., 2001; Sailor, 2003).

The LID CSO control options are expected to increase the City's vegetated acreage. Thus, the envisioned LID programs will mimic urban revegetation programs focused on addressing the UHI. As a result, the LID options are expected to generate ancillary health benefits by reducing urban summer temperatures.

This appendix first provides a summary of results from studies that have estimated urban temperature reductions associated with increasing urban vegetation. As described below, these results are used to define a range of plausible scenarios for how the increase in vegetated acreage under the LID CSO control options could affect urban weather conditions in Philadelphia. The meteorological changes defined in these scenarios are then used to estimate the potential benefit of the LID programs in terms of avoided heat-attributable deaths. The appendix concludes with a series of final comments and considerations including a review of potential omissions, biases, and uncertainties in the study methods and results.

C.2 Modeled and Predicted Urban Temperature Reductions from Increased Urban Vegetation

Complex spatial models have been used to estimate how increasing urban vegetation can affect solar energy absorption and ultimately local meteorological values such as temperature and humidity. In these applications, the study area is first divided into grid cells. Each grid cell is then assigned to a land category class that has its own unique combination of attribute values (e.g., solar reflectivity/absorption, moisture, roughness). The impact of a program that increases urban vegetation is then accounted for by recalculating and reassigning attribute values in cells where the policy would be implemented.

For example, in the simplest approach, each grid cell would be assigned to one of two land categories, nonvegetated or vegetated. A policy to increase urban vegetation would then describe a percentage increase in vegetation, for example, a 10% increase in the study area. To simulate the effects of this policy, a new set of attribute values would be calculated for all cells initially assigned to the nonvegetated category. These new attribute values would reflect a weighted average of the nonvegetated and vegetated attribute values. In this hypothetical scenario, the new attribute value in previously nonvegetated cells would now be equal to 90% of the original nonvegetated attribute value plus 10% of the vegetated attribute. Values for cells originally categorized as vegetated would remain unchanged in this example. The policy's impact on urban conditions is then calculated by running an urban meteorology model for the base case and the policy case and calculating the difference between meteorological values of interest (e.g., average daily temperature).

This approach has previously been used to estimate the impact of a 10% increase in urban vegetated acreage for a number of U.S. cities, including Philadelphia (Hudischewskyj et al., 2001; Sailor, 2003), over a limited number of days. In the Hudischewskyj et al. (2001) study, the modeling was limited to considering the period July 14–15, 1995. Sailor (2003) modeled a number of multi-day events from June through August 1991–2001. Table C.1 presents the results of both studies with respect to changes in various air temperature measures.

Table C.1. Summary of urban temperature impact results from increasing urban vegetation in Philadelphia

Study	Vegetation scenario	Modeled temperature change result (°F)	Notes
Sailor (2003)	10% increase in urban vegetation from increased deciduous broadleaf tree cover	0.39 (average temperature)	Average temperature is the average of hourly differences calculated from 8 a.m. to 7 p.m.
		0.49 (maximum temperature)	Maximum temperature is the difference between the maximum daily temperatures in the control and policy cases
Hudischewskyj et al. (2001)	10% increase in urban vegetation (type of vegetation not clearly specified)	0.70 (maximum temperature 7/14)	Difference in maximum surface temperatures in base and policy case
		0.40 (maximum temperature 7/15)	

The results in Table C.1 suggest that increasing vegetation by 10% in Philadelphia might reduce urban temperatures by between 0.40°F and 0.70°F depending on the temperature measure (i.e., maximum vs. average temperature).

A similar study (Columbia University Center for Climate Systems Research et al., 2006) evaluated a number of potential changes to the urban landscape in New York City. The study estimated that there would be a 0.40°F reduction in temperature at 3 p.m. in New York City if 6.7% of the total city area represented were to receive shading by adding trees along streets. The study also estimated a potential 1.10°F reduction at 3 p.m. if 31% of the city area were converted from its current mix of grass areas, streets without trees, and impervious roofs to areas with trees and living (i.e., vegetated) roofs.

C.3 The Meteorological Impact of the LID Scenarios

The green CSO compliance alternatives are expected to reduce daily maximum temperatures in the watershed area as a result of increased shading and replacement of dark paved surfaces with vegetation that absorbs less solar radiation. However, the increase in vegetated acreage is also expected to increase humidity due to increased evapotranspiration. Collectively, this would increase the dewpoint temperature.

Depending on the LID option implemented, the resulting increase in vegetated acreage would be equivalent to a 6% to 31% increase in vegetated acreage measured as a percentage of the original impervious acreage across all CSO areas in the watersheds. This is similar to how the vegetated acreage increase was measured in Sailor (2003). The vegetation increase under the LID options is also roughly equivalent to a 4% to 21% increase in vegetated area when measured as a percentage of the total area covered by combined sewers across all watersheds. This is similar to how the change in vegetation was measured in the Columbia University Center for Climate Systems Research et al. (2006) study.

Because the increases in vegetation planned for implementation under the LID options are similar to the increases in vegetation evaluated in Sailor (2003) and Columbia University Center for Climate Systems Research et al. (2006), we used these studies to estimate the meteorological changes that would occur under the LID options. Specifically, the values of the temperature reductions in the temperature-only scenarios in Table C.2 bound the temperature change results reported in these earlier studies (see Table C.1 and associated discussion). The scenario results that incorporate changes in temperature and dewpoint are intended to increase the overall reality of the LID option impacts by addressing the expected increase in the dewpoint with the additional vegetation while hopefully providing an additional set of realistic estimates for consideration.

Table C.2. Alternative heat and relative humidity scenarios for Philadelphia LID compliance heat-mortality modeling

Scenario	Reduction in daily max temperature (°F)	Increase in daytime dew point temperature (°F)
1. Temperature only: minimum	0.25	0.00
2. Temperature only: maximum	1.75	0.00
3. Temperature and relative humidity: minimum	0.75	0.25
4. Temperature and relative humidity: maximum	1.25	0.50

C.4 Estimating Future Health Benefits from Reduced EHE Temperatures in Philadelphia

Our current analysis reflects an expansion in scope from our previous work that estimated potential public health benefits for a program that reduced EHE-attributable health impacts in Philadelphia during selected EHEs, by increasing urban vegetation (based on Kalkstein and Sheridan, 2003). Because a similar method is used for this effort, we first begin this section with a review of Kalkstein and Sheridan (2003) to present critical methods. The rest of this section provides an overview of how the meteorological scenario changes for analyses selected in Section C.2 were applied to the available regionally downscaled climate change data and the associated heat-mortality calculation system encompassed in Philadelphia's Heat Health Watch Warning System.

C.4.1 A review of Kalkstein and Sheridan (2003)

Kalkstein and Sheridan (2003) used a five-step process to estimate how a hypothetical change in urban temperature could affect heat-attributable mortality by evaluating a subset of summertime days specifically selected because they represented EHE conditions. The study is particularly relevant because Philadelphia was one of the study cities evaluated.

In the first step, each selected day was assigned to an air mass category based on available meteorological data. Air mass categories characterize weather conditions based on the values for a set of meteorological variables including temperature, dew point, wind speed, and cloud cover. Specific air mass categories include:

- Dry moderate (DM): A warm, comfortable air mass that occurs in Philadelphia frequently in summer.
- Dry polar (DP): Cooler than DM, but still quite warm in the summertime. Usually occurs immediately after the passage of a cold front.
- Dry tropical (DT): The hottest air mass in the summer, with temperatures usually exceeding 95 degrees and sometimes topping 100. Little cloud cover and low humidity lead to potentially rapid dehydration.
- Moist moderate (MM): A cloudy, mild air mass that may sometimes be associated with fog and light rain.
- Moist polar (MP): Usually a winter, rather than summer, air mass, this situation is often associated with storms moving up the East Coast.

- Moist tropical (MT): Very warm and humid air mass, sometimes associated with summer thunderstorms. Sticky and uncomfortable, and quite common in summer.
- Moist tropical plus (MT+) and Moist tropical plus plus (MT++): These are particularly hot and humid subsets of the MT air mass. Dewpoint temperatures are very high, temperatures are in the 90s, and overnight temperatures are the warmest of any air masses. These hot, humid conditions have historically led to increased mortality in Philadelphia.
- Transition (T): Associated with a frontal passage, when temperature, dewpoint, and other meteorological factors are changing rapidly.

In the second step, the study days with offensive air masses are identified. In short, those air masses that have daily mortality values that are consistently larger than longer-term averages are labeled offensive. The identification of offensive air masses relies on the evaluating time series data over multiple years to evaluate the relationships between daily mortality totals and air mass categories. In Philadelphia, the offensive air mass categories include: DT, MT+, and MT++.

In the third step, the heat-attributable mortality for each offensive air mass day is calculated. These calculations are completed using mortality algorithms developed using an iterative process to identify the regression equation that provides the best explanation of the observed difference in mortality from the longer term trends (i.e., the heat-attributable mortality). In this iterative process, meteorological variables and factors such as the timing of the offensive air mass day within the summer season and the persistence of the EHE are evaluated as potential explanatory variables.

The fourth step repeats the process for the study day while also accounting for the predicted change in temperature as a result of the increased urban vegetation. In the fifth step, the difference in mortality from the two scenarios is calculated and reported to indicate the impact of the increased urban vegetation.

Kalkstein and Sheridan (2003) found that the impact of increased vegetation varied according to the EHE event, and often day-to-day. Overall, the study reported a net reduction in the estimate of heat-attributable deaths with the increase in urban vegetation. However, the mortality reductions were not evenly distributed across days and some days showed an increase in the mortality estimates. The strength of the conclusions and ability to generalize the results across longer time periods are constrained by the limited number of summertime days and EHEs considered.

C.4.2 New study of increased vegetation with climate change

To develop a more detailed assessment of the potential heat-health impacts of the LID scenarios, the possible changes in temperature and relative humidity presented in Table C.2 were evaluated using the same general approach as in Kalkstein and Sheridan (2003) and described above in Section C.4.1. However, because the LID programs are expected to take a number of years for the vegetation targets to be fully achieved, the meteorological data used for the evaluation was provided by regionally downscaled General Circulation Model (GCM) results from a compilation of the A1 family of climate change emissions scenarios.

The downscaled meteorological results are produced for each day, from April 1 through August 31, in a representative year using a deterministic method that incorporates linear monthly regressions to help adjust the GCM results and ensure the probability distributions for the values for a baseline period in the 1990s are generally consistent with observed values during this time. This approach has been used for similar assessments of potential future heat impacts (e.g., Hayhoe et al., 2004). To try and capture inter-annual variability and provide results at different points in the LID project lifecycle, downscaled results were calculated for two future decades: 2020–2030 and 2045–2055. To help provide a point of reference, similar calculations were made for the 1990–2000 period.

The results of this evaluation are presented in Tables C.3 and C.4 in terms of the estimated number of heat-attributable deaths and offensive air mass days in each decade using the downscaled GCM data alone (the *control* results), and when accounting for the temperature and dewpoint temperature changes being evaluated for the LID scenarios.

Looking at the results a number the general conclusions can be drawn:

- Any measurable cooling provided by implementing an LID scenario is likely to provide some reduction in EHE-attributable mortality
- EHE-attributable mortality reductions are roughly proportional to the relative magnitude of the assumed temperature change
- The health benefits of the LID scenario implementation are relatively constant across the different decades, comparing the lives lost in the scenario to the control with the exception of the 1.75°F temperature reduction which has a noticeable increase in lives saved moving from the 2020s to the 2045–2055 period
- EHEs are likely to become an increasing risk to public health in Philadelphia without continued adaptation.

Table C.3. Estimated heat-attributable deaths assuming alternative temperature and dewpoint impacts from LID options

Year	Control	Year	Control	Scenario 1	Scenario 2	Scenario 3	Scenario 4	Year	Control	Scenario 1	Scenario 2	Scenario 3	Scenario 4

Underlying most of the mortality estimates and most of the summary results identified above is the actual mortality algorithm that was incorporated for the offensive air mass days. This algorithm is presented as Equation 1.

Equation 1. Daily heat-attributable mortality

Daily heat attributable mortality = [-22.904+(1.79 × DIS)+(1.198 × Tmax) – (0.054 × Julian)] / 4.722

where:

DIS =	day in sequence value, where 1 is the first day of an offensive air mass, 2 is the second consecutive day, etc.
Tmax =	daily maximum temperature in °C
Julian =	time of year variable, with April 1 =1, April 2 = 2 … August 31 = 153
4.722 scalar **=**	adjustment value used so that the GCM 1990 control scenario mortality estimates match actual heat attributable mortality estimates for the decade.

The mortality algorithm shows why, because Tmax is the only meteorological variable in the equation, the mortality results can generally be sorted by in terms of the associated temperature changes. It also demonstrates why, with a coefficient value on maximum temperature of roughly 1, the results are generally proportional to the assumed temperature changes. However, this emphasis on the maximum temperature in the mortality algorithm overlooks that the assumed changes in dewpoint temperature do play an important role in the results as they influence the air mass categories a day is assigned to and thus, in some cases, whether it falls into an offensive or non-offensive category.

Perhaps the most important feature of both the mortality and EHE day estimates in Tables C.3 and C.4 is to note the significant variability within the year-by-year results for a scenario and across scenarios. Expressed as a percentage of the mean values for estimated EHE-attributable deaths, the standard deviation of the decadal results is roughly 45% in the 2020–2030 estimates and roughly 30% in the period 2045–2055. Within years, results for scenarios can be roughly 2–3 times as large when comparing the largest estimates to the smallest. In short, while the results show the benefits of pursuing an LID program in terms of reducing EHE-attributable mortality in Philadelphia, predicting the exact nature of benefits in any given time period is complicated and becomes increasingly uncertain if narrower time windows are considered.

C.5 Application to Philadelphia LID Option Scenarios

We used the temperature and relative humidity changes identified in Table C.2 to estimate changes in heat-related mortality under the LID alternatives. First, based on estimated increases in vegetated acreage, we assumed that Scenarios 1 and 3 represent a range of the changes that would occur under the 25% LID option. We also assumed that changes under the 100% LID option are best represented by Scenarios 2 and 4.

Based on these assumptions, we estimated the average number of lives each year, for three 10-year periods: 2020–2029, 2030–2039, and 2040–2049 under the 25% and 100% LID options. We then scaled the percent of benefits realized each year based on the timeline for program implementation provided by CDM and the effective tree model developed by Stratus Consulting (see Appendix H). We assume that no heat-reduction benefits are realized prior to 2020.

To estimate the number of lives saved under the 50% and 75% LID options, we scaled results for the 25% and 100% LID options based on the level (percentage) of LID for each option. We then estimated the monetary value associated with the number of lives saved under each LID option based on EPA's recommended VSL ($7,000,000). Table C.5 presents the results of this analysis on a City-wide basis.

Table C.5. City-wide benefits associated with reduced urban temperatures under the LID alternatives

CSO option	Number of lives saved, over 40-year period	Present value of lives saved (based on EPA's recommended VSL) (millions, 2009 USD)
25% LID	137	$739.4
50% LID	196	$1,057.6
75% LID	255	$1,375.9
100% LID	314	$1,694.1

To estimate benefits for each watershed, we allocated the City-wide estimates shown above based on watershed population. Table C.6 presents the present value benefits (for 40-year project period, 2009 USD) associated with reduced heat-related fatalities, by watershed.

Table C.6. Present value benefits associated with reduced heat-related fatalities under LID CSO options, allocated by watershed (millions, 2009 USD)

CSO option	% of total population in CSO watersheds	Tacony	Cobbs	Schuylkill	Delaware
25% LID	8%	$174.7	$62.8	$207.7	$294.2
50% LID	24%	$249.9	$89.8	$297.1	$420.9
75% LID	28%	$325.1	$116.8	$386.5	$547.5
100% LID	40%	$400.3	$143.8	$475.9	$674.2

C.6 Omissions, Biases, and Uncertainties Associated with Health Benefit Conclusions

The following sections provide a summary of the impact of critical assumptions and calculation approaches used to develop the results of this analysis.

C.6.1 Accuracy of any single temperature and dewpoint scenario result

Well-understood basic physical principles underlie the assumption that significantly increasing the vegetated acreage in Philadelphia through an LID program should reduce ambient temperatures and increase the relative humidity and dewpoint temperature. The extent of this change, however, is uncertain.

Past experiments calculate possible values using complex integrated models that also take the unrealistic step of instantaneously changing the nature of a significant portion of an urban area. The more realistic scenario is that these changes occur and are fully realized over time. What complicates calculating the associated impact of these changes is that they are also likely to be a function of other changes in the urban landscape. This uncertainty prevents assigning a likely direction of bias in the current estimates.

What the results and the mortality algorithm make clear though is that larger temperature reductions will, all else equal, increase the health benefit of LID implementation.

C.6.2 Uncertainty of climate change

Philadelphia has a long history of being adversely affected by EHEs. All else equal, climate change is likely to increase the public risks and impacts associated with future EHEs as shown in the results. However, while acceptance of climate change impacts continues to grow there is still considerable uncertainty over what the future climate will look like.

In particular, researchers have begun to note how several climate change-related impacts that were anticipated to begin appearing later in the century may have already begun and how the pace of climate change may be more rapid than previously anticipated. In this study, further warming would increase the number of EHE days. This would increase the mortality estimates across the control and LID scenarios and may have little impact on the estimate of lives saved with the LID scenarios. More importantly, increased warming could fundamentally alter the nature of the EHE-mortality relationship in Philadelphia. If tolerance/infrastructure thresholds are crossed in an increasingly warm climate before the population can adapt there is the chance that the mortality estimates presented could be conservative.

C.6.3 Changing population size, demographics and response to heat

Heat is a well-recognized public health threat in Philadelphia and the City has an active and aggressive education, notification, and response program to address EHE conditions. The current estimates assume that the future rate of EHE-attributable deaths in response to EHE conditions will remain unchanged. To the extent future heat programs become more effective or factors that make those most currently vulnerable to EHEs become less of an issue (e.g., better access and use of air conditioning), the current heat mortality estimates could be overstated. However, the potential benefits of the LID program, all else equal, could remain unchanged in this situation if the impact is relatively small. In addition, these estimates hold the City's population at a constant size for all time periods evaluated. The bias introduced as a result will result in an overstatement of impacts, all else equal, if the future population is expected to decline compared to 2000 levels. Results would similarly be understated if future populations are expected to grow relative to 2000 levels.

Heat has and will continue to be a public health threat in Philadelphia. By offering the potential to reduce urban temperatures, the envisioned LID scenarios directly address the fundamental nature of the risk associated with EHE conditions and hold the potential to help prevent lives being lost to future EHEs.

C.6.4 The benefits of nonfatal heat stress cases avoided are not included

This analysis has focused solely on the number of premature fatalities avoided due to the impact that LID options are projected to have on urban temperatures and heat stress deaths. The cooling anticipated from the green infrastructure approaches also will generate public health benefits for individuals who would otherwise suffer nonfatal heat stress-related episodes. For example, the LID approaches will reduce the number of nonfatal heat stress episodes, thereby reducing the pain, suffering, medical expenses, and other losses incurred by individuals who otherwise would have become ill or temporarily disabled by heat stress. Thus, the total anticipated value of reduced heat stress is underestimated here, because it focuses exclusively on mortality events and omits morbidity episodes.

D. Water Quality and Aquatic Habitat Enhancements and Values

Under all of the CSO control options currently being evaluated by the PWD, water quality will be improved in streams and rivers within the City's CSO service area. Under the LID CSO options, stream restoration, wetlands, and increased vegetated area will also result in substantial aquatic habitat enhancements.

As described below, individuals in Philadelphia not only benefit from the direct use of these improved resources (e.g., through recreation), but also from knowing that these resources exist at a given level of quality. In environmental economics, this is referred to as "nonuse" value.

The following sections provide further background on nonuse values and outline Stratus Consulting's methodology for estimating nonuse values for improved water quality and aquatic habitat under the different CSO control options. Estimates for the benefits associated with these improvements are also provided.

D.1 Nonuse Values and Benefit Transfer

The different CSO control options yield different types and levels of water quality-related benefits. For example, stream restoration and water quality improvements under LID options will result in recreational benefits for many Philadelphia residents (see Appendix A). Recreational benefits accrue to individuals who actually participate in recreational activities, and are therefore quantified based on "use values" associated with different types of stream-side recreation.

For most residents in the greater Philadelphia area (including those who rarely or never participate in stream-related recreational activities), the different CSO control options will also result in some level of "nonuse" benefits. These nonuse benefits stem from the inherent value that individuals place on environmental goods and resources (in this case, water quality and habitat improvements). A frequently discussed basis for nonuse value is the desire to maintain the functioning of specific ecosystems.

In environmental economics, nonuse values are often referred to as existence and bequest values (King and Mazzotta, 2005). Existence value is the benefit generated today by knowing that a resource exists even if no use of the resource is anticipated. Bequest value is the value individuals gain from the preservation of the resource for use by their heirs. The term nonuse value is typically used in a more general manner to encompass both of these constructs (Harpman et al., 1994).

Nonuse values can only be estimated using techniques called "stated preference" methods. Contingent valuation (CV) has been the most commonly used stated preference method for estimating nonuse value, although more sophisticated variants (such as conjoint or choice set approaches) are now sometimes applied. In its simplest terms, CV is a survey-based technique used to elicit the maximum amount (in dollar terms) that an individual would be willing to pay for a resource (or an improvement to a resource) of a specified quality. Stated preference methods for conducting economic analysis are so named because values are obtained based on the stated preferences of individual survey respondents. An original stated preference study typically requires a significant amount of time and financial resources, because there are several important design and sampling features that need to be developed and pre-tested to ensure the reliability of the values derived from the survey instrument. For this reason, researchers often use the *benefits transfer* approach to estimate "willingness to pay" values.

Bergstrom and De Civita (1999, p. 79) offer the following definition of benefits transfer:

> Benefits transfer can be defined practically as the transfer of existing economic values estimated in one context to estimate economic values in a different context …. In the case of natural resource and environmental policies and projects, benefits transfer involves transferring value estimates from a "study site" to a "policy site" where sites can vary across geographic space and or time.

Benefits transfer is commonly used in economics, and there is a well-developed literature on how to correctly apply this method (e.g., Rosenberger and Loomis, 2003). Federal guidelines for economic analysis discuss how and when benefits transfer should be applied (U.S. EPA, 2000; U.S. OMB, 2003).

In the present case, we use benefits transfer to estimate average WTP per household in the greater Philadelphia Metropolitan Area (MA) for water quality and aquatic habitat improvements under each of the CSO control options. Our estimates are based on a meta-analysis, conducted by Van Houtven et al. (2007), of 131 WTP estimates from 18 studies (21 publications) conducted between 1977 and 2003. The WTP estimates included in the meta-analysis were all derived using stated preference methods.

D.2 Methodology

As noted above, to estimate WTP values for water quality and aquatic habitat improvements in Philadelphia, we relied on a meta-analysis of water quality valuation studies conducted by Van Houtven et al. (2007). A primary objective of the meta-analysis was to develop a tool (regression model), based on existing (primary) studies that could be used in benefits transfer analysis to predict WTP estimates for different policy scenarios. The following sections summarize the methodology used to conduct the meta-analysis and the assumptions made to transfer results of the analysis to Philadelphia.

D.2.1 Meta-analysis: data collection and common influences on WTP estimates

The studies included in the Van Houtven et al. analysis were limited to stated preference studies conducted in the United States and to studies that described water quality in terms that could be converted to a common 10-point scale. Once studies that met these criteria were selected, the authors identified common variables across the studies that were likely to influence WTP estimates. In general, these variables can be categorized as follows:

- **The water quality "commodity."** The authors converted the water quality changes evaluated in each study into a common metric. To do this, they constructed a 10-point water quality index, WQI_{10}. This index is based in part on the water quality ladder (WQL) developed by Vaughan (1986) as a way of conveying water quality to the general public, particularly survey respondents. Vaughan defined the ladder such that, for example, a water quality index value of 2.5 (out of 10) was "boatable," 5.1 was "fishable," and 7.0 was "swimmable." Many researchers (e.g., Desvousges et al., 1987 and others) have used Vaughan's WQL to obtain WTP estimates for changes in the "steps" of the ladder. Van Houtven et al.'s WQI_{10} maps water quality characteristics not specifically related to recreational use (e.g., habitat suitability) to the WQL. Figure D.1 shows a schematic of Vaughan's original WQL. Table D.1 shows some specific water quality measures associated with the different use levels identified.

- **Study population characteristics.** WTP relates primarily to individuals' preferences, which are determined at least in part by personal characteristics. For example, individuals who are active recreational users of water resources are also likely to have stronger preferences for improving freshwater quality. Thus, users typically place higher values on water quality changes than nonusers, all else equal.

  Further, individual values for water quality changes reflect both their willingness and their ability to pay. The economic conditions that affect an individual's perceived ability to pay for water quality changes can be captured (at least in part) through personal or household income. If water quality is a normal good, then increasing income is expected to have a positive effect on WTP.

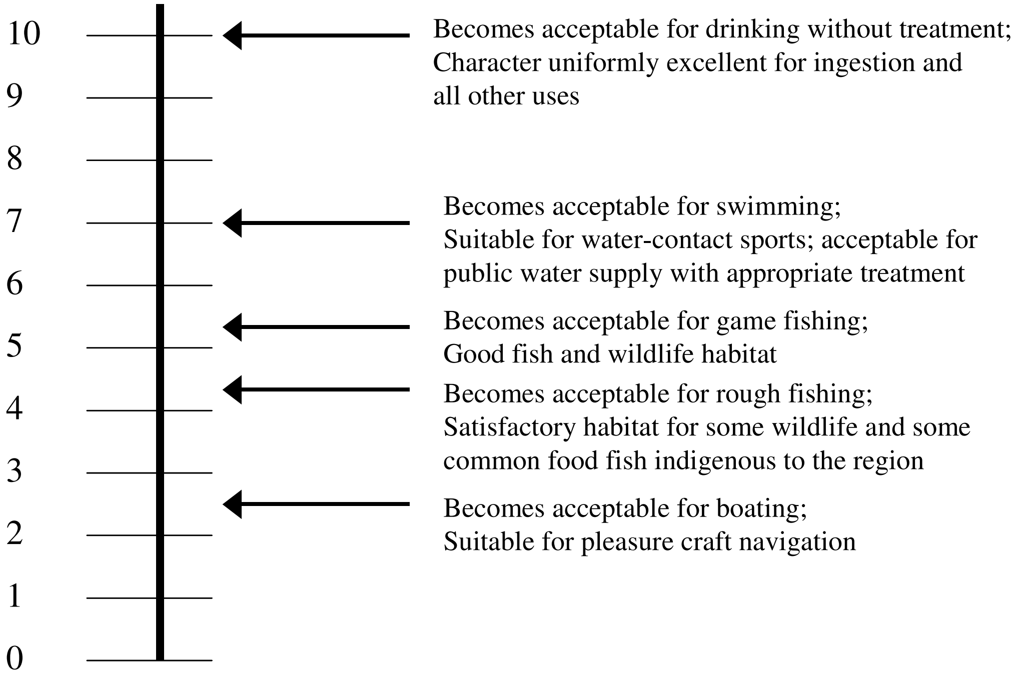

Figure D.1. Vaughan's (1986) water quality ladder.

Table D.1. Water quality characteristics for 5 classes of water use

	Fecal coliform (no./100 mL)	Dissolved oxygen (mg/L)	5-day BOD (mg/L)	Turbidity (NTU)	pH
Acceptable for drinking without treatment	0	7.0	0	5	7.25
Acceptable for swimming	200	6.5	1.5	10	7.25
Acceptable for game fishing	1,000	5.0	3	50	7.25
Acceptable for rough fishing	1,000	4.0	3	50	7.25
Acceptable for boating	2,000	3.5	4	100	4.25

Source: Russell et al., 2001.

- **Valuation method.** The magnitude of the value estimates for water quality changes is also expected to depend on the way in which the estimates were derived. As noted above, all of the WTP estimates included in the analysis are based on stated preference methods (either the CV method or conjoint analysis). However, a number of methodological differences have the potential to influence WTP. One potentially significant difference is the type of value elicitation format used (e.g., open-ended vs. dichotomous choice questions). WTP may also be influenced by whether the stated preference survey is conducted in person, over the phone, through a mailed questionnaire, or in another format. These variables are controlled for in the Van Houtven et al. (2007) analysis.

- **Other study characteristics.** WTP estimates may also be influenced by the overall quality of the methods and results of the study. Two potential indicators of study quality are the survey response rate and the publication outlet. Higher response rates and publication in peer-reviewed outlets are generally considered to reflect better quality studies. However, the publication selection process may result in estimation bias if, for example, reviewers and editors are more inclined to accept higher value estimates or if analysts are less likely to submit lower estimates (Stanley, 2001). Thus, while the expected effect of these characteristics on WTP is indeterminate, it is important to control for them in meta-analysis.

D.2.2 Meta-regression analysis

To evaluate societal preferences for water quality changes, Van Houtven et al. (2007) incorporated data from the 18 selected water valuation studies (based on the categories described in Section D.2.1 above) into a meta-regression analysis.

Table D.2 describes the specific variables used to estimate the author’s final regression models. The two primary variables of interest are WTP2000 (dependent variable), which is the estimated mean WTP per household for a defined change in water quality [converted to 2000 dollars using the consumer price index (CPI)], and $WQI_{10}CHANGE$, which captures the corresponding change in water quality in terms of the WQI_{10}.

The authors estimated the model using three different functional forms – linear, semi-log, and log-linear. Although all three of these forms are reasonable for approximating the relationship between WTP and the other variables, the log-linear approach has at least two conceptual advantages. First, it implies that, as changes in water quality approach zero, WTP also approaches zero. Second, it implies that the *marginal* effect of a water quality change on WTP depends on income. The semi-log model shares this second advantage; however, it also implies that if WTP increases with larger improvements in water quality, then it does so at an increasing rate.

Table D.2. Variables included in Van Houtven et al. meta-regression analysis

Variable	Description
WTP2000	Annual WTP for water quality change (in 2000 dollars)
WQI_{10}CHANGE	Water quality change (based on 10-point WQI)
WQ_REC_USE	= 1 if the water quality change described in the study includes a reference to recreational use support (e.g., suitable for recreational fishing)
WQI_{10}BASE	Baseline level of water quality from which water quality improves
ESTUARY	= 1 if the water quality change occurs in an estuary
LOCAL_FWATER	= 1 if the water quality change is restricted to freshwater in the local area (i.e., within a single waterbody, county, or metro area)
MIDWEST	= 1 if the affected waterbodies are in the Midwest region of the United States
SOUTH	= 1 if the affected waterbodies are in the Southern region of the United States
INCOME2000	Average household income (in thousands of 2000 dollars)
INCOME_APPROX	= 1 if average household income was approximated based on local Census data
PERCENT_USER	Percent of the sample population that are users of the affected water resource
PUBLISHED	= 1 if the study is published in a peer-reviewed book or journal
OPEN_ENDED	= 1 if the value was estimated from an open-ended valuation question
RESPONSE_RATE	Response rate for the survey used in the study
IN_PERSON	= 1 if the survey used in the study was administered with an in-person interview
STUDY_YR73	= Year SP survey was fielded (minus 1973)

Source: Van Houtven et al., 2007.

Van Houtven et al. report two similar model specifications for each functional form. The first is a full model with all of the main explanatory variables included, while the second is a restricted model using a more parsimonious specification. The restricted models exclude variables that are not individually significant at 0.10 level or less (based on t-statistics). As shown in Table D.2, the dropped variables include ESTUARY, LOCAL_FWATER, MIDWEST, SOUTH, OPEN_ENDED, and the interacted variable for INCOME2000 and INCOME_APPROX. Due to their conceptual and economic importance in the model, all water quality variables were retained in the restricted models regardless of their statistical significance.

Table D.3 shows the results of log-linear (full and restricted) models estimated by Van Houtven et al. The log-linear model is shown because this is the functional form we decided to use for our benefits transfer analysis. Although the numbers presented below are not inherently intuitive (because they are in logged form), the magnitude and sign of the coefficients provide a relative idea of how the different variables influence WTP estimates.

Table D.3. Meta-analysis regression results

Variables	**Model coefficient (full model)**	**Model coefficient (restricted model)**
Ln(WQI10CHANGE)	0.343	0.358
Ln(WQI$_{10}$CHANGE)xWQ_REC_USE	0.414*	0.465**
WQI$_{10}$BASE	0.091	0.08
ESTUARY	0.025	
LOCAL_FWATER	-0.11	
MIDWEST	0.329	
SOUTH	-0.052	
Ln(INCOME2000)	0.964*	0.897*
Ln(INCOME2000)xINCOME_APPROX	-0.008	
PERCENT_USER	0.011**	0.011**
PUBLISHED	0.960**	0.898**
OPEN_ENDED	0.051	
RESPONSE_RATE	-0.014	-0.013*
IN_PERSON	0.315	0.43
STUDY_YR73	-0.041**	-0.029**
CONSTANT	-0.399	-0.227

Note: ** and * respectively denote statistical significance at the 5% (p = 0.05) and 10% level (p = 0.10).

Source: Van Houtven et al., 2007.

As shown in Table D.3, most variables included in the model have a positive influence on WTP estimates (e.g., an individual with higher income will report higher WTP) to relative degrees. The negative effect of STUDY_YR73 indicates that, controlling for income and price effects, estimates of average real (inflation-adjusted) WTP for water quality improvements has declined over time. It is possible that this decline reflects changes in preferences over time; however, it may also be the result of other factors, such as possible changes in publication selection processes (e.g., by authors or editors) or in estimation methods, that tend to favor lower WTP estimates.

The effect of RESPONSE_RATE is also negative. The authors report that although there are no strong priors for how response rates should affect the magnitude of WTP estimates, these results suggest that surveys with lower response rates might exclude individuals with lower average WTP for water quality improvements.

For benefits transfer, the model coefficients shown above are multiplied by their respective input variable (the value of which is determined by the specific policy scenario). The sum of these products is then used to estimate WTP2000. For example, WTP estimates for the restricted model would be calculated as follows:

$$\begin{aligned}
&\text{Ln(WTP2000)} = -0.227 + (0.358 \times \text{Ln[WQI10CHANGE]}) \\
&+ (0.465 \times \text{Ln}(\text{WQI}_{10}\text{CHANGE}) \times \text{WQ\_REC\_USE}) + (0.08 \times \text{WQI}_{10}\text{BASE}) \\
&+ (0.897 \times \text{Ln(INCOME2000)}) + (0.011 \times \text{PERCENT\_USER}) \\
&+ (0.898 \times \text{PUBLISHED}) + (0.013 \times \text{RESPONSE\_RATE}) + (0.43 \times \text{IN\_PERSON}) \\
&+ (-0.029 \times \text{STUDY\_YR73})
\end{aligned}$$

D.2.3 Benefits transfer

As noted above, we used the log-linear model specification to predict WTP for the LID and non-LID CSO control options. We first estimated benefits associated with water quality/habitat changes under the 100% LID, 35’ Tunnel, and RTB HR01 alternatives. To estimate benefits associated with the less aggressive alternatives under each option (LID, Tunneling, Satellite Treatment), we scaled downwards based on the scope of the different alternatives. Further, we assumed the level of improvement under the Plant Expansion options to be equal to those of their corresponding LID component (e.g., benefits under the 100% LID + 215 MGD option will be the same as those estimated for the 100% LID option alone).

To provide a range of benefit values, we estimated results using both the full and restricted models from Van Houtven et al. We made the following assumptions in applying these models to Philadelphia:

- Benefits are estimated based on an average baseline water quality for all affected waterbodies (i.e., not by individual watershed). This is consistent with most studies included in the meta-analysis, which were conducted on a more regional scale. These estimates would be difficult to allocate across watersheds.
- We separately evaluate WTP per household for households within the City and households within the greater Philadelphia, MA but not within the City limits (including households in Bucks, Chester, Delaware, Montgomery counties). A number of factors led to this separate evaluation:
    - Households outside of the City have much higher incomes (on average) than households within Philadelphia. This affects WTP for water quality and ecological habitat improvements.
    - Distance from the water bodies being improved is expected to decrease WTP to some degree.

  - Households outside of the City are expected to have a much higher WTP for improvements in the Schuylkill and Delaware rivers (given their regional importance), as opposed to the more local Tacony and Cobbs creeks.
  - To account for these factors, we scaled WTP estimates for households outside of the City by 0.80 to account for distance and then multiplied these estimates by 0.61 (percent of CSO area stream miles in the Schuylkill and Delaware River watersheds).

- We assumed the baseline water quality in the affected streams and rivers (Cobbs Creek, Tacony Creek, and the tidal portions of the Schuylkill and Delaware rivers) to be 4.3 units. This score was determined based on knowledge of the WQI and affected streams. At 4.3, the water quality and habitat in the water body is assumed to support some “rough” fishing (not for game species), and is considered boatable.

- Under the 100% LID option, water quality is expected to improve by 2.5 units, up to 6.8. At this level, habitat (and fishing) is greatly improved but water quality levels do not allow for swimming.

- Under the most aggressive tunneling and satellite treatment options, water quality is assumed to improve by 1.2 units. This accounts for improved water quality but little change in aquatic habitat.

- In each case, we assumed that the stream restoration and water quality improvements will improve recreational opportunities in most areas (WQ_REC_USE equals 1). Although many residents do not use these areas for in-stream recreation, we can estimate the nonuse value they hold for these amenities.

- The variable PERCENT_USER is set at 0 because we are looking to capture only nonuse values in this part of the analysis.

- The variable INCOME_2000 is set at median household income for the City, which was estimated by the Census as $30,746 annually (lower than the 2000 national average). For households outside of the City but within the Philadelphia, MA, the model was estimated with INCOME_2000 equal to $64,736 (U.S. Census Bureau, 2000).

- The variables ESTUARY and LOCAL_FWATER were both set equal to 0.61 to reflect the percent of stream miles within PWD’s CSO boundaries that are considered “tidal” rather than freshwater.

- The study year is assumed to be 2009.

- Finally, consistent with Van Houtven et al., PUBLISHED was set at 0.5 (due to the uncertainties regarding whether this variable reflects study quality or publication bias). All other variables related to study format were set at the Van Houtven et al. sample means.

Based on these assumptions, Table D.4 shows the inputs used for each CSO control alternative for WTP for households within the City.

Table D.4. Meta-regression analysis inputs for Philadelphia CSO control options

	Variable input LID option	Variable input non-LID option
WQI_{10}CHANGE	2.5	1.2
WQI_{10}CHANGExWQ_REC_USE	2.5	1.2
Ln(WQI10CHANGE)	0.916	0.182
Ln(WQI_{10}CHANGE)xWQ_REC_USE	0.916	0.182
WQI_{10}BASE	4.3	4.3
ESTUARY	0.61	0.61
LOCAL_FWATER	0.61	0.61
MIDWEST	0	0
SOUTH	0	0
INCOME2000	30.746	30.746
INCOME2000xINCOME_APPROX	30.746	30.746
Ln(INCOME2000)	3.426	3.426
Ln(INCOME2000)xINCOME_APPROX	3.426	3.426
PERCENT_USER	0	0
PUBLISHED	0.5	0.5
OPEN_ENDED	0.6	0.6
RESPONSE_RATE	58.02	58.02
IN_PERSON	0.31	0.31
STUDY_YR73	36	36

Based on these inputs, Tables D.5 and D.6 show the results of the meta-analysis. Table D.5 shows estimated WTP in the greater Philadelphia, MA (per household) for water quality improvements under the 100% LID and most aggressive non-LID options. Table D.6 shows total present value estimates (over the 40-year project time period) for all CSO options within each watershed.

Table D.5. Estimated WTP (per household and total annual) for water quality improvements under the 100% LID and most aggressive non-LID options

	WTP per household per year (full model)	WTP per household per year (restricted model)	Total annual WTP (full model)	Total annual WTP (restricted model)
100% LID option				
City/County of Philadelphia	$11.48	$18.28	$6,774,451	$10,791,199
Philadelphia, MA (excluding Philadelphia County)[a]	$11.41	$17.40	$9,917,607	$15,119,047
Total annual WTP			$16,692,057	$25,910,246
Non-LID (most aggressive options)				
City/County of Philadelphia	$6.58	$9.99	$3,886,634	$5,898,359
Philadelphia, MA (excluding Philadelphia County)[a]	$6.55	$9.51	$5,689,925	$8,263,918
Total annual WTP			$9,576,559	$14,162,277

Note: Based on 1,459,331 households in Philadelphia, MA (2000 Census). Values adjusted to 2009 current year dollars based on percent increase in CPI from 2000.

a. Scaled to account for distance from waterbodies and WTP estimates for Delaware/Schuylkill only.

To estimate total benefits associated with the 24 different CSO alternatives, we applied a scalar based on the scope of each option compared to the most aggressive LID, Tunneling, or Satellite Treatment option. Consistent with our analysis of other benefits, we allocated benefits over the 40-year project time period based on construction and implementation timelines provided by CDM. We assumed that stream restoration and riparian improvements would occur under all the LID alternatives (25%–100% LID Options). Thus, at each level of LID, 75% of the maximum water quality/ecological habitat benefits will be realized (as a result of the stream restoration program). The remaining 25% of maximum benefits will vary based on the level of LID implemented.

To estimate WTP for water quality and ecological habitat improvements for each watershed, we allocated total WTP for households the City by restored stream mile within each affected CSO area. For households outside of Philadelphia County, but within the greater Philadelphia, MA, we allocated total WTP by restored stream mile within the Schuylkill and Delaware River CSO watersheds only. Thus, we assume $0 WTP by these households for improvements to Tacony-Frankford and Cobb creeks.

Table D.6. Total WTP in the Philadelphia, MA for water quality and ecological habitat improvements under different CSO control options (present value 2009 USD)

	Tacony	Cobbs	Schuylkill	Delaware
LID options/Transmission and new treatment capacity with LID component[a]				
25% LID	$21,576,660	$27,912,663	$78,631,310	$178,551,447
50% LID	$23,664,723	$30,613,888	$86,240,792	$195,830,619
75% LID	$25,752,787	$33,315,114	$93,850,273	$213,109,791
100% LID	$27,840,851	$36,016,339	$101,459,755	$230,388,963
Tunnel options[b]				
15’ Tunnel	$6,646,639	$8,598,429	$24,230,834	$55,021,981
20’ Tunnel	$8,862,185	$11,464,573	$32,307,779	$73,362,642
25’ Tunnel	$11,077,731	$14,330,716	$40,384,724	$91,703,302
30’ Tunnel	$13,293,277	$17,196,859	$48,461,668	$110,043,963
35’ Tunnel	$15,508,824	$20,063,002	$56,538,613	$128,384,623
Transmission and satellite treatment options				
25 Ofs	$15,508,824	$20,063,002	$56,538,613	$128,384,623
10 Ofs	$8,840,029	$11,435,911	$32,227,009	$73,179,235
4 Ofs	$2,481,412	$3,210,080	$9,046,178	$20,541,540
1 Ofs		$642,016	$2,985,239	

a. Analysis assumes that transmission treatment options will be combined with LID components to reach target level of water quality associated with each LID option.

b. Tunnel options in Delaware River Watershed are 15, 18, 21, 23, 28, and 31’.

Table D.6 shows total WTP (in present value terms) in the greater Philadelphia, MA (including Philadelphia City/County) for water quality and ecological improvements under each CSO control option. The benefit estimates shown below reflect total WTP based on the average WTP estimates per household as reported in Table D.5. Total benefits also reflect the aggregation of WTP by households within the City and those outside of the City but within the Philadelphia, MA.

D.3 Sensitivity Analysis

Stratus Consulting conducted a sensitivity analysis to evaluate how WTP per household fluctuates in response to changes in baseline water quality and the level of water quality/habitat improvement (as defined by the WQ_{10}). The results of this analysis (as summarized in Table D.7) indicate that within the reasonable range of assumptions related to these variables, WTP per household does not vary wildly as these inputs change but seem to follow a reasonable progression. WTP is more sensitive to the actual improvement in water quality as opposed to the baseline index value used in the analysis.

Table D.7. Summary of sensitivity analysis of household WTP for water quality improvements

				Household WTP within Philadelphia		Household WTP within Philadelphia, MA	
Scenario	**Baseline WQI**	**Increase in WQI**	**Endpoint WQI**	**Full model**	**Restricted model**	**Full model**	**Restricted model**
1	4.3	2.5	6.8	$11.48	$18.28	$23.39	$35.65
2	4.3	1.9	6.2	$ 9.32	$14.59	$19.00	$28.44
3	4.8	2	6.8	$10.14	$15.84	$20.67	$30.88
4	4.8	1.4	6.2	$7.74	$11.81	$15.78	$23.02
5	5	1.8	6.8	$9.54	$14.75	$19.44	$28.77
6	5	1.2	6.2	$7.02	$10.57	$14.30	$20.61
7	4.3	1.2	5.5	$6.58	$9.99	$13.42	$19.49

Numerous studies have examined water quality issues using a variety of techniques including CV (Hurley et al., 1999; Loomis et al., 2000; Whitehead, 2000; Stumborg et al., 2001; Eisen-Hecht and Kramer, 2002; Brox et al., 2003; Collins et al., 2005). To further validate our results, we reviewed many of these studies in order to obtain a range of current estimates. However, we found very few studies that evaluated water quality improvements within a context similar to the Philadelphia policy case. Very few studies have been conducted in urban areas and most studies include use values, as well as non-use values, in the stated WTP. The estimates for WTP per household reported in Table D.5 therefore reflect the lower end of the range of WTP values reported in most studies. However, we feel that these estimates represent a reasonable WTP per household.

D.4 Omissions, Biases and Uncertainties

In the absence of site-specific data, it was necessary to make a number of assumptions in order to estimate WTP per household for water quality and habitat improvements under the CSO control options. In addition, a number of data omissions and uncertainties surrounding the analysis have been identified throughout this report. Table D.8 provides a summary of these assumptions and uncertainties and their likely impact on total benefits.

Table D.8. Omissions, biases and uncertainties

Assumption/ methodology	Likely impact on net benefits[a]	Comment/explanation
Analysis of improvements in the Schuylkill and Delaware River watersheds include households in the Philadelphia, MA region (i.e., more than City residents).	--	The inclusion of households in Bucks, Chester, Delaware, and Montgomery counties substantially increases total WTP due to (1) the large number of households in these counties, and (2) the high average income of households in these counties, which is correlated with estimated WTP. In contrast, households in the City have a relatively low average income and, thus, a lower estimated WTP for water quality/habitat improvements. No adjustment is made to WTP estimates for these households even though they do not live close by. A distance adjustment would serve to decrease overall benefits.
In the absence of a study specific to the Philadelphia area, we relied on a meta-analysis of WTP for water quality/habitat improvements to estimate total benefits.	U	There are limitations of using the meta-regression model as a benefits transfer tool. For example, results provide very limited evidence about how WTP is related to the spatial characteristics of water quality changes. The meta-regression does not measure how WTP varies with respect to the proportion or amount of waters that are improved or the distance of the water quality changes from populations. This lack of specificity imposes limitations on the precision of policy-relevant benefits transfer, since policies almost always impact waterbodies in spatially non-uniform ways.
There are uncertainties surrounding the baseline WQI and estimated improvements under CSO options.	U	It is difficult to estimate the WQI index improvements in each watershed under the different CSO options. However, as demonstrated through sensitivity analysis (see Table D.7), this is not likely to have a significant impact on total benefits within the reasonable range of WQI estimates. Additionally, we currently assume that the Transmission/Treatment options combined with the LID options, will not achieve water quality and habitat benefits beyond those that would be achieved through the implementation of LID alone. Revising this assumption would serve to increase total benefits.

a. Indicating how addressing the assumption or overcoming the omission would probably impact the analysis, using the following key: + would likely increase net benefits; ++ would increase net benefits significantly; U direction of change in net benefit is uncertain; - would diminish net benefits; -- would diminish net benefits significantly.

E. Wetland Enhancement and Creation

As described in the main body of this report, PWD is currently evaluating a number of LID options for controlling CSO events. A major component of these LID alternatives is an aggressive stream restoration program intended to improve water quality and aquatic habitat within affected streams. As part of the stream restoration program, PWD has planned for the enhancement and creation of a number of wetlands within each of the CSO watersheds.

Long regarded as wastelands, wetlands are now recognized as important features in the landscape that provide numerous beneficial services to people and to fish and wildlife. Some of these services include improved water quality, groundwater recharge, shoreline anchoring, flood control, and habitat for species. In addition, wetlands, like other natural resources such as streams and lakes, can provide positive amenity values for nearby residents. These include open space, enhanced views, increased wildlife, and a buffer against noise and other forms of pollution.

Increased awareness of the value of wetlands has resulted in a number of studies to determine the value of their services. However, determining the value of individual wetlands is difficult because they differ widely and do not all perform the same functions or perform functions equally well. Further, a number of factors can influence how a wetland is valued, including wetland size, location, surrounding environment, characteristics of the surrounding population, and others.

Despite these uncertainties, we provide estimates for the benefits associated with the enhancement and creation of wetlands in the CSO watersheds under the LID CSO options. Our analysis is based on a review of the wetland valuation literature. As shown below, our per-acre benefit estimates represent the lower end of the range from most studies. This is because many of the benefits associated with wetlands are captured in the other analyses described in this report (e.g., recreation and water quality – to some extent).

The following sections provide a summary of Stratus Consulting's approach to assigning a value (or range of benefits estimates) to the wetlands planned for implementation as part of the LID CSO control options. The results of this analysis are also provided.

E.1 Acres of Wetlands Planned

The first step to this analysis was to determine the number of wetland acres that would be restored or created in each of the CSO watersheds. For the Schuylkill and Delaware River Watersheds, this information was provided by PWD and CDM.

To obtain estimates for planned wetland acres in the Cobbs Creek Watershed, we relied on a November 2008 report provided by CDM: "Cobbs Creek: A Gateway to Many Places and to Cleaner Water." This report was completed by CDM in partnership with PWD.

In the absence of specific data for Tacony-Frankford Creek, we determined the number of wetland acres per restored stream mile in Cobbs Creek and applied that ratio to the number of restored stream miles planned for the Tacony-Frankford.

Table E.1 presents the number of wetland acres planned for enhancement/creation in each CSO watershed as part of the LID CSO stream restoration program.

Table E.1. Wetland acres restored and created under LID CSO options

	Tacony-Frankford	Cobbs	Schuylkill	Delaware
Wetland areas in need of vegetative enhancement (acres)	8.4	9.7		26.7
Wetland creation (acres)	26.3	30.3	30.1	61.3
Total acres (may not add due to rounding)	34.8	39.9	30.1	88.0

E.2 Wetland Value

To assign a range of per-acre values to the wetland acres planned for enhancement or creation, we conducted a literature review of wetland valuation studies. Although a number of these studies have been conducted, we did not find any studies that could be directly applied to the Philadelphia policy case. Very few valuation studies have been conducted in urban areas. In addition, many studies include very high per-acre or WTP estimates based on services that will not be provided by the relatively small number of wetland acres planned in Philadelphia (e.g., flood control is not a relevant service anticipated from the wetlands created or enhanced in this study area).

As described below, we therefore relied on estimates from two meta-analyses to obtain an average value per wetland acre. This approach allows us to provide a reasonable, yet conservative estimate for specific wetland functions.

E.2.1 Brief review of wetland valuation literature

The range of estimates associated with wetland valuation studies is remarkable. For example, Woodward and Wui (2001) report per-acre values from 39 different studies ranging from $5 to $1,877 (updated to 2009 USD). In a recent meta-analysis, Borisova-Kidder (2006) estimated per-acre values for wetlands in different regions of the United States ranging from $93 to $1,935 (2009 USD). The meta-analysis incorporated 72 separate observations of wetland value from 33 studies.

A broad range of valuation methodologies has been applied to value wetlands. The method most commonly used in the literature has been to observe the market prices of products related to wetland services and then ascribe the total revenue from the sale of such products as the value of the wetland (Brander et al., 2003). This methodology is not applicable to the situation in Philadelphia, where the wetlands planned for implementation are not expected to provide market-related products to any extent.

The contingent valuation method (CVM) (see Appendix D) has also been widely used. For example, a common method is to use a hypothetical referendum, where households are asked if they would vote in favor of a particular resource protection action, if it cost their household $X. The amount of $X varies across households, so that a demand curve can be traced. From this demand curve, WTP is calculated. WTP values are commonly reported in dollars per year (or per month or other specified period of time) per household.

As expected, different valuation methodologies have been applied to value different wetland services. For example, CVM, hedonic pricing, and the travel cost method (TCM) have been applied to value amenity and recreational values. Replacement cost has largely been used to value the role of wetlands in improving water quality, and the production function approach has been used to value the habitat and nursery services of wetlands. Further, wetland values have been reported in the literature in many different metrics, currencies, and referring to different years (e.g., WTP per household per year, capitalized values, marginal value per acre).

To exemplify the differences and range of value estimates associated with wetland valuation studies, Tables E.2 and E.3 present some observations from the literature.

Table E.2. Examples of values of wetlands

Value (April 2009 USD)	Description	Source
$14,047 per wetland acre	Using a discount rate of 3%, this study estimated that present values per wetland acre are: commercial fishery = $846; trapping = $401; recreation = $181; storm protection = $7,549; total of these values = $8,977/acre (1983$).	Costanza et al., 1989
$74 annually per household	This study examined what Ohio residents were willing to pay for increased protection of wetlands of the Maumee River and Western Lake Erie basins in Ohio.	De Zoysa, 1995
$10–$38 per household per year	This study estimated WTP for wetland preservation benefits in western Kentucky.	Dalecki et al., 1993
$1,392 per acre per year for 30 years ($381,401 per acre over 15 years)	This study estimated economic benefits of wetlands for wastewater treatment use, in terms of savings over conventional wastewater treatment methods.	Breaux et al., 1995
$8 and $27 annually per household	This study estimated WTP for preserving the Clear Creek wetland in western Kentucky.	Whitehead and Bloomquist, 1991
$169–$2,688 per acre lump sum	Values reflect the range of restoring wetlands from croplands, by estimating easement costs, restoration costs, and the present discounted value of perpetual crop production.	Heimlich, 1994
$106–$164 annually per respondent	Values reflect what respondents are willing to pay for protection of wetlands in New England.	Stevens et al., 1995
$56 annually per household	This study is a meta-analysis of 30 studies. The largest mean WTP by wetland function was in terms of flood control ($84), with the smallest for water generation ($20).	Brouwer et al., 1997
$657–$11,830 per acre for residents of the drainage basin, and from $9,463 to $80,380 across residents of the State of Michigan.	The study estimated wetland benefits for Saginaw Bay, Michigan.	Cangelosi et al., 2001
$4–$1,877 per acre annually	The predicted values per acre of single-service wetlands range from $4 for presence of amenities to $1,868 for presence of birdwatching opportunities, with most services having predicted values in the $275–$600 range (see Table E.3 for breakdown of all values).	Woodward and Wui, 2001
$93–$1,935 per wetland acre	This range of values is from a meta-analysis of 72 observations of wetland values from 33 studies. This range represents predicted values for different regions in the United States.	Borisova-Kidder, 2006

Table E.3. Per acre annual values of wetland services

Service	Mean value per acre[a] (April 2009 USD)
Flood	$641
Quality	$681
Quantity	$207
Recreational fishing	$583
Commercial fishing	$1,270
Bird hunting	$114
Bird watching	$1,978
Amenity	$5
Habitat	$498
Storm	$387

a The predicted values are obtained at the means of year and acre variables. It must be emphasized that the values do not represent marginal values and cannot be summed to obtain the value of multiple function wetlands.

Source: Woodward and Wui, 2001.

E.2.2 Applying wetland value estimates to PWD's LID options

As noted above, we relied on two meta-analyses to estimate the value of the wetlands planned for implementation under the LID CSO control options. The meta-analyses allowed us to assign a per-acre value to area of wetlands within each watershed.

The first analysis was conducted in 2006 by Borisova-Kidder as part of a Master's thesis. All of the studies included in this analysis (1) evaluated wetlands within the United States, and (2) allowed for the calculation of wetland value on a per-acre basis. Based on this criteria, the meta-analysis incorporated 72 separate observations of wetland value from 33 studies. The studies include 22 journal articles, seven research reports or academic papers, two chapters in a book, one PhD dissertation, and one Master's thesis.

Rather than apply the results of Borisova-Kidder's meta-regression analysis, which allows for valuation of wetlands with only one primary function (e.g., flood control, recreation), we use the average value of the 72 estimates included in the study. This amounts to about $303.38 per acre in 2009 USD (adjusted from 2003 USD based on the CPI). We applied this value to obtain a lower bound estimate for the value of each new acre of wetlands created. For restored wetlands, we used half of this amount, or $151.69 (2009 USD).

As an upper bound for per-acre value estimates, we relied on the results of Woodward and Wui's (2001) meta-regression analysis of the value of a single service wetland. Woodward and Wui's analysis focuses on two types of variation in wetland values: deviations from the valuation function due to bias or errors in estimation, and variations along the valuation function attributable to different wetland characteristics (e.g., whether it is suitable for flood control, habitat, water quality). These factors were controlled for through a number of variables included in the regression analysis (e.g., through dummy variables for wetland services as well as the valuation method).

The dependent variable in Woodward and Wui's regression model is the natural log of the value per acre of wetland converted to 1990 dollars. In addition to the variables discussed above, the regression analysis includes variables for the year the study was conducted, whether the wetland was a coastal wetland, whether the value was an estimate of producer's surplus, and whether the results had been published. Three additional dummy variables were included in the analysis to indicate whether the data, theory, or econometrics used in the study were deemed highly questionable (see Woodward and Wui, 2001, for more detail).[1]

The results of the meta-analysis are shown in Table E.3. As an upper bound for the value of wetlands in Philadelphia, we applied the value estimate for a single service wetland providing habitat. We chose to use the single service value for habitat because it represents a middle ground for the single service wetlands evaluated and it excludes values that are accounted for in other areas of our analysis (e.g., recreation) or that are not applicable to the Philadelphia policy case (e.g., flood control). As shown in Table E.3, Woodward and Wui estimate that the value of a single service wetland providing habitat amounts to about $498 per acre (2009 USD). To value restored wetlands (as opposed to newly created wetlands), we applied half this amount on a per-acre basis.

Based on the values described above, Table E.4 shows the range of annual benefit estimates for the new and restored wetlands planned under the LID options within each watershed. Present value estimates for the 40-year project period are also provided. These values were obtained based on the stream restoration timeline provided by CDM. The stream restoration program is expected to be fully implemented by 2025.

---

[1] The authors recognize that important variables that determine a wetland's value are omitted from their model. For example, characteristics of the population near a wetland are particularly likely to influence the value placed on the area. However, such data could not be identified in most of the studies included in the analysis and these types of variables were therefore not included in the model. According to the authors, while the absence of these variables no doubt diminishes the explanatory power of the analysis, it need not bias the estimated coefficients if these variables are uncorrelated with the included set (Kennedy, 1986).

Table E.4. Total benefits provided by wetland services under LID options (2009 USD)

	Total annual wetland benefits (range of estimates assuming full program implementation)		Present value wetland benefits (range of estimates)	
Delaware River (tidal wetlands)				
Wetlands restored	$4,055	$6,657	$97,320	$159,751
Wetlands created	$18,585	$30,507	$445,910	$731,964
Total commitment	$22,640	$37,164	**$543,230**	**$891,715**
Schuylkill River (tidal wetlands)				
Wetlands created	$9,134	$14,994	$219,170	$359,769
Total commitment	$9,134	$14,994	**$219,170**	**$359,769**
Cobbs Creek				
Wetlands restored	$1,465	$2,405	$35,157	$57,711
Wetlands created	$9,183	$15,074	$220,335	$361,681
Total commitment	$10,649	$17,480	**$255,492**	**$419,392**
Tacony-Frankford Creek				
Wetlands restored	$1,276	$2,094	$30,608	$50,243
Wetlands created	$7,991	$13,117	$191,728	$314,723
Total commitment	$9,267	$15,211	**$222,336**	**$364,966**

E.3 Omissions, Biases, and Uncertainties

Although the economic literature on wetland valuation is relatively expansive, very few wetland valuation studies have been conducted in urban areas on wetlands similar to those planned for implementation in Philadelphia. We therefore relied on two meta-analyses reporting wetland value on a per-acre basis. Table E.5 identifies the key issues and uncertainties associated with this approach.

Table E.5. Omissions, biases, and uncertainties

Assumption/methodology	Likely impact on net benefits[a]	Comment/explanation
Wetland valuation studies are remarkably diverse in terms of the values obtained, the wetlands evaluated, and the characteristics of the studies.	U	Although we use an average estimate, as well as an estimate derived through meta-regression analysis, the characteristics of the wetlands in Philadelphia may be quite different than those of wetlands included in the base estimates. This could serve to increase or decrease overall benefits depending on the nature of these characteristics, however, we feel our estimates provide a reasonable range of benefits per acre given that they are intended to exclude the more "high-dollar" benefits associated with wetland services such as recreation and flood control.
The wetlands planned under the LID CSO control options are smaller in size than wetlands evaluated in most studies (and are not contiguous).	U	It is difficult to determine how this might impact overall benefits. On one hand, the scarcity of wetlands in the City may result in a higher value associated with them. On the other hand, larger wetlands can often provide additional ecosystem benefits that cannot be supported by wetlands of smaller size.
Our benefits transfer does not take into account demographic characteristics of surrounding communities.	-	Several of the wetland valuation studies included in the two meta-analyses are based on household WTP estimates, which are almost always correlated with average household income of the study population. Given the relatively low average income of households in Philadelphia (e.g., compared to the national average), the inclusion of demographic characteristics would likely slightly decrease the overall benefits.

a. Indicating how addressing the assumption or overcoming the omission would probably impact the analysis, using the following key: + would likely increase net benefits; ++ would increase net benefits significantly; U direction of change in net benefit is uncertain; - would diminish net benefits; -- would diminish net benefits significantly.

F. Poverty Reduction Benefits of Local Green Infrastructure Jobs

Benefit-cost analysis of public infrastructure investment projects does not traditionally consider job creation as a category of project benefits. Although creating jobs is universally perceived as beneficial, it is reasoned that jobs created by public investment are no more beneficial than jobs created by the private sector.

A public investment project must be funded with revenues drawn from the private sector – in this case, from PWD rate revenues collected from customers. If these funds were instead allowed to remain in private hands and be used for other private purposes, it is argued that an equivalent level of jobs would be supported. Stated another way, any jobs created by public investment are generally created at the expense of jobs in the private sector, so there is no net benefit in the overall level of employment arising from public expenditures (instead, under normal conditions, there is simply a transfer of employment across locations and sectors).

The only exception to this reasoning is the special case of a severe economic downturn in which private demand is so depressed that job creation is more assured through public expenditures. Despite the fact that recent economic events actually reflect this special case, the approach adopted here does not attempt to evaluate benefits of job creation in that context. Instead, we examine the value of specific types of job opportunities created within a certain socioeconomic niche.

In the popular media, “green jobs” or “green collar jobs” are described as encompassing many diverse job categories that have a bearing on environmental improvement in one way or another. In contrast, this analysis focuses only on the unique character of jobs created in the construction and maintenance of green infrastructure systems installed for purposes of urban stormwater management as part of an aggressive campaign to transform urban landscapes and neighborhoods. “Green infrastructure jobs” as defined here are essentially landscaping jobs, suitable for unskilled laborers and requiring no experience. There are significant social benefits that result from creating these specific types of jobs in an urban setting as part of a greening campaign. Such jobs can serve as a crucial stepping stone out of poverty for otherwise unemployed persons who reside in the very same neighborhoods in which the greening is targeted. The stabilizing and transforming effects of the green infrastructure on these neighborhoods reinforces and supports the benefits of providing employment to this population that is outside the labor force and trapped in poverty.

Traditional infrastructure – consisting of multi-billion dollar concrete tunnels – produces no such benefits. When the large construction contractors engage in large-scale traditional infrastructure projects, they have pre-negotiated labor agreements with all of the appropriate trade unions that enable them to expedite the project with no obstacles to obtaining the required labor when and where it is needed. For the most part, traditional stormwater infrastructure requires skilled laborers such as those represented by the trade unions. As implied by their status as union members, these are also people who are already in the labor force. When a city water department implements a traditional infrastructure project in this manner, the net effect is just to bid these already employed workers away from other construction projects.

This appendix presents some additional background on the connections between green infrastructure and poverty. The methodology employed in evaluating the poverty reduction benefits of "green infrastructure jobs" is described, and results are summarized and discussed.

F.1 Urban Poverty and Green Infrastructure

Most large older cities have been faced with long-standing problems in coping with poverty in their midst. Philadelphia is a typical example, as made clear in results of the U.S. Census Bureau's 2005–2007 American Community Survey (U.S. Census Bureau, 2008).

- Median household income in 2007 was $34,767 in Philadelphia, compared to $50,007 for the nation as a whole – 30% less household income at the median.
- Using a household income of $25,000 per year as a measure of poverty status, there were 212,093 households below this level in Philadelphia in 2007 – 38% of all households in the City. Nationally, the proportion of households with incomes below $25,000 per year was 25%.
- In Philadelphia, 57.8% of people over age 16 were in the labor force, compared to 64.7% for the nation as a whole.

Cities incur many types of costs in coping with poverty. Many types of assistance programs are supported to help people in poverty. But one of the greatest expenditure categories is unfortunately coping with crime, for which the poverty trap is a major causative factor. In this regard, Philadelphia is incurring relatively high costs (Heller, 2008).

- Philadelphia has the highest incarceration rate of any big U.S. city. The recidivism rate is 80% and the annual cost per inmate is among the highest at $30,000 per year.
- The City spends about $1 billion per year on the criminal justice system, which is about a quarter of the City budget.

The growing movement to transform urban landscapes with green infrastructure in the name of stormwater management and energy conservation holds the promise of a number of spillover benefits in reducing poverty. The installation and maintenance of green infrastructure requires large amounts of unskilled labor in what is essentially landscaping work. Large amounts of the work is to be performed in neighborhoods where many unemployed and relatively unskilled people live in poverty. Moreover, the transforming effect of green infrastructure on these neighborhoods can provide a foundation to stabilize troubled communities, reduce crime rates, and set a course for further progress against poverty. In the words of a leading green infrastructure activist, "If you give opportunities to the young men and women of this community to support themselves and their families, the need to build a jail goes away" (Carter, 2007).

Proof of these broader spillover benefits of green infrastructure is provided in the experience of the "Weed and Seed" program of the Community Capacity Development Office of the U.S. Department of Justice (U.S. DOJ, 2009). Launched in 2003, this program is now being demonstrated in 300 sites across the country. The strategy involves a two-pronged approach: law enforcement agencies and prosecutors cooperate in "weeding out" violent criminals and drug abusers, and public agencies and community-based private organizations collaborate to "seed" much-needed human services, including prevention, intervention, treatment, and neighborhood restoration programs. Through coordinated use of federal, state, local, and private-sector resources, neighborhood restoration strategies focus on economic development, employment opportunities for residents, and improvements to the housing stock and physical environment of the neighborhood. In the period between 2003 and 2006, major crimes decreased 2% within Weed and Seed areas (Baker, 2009).

F.2 Estimating Poverty Reduction Benefits of "Green Infrastructure Jobs"

The methodology for estimating benefits of "green infrastructure jobs" is based on the expectation that providing such jobs to unskilled residents within the targeted neighborhoods will provide these individuals with an important stepping stone on the path out of poverty which would not otherwise exist. The presence of the green infrastructure in these neighborhoods will enhance the opportunity for community stabilization and recovery that can further support progress against poverty.

As discussed above, society spends large amounts every year in its efforts to cope with the effects of poverty. If PWD chooses an LID approach to CSO control providing "green infrastructure jobs" to unskilled and unemployed residents who are currently living in poverty, they will be less impoverished and impose a lower level of societal costs. If PWD chooses a traditional infrastructure approach, the jobs created will be much less likely to be filled by unskilled workers who are currently not in the workforce, yielding no benefits in reducing the societal cost of poverty.

The benefits of "green infrastructure jobs" are estimated by multiplying the total number of jobs created by an assumed per-employee amount of societal costs that will be avoided due to the altered poverty status of the new employee. The number of labor hours required for construction and maintenance of the LID alternatives was estimated as part of the engineering cost analysis. It is further assumed that one-quarter of these hours will be supervisory positions and therefore less likely to result in the hiring of unskilled and otherwise unemployed people. The avoided societal cost of poverty per non-supervisory employee used to value this benefit is estimated to be about $10,000 per year. This figure is derived from a review of different sources, as described below.

A 1993 analysis produced by the Institute for the Study of Civic Values reviewed local budget data sources for Philadelphia and produced an estimate of the total public cost of poverty shown in Table F.1. This estimate seems low because it does not include an element relating to coping with crime.

Table F.1. Estimate of the cost of poverty in Philadelphia

Element	Estimated annual cost (1992 USD millions)
Income, Medicaid, food stamps	1,000
Health and social services	400
Public housing	150
Community development	100
Homeless expenditure	15
Education	200
Total	**2,000**

Source: Schwartz, 1993.

A 1998 analysis by Wharton researchers also employed a bottom-up approach to identify direct poverty related expenditures in the City's 1996 budget amounting to about a billion dollars (Summers and Jakubowski, 1996). This study left out additional costs of crime and education, although acknowledging their potential significance. It also omitted direct expenditures by the Federal government that were estimated to be on the order of another billion dollars by Schwartz.

In a landmark study in the mid-1990s, econometric research was applied to a survey of U.S. cities and demonstrated statistically that a high incidence of urban poverty not only increases direct poverty expenditures of city governments, but also significantly increases the cost of many other seemingly unrelated city services (Pack, 1998). Applying the approaches of Summers and Jakubowski as well as those of Pack to the Philadelphia 2009 city budget, implies that as much as $3.5 billion of the $4 billion total is attributable to poverty. That total still omits additional direct poverty related outlays in Philadelphia by the Federal government.

A top-down national analysis of the "avoidable costs of poverty" was developed in a study prepared for the Entergy Corporation (Oppenheim and MacGregor, 2006), yielding the estimates shown in Table F.2.

Table F.2. National estimate of the avoidable costs of poverty

Element	**Description**	**Estimated annual cost (2005 USD millions)**
Crime	Cost of criminal activity, including property losses, costs of the judicial and correctional system, and security costs.	660,791
Health	Costs of health care, including costs that are preventable by improving health care and costs of low-income health care that are spread through society.	335,841
Unemployment/ underemployment	Costs of unemployment and underemployment, including unemployment compensation, job training, and the multiplier effects of lost economic activity.	222,492
Anti-poverty investments	Costs of current anti-poverty investments, including costs for social services, elderly services, income supports, affordable housing, food, education, energy and utility supports, and block grants for community services and community development.	270,053
Total		**1,489,178**

Source: Oppenheim and MacGregor, 2006.

Another top-down analysis developed by the Center for American Progress (Holzer et al., 2007) produced a national estimate of the cost of poverty from a different perspective. Their approach was to compute the costs to society resulting from having children grow up in poverty. They focused on the individual as a means of capturing both lost economic productivity and additional costs associated with higher crime and poorer health later in life. Although this is a different approach to the analysis, it covers many of the same impacts in arriving at an estimate of the total cost of poverty. They summarize their results in terms of the net impact on the U.S. Gross Domestic Product (GDP), as shown in Table F.3.

Table F.3. Economic costs of poverty in the United States

Element	Estimated annual cost (% of GDP)
Foregone earnings	1.3
Crime	1.3
Health	1.2
Total	**3.8**

Source: Holzer et al., 2007.

Their indicated percentage of GDP attributable to poverty (3.8%) translates into a national cost estimate of about $500 billion per year which is only about one-third the national cost estimate developed in the previously discussed study for the Entergy Corporation. The differences lie in the approaches used to assign part of the cost of crime to poverty and also in the lack of accounting for the costs of social assistance programs in the work by the Center for American Progress which the Entergy study showed to be 18% of the total. In addition, the authors of the Center for American Progress study stressed that it was their very deliberate analytical objective to produce a lower bound estimate of the cost of poverty. In contrast to their results, another interesting study of the cost of poverty in Ontario (Laurie, 2008) produced an estimate that poverty expenditures accounted for between 5.5 and 6.6% of the provincial GDP.

The Philadelphia region (including the suburbs) is the fourth largest urban area in the United States in terms of GDP (PricewaterhouseCoopers, 2006). Apportioning the $500 billion national estimate from the Center for American Progress study on the basis of the Philadelphia share of national GDP yields an estimate of the cost of poverty to the region of $12 billion per year. Apportioning the $500 billion instead on the basis of the share of the nation's low-income households that lie within the City yields an estimate of about $3 billion per year. If a higher percentage of GDP (e.g., ~6% found in Ontario) is applied, the Philadelphia share of the $500 billion would be closer to $5 billion per year.

This latter range of "top-down" estimates is similar to the $2.0 to $3.5 billion per year range derived from the several "bottom-up" estimates for Philadelphia described earlier. However, the bottom-up studies mostly omitted direct Federal expenditures. The Entergy study described above is judged to provide the most complete top-down estimate of the total annual cost of poverty in the United States. Apportioning their $1.5 trillion per year national estimate on the basis of the share of the nation's low-income households that lie within the City yields an estimate of about $9 billion per year.

In estimating the spillover benefits of "green collar jobs" in reducing the costs of poverty, it is assumed that currently unemployed people living in poverty would be hired into the unskilled, non-supervisory positions. By the latest Census figures, there are about 227,500 such people residing in the City. If the $12 billion per year estimate of the cost of poverty is correct, it implies an annual cost of $57,000 per unemployed person in Philadelphia. An estimate of $9 billion per year implies about $45,000 per unemployed person per year. An estimate of $5 billion per year implies $25,000 per unemployed person per year. An estimate of $3 billion per year implies $15,000 per unemployed person per year.

The benefit assumed here is $10,000 per year in offsets to all the societal costs of coping with poverty. Hence an estimated savings of $10,000 per year is multiplied times the number of work years in "green infrastructure jobs" provided by each LID option.

F.3 Results

Table F.4 presents a summary of the total number of work years in "green infrastructure jobs" provided by each of the LID options in each watershed over the 40-year implementation period. Table F.5 presents a similar summary of the total present value (over 40 years) of the avoided societal cost of poverty attributable to the provision of these "green infrastructure jobs."

Table F.4. Total work years in "green infrastructure jobs" provided by LID alternatives

LID %	Delaware	Schuylkill	Cobbs	Tacony	Totals
25	3,341	1,607	476	1,490	**6,914**
50	7,379	3,535	1,050	3,303	**15,266**
75	11,307	5,409	1,608	5,040	**23,364**
100	14,778	7,081	2,105	6,590	**30,554**

Table F.5. Total present value (2009 USD millions) of "green infrastructure jobs" provided by LID alternatives

LID %	Delaware	Schuylkill	Cobbs	Tacony	Totals
25	28	13	4	12	**57**
50	60	29	9	27	**125**
75	93	44	13	41	**192**
100	121	58	17	54	**251**

F.4 Omissions, Biases, and Uncertainties

The analysis of poverty reduction benefits of "green infrastructure jobs" is straightforward; multiplying the number of work years provided times the estimated amount of avoided social costs. The basis for the estimate of the societal costs of poverty is the largest area of uncertainty in this procedure, as described further in Table F.6.

Table F.6. Omissions, biases, and uncertainties affecting valuation of "green infrastructure jobs"

Assumption/ methodology	Likely impact on net benefits[a]	Comment/explanation
It is assumed that LID options can be implemented in a manner that makes most non-supervisory "green infrastructure jobs" available to the target population.	-	If it is not possible to make many of the "green infrastructure jobs" available to the target population of unskilled and otherwise unemployed people living in poverty, then the spillover benefits of poverty reduction will be correspondingly reduced. We have assumed 75% of the job hours can be targeted to the relevant population.
The estimated value of the societal costs of poverty is supported by only a half dozen studies that were designed for different purposes.	U	Despite extensive research on poverty, the total social cost of poverty is not as well studied as a concept. We found only a few studies. Although they seem to bound a roughly comparable overall order of magnitude, confidence would be enhanced if there were a few more estimates to draw from.
It is assumed that the societal costs of poverty are reduced by $10,00 if a targeted recipient obtains a "green infrastructure job."	U	There is evidence that an unskilled job, alone, is inadequate to boost a person out of poverty. A skilled job is required. Thus, "green infrastructure jobs" are just a stepping stone on the path out of poverty. We assumed a $10,000 reduction in the avoided societal costs of coping with poverty.

a. Indicating how addressing the assumption or overcoming the omission would probably impact the analysis, using the following key: + would probably increase net benefits; ++ would increase net benefits significantly; U direction of change in net benefit is uncertain; - would diminish net benefits; -- would diminish net benefits significantly.

G. Energy Usage and Related Changes in Carbon and Other Emissions

This appendix provides a summary of Stratus Consulting's approach for estimating the net energy use, and associated external costs, of the CSO control options currently being evaluated by the PWD. As described below, we have identified several key categories related to energy use (and associated emissions) for quantitative assessment, including:

- Electricity and natural gas savings due to cooling effect under the LID CSO control options
- "Wasted" fuel consumed by vehicles stuck in traffic delays caused by construction and maintenance activities
- Resulting energy costs and/or cost savings
- Carbon emissions/offsets associated with energy use (including fuel used by construction and maintenance vehicles) and/or savings under each option
- Estimated social value of carbon emissions and/or savings
- NO_x and SO_2 emissions/offsets, and associated health costs, related to energy use and/or savings under each option.

The following sections identify key inputs and assumptions used in our analysis and describe the general methodology employed to evaluate energy-related benefits and external costs. Final results for each CSO watershed are also presented.

G.1 Key Inputs and Assumptions

To estimate the energy-related benefits and external costs under each CSO control option, we employed standard industry methodology. In the absence of specific data, it was also necessary to make a number of assumptions based on our understanding of the different program components. Key inputs and assumptions are detailed below. Individual assumptions related to specific program components are provided in subsequent sections.

- **Energy costs.** To estimate the monetary benefits of electricity and natural gas savings under the LID options, we used PECO estimated electricity rates and natural gas rates provided by CDM ($0.10/kWh and $0.0135/MM Btu, respectively). The electricity rates used in this analysis are relatively conservative. Section G.4.2 discusses how our overall results change as electricity rates are increased. To estimate the cost of additional fuel consumed in construction -related traffic delays, we assumed a cost of $2.50 per gallon of gasoline.

- **Energy-related emissions factors.** We evaluate emissions of CO_2, SO_2, and NO_x associated with net energy use under each CSO option. To do this, we use average air pollution emission factors for the State of Pennsylvania's electricity sector [in terms of tons of emissions per megawatt hour (MWh); EIA, 2007]. When the specific generating plants cannot be determined for an electricity grid like Philadelphia's, these estimated emissions are used at the state or regional level. The EIA estimates that Pennsylvania's CO_2 emission factor is 0.574 MT/MWh. SO_2 and NO_x factors at Pennsylvania power plants are estimated at 0.0041 and 0.00076 MT/MWh, respectively. To estimate emissions related to the use of natural gas, we use the CO_2 emission factor of 0.0527 MT of CO_2/MM Btu (EIA, 2007).

- **Social cost of carbon**. Another input used for this analysis is the dollar value assigned to GHG emissions, measured in CO_2e. The social cost of carbon is estimated as the aggregate net economic value of damages from climate change across the globe, and is expressed in terms of future net benefits and costs that are discounted to the present (IPCC, 2007). The most recent IPCC Assessment Report contained peer-reviewed estimates of the social cost of carbon. The IPCC found an average value of $12 per MT CO_2, but added that the range around this mean is large. For example, in a survey of 100 estimates, the values ran from USD $-3 per MT CO_2 up to $95 per MT CO_2. The often-cited Stern Review on the Economics of Climate Change estimates a social cost of carbon at $85 per MT CO_2 (Stern, 2006).

  For this analysis, the IPCC's average value of $12 was used when calculating social benefits and costs, which produces conservative estimates for the benefits and costs associated with GHG emissions (a conservative estimate). To determine total costs over the 40-year project period, we escalated the social cost of carbon by 2.4% per year,[1] above the general rate of inflation.

- **Cooling effect and carbon sinks of green infrastructure**. To estimate the benefits associated with the cooling effect and carbon sinks under the LID options, we relied on previous studies by the U.S. Department of Agriculture (USDA) Forest Service. The Urban Forest Effects Model (UFORE) provides estimates of energy savings via shading

---

[1] The United Kingdom has established an official estimate of the social cost of carbon for use in many of its project evaluations and models the growth rate of the cost at 2.4% per year.

of trees and insulation by green roofs. It also provides carbon storage and sequestration data by species of tree. For our research, we used one type of tree of average size and average storage capabilities for all the cooling and carbon sinks. We also assumed that 30% of trees planted would be close enough to buildings to provide shading. Our results can easily be adjusted for specific species of trees.

- **Engineering estimates versus external costs**. The amount of energy required for excavation and other construction activities serves as a key input into our analysis. However, the costs associated with this energy use (i.e., electricity costs and the cost of fuel for construction and maintenance vehicles) are not included in our estimate of total benefits and external costs. The cost of energy used for these purposes is assumed to be included in the engineering cost estimates for each CSO option. However, we estimate and include the external costs associated with the energy consumption [e.g., CO_2, sulfur oxides (SO_x), and NO_x emissions and costs].

G.2 Methods

G.2.1 Estimating the external costs of traditional infrastructure CSO control options

We first estimated total energy use (electric and gasoline) under each of the non-LID CSO control options. Total electrical energy use was calculated based on power requirements for excavation, building, equipment, and pumping, as provided by CDM. Total fuel use was determined based on the estimated number of vehicle miles traveled (VMT) by construction and maintenance vehicles throughout the course of the project. Total fuel use also took into account the additional fuel used by individuals traveling on Philadelphia roadways as a result of construction-related traffic delays (see Appendix I).

Based on estimated total energy use, we were able to estimate total NO_x, SO_2, and carbon emissions (and associated monetary costs) under each CSO option. The individual components of our analysis are described below.

Emissions associated with energy used for excavation, building, equipment, and pumping. CDM provided estimates of the power needed for excavation, building, equipment, and pumping under each of the traditional infrastructure CSO control option (i.e., tunneling, plant expansion, and satellite treatment). We used these inputs to estimate total emissions generated under each option.

To determine total carbon emissions, we used average air pollution emission factors for the State of Pennsylvania's electricity sector (0.574 MT of CO_2/MWh) (EIA, 2007). We applied these estimates to total power use required under each option. The monetary cost of these emissions was then estimated based on IPCC's average estimate for the social cost of carbon ($12/MT).

In addition to carbon emissions, we also evaluated the SO_x and NO_x emissions associated with electricity use under the different CSO control options. This analysis was also based on average air pollution emission factors for Pennsylvania power plants (EIA, 2007). We applied these emission factors (0.00414 MT SO_2/MWh and 0.000766 MT NO_x/MWh) to total electricity use under each option.

We then estimated the human health costs of SO_2 and NO_x emissions based on EPA-generated national averages. These estimates reflect the change in health risks, and associated values, of a typical ton of emissions for each pollutant (U.S. EPA, 2008b). They do not reflect only benefits in the local area, but take into account long-range transport of the pollution (emissions in one location spread over a wide area).

EPA estimates that the health-related costs of SO_x emissions from electricity-generating sources ranges from $25,234 to $53,985 per ton. For NO_x emissions, these costs range from $2,681 to $5,733 per ton. To determine total costs of SO_x and NO_x under the CSO control options, we applied the midpoints of these estimates to total emissions.

It should be noted that the power requirements provided by CDM for excavation, building, and equipment were provided as totals over the 40-year period, and the power requirements for pumping were provided as annual estimates. It is difficult to estimate energy-related costs far into the future due to a number of significant variables. These include a change in the generation mix for electricity, a change in retail energy prices, changes in both the social costs of carbon emissions and air pollution, and the change in the price of carbon emissions under a federal or regional carbon policy.

Emissions associated with fuel used by heavy construction vehicles. To evaluate fuel use and emissions associated with construction activities, we relied on CDM's estimate for the number of heavy-duty truck trips under each CSO control option. We estimated the total gallons of diesel fuel consumed by heavy-duty trucks based on an average distance of 20 miles per truck trip and an average mile per gallon of 6.6 (U.S. EPA, 2007).

We then calculated CO_2, SO_x, and NO_x emissions associated with heavy-duty vehicles based on emission factors for heavy-duty trucks (lbs CO_2/mile) as determined by the South Coast Air Quality Management District (SCAQMD, 2007). The social cost of carbon was used to measure the costs of carbon emissions from these truck trips. For SO_x and NO_x emissions, we applied the midpoint of EPA's estimates for health-related costs of SO_2 and NO_x from mobile sources. EPA's estimates range from $13,200 to $28,264 and $4,357 to $9,350 for SO_x and NO_x, respectively.

Emissions associated with fuel use by concrete delivery trucks. To determine the external costs associated with heavy-duty trucks used to deliver concrete materials, we used the same approach mentioned above. Because the number of concrete trucks under each option was not an input provided by CDM, we assumed the number of these trucks to equal half of the number of heavy-duty trucks used for excavation and construction.

Concrete manufacturing. One of the most energy-intensive industrial processes in the world is the production of cement, a key ingredient in the large amounts of concrete used in construction of traditional CSO infrastructure. The cement manufacturing process uses both electricity and a significant amount of fossil fuels directly in a heating process. While the direct energy costs of cement manufacturing do not affect this benefit-cost analysis, the carbon and air pollution costs that result do play a role. We were able to analyze the energy used and resulting carbon emissions and air pollution that result from this process.

First, using the total cubic feet of concrete (an input provided by CDM), we estimated the amount of cement used for each non-LID scenario based on standard concrete-cement conversion methods. We estimate the energy and emissions associated with the cement manufacturing process for each of the non-LID scenarios based on standard energy/emissions factors (Worrell and Galitsky, 2004, and as described above).

Traffic disruption. Under all of the CSO control options, construction and maintenance activities will cause traffic delays on Philadelphia roadways. There is an increase in fuel use associated with these delays due to increased time spent idling and traveling at slower speeds. The methods used to estimate additional fuel used as a result of construction-related delays are detailed in Appendix I. However, actual fuel use and associated costs are reported in the energy use/cost category in Tables G.1 through G.8.

We used standard emissions conversion factors, as described above, to estimate tons of CO_2, SO_x, and NO_x emitted into the atmosphere as a result of this additional fuel use.

G.2.2 Estimating the external costs and benefits of green infrastructure

Emissions associated with energy used for excavation. Similar to the traditional infrastructure options, the LID options will require large amounts of power (electricity) to excavate areas for LID coverage. This input was provided by CDM. We use the same methods as described above to estimate the external costs of emissions associated with this energy use.

Emissions associated with fuel used by construction and operation vehicles. For the development of green infrastructure, heavy-duty vehicles will be needed during the construction process. For the LID options, we used the same techniques and assumptions described above to estimate emissions associated with these vehicles. As part of this analysis, we also included the emissions generated by operations and maintenance vehicles. For these trucks, we assume an average truck trip of 15 miles and an average mile per gallon of 20.2.

Table G.1. Energy-related benefits and external costs of CSO control options in the Tacony-Frankford Creek Watershed, over 40-year project period (present value, 2009 USD)

	Energy savings (costs)	Air quality health-related improvements (costs)	Carbon footprint reduction benefit (cost of increase)
LID options			
25% LID	$2,994,995	$4,380,801	$2,022,051

Energy savings and emissions offsets: trees. When properly placed, trees can affect energy consumption by shading buildings, providing evaporative cooling, and by blocking winter winds (USDA, 2007). Using data obtained from the USDA, we calculated the energy savings from trees based on average heating and cooling per building. This allowed us to estimate savings in energy costs for the entire community of shaded buildings. We also estimated the reduction in emissions (offsets) associated with these savings.

Energy savings and emissions offsets: green roofs. Green roofs provide insulation and shade for buildings, thus reducing their need for both heating and cooling costs. Using energy savings estimates confirmed by two separate studies, we quantified the energy savings associated with green roofs under each LID CSO control option. To estimate electricity savings (from reduced cooling), we applied an average savings of 0.39 kWh/sq ft of green roof. For natural gas savings (from reduced heating), we used an estimate of 123 MM Btu per building (Doshi, 2005; Green Roofs for Healthy Cities, Undated).

Green sinks – trees. Trees provide a valuable resource for green infrastructure projects by removing (sequestering) CO_2. Trees therefore act as a carbon sink by removing the carbon and storing it as cellulose in their trunk, branches, leaves, and roots while releasing oxygen back into the air. The USDA's UFORE model estimates the CO_2 storage capacity for many species of trees. For our analysis, we used the storage capacity associated with the average-sized tree from the UFORE model as a model for all trees planted under the LID options. We estimated carbon stored simply by multiplying the storage capacity of an average tree according to the USDA by the number of total trees planted.

Green sinks – green roof and bioretention. Green roofs and vegetated bioretention areas also store large amounts of CO_2. The United Kingdom's Department of Environment, Food and Rural Affairs (DEFRA) provides an estimate of sequestered CO_2 per 1,000 square meters (U.K. DEFRA, 2007). Using this rule of thumb, we calculated CO_2 sinks based on the total estimated new green acreage under each LID scenario.

G.3 Summary of Results

Tables G.1 through G.8 show the energy-related benefits and external costs for the different CSO control options in each watershed. Tables G.1 through G.4 show results in physical units (e.g., tons of emissions, energy savings). Tables G.5 through G.8 show the monetary values tied to the physical units in Tables G.1 through G.4. As shown, the largest benefits and costs (in terms of monetary value) under each option can generally be attributed to a reduction of SO_x and NO_x emissions (or net emissions). Under some of the LID options, reductions in NO_x emissions do not completely offset the NO_x emissions associated with energy use (thus, there are positive net emissions).

G.4 Uncertainties and Sensitivity Analysis

G.4.1 Omissions, biases, and uncertainties

To estimate energy savings, costs, and emissions under the different CSO control options, it was necessary to make a number of assumptions. In addition, a number of data omissions and uncertainties surrounding the analysis have been identified throughout this report. Table G.9 provides a summary of these assumptions and uncertainties and their likely impact on the results of our analysis.

Table G.9. Omissions, biases, and uncertainties

Assumption/ methodology	Likely impact on net benefits[a]	Comment/explanation
Estimates of the social cost of carbon are wide ranging and uncertain	+	The IPCC evaluated a range of cost estimates and found an average of \$12/MT CO_2. Many recent estimates of the social cost of carbon are found in the upper bound of IPCC's range, including the Stern estimate of \$85. Section G.4.2 shows the results of a sensitivity analysis in which a higher social cost of carbon of \$48 is used.
Electricity prices are conservative	+	A federal climate policy could increase fossil fuel based energy prices at a much higher rate than the estimates provided in this study. However, an economy-wide policy that would limit GHG emissions is expected, but not a certainty. Section G.4.2 shows the results of a sensitivity analysis in which higher electricity rates are used.
GHG emissions associated with electricity generation in Pennsylvania vary	U	GHG emission factors from power plants vary from plant to plant and from region to region. The actual emissions from the CSO options may be higher or lower than the average emissions factor for the State of Pennsylvania used in this analysis. The emissions factors used in this analysis are the best available option.
Transportation fuel costs	U	An average cost of gasoline and diesel fuel were chosen based on recent prices and adjusted to rise with inflation. It should be noted that fuel prices are volatile and many experts expect fuel prices will rise faster than inflation during the life of this project life. These increases would be expected to be even larger under a federal climate policy. However, technology gains in vehicle efficiency could ease any price increases.
Reduction of energy usage from the planting of trees	-	The blocking of wind in the winter and the shading of buildings during summertime depend on the type of tree planted and the distance and direction from the building. This analysis assumed an estimate of 30% of total trees planted were properly placed to shade during the summer and block wind during the winter. The analysis may be sensitive to this assumption. Benefits would be decreased if 30% is too high.

Table G.9. Omissions, biases, and uncertainties (cont.)

Assumption/ methodology	Likely impact on net benefits[a]	Comment/explanation
Carbon sequestration from trees are based on USDA's UFORE analysis of the benefits of Philadelphia's urban forest	U	Different species of trees at different stages of life are able to sequester carbon in varying amounts. This analysis used an average sized tree to calculate total carbon sequestration. A tree growth model was used to simulate the different stages of sequestration as the trees grow over time.

a. Indicating how addressing the assumption or overcoming the omission would probably impact the analysis, using the following key: + would likely increase net benefits; ++ would increase net benefits significantly; U direction of change in net benefit is uncertain; - would diminish net benefits; -- would diminish net benefits significantly.

G.4.2 Sensitivity analysis

We conducted a sensitivity analysis to evaluate the effect of electricity rates and the social cost of carbon on our overall results. This sensitivity analysis compares the benefits and external costs of two CSO control options (50% LID and 30' Tunnel) when a higher social cost of carbon (\$48/MT CO_2) versus the IPCC's average (\$12/MT CO_2) is used. Our analysis also evaluates the effect on energy savings under the LID options if a doubling in the price of electricity is assumed. Table G.10 shows the results of this analysis.

Table G.10. Sensitivity analysis for city-wide present value benefits of key CSO options: Cumulative through 2049

	50% LID option	30' Tunnel option
Social cost of carbon increase	Total benefits minus external costs	
\$12	\$2,846.4	\$122.0
\$48	\$2,910.0	\$104.3
Percent change in overall results	2.23%	-14.53%
Electricity rate increase resulting from a enacted federal climate policy	Energy savings (usage)	
\$0.1 kWh	\$2,846.4	\$122.0
\$0.2 kWh	\$2,874.9	\$122.0
Percent change in overall results	1.00%	0%

a. Our external cost analysis does not include higher electricity costs associated with the engineering costs for the 30' Tunnel option, but it is assumed that electricity costs would double in this scenario as well. This would be reflected in engineering cost estimates for this option.

H. Air Quality Pollutant Removal from Added Vegetation

The LID CSO control options currently being evaluated by the PWD would provide (and enhance) recreational amenities within PWD's CSO watersheds. Under the LID options, PWD plans to substantially increase vegetated acreage (including "treed" acreage) throughout the City. Expanding the amount of trees and vegetated acres in Philadelphia will help improve Philadelphia's air quality by removing air pollutants from the atmosphere. Conventional air pollution is a persistent problem for most cities in the United States. Even after decades of concerted federal and state efforts to improve air quality, the majority of the U.S. population lives in areas with ambient air quality above the National Ambient Air Quality Standards (NAAQS). The two air pollutants most damaging to human health are ozone (a gaseous pollutant that is a primary ingredient of smog) and fine particulate matter ($PM_{2.5}$, aerosol particles less than 2.5 microns in diameter, commonly referred to as soot).

The following sections outline Stratus Consulting's methods for estimating the health benefits associated with the improved air quality due to increasing the number of trees that will be planted under the LID options for CSO control. Estimates of total health benefits deriving from trees planted within each watershed are also provided. Additional benefits of air quality relating to avoiding certain air emissions (such as sulfur dioxide and hydrocarbons) related to construction and changes in vehicle traffic are presented in Appendix G.

H.1 Impacts of Trees on Ozone and Particulate Matter

Trees and shrubs have an important effect on reducing important air pollutants including ozone and particulate matter. In addition to other benefits, trees reduce air pollution concentrations. Increased plantings of some tree species (especially trees that naturally emit low levels of biogenic volatile organic compounds) can be a viable component of an air pollution control strategy because trees remove small but significant amounts of ozone and particulate matter from the ambient air. Trees thus can help reduce the air pollution exposure levels of the local population, and help urban areas meet air quality goals.

Ozone (and other gaseous pollutants) are taken into the leaves of trees through stomata respiration. Once inside the leaf, ozone diffuses into intercellular spaces and reacts with inner-leaf surfaces (Nowak et al., 2006). Additional ozone and particulate matter are removed from the ambient air by direct interaction with the leaf surface. Although some particles are absorbed into the leaves, most particles are retained on the surface of the leaf, with 50% assumed to be re-

released to the atmosphere. The remainder is washed off during rain events, or deposited during autumn leaf drop, effectively removing the particulate matter from the air.

A U.S. Forest Service report on the benefits of the Philadelphia urban forests (USDA, 2007) estimates that the existing forest cover in Philadelphia removes 0.33% of the annual mean ozone, and 0.38% of the annual mean particulate matter (PM_{10}), from Philadelphia's air. This removal is from the entire amount of trees and shrubs in Philadelphia. There are an estimated 2.1 million trees covering 15.7% of the land area of Philadelphia; an additional 5.9% of the land area is covered by shrubs.

These Forest Service estimates of the impact of Philadelphia's trees are used as the basis for the air pollution-related health analysis, and the subsequent economic benefit analysis, reported in this appendix. This analysis assumes that $PM_{2.5}$ is reduced by the same proportion (0.38%) as total respirable particulate matter (PM_{10}), and calculates the avoidable health effects from reducing $PM_{2.5}$ levels.

H.2 Philadelphia Air Quality Situation

Like most major cities in the United States, EPA currently classifies Philadelphia County (and the entire greater Philadelphia metropolitan area) as exceeding the current NAAQS for both ozone and $PM_{2.5}$. Recent ozone levels[1] in Philadelphia exceed the current ozone standard by 19%. Philadelphia County's $PM_{2.5}$ levels are below the national fine particle standards (maximum 2008 monitor value in Philadelphia County had an annual mean of 13.49 $\mu g/m^3$, compared with the NAAQS of 15.0 $\mu g/m^3$), although higher $PM_{2.5}$ levels in adjoining counties result in the Philadelphia metropolitan area being classified as a $PM_{2.5}$ non-attainment area. As a designated non-attainment area, Philadelphia must develop and periodically update their State Implementation Plan, identifying additional control measures that will allow Philadelphia to achieve attainment by 2015, and maintain the level of the standards thereafter.

Air pollution levels in Philadelphia vary year to year, reflecting variability both in meteorology and economic activity. Non-attainment designations are based on three years of monitoring data to accommodate the year-to-year variability. Philadelphia's air quality has been generally getting better over time, as numerous federal, state, and local emission control requirements take effect.

This analysis of the air pollution impacts of increasing the number of trees in Philadelphia County uses monitor data from 2007 (the most recent complete year at the time of the analysis). In 2007, the highest monitor in Philadelphia County had a second highest 8-hour ozone level (the

---

[1] The three-year (2006–2008) ozone fourth highest maximum for eight hour ozone in Philadelphia County is 89 ppb. The 2008 revision to the ozone NAAQS set the standard (as measured by the same metric) at 75 ppb.

averaging time of the NAAQS) of 110 parts per billion (ppb); the lowest monitor was 87 ppb (all exceeding the NAAQS). The 2007 annual mean $PM_{2.5}$ levels at the highest monitor in Philadelphia County was 14.83 μg/m^3 (below the standard of 15.0 and the lowest monitor was 12.77).

The initial air pollution levels in this analysis are derived from the 2007 ozone and $PM_{2.5}$ air quality monitors in Philadelphia County. In this analysis the county-wide population-weighted average annual average $PM_{2.5}$ level is 13.60 μg/m^3. The county-wide population-weighted seven month (April through October) seasonal average of the daily 8-hour maximum ozone is 42.4 ppm. Changes in the seasonal average of ozone are the determinates of ozone's impact on human health, rather than changes in peak daily values used to determine attainment of the ozone NAAQS.

As described above, increasing the size of the urban forest in Philadelphia County is expected to lower the ambient ozone and $PM_{2.5}$ concentrations. Using the relationship from the Forest Service report (USDA, 2007) that the current 2.1 million tree urban forest reduces ozone by 0.33% and $PM_{2.5}$ by 0.38%, an increase in the number of trees planted in the 50% LID option[2] would reduce recent (2007) ozone levels by 0.04 ppb, and $PM_{2.5}$ by 0.02 μg/m^3 when the trees are fully mature. The benefits analysis assumes that future ozone and $PM_{2.5}$ levels will be reduced by the same amount (for the same number of planted trees). Varying the number of trees planted, such as in other LID options, is assumed to proportionally effect the changes in ozone and $PM_{2.5}$ levels.

H.3 Human Health Effects of Ozone and $PM_{2.5}$ Exposure

The adverse health effects of ozone and $PM_{2.5}$ are well established, and are extensively documented in recent EPA documents such as EPA's Regulatory Impact Analysis (RIA) for the 2008 revisions to the ozone NAAQS (U.S. EPA, 2008b). Adverse human health effects that can be avoided by reducing ambient levels of ozone and $PM_{2.5}$ include premature mortality and a broad array of respiratory and cardiovascular health effects. Health effects occur not only above the level of the NAAQS, but also below the level of the standards.

The avoidable air pollution-related health effects estimated in this analysis are:

- Premature mortality (from ozone and $PM_{2.5}$)
- Onset of irreversible chronic bronchitis ($PM_{2.5}$)

---

[2] The 50% LID option includes planting 637,000 trees if implemented in all four watersheds, or an increase of 30% in the total number of trees in Philadelphia County.

- Heart attacks (non-fatal acute myocardial infarctions) ($PM_{2.5}$)
- Hospital admissions (non-fatal) for respiratory and cardiovascular conditions (from ozone and $PM_{2.5}$)
- Emergency room visits for asthma (from ozone and $PM_{2.5}$)
- Respiratory symptoms (days of illness) (from ozone and $PM_{2.5}$)
- Work loss days ($PM_{2.5}$) and school absence (ozone).

This analysis uses software developed by the EPA to calculate the avoided health effects from the contribution of trees to reducing ozone and $PM_{2.5}$ concentrations, and to estimate the economic value of the avoided health effects. EPA's BenMAP (U.S. EPA, 2008a), the Environmental Benefits Mapping and Analysis Program (Ver. 3.0.15), was used to conduct this analysis.

H.4 Methods of Estimating Health Effects of Improvements in Air Pollution from an Increase in the Number of Trees

The fundamental method used in this analysis is to calculate the avoided health effects associated with "rolling-back" the air quality levels recorded by Philadelphia monitors in 2007 by the Forest Service's estimate of the percentage that trees reduce air pollution. As a first step in the analysis, BenMAP estimated the health effects associated with reducing 2007 monitor levels of both ozone and $PM_{2.5}$ by 1%. These estimated health effects are proportionally adjusted to estimate the health effects associated with the specific estimated air pollution changes resulting from increasing the amount of urban forest in Philadelphia by the amounts associated with tree planting in each of the LID options.

The BenMAP closest monitor algorithm was used to estimate the population-weighted average change in ozone and $PM_{2.5}$ by assigning the population in Philadelphia (BenMAP forecast for 2010 = 1,438,198, based on 2000 tract level Census data and EPA forecasts of county-level population changes) to the closest monitor to their point of residence. There are four EPA monitors in Philadelphia County; all four monitors record ozone and $PM_{2.5}$ levels.

The health effects analysis methods are adopted from the methods used by EPA in the 2008 ozone NAAQS RIA (U.S. EPA, 2008b). BenMAP was used to estimate the avoided health effects using a concentration-response function from each of the individual concentration-response functions that EPA used in the 2008 ozone NAAQS RIA.

Because the benefits calculations are dominated by premature mortality associated with $PM_{2.5}$, the benefit estimates are made using two different estimates of $PM_{2.5}$-related adult premature mortality. This use of two estimates creates a high estimate and a low estimate for the benefits. The high estimate is from a concentration-response function derived from a long-term cohort tracking epidemiology study in six eastern U.S. cities (Laden et al., 2006). The low estimate is from a long-term cohort tracking epidemiology study of 50 cities nationwide (Pope et al., 2002).

The health analysis estimates the annual cases in Philadelphia of each category of avoided health effects associated with implanting each of the four LID options. Table H.1 presents a representative result; the numbers of avoided cases for implementing the 50% LID option in all four watersheds (e.g., the health benefits of planting 637,000 trees, when the trees reach mature size).

Table H.1. Avoided cases in Philadelphia County for the 50% LID option implemented in all four watersheds (assuming 2010 population)

Health effect	Avoided cases
Premature mortality	1.0 deaths/year (low estimate from Pope et al., 2002)
	2.4 deaths/year (high estimate from Laden et al., 2006)
New cases of chronic bronchitis	0.4 cases/year
Heart attacks	1.2 cases/year
Hospital admissions (all types)	1.0 cases/year
Asthma attacks	23 cases/year
Respiratory illness days	708 days of illness/year
Work loss days and school absence	250 days/year

Varying the number of trees planted, such as in other LID options, is assumed to proportionally effect the health benefits of the changes in ozone and $PM_{2.5}$ levels.

H.5 Economic Valuation of the Avoided Health Effects

In order to include the air quality-related health effects in a benefit-cost analysis containing other benefit categories (energy savings, cooling effects, etc.), it is useful to estimate the economic value of the health effects. For purposes of air pollution policy analysis, the EPA estimates the value of avoiding a case of each estimated health effect, and these estimates (expressed in terms of 2006 prices and forecasted 2010 income levels) are used in this analysis. The EPA valuation estimates are included in the BenMAP software (U.S. EPA, 2008a), which was used to conduct both the health and valuation analyses.

According to economic theory, the best measure of the value of reducing the risk of an adverse health effect is the average that individuals are WTP to reduce the risk a small amount. EPA's methods for valuing air pollution health effects use WTP valuation measures wherever possible, relying on periodic EPA reviews of existing economic studies. However, for certain endpoints reliable WTP studies are not available. EPA has developed alternative methods for valuing the health effects without WTP valuations. The alternative methods produce a lower value estimate than a WTP method because they only consider a portion of the total demand (WTP) for avoiding a health risk. For example, hospital admissions are valued using the medical costs incurred during the stay in the hospital; this ignores the pain and suffering components of value that would be included in WTP. Heart attacks are valued using a combination of medical cost information plus the lost stream of income from people not able to re-enter the workforce (or who must work at a reduced level of income) after a heart attack. The heart attack valuation thus also ignores the pain and suffering components of WTP, and does not include lost income for people assumed to be out of the workforce (e.g., retirees and unemployed adults).

Background and detailed sources of all values used in this analysis are available in the BenMAP documentation and technical appendices (U.S. EPA, 2008a). The values for each health effect are presented in Table H.2.

Table H.2. Values for one case of each health effect

Health effect	Value per case (2006 prices, 2010 income)
Premature mortality	$7,000,000
Chronic bronchitis	$196,000
Heart attack	$141,000 to $233,000 (varies by age)
Hospital admission	$15,000 to $33,000 (varies by cause of hospitalization and age)
Emergency room visit	$336
Asthma attack	$189
Illness day	$18 to $59 (varies by illness)
Work loss days	$143
School absence	$89

Using the methods described above, the total annual health value implementing the 50% LID option in all four watersheds (an increase of 30% in the number of trees in Philadelphia County) is between $12.5 million (based on the low estimate of $PM_{2.5}$ adult mortality from Pope et al., 2002) and $20.5 million (with the high estimate of $PM_{2.5}$ adult mortality from Laden et al., 2006). The corresponding annual benefits per tree planted are between $19 (low estimate) and $45 (high estimate). The mean per tree annual benefit is $32. Varying the number of trees planted, such as in other LID options, is assumed to proportionally affect the total health benefits of the changes in ozone and $PM_{2.5}$ levels, but the benefit per tree will remain constant.

As described in the following sections however, these benefit estimates are not realized immediately when a tree is planted. The schedule in planting trees, plus the time required for a tree to grow to maturity, significantly reduce the present value of planting each tree due to discounting of the value of the avoided health effects.

H.6 Estimates of Trees Planted, the Timeline for Planting Trees, and Time to Reach Maturity

The number of trees planted under each LID option in each of the four watersheds are presented in Table H.3.

Table H.3. Number of trees planted in each watershed under the LID options

	Tacony-Frankford	Cobbs Creek	Schuylkill	Delaware
25% LID	38,612	12,331	41,470	86,553
50% LID	137,537	43,923	147,718	308,304
75% LID	195,743	62,511	210,231	438,776
100% LID	235,032	75,059	252,429	526,848

There are two assumptions about trees that influence the benefits estimation: the schedule for tree planting, and the time it takes for trees to grow to maturity. Both of these factors result in the full air quality health benefits of the increased number of trees being realized well after the LID program activities begin.

The timeline of program activities provided by CDM shows the total number of trees planted in each LID option will be planted over a 35-year period. Approximately 10% of the trees will be planted over the first 6 years of the planting program, 35% planted over the following 14 years, and 55% planted over the final 15 years. Planting begins in 2010, and is not completed until 2045.

When initially planted trees are not fully mature, and cannot produce the full air quality improvement benefits immediately. For the purpose of this analysis, each newly planted tree is assumed to take 20 years to reach maturity in terms of improving air quality. Newly planted trees are assumed to grow at a uniform rate (in air quality removal terms) throughout the 20-year growth period. After the 20-year growth period, the air quality improving characteristics of a planted tree are assumed to remain constant, with urban forestry management practices replacing the trees as necessary to maintain the same effective level of air pollution improvements.

The combination of the 35 year planting schedule and the 20-year tree growth assumption results in the full benefits of air quality improvements for an LID option not being realized until 55 years after the planting begins. The effect of the time delays in the planted trees reaching their full effect on air quality and human health is reflected in the benefit cost analysis through discounting the value of the health effects from the year the health effects are realized back to the time the LID program begins. The discount rate (4.875%) and project initiation year (2008) are the same as used in all portions of the benefits analysis.

H.7 Estimated Economic Benefits

Table H.4 presents a summary of the present value of the health related benefits deriving from air quality improvements resulting from the trees planted in each LID option.

Table H.4. Present value of air quality-related health benefits from tree planting under the LID options (USD millions)

	Tacony-Frankford	Cobbs Creek	Schuylkill	Delaware	Total
25% LID	$7.9	$2.5	$8.5	$17.8	$36.8
50% LID	$28.3	$9.0	$30.4	$63.4	$131.0
75% LID	$40.2	$12.8	$43.2	$90.2	$186.5
100% LID	$48.3	$15.4	$51.9	$108.3	$223.9

H.8 Omissions, Biases, and Uncertainties

To estimate the health benefits from air quality improvements associated with planting trees under the LID alternatives, it was necessary to make a number of assumptions in the absence of specific data. In addition, a number of data omissions and uncertainties surrounding the analysis have been identified throughout this report. Table H.5 provides a summary of these assumptions and uncertainties and their likely impact on our estimation of our air quality related health benefits from tree planting.

Table H.5. Omissions, biases, and uncertainties

Assumption/methodology	Likely impact on net benefits	Comment/explanation
Air quality improvements are based on the Forest Service analysis of the air quality benefits of the existing Philadelphia urban forest	U	The ozone and $PM_{2.5}$ improvements from increasing the number of trees in Philadelphia's urban forest is projected to increase proportionally as the size of the urban forest is increased. Changes in species composition of the planted trees may make the relationship nonlinear, making the impact on benefits uncertain.
Non-Philadelphia residents are not included in the analysis	+	Planting trees in Philadelphia County will likely improve air quality in adjoining counties as well. Air quality improvements in the densely populated adjoining locations are not included in the analysis, and would increase the benefits.
Trees are assumed to decrease $PM_{2.5}$ the same amount that the USDA UFORE analysis estimated PM_{10} is reduced by the existing Philadelphia urban forest	--	$PM_{2.5}$ is more toxic than an equal amount of PM_{10}. If trees are less effective at reducing $PM_{2.5}$ concentrations than in reducing PM_{10}, the tree planting will result in smaller $PM_{2.5}$ changes than estimated in this report. $PM_{2.5}$ contributes more to the total benefit value than ozone, so a smaller change in $PM_{2.5}$ levels would reduce benefits more than a comparable degree of change in ozone.
Trees are assumed to have the same reductions in ozone and PM levels in the future as they do now	-	Over the past several decades air quality levels in Philadelphia have been improving steadily since air pollution programs began to substantially reduce emissions. This trend will generally continue as older cars are retired, additional control programs are implemented, etc. If air quality is cleaner in the future, the impact of additional trees could be less, resulting in smaller improvements in $PM_{2.5}$ and ozone levels than modeled here.

+ would increase benefits; ++ would increase net benefits significantly; U uncertain direction of change; - would diminish net benefits; -- would diminish net benefits significantly

I. Construction- and Maintenance-Related Disruption Impacts

Under all of the CSO options, construction activities will likely result in occasional delays and increased travel times for passenger and commercial vehicle travelers in Philadelphia. Travel time delays can be caused by:

- General traffic slowdowns associated with an increase in the number of trucks and construction equipment on the road
- Slowdowns from trucks entering and exiting construction or landscaping sites
- Lane or road closures associated with construction in the roadway or road right-of-way.

In addition to the value of "lost" time spent in traffic, construction-related delays can result in increased costs associated with additional fuel used by vehicles as a result of slower speeds and occasional vehicle stops and idling.

The following sections outline Stratus Consulting's approach for estimating the costs associated with travel time delay and additional fuel used under the different CSO options. Cost estimates associated with construction-related delays are also provided.

I.1 Impact of Additional Construction and Maintenance Vehicles on Philadelphia Roadways

To estimate travel time delay caused by an increase in the number of construction and maintenance vehicles on Philadelphia's roadways, we first estimated the number of miles traveled by these vehicles under the different CSO alternatives. We calculated total VMT based on inputs received from CDM, including the number of heavy truck trips over the construction period and total person-hours of O&M labor per year. We made several assumptions regarding average trip length per vehicle, number of concrete trucks under the non-LID alternatives, and the average number of employees per truck (crew size) for O&M vehicles.

Table I.1 shows the inputs and assumptions used to determine additional truck miles traveled under the different CSO options.

Table I.1. Inputs and assumptions for estimating additional VMT under CSO options

	LID alternatives
Heavy truck trips	
Vehicle trips (heavy trucks/construction)	Provided by CDM for each alternative
Vehicle trips (concrete trucks)	For non-LID alternatives, assumed to equal ½ of heavy vehicle construction trips
Average trip length (miles)	20
Light truck trips (LID options only)	
Person-hours of O&M labor per year	Provided by CDM for each LID alternative
Working hours per year	2,000
Persons per truck (crew size)	4
Number of additional trucks on the road each day	Number of employees divided by crew size
Average trip length (miles)	15

Using the total VMT by construction and maintenance vehicles under each option, we were able to estimate the travel time delay caused by these vehicles based on methodology developed by the Texas Transportation Institute (TTI) (Schrank and Lomax, 2007). The following sections outline our general approach and provide monetary and non-monetary cost estimates for construction-related impacts under each of the CSO alternatives. Non-monetary estimates are presented in terms of total hours of delay.

Step 1: Determine congested peak period VMT. This first step is based on the assumption that an increase in the number of construction vehicles on Philadelphia's roadways will only affect vehicles already traveling in congested conditions. Thus, vehicles traveling in uncongested conditions would continue to travel at "free-flow" speeds despite the addition of extra vehicles. We assume that congestion is typically only experienced during certain times of the day (i.e., during "peak" periods).

Based on the TTI's Annual Mobility Report (Schrank and Lomax, 2007), peak period travel accounts for 50% of DVMT. Further, TTI estimates that in Philadelphia, 63% of peak period travel is spent in congested conditions. Thus, approximately 32% (50% × 63%) of DVMT is considered to be congested, peak period travel.

Step 2: Determine VMT impacted. Only a small percentage of congested peak period travel will experience traffic delays or slow downs due to an increase in the number of trucks on the road. To determine total VMT affected, we assume that for each heavy construction vehicle mile traveled, an additional 30 vehicle miles (or 30 vehicles) are impacted. Thus, if 10 million vehicle miles are traveled under a given CSO option, we assume that 300 million passenger and/or commercial vehicle miles are traveled at slower speeds. In the absence of specific roadway data, this assumption is intended to serve as a benchmark to provide an order of magnitude of costs.

Step 3: Estimate impact on traffic speed. We assume construction vehicle travel to be consistent with current traffic patterns, with approximately 42% of travel taking place on highways and 58% on arterial roads (Schrank and Lomax, 2007). TTI reports that during peak periods, the average highway speed in Philadelphia is about 45.6 miles per hour (mph). On arterial roads, the average speed is approximately 27.5 mph. We estimate that the speed of affected vehicles will decrease by approximately 8 and 10% on highways and arterial roads, respectively (to 42 and 24.8 mph). Again, in the absence of specific roadway data, this assumption is intended to serve as a benchmark to provide an order of magnitude for potential impacts.

Step 4: Estimate travel time and determine annual delay. The fourth step involves calculating the amount of time it would take to travel the affected vehicle miles at decreased speeds and at current (or baseline) speeds. This calculation yields travel time on an hourly basis and was performed separately for arterials and freeways under each scenario. Total annual vehicle *delay* was then determined by comparing travel time under decreased speeds for each alternative to travel times at current speeds.

To determine total person delay, we distinguish between heavy truck travel and passenger vehicle travel. Based on TTI data, we assume that 5% of total travel can be attributed to heavy trucks and that these vehicles typically have only one passenger (the truck driver). Passenger vehicles are assumed to contain an average of 1.25 passengers per vehicle, including the driver (Schrank and Lomax, 2007).

Based on the steps described above, we were able to estimate travel time delay caused by construction and implementation activities under each CSO option. Our estimates reflect total delay over the 40-year project period. To estimate annual delay over the project life, we allocated total delay based on construction and implementation timelines provided by CDM.

Table I.2 provides total person-delay estimates (accounting for 1.25 persons per passenger vehicle) for the CSO options in each watershed.

Table I.2. Total vehicle delay caused by additional construction and maintenance vehicles on Philadelphia roadways under PWD's CSO options (person-hours)

	Tacony	Cobbs	Schuylkill	Delaware
LID options				
25% LID	41,801	13,349	44,895	93,701
50% LID	74,840	23,901	80,380	167,762
75% LID	128,378	40,998	137,881	287,772
100% LID	174,087	55,596	186,973	390,233

Table I.2. Total vehicle delay caused by additional construction and maintenance vehicles on Philadelphia roadways under PWD's CSO options (person-hours) (cont.)

	Tacony	Cobbs	Schuylkill	Delaware
Transmission and new treatment capacity (excluding LID component)[a]				
Level 1	10,541	5,678	4,947	42,162
Level 2	12,048	6,251	10,763	43,357
Level 3	17,781	6,412	15,989	71,479
Level 4	26,184			73,667
Tunnel options[b]				
15' Tunnel	40,098	61,176	88,027	131,922
20' Tunnel	62,873	85,803	116,932	158,123
25' Tunnel	92,388	125,811	154,421	220,393
30' Tunnel	129,672	166,009	200,775	300,141
35' Tunnel	173,954	213,537	256,275	351,764
Transmission and satellite treatment options				
25 Ofs	695	485	2,147	2,846
10 Ofs	2,826	2,299	6,643	8,062
4 Ofs	11,806	6,364	16,666	20,949
1 Ofs	33,892	10,880	37,413	44,299

a. Levels 1–4 correspond to the different capacity options within each watershed (e.g., for Tacony-Frankford Watershed, Levels 1–4 are 215, 298, 490, and 820 MGD, respectively.

b. Tunnel options in Delaware River Watershed are 15, 18, 21, 23, 28 and 31'.

I.2 Wasted Fuel

To calculate wasted fuel due to vehicles moving at slower speeds, we again draw upon methodology developed by TTI. We first calculate average fuel economy based on a linear regression applied to a modified version of fuel consumption reported by Raus (1981), as follows:

Average fuel economy = 8.8 + 0.25 (average speed)

This equation is applied to average speeds for arterials and freeways. Annual fuel consumed as a result of the delay under each CSO option is then calculated:

Annual fuel consumed = Travel delay (vehicle hours) × Average speed / Average fuel economy

The additional fuel use associated with construction-related delay is reported under the "energy usage/savings" category for each CSO alternative (Appendix G). The value of this "wasted" fuel is also reported as part of this category (in terms of total energy costs). However, we can provide an idea of total costs associated with additional fuel used as a result of construction-related delay. At $3.00 per gallon, additional fuel use amounts to about 16% of the total costs estimated for travel time delay, which is reported below.

I.3 The Value of Travel Time Delay Caused by Additional Construction Vehicles on the Roadways

To determine the value of extra time spent in traffic, we applied hourly rates used by the U.S. Department of Transportation and TTI to value an individual's time. Hourly rates for passenger vehicle travelers are weighted by a standard to account for both leisure and work-related travel (approximately $16.00 per hour). Heavy truck travel (assumed to be commercial truck travel) represents hourly wage plus fringe benefits (approximately $84 per hour). These values are based on 2005 TTI estimates and inflated by 3% to reflect 2008 values.

Table I.3 shows the total value of travel time delay caused by additional vehicles on Philadelphia roadways. The values shown here represent present value estimates for the 40-year project timeline. Similar to hours of delay, these costs were allocated by year based on construction and implementation timelines provided by CDM.

Table I.3. Monetary value of total vehicle delay caused by additional construction and maintenance vehicles on Philadelphia roadways under PWD's CSO options (present value, 2009 USD)

	Tacony	Cobbs	Schuylkill	Delaware
LID options				
25% LID	$677,244	$216,282	$727,374	$1,518,111
50% LID	$1,210,066	$386,441	$1,299,636	$2,712,484
75% LID	$2,077,509	$663,464	$2,231,286	$4,656,943
100% LID	$2,818,088	$899,972	$3,026,684	$6,317,026
Transmission and new treatment capacity (excluding LID component)[a]				
Level 1	$177,872	$95,815	$83,479	$711,433
Level 2	$203,292	$105,483	$181,616	$731,600
Level 3	$300,043	$108,195	$269,800	$1,206,134
Level 4	$441,823	NA	NA	$1,243,061

Table I.3. Monetary value of total vehicle delay caused by additional construction and maintenance vehicles on Philadelphia roadways under PWD's CSO options (present value, 2009 USD) (cont.)

	Tacony	Cobbs	Schuylkill	Delaware
Tunnel options[b]				
15' Tunnel	$676,617	$1,032,283	$1,485,367	$2,226,049
20' Tunnel	$1,060,923	$1,447,835	$1,973,102	$2,668,168
25' Tunnel	$1,558,954	$2,122,931	$2,605,699	$3,718,904
30' Tunnel	$2,188,081	$2,801,233	$3,387,882	$5,064,569
35' Tunnel	$2,935,292	$3,603,223	$4,324,377	$5,935,660
Transmission and satellite treatment options				
25 Ofs	$11,731	$8,177	$36,234	$48,025
10 Ofs	$47,680	$38,799	$112,099	$136,036
4 Ofs	$199,213	$107,387	$281,222	$353,488
1 Ofs	$571,892	$183,593	$631,312	$747,498

a. Levels 1–4 correspond to the different capacity options within each watershed (e.g., for Tacony-Frankford Watershed, Levels 1–4 are 215, 298, 490, and 820 MGD, respectively.

b. Tunnel options in Delaware River Watershed are 15, 18, 21, 23, 28, and 31'.

I.4 Delay Associated with Temporary Lane/Road Closures

To estimate annual vehicle delay associated with detours and temporary lane and/or road closures, we would ideally know the location and duration of each closure as well as the number of travelers affected and their speed over the impacted area. Because we are uncertain of how these variables might vary under each alternative, we do not include the impact of lane and road closures in our overall analysis.

In the absence of this detailed information, we can provide a rough benchmark estimate of annual delay caused by construction activities in the roadway based on the following assumptions:

- Five percent of travelers are impacted
- Each affected traveler experiences an average of a 5-minute delay per lane/road closure and/or detour
- Affected travelers experience the delay twice a day, an average 250 days each year (total working days in a year)

- Vehicles will experience these delays on arterial streets as opposed to freeways
- Travelers can experience delays throughout the day (not just during peak periods)
- Heavy trucks account for approximately 5% of total traffic and typically contain only one person (the driver)
- Passenger vehicles have an average of 1.25 persons per vehicle.

Based on these assumptions, we estimate that increased construction activities under the different CSO options could delay Philadelphia truck drivers and passenger vehicle occupants by an additional 12,200 hours each year (about 15,100 person-hours). If this is assumed to be the average impact each year over the 40-year project, total vehicle delay would amount to about 490,000 hours.

The key variables here are the percent of travelers affected and the amount of time and frequency that each vehicle is delayed. Again, it is uncertain how these variables might vary across the different options. The assumptions described above are intended to provide a benchmark estimate from which to gauge potential impacts.

Table I.4 shows the inputs and the order-of-magnitude estimate associated with this city-wide impact.

Table I.4. Inputs and preliminary estimates for total delay caused by lane closures and/or detours

	Input/preliminary estimate
Daily vehicle-miles of travel (1,000s) on arterial roads	48,235
Arterial road lane miles	8,240
Total number of vehicles on arterial roads per day	5,850
Percent of total travelers affected	5%
Total travelers affected	290
Daily hours of delay	49
Number of days delay is experienced	250
Annual hours of vehicle delay	12,200
Annual hours of delay for heavy trucks	610
Annual hours of passenger vehicle person-delay	14,480
Total annual hours of person delay	15,100

This estimate will vary each year depending on the level of activity in any given year. In the absence of this information, it is difficult to estimate the present value of this benefit. Further, due to lack of more detailed information, we were unable to calculate the cost of wasted fuel due to idling and slower speeds associated with this type of delay.

I.5 Other Non-quantifiable Impacts

I.5.1 Neighborhood and business access issues

In some cases, access to residential areas and local businesses may be made difficult by construction and maintenance activities. In residential areas, access issues can result in increased travel time for residents having to choose alternate routes in traveling to and from their homes. Employees and customers of local businesses may also experience increased travel times from having to choose alternate routes or visit other businesses. Some local businesses may temporarily see a decline in the number of customers visiting their businesses.

I.5.2 Temporary construction impacts

Other public impacts from construction and maintenance can include mitigation or repair of construction-related damage due to tunneling settlement and vibration or equipment damage to private property. Additional impacts may include noise, dust, vibration, and safety issues associated with construction activities. These impacts are typically experienced by residents and businesses within the project area, including those located on streets where detours have been routed. These miscellaneous other social costs will not likely represent a large portion of overall project costs and in the absence of specific data, they are described qualitatively.

I.6 Omissions, Biases, and Uncertainties

As detailed throughout this report, to estimate traffic-related impacts associated with the different CSO control options, it was necessary to make a number of assumptions. Many of these assumptions are based on Philadelphia-specific data (average speeds, annual VMT, etc.) or represent standard industry estimates (e.g., number of person per vehicle, wage rates). Although there is a degree of uncertainty surrounding these assumptions, they are developed based on well-accepted methodology (see Schranx and Lomax, 2007) that has been used to evaluate mobility and traffic patterns in urban areas for a number of years.

Additional uncertainties surrounding our analysis of construction-related costs generally stem from a lack of specific data related to on-the-ground implementation of the CSO options (location, expected road closures, etc.). Table I.5 provides a summary of these assumptions and uncertainties and their likely impact on total benefits.

Table I.5. Omissions, biases and uncertainties

Assumption/ methodology	Likely impact on net benefits[a]	Comment/explanation
Analysis does not include the impact of temporary lane and/or road closures during construction.	++	Depending on their timing and location, temporary lane and road closures could significantly increase the overall costs associated with construction disruption, in terms of additional time spent in traffic and wasted fuel. Further, individual businesses could experience significant impacts if they are located on a closed road. This would not likely result in substantial impacts on a city-wide basis (e.g., residents would continue to shop, just in different locations).
Analysis assumes miles traveled by additional construction vehicles on highways versus arterial roads, follows current traffic patterns.	U	It is unclear how this assumption affects our current estimates. If construction vehicles spend more time driving on arterial roads, impacts would be greater because we assume a larger impact on arterial roads for each vehicle. (e.g., we estimate that the speed of affected vehicles will decrease by approximately 8 and 10% on highways and arterial roads, respectively)
Analysis includes assumption for VMT impacted by additional construction vehicles.	U	To determine total VMT affected, we assume that for each heavy construction vehicle mile traveled, an additional 30 vehicle miles (or 30 vehicles) are impacted. In the absence of specific roadway data, this assumption is intended to serve as a benchmark to provide an order of magnitude of costs.

a. Indicating how addressing the assumption or overcoming the omission would probably impact the analysis, using the following key: + would likely increase net benefits; ++ would increase net benefits significantly; U direction of change in net benefit is uncertain; - would diminish net benefits; -- would diminish net benefits significantly.

Basis of Cost Opinions

Updated: September 1, 2009

Combined Sewer Overflow Control Alternatives Costing Tool Reference Manual

September, 2009

Table of Contents

1.0 INTRODUCTION AND OVERVIEW

The Philadelphia Water Department (PWD) has developed an alternatives cost estimation calculation tool (ACT) for use in planning level screening and comparison of CSO control technologies. The ACT provides planning-level cost estimates to facilitate the evaluation and comparison of preliminary alternatives for Philadelphia's Long Term CSO Control Plan Update.

The cost opinions created using the ACT are to be considered Level 4 cost estimates, as designated by The Association for the Advancement of Cost Engineering Recommended Practice No. 18R-97 (AACE, 2005), and actual costs are expected to fall within a range of 30% less to 50% more than the cost opinions given in this section. This estimate class and accuracy is appropriate for long term planning level use.

This user reference manual presents an overview of the contents, working and internal logic of the ACT.

1.1 Alternatives Costing Tool Scope

The ACT is an EXCEL workbook-based program which provides capital and operation and maintenance (O&M) costs of wet-weather conveyance, storage and treatment facilities based on costing algorithms developed from evolving and expanding national data sets, from PWD, and other regional capital and O&M cost data. Key outputs include:

- Current year (anticipated 2009) capital cost
- Current year O&M costs
- Present worth based on capital costs and projected O&M costs
- Future years' O&M costs based on assumed inflation
- Annual debt service costs
  Total capital costs

The user is to develop control alternatives which include conceptual level determinations of facility size, type and configuration. This information is entered into the costing tool through standardized templates. The ACT is configured to allow the user to rapidly evaluate sizing and configuration alternatives. Assumptions and calculations are displayed in a step-wise manner in the ACT, while providing the user the ability to reference the source data.

1.2 Control Technologies

Figure 1.2-1 displays the control technologies which are included in the ACT. The costing methodologies, inputs (conceptual design values) to be provided by the user, and conceptual design approach assumptions to be incorporated into the ACT are detailed in Section 2.0.

Table 1.2-1 ACT Technology Summary

Source Controls: Land-Based Stormwater Management (Green Stormwater Infrastructure) Private I/I Reduction Municipal I/I Reduction
Storage: Conventional Tunnel Tank Storage
Conveyance: Open Cut Pipe Pump Station Short-Bore Tunnel (Trenchless) Sewer Separation
Treatment: Retention Treatment Basin Vortex Separation High-Rate Clarification Screening Disinfection
Miscellaneous

1.3 Terminology

For purposes of this documentation the following definitions will apply. The specific meanings of some terms may vary depending on the context.

Control Element

"Control Element" means a facility serving as one component of a control alternative. A high-rate treatment (HRT) facility or a relief interceptor would be examples of control elements. Source reduction through municipal collection system rehabilitation or through green stormwater infrastructure would also be examples of control elements. The ACT will output estimated capital costs for control elements (e.g., the capital cost of a 30 million gallon per day (mgd) HRT based on the design and other parameters set by the user and the system-wide design assumptions discussed below in Section 2).

Control Alternative

"Control alternative" means an array of one or more control elements providing watershed-level overflow control at some specified level of performance. A relief interceptor sewer discharging to a HRT facility that was sized for eight overflows per typical year would be an example of a watershed-control alternative. The capital cost of a control alternative is the sum of the control element capital costs.

Construction Costs

"Construction costs" means the raw costs of building new control facilities, upgrading or expanding existing facilities or rehabilitating existing sewerage (i.e., the contractors' bid costs). Construction costs include: general conditions, overhead and profit, mobilization, demobilization, contractor's bonds and insurance, and sub-contractor markups.

Non-Construction Costs

Non-construction costs include all costs related to a control alternative other than building costs. Design and construction engineering costs are examples. Estimated non-construction costs, except for land acquisition, are based on a percentage of construction costs.

Capital Costs

Capital costs will be the sum of the estimated construction costs and the estimated non-construction costs.

Planning Period

For purposes of control alternatives evaluation, the planning period will be set at a default of 40 years. The planning period is relevant to calculating the present worth of various control elements.

Useful Life

The useful life of a control element is the period during which the control element will operate without requiring replacement or substantial reconstruction to maintain design performance. Preventive and corrective maintenance are assumed when establishing the useful lives of the control element components.

1.4 Economic Parameters

The following parameters have been incorporated into the ACT as standard values.

1.4.1 Useful Life

Useful life is relevant to alternatives evaluation because of the extended planning period. Present worth calculations need to include structural replacement or rehabilitation and equipment replacement costs that would occur during the planning period (e.g., a storage tank with effluent pumps coming on line in 2029 would likely require pump replacement or major overhaul before 2048). Because of the intermittent operation of wet-weather facilities, traditional estimates of equipment useful life may be inappropriate.

1.4.2 Discount Rate

The discount rate utilized by the ACT to calculate the present worth of control elements is an input variable. The default discount rate is 4.875%, and is based on the Department of Interior Federal water resources planning discount rate for fiscal year 2008.

1.4.3 Construction Cost Base Date

The base date, likely to be the current year, is a user input, and represents the date that the opinion of cost is in terms of. The default base date in the ACT is January 2009 as the base date for estimated construction costs.

1.4.4 Cost Inflation

Future Capital Costs

The ACT estimates future capital costs both in current year dollars and in future dollars. The default inflation value in the ACT is 4.0%.

Operations and Maintenance Cost Inflation

Base date (January 2009) O&M costs are inflated to the first year of operation as input into the model and for subsequent years throughout the planning period. The initiation of operation will be assumed to occur on January 1 of the year following construction completion. The default O&M cost inflation in the ACT is 4.0%.

1.4.5 Cost Indexes

Because the cost estimating sources were based on different dates and geographic locations, the cost estimates for the base year and base location were adjusted through cost indexes. Specifically, the Engineering News Record Construction Cost Index (ENRCCI) was used to adjust for the year of the cost estimate, and the 2008 RSMeans Location Factor (RSMeans) was used to adjust for the geographic location of the cost estimates. Table 1.4.5-1 shows the cost indexes for the cost estimating sources. The default base ENRCCI in the ACT is 8549, and the default RSMeans in the ACT is 115.2.

Table 1.4.5-1 Summary of Base Index Values for ACT Technologies Cost Data

Technology	Cost Equation Data Base Index Values			
	ENRCCI Construction	RS Means Construction	ENRCCI O&M	RS Means O&M
Default ACT Project Analysis	8551	100.0	8551	100.0
Land-Based Stormwater Management	7966	115.2	8141	115.2
Private I/I Removal	8551	100.0	8551	100.0
Municipal I/I Removal	8551	100.0	8551	100.0
Conventional Tunnel	8551	100.0	8551	100.0
Tank Storage	8551	100.0	8551	100.0
Open Cut Pipe	7312	92.9	6771 (Detroit)	103.9 (Detroit)
Pump Station	8551	100.0	7939 (PWD)	115.2 (PWD)
			7966 (EPA)	100.0 (EPA)
Trenchless Technologies	8578	113.2	6771 (Detroit)	103.9 (Detroit)
Sewer Separation	8551	100.0	8551	100.0
Retention Treatment Basins	8551	100.0	8551	100.0
Vortex Separation	8551	100.0	8551	100.0
High-Rate Clarification	8551	100.0	8551	100.0
Screening	8551	100.0	8551	100.0
Disinfection	8551	100.0	8551	100.0

Note: The unit cost values in the subsequent appendices reflect unadjusted costs. The index values are used for adjustment of cost to the project analysis ENRCCI and RSMeans values input by the user.

2.0 COST ESTIMATING APPROACH

This section outlines the wet-weather controls that are included in the ACT and the methodologies to be used in the ACT to scale estimated capital costs to the sizes and complexities identified by the user.

2.1 Non-Construction Costs

The ACT includes non-construction costs and economic parameters that impact the estimated total capital cost of a given control alternative.

The ACT automatically assigns non-construction costs to the construction costs calculated for a control element. With the exception of land acquisition and easement costs which are determined by the user, each non-construction cost is calculated as a percent of the estimated construction cost either before or after other multipliers are applied.

2.1.1 Construction Contingency

Construction contingencies are added to take into account how far advanced a design has proceeded. This contingency takes into account any design development concerns based on the status and phase of the project. For the initial planning work that is being done, a 25 percent contingency is added to the construction cost, which already includes (implicitly), the contractor's overhead and mark-up. The construction cost with this contingency included will be referred to as the opinion of probable construction cost.

2.1.2 Project Contingency

The ACT adds a project contingency to the opinion of probable construction cost. This contingency typically ranges from 5 to 30% depending upon such things as the level of difficulty of the project, the volatility of the bidding climate for the project type, the level of complexity of the site conditions, and the type and stage of funding being required. The default project contingency in the ACT is 20%.

2.1.3 Capitalized Interest

Capitalized interest, or interest during construction, reflects interest payments on the amount borrowed (through bonds), payment of which is deferred during construction. The ACT calculates the cost of capitalizing interest during construction based on the anticipated duration(s) of construction input by the user. For planning purposes, the annual draws on construction funding will be assumed to be straight line.

2.1.4 Land Acquisition and Easements/Rights-of-Way

Because of the specificity of local conditions, the ACT will not include a standard multiplier for land acquisition, easements and Rights-of-Way (ROW). Upon identifying preliminary routing (for relief or consolidation interceptors) or sites for control facilities, the user should overlay the potential routes and sites with existing easements and ROW to identify the need for new easements, ROW or parcels. The user will enter the total estimated costs for land acquisition, easements and ROW into the ACT.

2.1.5 Engineering and Implementation

Engineering and implementation costs are added as a percentage to the total of all costs described above. The ACT has a default setting of 20%, and is intended to address the following typical project costs:

- Permitting
- Engineering design
- Construction oversight /resident engineering
- Administration and program management
- Finance bonding costs
- Legal
- Geotechnical
- Survey
- Public participation.

2.1.6 Contractor's Overhead and Profit and Indirect Costs

Cost estimate sources presented in the ACT are in two different levels of cost. Most cost sources are in terms of construction costs as defined above: contractor's bid cost including overhead and profit and indirect costs. However, a few cost sources assembled directly from materials, labor, and equipment estimates are in terms of direct construction costs, excluding contractor's overhead and profit and indirect costs. Table 2.1.6 shows the breakdown between construction and direct construction in the ACT.

Overhead and profit and indirect costs are applied to the cost sources based on direct construction costs. The default value for contractor's overhead and profit in the ACT is 20%. The default value for contractor's indirect costs in the ACT is 4%.

Table 2.1.6 ACT Technology Cost Source Level of Cost

Technology Cost Curve/Cost Module	Direct Construction Cost (i.e. materials, labor, equipment)	Construction Cost Including Contractor's Overhead, Profit and Indirect Costs
Land Based Stormwater Management	X	
Trenchless Technologies	X	
Open Cut Pipe	X	
All Other Technologies		X

2.2 Construction Cost Approach

2.2.1 Cost Scaling

The ACT scales construction costs based on a series of cost per facility size equations developed for each of the structural control alternatives outlined in Section 2.3. Otherwise, it assembles construction and O&M costs from smaller components (e.g. material cost of a particular type and size of pipe, energy cost for pumping at a specific total dynamic head, flow rate, duration and electrical rate, etc).

2.2.2 Cost Data Sources

A variety of construction cost estimate data sources were used in development of the ACT. National wet-weather control facility costs of facilities in operation, as well as unit cost breakouts for such facilities (as they are available) were used extensively. These costs were updated for time and location.

The ACT also relied on cost curve data sets that have been developed for other wet weather programs nationally, such as: Perth Amboy, New Jersey; Indianapolis, Indiana; Cincinnati; Allegheny County, PA; Detroit, Michigan and Omaha, Nebraska. Data was also provided from the Philadelphia Water Department (PWD), and the Detroit Water and Sewer Department (DWSD). These cost curves were used for comparison purposes to verify the feasibility of the selected cost curve for a given technology. This combined knowledge base allowed for comparison of different cost estimation methodologies for each technology within the ACT.

The United States Environmental Protection Agency (U.S. EPA) publications containing control facilities cost data and cost curves will be used as a secondary source of guidance. These cost estimating curves were compared to installed project data, and adjusted chronologically using ENRCCI Index values.

2.3 Cost Estimation Methodology

The following subsection outlines inputs, default assumptions and methodologies used in the ACT to estimate construction costs of various control technologies that were identified in Section 1.2.

2.3.1 Land-Based Stormwater Management (Green Stormwater Infrastructure)

Land Based Stormwater Management (LBSM) costs are estimated using unit-area estimates. Underlying those unit-area estimates are more precise engineering cost opinions based on real site plans representing a variety of technologies, land use types, sizes, and land ownership.

A range of stormwater management plans using different LID techniques was selected. Five of these represented plans submitted by private developers and approved as complying with Philadelphia's stormwater ordinance and regulations. Ten plans were considered public funded projects, including two PWD demonstration projects. Engineering cost estimates were developed based on materials, labor, overhead, and profit using unit costs from RSMeans CostWorks (see example in Table 2.3.1-1). Costs were adjusted to represent construction taking place within Philadelphia with union labor rates in 2008 dollars and are considered construction costs with overhead, profit and without indirect costs.

Direct construction costs were estimated using materials and labor quantities for the following two cases:

- The marginal construction cost (beyond the cost of traditional measures) to implement each LBSM approach assuming that redevelopment is already taking place.
- The full construction cost required to implement each LBSM approach by retrofitting traditional development on an existing site.

Table 2.3.1-1 Example of Project Cost Estimate based on Quantities and Unit Costs

Category	Material	Units	Quantity	Unit Cost	Total Cost	Source*
Trees	Deciduous Tree	total	6	$385.00	$2,310.00	Means 32 93 4320 1600
	Bark Mulch	sq. yd	10.66	$6.15	$65.56	Means 32 91 1316 0100
	Geotextile Separation Fabric	sq. yd	10.67	$1.95	$20.80	Means 02620-300-0110
	Planting Backfill Mixture	cu. Yd	9.48	$29.50	$279.70	Means 31 05 1310 0700
	Hauling Backfill Mixture to Site	cu. Yd	9.48	$30.55	$289.66	Calculation
	Excavation	cu. Yd	10.67	$2.75	$29.31	Calculation
Porous Pavement	Pervious Asphalt	sq. yd	652.36	$20.90	$13,634.32	2X cost of traditional pavement
	AASHTO No. 57 Choker	cu. yd	18.12	$37.69	$682.94	Means 31 05 1610 0300
	AASHTO No. 2 Coarse Aggregate	sq. yd	652.36	$9.55	$6,230.04	Means 32 11 2323 0302
	Non-Woven Geotextile	sq. yd	784.36	$1.95	$1,529.50	Means 02620-300-0110
	Excavation	cu. Yd	217.88	$2.75	$598.84	Calculation
	Hauling Asphalt Materials to Site	cu. yd	163.20	$30.55	$4,985.76	Calculation
	Hauling for excavated soil	cu. Yd	217.88	$30.55	$6,656.17	Calculation
Pipe Trench Under Porous Pavement	24" Perf. Pipes	ft	774.00	$62.00	$47,988.00	Means 3311 1325 3070
	24" LF HDPE Header	ft	22.00	$62.00	$1,364.00	Means 3311 1325 3070
	Gravel	sq. yd	95.30	$15.40	$1,467.56	Means 32 11 2323 0300
	AASHTO No. 2 Coarse Aggregate	sq yd	91.21	$9.55	$871.06	Means 32 11 2323 0302
	Hauling Aggregate to Site	cu yd	91.21	$30.55	$2,786.47	Calculation
Inlet Structure	Reinforced Concrete Inlet Box	total	1	$4,800.00	$4,800.00	Means 334913-10-1000
	Excavation volume	cu. Yd	4.74	$2.75	$13.03	Calculation
	Hauling for excavated soil	cu. yd	4.74	$30.55	$144.83	Calculation
	Footing	each	1	$27.78	$27.78	Anecdotal
	Reinforced Concrete Top Unit	total	1	$440.00	$440.00	Means 33-49-1310-1300
	Heavy Duty Inlet Frame	total	1	$1,125.00	$1,125.00	Means 02630-110-1582
	AASHTO Coarse Aggregate Size No. 57	cu yd	0.67	$37.69	$25.13	Means 31 05 1610 0300
	Hauling Aggregate to Site	cu yd	0.67	$30.55	$20.37	Calculation
Outlet Structure	Cast Iron Manhole Frame and Cover	total	1	$505.00	$505.00	Means 33-44-1313-2100
	Precast Manhole Slab	total	1	$650.00	$650.00	Means 33-49-1310-1400
	Precast Reinforced Concrete Inlet Box	total	1	$4,800.00	$4,800.00	Means 334913-10-1000
	Cast Iron Trap	total	1	$550.00	$550.00	Means 22-13-1660-1160
	AASHTO Coarse Aggregate Size No. 57	cu yd	0.89	$37.69	$33.50	Means 31 05 1610 0300
	Hauling Aggregate to Site	cu yd	0.89	$30.55	$27.15	Calculation
Cleanout (Storm water piping)	Cast Iron Cleanout Housing	total	1	$880.00	$880.00	Means 22-05-7620-0280
	8" Dia. PVC Cleanout with Screw Plug	ft	0.75	$14.30	$10.73	Means 33-31-1325-2080
	8" Dia. PVC Spool Piece	ft	0.33	$14.30	$4.77	Means 33-31-1325-2080
Piping	12" Dia. PVC Pipe	ft	80.00	$23.50	$1,880.00	Means 33-31-1325-2160
	Redevelopment Cost				**$107,727**	

* Most unit costs are taken from R.S. Means Costworks Version 11.0, Building Construction Cost Data 2008. Some are based on local bid data or best engineering judgment. Some are calculations based on combinations of individual items and are too complex to describe in this table. Detailed calculations are available on request.

LBSM Input Variables

To calculate the construction cost of a LBSM technology, the following variables must be input into the ACT by the user:

Impervious Area - For calculating the LBSM construction cost, the user must first input the calculated impervious area (in acres) proposed for the LBSM technology alternative. This value will be determined by the user based on the alternative design.

Control Type - Next, the type of control is to be selected out of the five LBSM technologies: Bioretention, Green Roof, Porous Pavement, Street Trees, and Subsurface Infiltration.

Control Level - The third input variable is the control level, either retrofit or redevelopment.

Based on the user input values, the ACT will calculate direct construction costs as well as operation and maintenance (O&M) costs. These values were developed from unit costs per acre for each scenario provided in the ACT. A summary of the LBSM unit costs is provided in Table 2.3.1-6. A summary of LBSM O&M costs is provided in Table 2.3.1-14.

Summary of Results

The results from the takeoffs of LID stormwater management plans are summarized in the following sections. Descriptions of the projects that are selected for the analysis are listed in Table 2.3.1-2. A list of the cost estimates that were calculated for direct construction costs are shown in Table 2.3.1-3. The estimates were summarized into five categories: bioretention, subsurface infiltration, green roof, porous pavement and street trees in Table 2.3.1-4. Each category was further broken down into a redevelopment and retrofit cost. Due to the small sample size costs for bioretention, subsurface infiltration and porous pavement do not appear to be significantly different. For the purpose of the study the pooled value for all controls was assigned to these three types.

Table 2.3.1-2 Project Descriptions and Characteristics

Project Name	BMP Type	Land Use	Lot Size (sq ft)	Pre Construction Impervious Cover (sq ft)	Post Construction Impervious Cover (sq ft)
Private (1)	Subsurface Infiltration	High Density Residential	23760	21701	23760
47th and Grays Ferry Traffic Triangle	Bioretention	Street	6835	19318	19318
Private (2)	Green Roof	High Density Mixed Use	30593	0	23012
Public (2)	Pervious Pavement and Detention	School	52254	43655	52254
Private (3)	Subsurface Infiltration	School and Parking	371239	107530	121384
Mill Creek Tree Trench	Subsurface Infiltration	Street	1131	17346	17346
Private (4)	Green Roof and Pervious Pavement	High Density Residential	64600	25874	52230
Private (5)	Subsurface Infiltration	Commercial	122839	0	105415
Public (4)	Bioretention	Parking	551470	12235	424870
Public (5)	Subsurface Infiltration	School	95738	81218	29053
Curb Extension	Bioretention	Street	190	3508	3358
Swale without Parking	Bioretention	Street	192	2716	2550
Swale with Parking	Bioretention	Street	192	2429	2263
Planter with parking	Bioretention	Street	175	922	862
Planter without parking	Bioretention	Street	99	1147	1067
Street Trees	street trees	Street	43560	43560	43000*

* - 30.2 trees per acre placed in 16 sq. ft. tree boxes.

Table 2.3.1-3 Direct Construction Cost Estimates in 2008 Dollars

Project Name	BMP Type	Cost Estimates ($/impervious acre)		Actual Project Cost (PWD projects)
		Redevelopment	Retrofit	($/acre)
Private (1)	Subsurface Infiltration	$150,000	$230,000	
47th and Grays Ferry Traffic Triangle	Bioretention	$72,000	$80,000	$150,000
Private (2)	Green Roof	$290,000	$570,000	
Public (2)	Pervious Pavement and Detention	$85,000	$128,000	
Private (3)	Subsurface Infiltration	$44,000	$79,000	
Mill Creek Tree Trench	Subsurface Infiltration	$100,000	$120,000	$170,000
Private (4a)	Green Roof	$200,000	$430,000	
Private (4b)	Pervious Pavement	$190,000	$410,000	
Private (5)	Subsurface Infiltration	$120,000	$170,000	
Public (4)	Bioretention	$150,000	$200,000	
Public (5)	Subsurface Infiltration	$200,000	$350,000	
Curb Extension	Bioretention	$50,000	$65,100	
Swale without Parking	Bioretention	$70,000	$90,000	
Swale with Parking	Bioretention	$80,000	$100,000	
Planter with parking	Bioretention	$130,000	$160,000	
Planter without parking	Bioretention	$80,000	$100,000	
Street Trees	street trees	$15,000	$18,000	

Table 2.3.1-4 Summary of Direct Construction Cost Estimates [ENRCCI 7966; RSMEAN 115.2]

Control	**Type**	**Minimum Cost ($ / impervious acre)**	**Median Cost ($ / impervious acre)**	**Mean Cost ($ / impervious acre)**	**Max Cost ($ / impervious acre)**
Bioretention	Retrofit	$65,000	$120,000	$160,000	$410,000
	Redevelopment	$44,000	$90,000	$110,000	$200,000
Subsurface Infiltration	Retrofit	$65,000	$120,000	$160,000	$410,000
	Redevelopment	$44,000	$90,000	$110,000	$200,000
Green Roof	Retrofit	$430,000	$500,000*	$500,000	$570,000
	Redevelopment	$200,000	$250,000*	$250,000	$290,000
Porous Pavement	Retrofit	$65,000	$120,000	$160,000	$410,000
	Redevelopment	$44,000	$90,000	$110,000	$200,000
Street Trees	Retrofit	$18,000	$18,000	$18,000	$18,000
	Redevelopment	$15,000	$15,000	$15,000	$15,000

* Other cities have been experiencing costs in the range of $7-16 per square foot ($305,000 - $700,000 per impervious acre), with a typical range of $10-14 per square foot ($435,000 - $610,000 per impervious acre). A

recent green roof at Temple-Ambler campus was approximately $11 per square foot ($480,000 per impervious acre). The least expensive green roofs in Chicago, which has the largest-scale program in the U.S., are on the order of $6-7 per square foot ($285,000 per impervious acre), and this may be a reasonable estimate of what can be achieved in the future with a large-scale program in Philadelphia.

Learning Curve Assumptions

Over the long term, the cost of low impact development techniques is expected to decline for a number of reasons. A list of estimated long-term reduced construction costs in shown in Table 2.3.1-5 and summary statistics are shown in Table 2.3.1-6. The reductions shown in this table are credited to improvements in site layouts, a reduction in the cost for materials, reduction in design costs, and reductions in perceived risk as low impact development becomes the standard way of doing business.

Better Site Design: Site designers are required to comply with Philadelphia's stormwater regulations today. However, design features needed to comply are often added as an afterthought, after the site layout has been determined. Designs are very dense and do not leave open space for stormwater management (or resident enjoyment). This forces stormwater management features into underground, infrastructure-intensive facilities. Over time, local engineers will adopt better site design techniques. In the estimates in Table 2.3.1-5, it is assumed that impervious area on each site is reduced by 20% compared to the actual designs submitted in recent years. A 20% reduction is reasonable; the Philadelphia stormwater regulations provide an incentive for a 20% reduction, and there is a precedent for this level of reduction in surrounding states.

Reductions in Material Cost: As low impact development techniques such as porous pavement and green roofs become the standard way of doing business, materials needed to build them will no longer be considered specialty materials. For example, the estimates in Table 2.3.1-5 assume that in the future porous pavement have the same unit cost as traditional pavement today.

Reductions in Design Cost: Because low impact development techniques are unfamiliar to many local engineers, design costs are currently high relative to total construction cost. In the Alternative Costing Tool, future design costs are assumed to be no more than a project of "typical complexity" on the ASCE engineering fee cost curve (discussed in more detail in ACT cost curve). This assumption does not affect the direct construction costs shown in Table 2.3.1-5.

Reductions in Perceived Risk: In the ACT, a relatively low contingency will be used for low impact development, assuming that contractors will perceive less risk over time as these techniques become the standard way of doing business. This assumption does not affect the direct construction costs shown in Table 2.3.1-5.

Table 2.3.1-5 Summary of Direct Construction Cost Estimates with Improved Development Practices and Economies of Scale in 2008 Dollars

Project Name	BMP Type	Cost Estimates ($/impervious acre)		Percent Reduction	
		Redevelopment	Retrofit	Redevelopment	Retrofit
Private (1)	Subsurface Infiltration	$110,000	$180,000	27%	24%
47th and Grays Ferry Traffic Triangle	Bioretention	$57,000	$64,000	20%	20%
Private (2)	Green Roof	$230,000	$460,000	20%	20%
Public (2)	Pervious Pavement	$66,000	$100,000	22%	22%
Private (3)	Subsurface Infiltration	$35,000	$63,000	20%	20%
Mill Creek Tree Trench	Subsurface Infiltration	$80,000	$100,000	19%	19%
Private (4a)	Green Roof	$160,000	$340,000	20%	20%
Private (4b)	Pervious Pavement	$120,000	$290,000	36%	27%
Private (5)	Subsurface Infiltration	$90,000	$130,000	20%	20%
Public (4)	Bioretention	$120,000	$160,000	20%	20%
Public (5)	Subsurface Infiltration	$160,000	$280,000	20%	20%
Curb Extension	Bioretention	$43,000	$52,000	20%	20%
Swale without Parking	Bioretention	$58,000	$74,000	20%	20%
Swale with Parking	Bioretention	$70,000	$80,000	20%	20%
Planter with parking	Bioretention	$100,000	$130,000	20%	20%
Planter without parking	Bioretention	$60,000	$79,000	20%	20%
Street Trees	street trees	$12,000	$15,000	20%	20%

The green roof cost estimate for improved development practices is based on the direct construction cost estimate with no improved practices/economies of scale.

Table 2.3.1-6 Summary Statistics of Direct Construction Cost Estimates with Improved Development Practices and Economies of Scale in 2008 Dollars

Control	Type	Minimum Cost ($ / impervious acre)	Median Cost ($ / impervious acre)	Mean Cost ($ / impervious acre)	Max Cost ($ / impervious acre)
Bioretention	Retrofit	$52,000	$100,000	$130,000	$290,000
	Redevelopment	$35,000	$80,000	$80,000	$160,000
Subsurface Infiltration	Retrofit	$52,000	$100,000	$130,000	$290,000
	Redevelopment	$35,000	$80,000	$80,000	$160,000
Green Roof	Retrofit	$340,000	$400,000	$400,000	$460,000
	Redevelopment	$160,000	$200,000	$200,000	$230,000
Porous Pavement	Retrofit	$52,000	$100,000	$130,000	$290,000
	Redevelopment	$35,000	$80,000	$80,000	$160,000
Street Trees	Retrofit	$15,000	$15,000	$15,000	$15,000
	Redevelopment	$12,000	$12,000	$12,000	$12,000

* Based on anecdotal information, resulting costs of approximately $6-9 per square foot ($260,000 - $395,000 per impervious acre) are in line with the experience of the large-scale program in Chicago.

Public-Sector Cost Sharing Assumptions

For some land use types, it is assumed that entities other than PWD assume a portion of the stormwater retrofit capital and O&M costs as follows:

- Schools (50% PWD, 50% other public entities)
- Park and recreation facilities (50% PWD, 50% other public entities)
- Other public lands - libraries, police, fire, health, etc. (50% PWD, 50% other public entities)
- Street trees - not part of green streets; this refers to street trees in the absence of other controls (50% PWD, 50% other public entities)
- Sidewalk replacement grant programs (50% PWD, 50% other public entities)
- Waterfront sewer separation (0% PWD, 100% other entities)
- Retrofit of vacant and abandoned lands (0% PWD, 100% other entities)
- Private lands affected by the stormwater ordinance and regulations (0% PWD, 100% other entities)

Operations & Maintenance Cost Analyses

Operations and maintenance (O&M) costs were summarized into five categories, Porous Pavement, Subsurface Vault, Green Roofs, Bioretention, and Street Trees, for the selected LID stormwater management plans. For each category O&M costs were broken down into required operations and maintenance activities as described in the Philadelphia Stormwater Management Guidance Manual. Operations and maintenance activities, length and frequency were also estimated. The operations and maintenance labor costs associated with each LID design were determined from union contract agreements with the city of Philadelphia. The operations and maintenance costs were marked up to cover the costs associated with overhead & profit, estimated at 25%. The labor rates that were used in the analysis are shown in Table

2.3.1-7. The equipment costs utilized in the analysis are presented in Table 2.3.1-8. All equipment costs are from RS Means Costworks 2008. Materials costs were assumed to be the 10% of the median marginal redevelopment cost (see Table 2.3.1-6) distributed over 25 years.

Table 2.3.1-7 Labor Rates

General Description	Class	Basic Hourly Rate	Fringe Benefits
Truck Driver	Journeyman Class II	$22.60	$11.37
Truck Driver	Journeyman Class III	$22.85	$11.37
Landscape Laborer	Class I	$17.13	$16.87
Landscape Laborer	Class II	$17.88	$16.87

Table 2.3.1-8 Equipment Costs

General Description	Units	Unit Cost
Rent Vacuum Truck, hazardous materials, 5000 gallons	per day	$335.00
Rented sewer/catch basin vacuum, 14 cy, 1500 gallon	per day	$485.00
Truck, pickup, 3/4 ton, 2 wheel drive	per day	$80.50

The O&M activity and schedule associated with porous pavement are included in Table 2.3.1-9.

Table 2.3.1-9 Porous Pavement O&M Activities

Activity	Schedule	Visits Per Year Per Impervious Acre	Hours Per Visit Per Impervious Acre	Total Hours Per Year per Impervious Acre
Vacuum porous asphalt or concrete surface with commercial cleaning unit (Pavement washing systems and compressed air units are not recommended)	Twice per Year	2	4	8
Clean out inlet structures within or draining to the subsurface bedding beneath porous surface	Twice per Year	2	4	8
Maintain records of all Inspections and maintenance activity	Ongoing	1	1	1

The O&M activity and schedule associated with subsurface infiltration are included in Table 2.3.1-10.

Table 2.3.1-10 Subsurface Infiltration O&M Activities

Activity	Schedule	Visits Per Year Per Impervious Acre	Hours Per Visit Per Impervious Acre	Total Hours Per Year per Impervious Acre
Regularly clean out gutters and catch basins to reduce sediment load to infiltration system. Clean intermediate sump boxes, replace filters, and otherwise clean pretreatment areas in directly connected systems	As needed	3	5	15
Inspect and clean as needed all components of and connections to subsurface infiltration systems	Twice per Year	2	3	6
Evaluate the drain-down town of the subsurface infiltration system to ensure the drain-down time of 24-72 hours	Twice per Year	2	1	2
Maintain records of all inspections and maintenance	Ongoing	1	1	1

The O&M activity and schedule associated with green roofs are included in Table 2.3.1-11.

Table 2.3.1-11 Green Roof O&M Activities

Activity	Schedule	Visits Per Year Per Impervious Acre	Hours Per Visit Per Impervious Acre	Total Hours Per Year per Impervious Acre
Roof drains should be cleared when soil substrate, vegetation, debris or other materials clog the drain inlet. Sources of sediment and debris may be identified and corrected	As needed	2	3	6
Plant material should be maintained to provide 90% plant cover. Weeding should be manual with no herbicides or pesticides used. Weeds should be removed regularly	As needed	2	8	16
Irrigation can be accomplished either through hand watering or automatic sprinkler system if necessary during the establishment period.	As needed	5	1	5
Growing medium should be inspected for evidence of erosion from wind or water. If erosion channels are evident, they can be stabilized with additional growth medium similar to the original material.	Quarterly	4	3	12
Inspect drain inlet pipe and containment system	Annually	1	4	4
Test growing medium for soluble nitrogen content. Fertilize as needed	Annually	1	1	1

Activity	Schedule	Visits Per Year Per Impervious Acre	Hours Per Visit Per Impervious Acre	Total Hours Per Year per Impervious Acre
Maintain a record of all inspections and maintenance activity	Ongoing	1	1	1

The O&M activity and schedule associated with bioretention are included in Table 2.3.1-12.

Table 2.3.1-12 Bioretention O&M Activities

Activity	Schedule	Visits Per Year Per Impervious Acre	Hours Per Visit Per Impervious Acre	Total Hours Per Year per Impervious Acre
Remulch void areas	As needed	1	0.5	0.5
Treat diseased trees and shrubs	As needed	1	0.5	0.5
Keep overflow free and clear of leaves	As needed	3	0.5	1.5
Inspect soil and repair eroded areas	Monthly	12	0.5	6
Remove litter and debris	Monthly	12	0.5	6
Clear leaves and debris from overflow	Monthly	12	0.5	6
Inspect trees and shrubs to evaluate health, replace if necessary	Twice per Year	2	1	2
Inspect underdrain cleanout	Twice per Year	2	2	4
Verify drained out time of system	Twice per Year	2	1	2
Add additional mulch	Annually	1	1	1
Inspect for sediment buildup, erosion, vegetative conditions, etc.	Annually	1	1	1
Maintain records of all inspections and maintenance activity	Ongoing	1	1	1

The O&M activity and schedule associated with street trees are included in Table 2.3.1-13.

Table 2.3.1-13 Street Trees O&M Activities

Activity	Schedule	Visits Per Year Per Impervious Acre	Hours Per Visit Per Impervious Acre	Total Hours Per Year per Impervious Acre
Treat diseased trees and shrubs	As needed	3	3	9
Remove litter and debris	Monthly	12	1	12
Inspect trees and shrubs to evaluate health	Twice per Year	2	3	6

A summary of annual operation and maintenance costs are listed in Table 2.3.1-14.

Table 2.3.1-14 Annual Operation & Maintenance Costs [ENRCCI 8141; RSMEAN 115.2]

Control	Annual O&M Costs ($/imp. Acre/yr)
Porous Pavement	$2,400
Subsurface Infiltration	$2,900
Green Roof	$4,000
Bioretention	$3,100
Street Tree	$1,800

<u>Personnel Estimates for Green Streets</u>

Based on the assumptions presented in the operations and maintenance descriptions, each acre of impervious drainage area requires approximately 24 hours of labor per year. Street lengths and widths vary widely, but on average the street and two sidewalks on one block make up approximately 0.5 acres of impervious surfaces. Assuming each employee averages 1600 hours of task work per year (excluding vacation, training), the following estimates are reached:

- 12 hours of labor are required per block of green streets per year.
- A 2-person crew can visit 266 blocks once per year, 133 blocks twice per year, or 66 blocks four times per year. In all cases, the crew would visit approximately 1 block per day.
- Streets and sidewalks make up 10,774 acres in the City-wide combined areas. A program to mitigate a portion of these through green infrastructure would result in the following estimated personnel requirements:
  - 10% (1,077 ac): 17 employees
  - 25% (2,693 ac): 41 employees
  - 50% (5,387 ac): 81 employees
  - 75% (8,080 ac): 122 employees
  - 100% (10,774 ac): 162 employees

Life Cycle Assumptions

During the analysis a literature study was conducted on lifespan assumptions for each of the five categories of LID stormwater management designs and results can be found in Table 2.3.1-15.

Table 2.3.1-15 Life Cycle Assumptions

Control	Lifespan
Bioretention	25[1]
Green Roofs	25-30[1,2]
Subsurface Infiltration	25[1]
Porous Pavement	25[1]
Street Trees	25-40[1,2]

[1]- EconNorthwest, 2007

[2]- internal communications

Based on these results, green infrastructure is typically overhauled or replaced every 25-40 years. Based on this and assuming a comprehensive O&M program, it appears reasonable to assume that an overhaul will not be performed until the end of the LTCPU planning horizon of 40 years. However, replacement costs are discussed in the following section in case they are needed.

Replacement Costs

Replacement cost is determined by assuming that most traditional stormwater infrastructure components do not need replacing based on PWDs existing infrastructure life cycle. Traditional components include inlets, manholes, diversion structures, and pipes and related materials (i.e. gravel and fill). Most green infrastructure components have a shorter lifecycle and may need to be replaced more often. These costs are weighted with a percentage to determine the extent of the components cost to the replacement for a given LID technique. Trees and plants have definite lifecycles and are assumed to be replaced completely if used in a given technique. Components such as gravel and soil are assumed to be replaced to a lesser extent, because their functionality is longer lasting. Other specific components, such as porous pavement and green roof components are assumed to be replaced completely. Table 2.3.1-16 is an example of how replacement costs are determined

Table 2.3.1-16 Example Specific Material Replacement Costs

Material	Units	Quantity	Unit Cost	Total Cost	Replacement Cost % Of Original	Replacement Cost
Deciduous Tree	total	6	$385.00	$2,310.00	100%	$2,310
Bark Mulch	sq. yd	10.7	$6.15	$65.56	100%	$66
Geotextile Separation Fabric	sq. yd	10.7	$1.95	$20.80	100%	$21
Planting Backfill Mixture	cu. Yd	9.5	$29.50	$279.70	100%	$280
Hauling Backfill Mixture to Site	cu. Yd	9.5	$30.55	$289.66	100%	$290
Excavation	cu. Yd	10.7	$2.75	$29.31	100%	$29
Porous Pavement						
Pervious Asphalt	sq. yd	652	$10.45	$6,817.16	100%	$6,817
AASHTO No. 57 Choker	cu. yd	18	$37.69	$682.94	50%	$341
AASHTO No. 2 Coarse Aggregate	sq. yd	652	$9.55	$6,230.04	50%	$3,115
Non-Woven Geotextile	sq. yd	784	$1.95	$1,529.50	50%	$765
Excavation	cu. Yd	218	$2.75	$598.84	50%	$299
Hauling Asphalt Materials to Site	cu. yd	163	$30.55	$4,985.76	100%	$4,986
Hauling for excavated soil	cu. Yd	218	$30.55	$6,656.17	50%	$3,328
Pipe Trench Under Porous Pavement						
24" Perf. Pipes	ft	774	$62.00	$47,988.00	0%	$0
24" LF HDPE Header	ft	22	$62.00	$1,364.00	0%	$0
Gravel	sq. yd	95	$15.40	$1,467.56	0%	$0

Hauling Aggregate to Site	cu yd	91.2	$30.55	$2,786.47	0%	$0
Inlet Structure						
Reinforced Concrete Inlet Box	total	1	$4,800.00	$4,800.00	0%	$0

Material	Units	Quantity	Unit Cost	Total Cost	Replacement Cost % Of Original	Replacement Cost
Excavation volume	cu. Yd	4.7	$2.75	$13.03	0%	$0
Hauling for excavated soil	cu. yd	4.7	$30.55	$144.83	0%	$0
Footing	each	1	$27.78	$27.78	0%	$0
Reinforced Concrete Top Unit	total	1	$440.00	$440.00	0%	$0
Heavy Duty Inlet Frame	total	1	$1,125.00	$1,125.00	0%	$0
Coarse Aggregate Size No. 57	cu yd	0.67	$37.69	$25.13	0%	$0
Hauling Aggregate to Site	cu yd	0.67	$30.55	$20.37	0%	$0

The summary of estimated replacement costs for specific control techniques is summarized in Table 2.3.1-17.

Table 2.3.1-17 Replacement costs

Control	Median Cost ($ / Impervious Acre)
Bioretention	$35,000
Subsurface Infiltration	$35,000
Green Roof	$220,000
Porous Pavement	$35,000
Street Trees	$12,000

Literature Review

A literature review of documents referencing stormwater management construction cost information utilizing low impact development was performed. The estimates were then updated to account for changes in cost due to inflation and location. Cost estimates were adjusted for inflation using the ENR cost index and adjusted for location using RS Means location factors. Stormwater management practices are listed in Table 2.3.1-18. This table lists the redevelopment construction cost ranges from CWP, 2007. The retrofit construction cost ranges are listed within Table 2.3.1-19. The construction cost range for retrofits are broken down into three stormwater management practices pond retrofit, new storage retrofit, and urban on-site retrofit. Urban on-site retrofit is the most similar to the type of development we expect in Philadelphia.

Table 2.3.1-18 Construction Cost Ranges by Category for New Development

Stormwater Practice	Min ($/impervious acre)	Median ($/impervious acre)	Max ($/impervious acre)
Constructed Wetlands	$2,100.00	$3,000.00	$10,000.00
Extended Detention	$2,300.00	$4,000.00	$7,800.00
Wet Ponds	$3,200.00	$8,700.00	$30,000.00
Water Quality Swales	$11,000.00	$19,000.00	$38,000.00
Bioretention	$21,000.00	$27,000.00	$44,000.00
Infiltration	$21,000.00	$27,000.00	$44,000.00
Residential Green Rooftop	$11,000.00	$28,000.00	$51,000.00
Filtering Practices	$19,000.00	$60,000.00	$83,000.00
Non-Residential Green Roof	$23,000.00	$95,000.00	$1,100,000.00

Table 2.3.1-19 Construction Cost Range by Category for Retrofit

Stormwater Practice	Min ($/impervious acre)	Median ($/impervious acre)	Max ($/impervious acre)
Pond Retrofit	$3,800	$12,000	$39,000
New Storage Retrofit	$9,400	$20,000	$34,000
Urban On-site Retrofit	$61,000	$92,000	$160,000

Additional & Validation Cost Estimates

The continued implementation of additional green infrastructure and LID stormwater features in Philadelphia has allowed for the addition of more projects and plans, which can be used to validate the original cost estimates created in the beginning of this memo. Additional estimates include an on street retrofit and a compilation of the draft PWD standard details for stormwater management.

An example project is a street level tree planter and subsurface infiltration system. The construction cost estimate for the project was determined to be $250,000 per impervious acre. The construction cost estimate for the project is within the maximum range of the retrofit cost estimates in Table 2.3.1-4.

PWD has drafted several standard details for street retrofits of green infrastructure. These include on street planters, porous pavement and other types of street retrofits to manage stormwater. Table 2.3.1-20 is a summary of the construction cost estimates for the standard detail plans with a summary of the average and median of these estimates.

Table 2.3.1-20: Construction Cost Estimates of Draft PWD Standard Details

Standard Detail Description	Retrofit Cost ($ / Impervious Acre)
Curb Extention - Apex Inlet	$162,000
Curb Extention - End Inlet	$168,000
Mid-Block Curb Extention	$116,000
Infiltration Planter	$138,000
Porous Pavement	$151,000
Tree Planter	$79,000
Tree Planter - No Tree Grate	$38,000
Tree Planter Direct Opening	$158,000
Tree Planter Direct Opening - No Tree Grate	$116,000
Tree Planter w/additional storage	$128,000
Tree Planter w/additional storage - No Tree Grate	$86,000
Tree Trench	$108,000
Tree Trench - No Tree Grates	$82,000
Average	$118,000
Median	$116,000

2.3.2 Municipal Inflow and Infiltration Reduction

The ACT allows for planning level estimation of rehabilitation costs of municipal sewer infrastructure in an effort to reduce inflow and infiltration (I/I). Calculations for estimating cost of these rehabilitation alternatives are structured into the ACT with the user providing any additional costs for O&M of a given alternative. The ACT includes rehabilitation costs for the following municipal I/I reduction measures. Tables 2.3.2-1 and 2.3.2-2 summarize the Municipal I/I unit costs within the ACT.

Pipe Lining

The ACT determines pipe lining costs based on the following user inputs:

- Type of lining (cured-in-place or user defined)
- Pipe diameter (8-inch through 48-inch; see Table 2.3.2-1 for unit costs)
- Pipe length (in linear feet)

The ACT calculates the cost of pipe lining per linear foot of pipe installed. A default unit cost per linear foot, varying by pipe diameter, is provided in the ACT. The user has the ability to change this unit cost, but must provide acceptable documentation of the basis of cost.

Manhole Rehabilitation

The ACT assumes that manhole rehabilitation includes sealing manholes and installing water tight frames and covers. The user inputs the number of manholes to be rehabbed, which are multiplied by a default unit cost value ($2500 per manhole) to determine the total manhole rehabilitation cost. The user has the ability to change this unit cost, but must provide documentation of the basis of cost.

Catch Basin Rehabilitation

Catch basin rehabilitation includes sealing-off the connection from a catch basin to a sanitary or combined sewer. Construction cost estimates are based upon the input of number of catch basins or storm inlets to be removed, with a default unit cost per rehabilitation to be applied ($600 per catch basin). This unit cost does not include the new pipe and surface restoration required to reroute the catch basin. These items can be calculated separately in the open cut pipe section of the ACT. The ACT unit cost is configured for this default type of catch basin rehabilitation; the user has the ability to change this unit cost, but must provide documentation of the basis of cost.

Service Lateral Spot Repair

The ACT estimates the cost spot repair cost of municipal service laterals. Existing laterals would be reconnected with street wyes replaced. Construction cost estimates are based upon the input of linear feet of laterals to be repaired, with a default unit cost to be applied ($350 per LF repaired). The unit cost value in the ACT is configured for this default type of service lateral repair. The user has the ability to change this unit cost, but must provide acceptable documentation of the basis of cost.

Table 2.3.2-1 Municipal Pipe Lining Unit Costs in ACT [ENRCCI 8551; RSMEAN 100]

Diameter (in)	CIPP Pipe Lining Unit Cost ($/LF)
8	$137
10	$159
12	$199
15	$258
18	$280
21	$318
24	$395
27	$476
30	$572
36	$706
42	$846
48	$985

Table 2.3.2-2 Municipal Pipe Lining Unit Costs in ACT [ENRCCI 8551; RSMEAN 100]

Technology	Default Unit Cost	Units	User Defined Unit Cost Option?	O&M Cost Estimate
Manhole Rehabilitation	$2500	Per manhole	Yes	User to input a lump sum value for all Municipal I/I reduction alternatives where applicable.
Catch Basin Rehabilitation	$600	Per catch basin	Yes	
Service Lateral Pipe Repair	$350	Per LF of lateral repair	Yes	

2.3.3 Private Inflow and Infiltration Removal

As for municipal collection sewer rehabilitation, the user may choose to evaluate the cost-effectiveness of wet-weather flow reduction by reducing I/I from private sources. Calculations for estimating cost of these removal alternatives are structured into the ACT with the user providing any additional costs for O&M of a given alternative. The ACT includes rehabilitation costs for the following private I/I reduction measures. Table 2.3.3-1 summarizes the Private I/I unit costs within the ACT.

Service Lateral Lining

This work includes spot repairs to the service lateral from a house or other building to the sewer pipe. Construction cost estimates are based upon the input of the combined length (in LF) of service laterals which require lining, with a default unit cost per LF to be applied ($120 per LF). The unit cost value in the ACT is configured for this default type of service lateral repair. The user has the ability to change this unit cost, but must provide acceptable documentation of the basis of cost.

Sump Pump Discharge Rerouting

For existing homes or other establishments with a sump pump that discharges flow from footing drains (and possibly roof leaders) into the sanitary system, this work includes constructing a hard pipe from the sump pump through the basement wall to an adequate discharge location (work will conform to applicable plumbing codes and other municipal regulations). The user will input the number of homes or other establishments for which this work will be performed, with a default unit cost per home to route sump pump discharge below grade to storm system ($4,700 per rerouting). The user has the ability to change this unit cost, but must provide acceptable documentation of the basis of cost.

Footing Drain Disconnection

For existing homes or other establishments where footing drains (and possibly roof leaders) are tied into the interior sanitary plumbing, this work includes removing and replacing portions of the basement floor as needed to separate the interior plumbing so that footing drains are routed to new sump. This work also includes constructing a hard pipe form the sump pump through the basement wall to a curb drain system, or existing catch basin. The unit cost includes the homeowner’s share of the curb drain system cost. The user will input the number of homes or other establishments for which this work will be performed, with a default unit cost applied ($8,000 per disconnection). The user has the ability to change this unit cost, but must provide acceptable documentation of the basis of cost.

Exterior Roof Leader Disconnect

For buildings where roof leaders are tied into the footing drains and make their way to the sanitary lateral, this work includes disconnecting (cutting) the down pipe and providing a discharge to the ground for homes or other establishments with an adequate discharge location and where local codes permit. The user will need to specify the estimated number of roof leaders to be disconnected, as well as distinguish the type of roof leader disconnection. The user also needs to specify whether will be performed by the homeowner or municipality. The user has the ability to change this unit cost, but must provide acceptable documentation of the basis of cost.

Private Drain Disconnection

This work includes sealing the connection from a driveway drain or other private storm drain to a sanitary sewer. It also includes re-routing the drain line to an existing storm outlet or constructing a new drain outlet. The user will need to specify the estimated number of drains to remove and the total length of new storm sewer required. Based on these assumptions, a default unit cost is applied ($600 per disconnection). The user has the ability to change this unit cost, but must provide acceptable documentation of the basis of cost.

Table 2.3.3-1 Private I/I Removal Unit Costs [ENRCCI 8551; RSMEAN 100]

Technology	Default Unit Cost	Units	User Defined Unit Cost Option?	O&M Cost Estimate
Service Lateral Lining	$120	Per LF of lateral lining	Yes	User to input a lump sum value for all Private I/I reduction alternatives where applicable.
Sump Pump Discharge Rerouting	$4700	Per sump pump rerouting	Yes	
Footing Drain Disconnection	$8000	Per disconnection	Yes	
Exterior Roof Leader Disconnection	$20	Per homeowner disconnection	Yes	
	$70	Per municipality disconnection		
Private Drain Disconnection	$600	Per drain disconnection	Yes	

2.3.4 Sewer Separation

Sewer separation construction costs were based on three components: new sanitary sewer construction costs, sewer lateral construction costs, and streetscape reconstruction cost. Unit cost data is based on recent construction bids received by PWD and are considered construction costs with overhead, profit and indirect costs included. Data is summarized in Table 2.3.4.1.

Table 2.3.4.1 Sewer Separation Component Costs [ENRCCI: 8551; RSMeans: 115.2]

Component	Unit Cost	Units
New Sanitary Sewers	$1,700,000	$/mile
Lateral from new sewer to property	$6,000	$/lateral
Interior plumbing modifications - Residential	$6,000	$/lateral
Interior plumbing modifications - Non-Residential	$20,000	$/lateral
Concrete Street Base	$6	$/square foot
Asphalt Paving	$3	$/square foot
Concrete Sidewalk	$7	$/square foot
Concrete Curb	$26	$/foot

2.3.5 Open Cut Pipe

The ACT performs cost estimation for new conveyance. Open cut installation of gravity sewer pipe is included as a technology alternative in the ACT. Construction cost estimates for open cut pipe in the ACT require the following user input values:

- Pipe cross-section, either circular or a box section;
- The nominal size of the cross-section in terms of diameter for circular pipe or a specified box size
  - Circular pipe nominal diameters range between six and 108 inches. In addition to the nominal diameter, the pipe material must be chosen by the user from a menu list (PVC, Class II, III, IV, and V concrete pipe, or ductile iron).
  - Box culverts range in size between four foot by eight foot and 12 foot by 12 foot. The orientation of the box is also an input value, either wide or tall dependant on the orientation of the longer side of the box. A "wide" box would have a longer horizontal orientation, while a "tall" box would have a longer vertical orientation. The orientation designation of a square box will have no effect on unit cost.
- The proposed length of the pipe in the street as well as the length of the pipe out of the street, both in linear feet.
- The average depth to the pipe invert in vertical feet. The maximum depth to invert is 24 vertical feet.
- The volume percentage of rock excavation to total excavation.
- The pavement type. The tool has default values for eight inch bituminous pavement or 11.5 inch pavement. There is also an option of a user-defined pavement type in which the user must input the pavement thickness and the street restoration unit cost in dollars per square yard.
- The user must define the street restoration efforts, choosing between two configurations: a partial street opening which equals the trench width plus one foot on either side of the trench, or a complete restoration equal to the entire street width. The street width is a user input.
- The number of manholes and their typical diameter.
- The number of utility crossings encountered in the street.
- The number of service laterals to be installed or restored.
- Any sidewalk or curb restoration anticipated, and several user inputs for this type of restoration if it is needed.
- User defined costs including: railroad costs, stream crossing costs, additional force main costs, and miscellaneous.
- Finally, several open pipe construction conditions are estimated as a percentage of total construction cost. These conditions include dewatering requirements, flow maintenance requirements, and traffic maintenance requirements.

The total cost estimate for open cut is determined by summing numerous direct unit construction costs (e.g. pipe material costs, equipment and labor costs for soil excavation).

Open Cut cost data is considered to be direct construction costs excluding overhead and profit, and indirect costs, and are summarized in Tables 2.3.5-1 through 2.3.5-14. The base index values for all open cut pipe cost data is ENRCCI 7312 and RS Means 92.9.

Figure 2.3.5-1 displays the open cut pipe cost estimating schematic which outlines the methodology followed in the ACT.

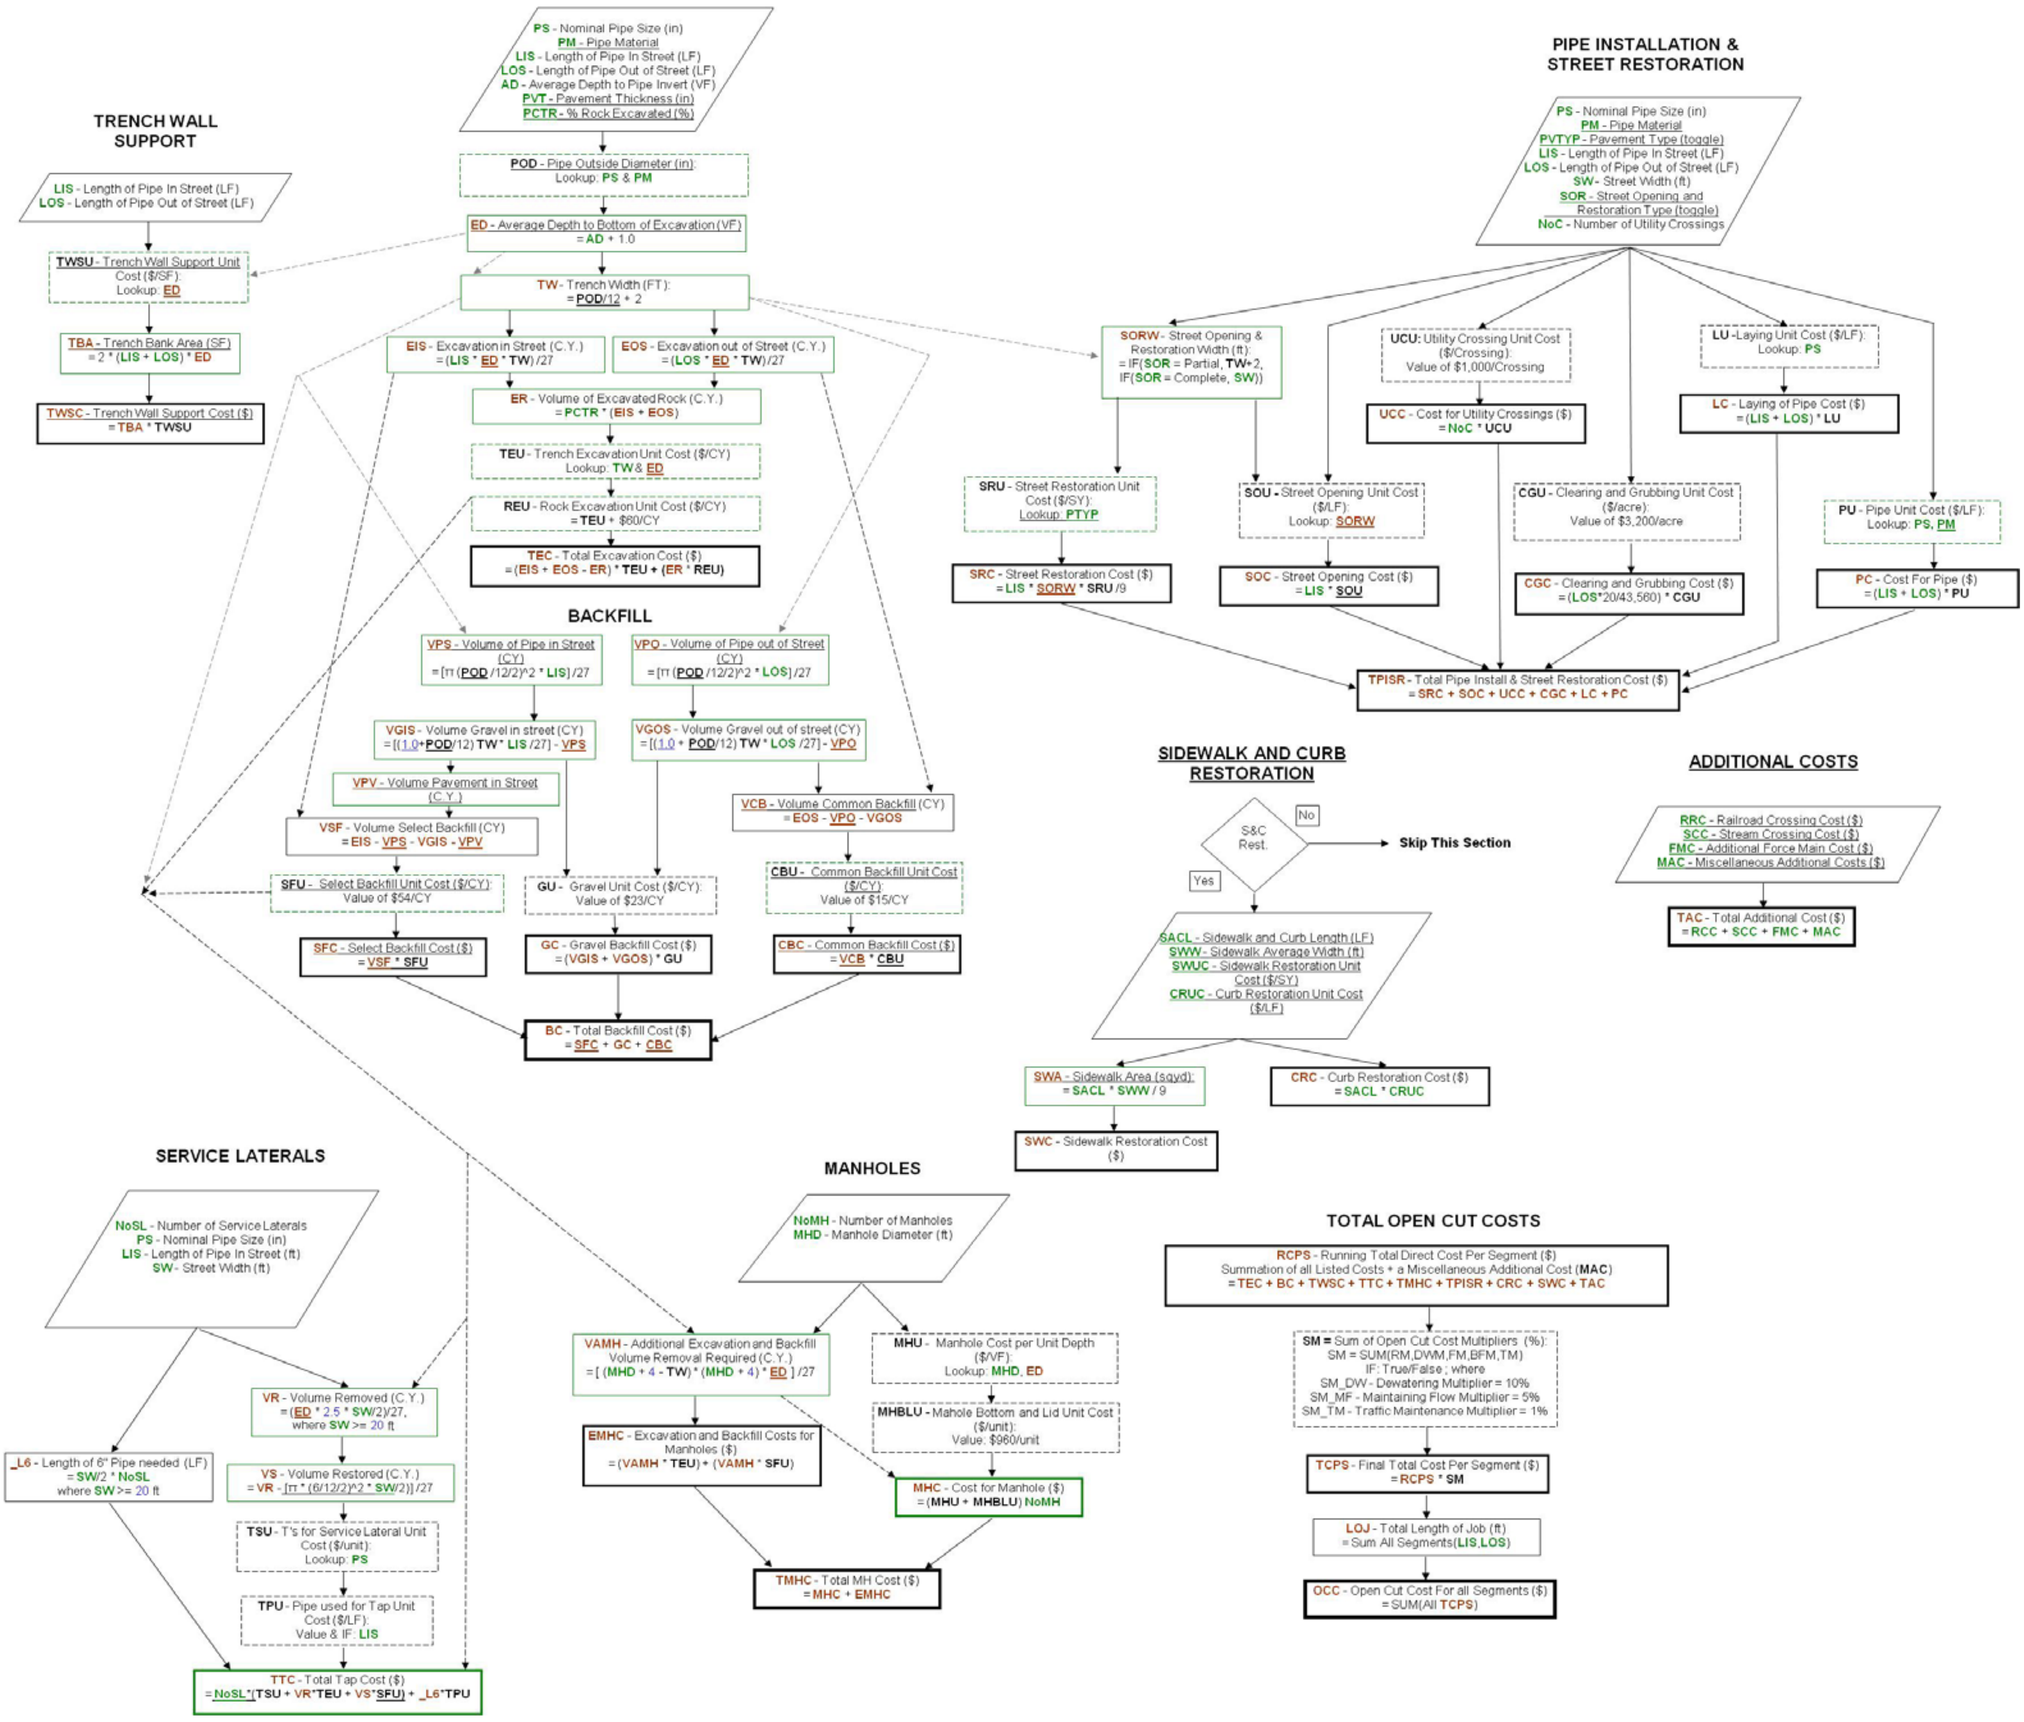

Figure 2.3.5-1 Open Cut Pipe Logic and Flow Diagram

Traffic Maintenance Required (Y/N)?	1.00%

Conveyance Pipe O&M Costs

Maintenance of open-cut and trenchless pipes are based upon the same data set, and the costs to maintain both conveyance means can be estimated in a similar manner. The reference for O&M of both is a 2003 Detroit Water and Sewer Department (DWSD) report titled *Wastewater Master Plan Volume 4: Capital Improvements Program*. This report analyzed operation and maintenance of the conveyance pipe in the DWSD system between 1992 and 1996, and developed target maintenance frequency equations for three most important maintenance issues: pipe cleaning, root intrusion removal, and TV inspections. The report also provided an audit of O&M costs and assigned a maintenance unit cost in dollars per linear foot of pipe for each of the three maintenance issues. These values were updated for time and location within the ACT using ENR CCI and RS Means index values respectively.

Similar to the pipe maintenance analysis, an additional analysis of O&M costs related to manhole cleaning was determined in the DWSD report. This value is reported in dollars per manhole per year.

An additional option for calculating O&M costs for conveyance pipe in the ACT is for the user to input their own unit costs. The default configuration is based on the same units used in the DWSD report. Table 2.3.5-15 contains open cut pipe O&M costs.

Table 2.3.5-15 Open Cut Pipe O&M Cost Data [ENRCCI 7312; RS MEANS 92.9]

Detroit Conduit O&M	$/LF-yr	4.00

Detroit O&M ENRCCI		6771.00
Detroit O&M Means		103.90

2.3.6 Pump Stations

For purposes of the ACT, all pump stations were assumed to be constructed as stand-alone structures − not part of a larger treatment or storage facility.

Construction cost estimates including overhead and profit, and indirect costs for three different pump station types were developed: custom built wet-well/dry well, submersible, and deep tunnel dewatering. Deep tunnel dewatering pump stations can be significantly deeper than typical pump stations and will be used to dewater CSO storage tunnels. Custom built wet-well/dry-well and submersible pump stations are typical wet weather pump types, and will be used for collection and interceptor transmission, pumping into and dewatering satellite treatment facilities, and pumping into and through treatment plants. Low, intermediate, and high cost curves were determined for custom built wet-well/dry well and submersible pump stations. The primary factor for selecting a cost curve range is total dynamic head (TDH). For the purposes of cost estimating in the ACT, high cost custom built wet-well/dry well pump stations generally have a TDH greater than 70 feet, whereas high cost submersible pump stations generally have a TDH greater than 50 feet. A secondary factor for selecting a cost curve range is standby power. For the purposes of cost estimating in the ACT, intermediate cost pump stations are generally shallower than high cost pump station and have standby power, whereas low cost pump stations are generally shallower and without standby power.

The ACT provides pump station cost estimates based on the following user inputs:

- Type of pump station including low, intermediate, and high cost range
- Required firm pumping capacity

In addition, the user has the option of adding user defined cost multipliers for pump station facility components which could add to typical pump station costs such as: bar screens, maintenance dewatering pumps, grit removal provisions, odor control, variable speed motors, and special building requirements for motors and electrical controls.

The custom built wet-well/dry-well and submersible pump station cost estimating curves were based on the 2006 text book reference *Pumping Station Design (Third Edition).* The deep tunnel dewatering pump station cost curve was based on a collection of costs for existing and proposed large capacity deep tunnel dewatering pump stations in the United Stated. These costs were in the form of bids and basis of design costs, and a power trendline was developed through the cost data points.

Pump station construction cost data is included in Figure 2.3.6-1.

The design curves for pump stations were developed from Jones et al. *Pumping Station Design (3rd Ed.).* Cost estimation curves from this publication were developed from a range of pump station installations around the US, and classified as either a custom built wet-well/dry-well facilities (Figure 2.3.6-1) or submersible facilities (Figure 2.3.6-2).

From each of these classifications, a low, intermediate, and high cost curve was developed to encapsulate the range of costs which can be encountered in different pump station applications.

The selection of which curve to use is dependant primarily on depth and secondarily on whether standby power is needed at the station. Table 2.3.6-1 is a matrix for selecting low, intermediate or high cost curves. These curves represent construction costs including contractor's overhead and profit and indirect costs.

In addition, a cost estimation curve was provided for deep tunnel dewatering pump stations (Figure 2.3.6-3). This curve was developed from project cost data of installed dewatering pump stations. (Note: Figure 2.3.6-3 also displays two curves along with equations, developed via the *Pumping Station Design (3rd Ed.)* method. These curves are used for comparison; the ACT only contains one cost estimation curve for deep tunnel dewatering).

Table 2.3.6-1 Cost Curve Selection Matrix for Pump Stations
[ENRCCI 8551; RS MEANS 100]

Cost Curve	Depth[1]	Standby Power[2]
High	Deep	Yes or No
Intermediate	Shallow	Yes
Low	Shallow	No

[1] Deep Depths: Submersible (>50' TDH)
Custom-Built Wet Well-Dry Well (>70' TDH)
[2] Standby Power: Back-up generators or dual electrical supply

For custom-built wet well/dry well pumping stations, the selected curves are as follows:

$$\text{High Cost Curve: } y = 803{,}151x^{0.9002}$$
$$\text{Intermediate Cost Curve: } y = 385{,}002x^{0.8941}$$
$$\text{Low Cost Curve: } y = 182{,}255x^{0.8914}$$

For submersible pumping stations, the selected curves are as follows:

$$\text{High Cost Curve: } y = 1{,}077{,}394x^{0.6158}$$
$$\text{Intermediate Cost Curve: } y = 473{,}381x^{0.6910}$$
$$\text{Low Cost Curve: } y = 207{,}992x^{0.7662}$$

For deep tunnel dewatering pumping stations, the equation for the selected curve was:

$$y = 1{,}077{,}394x^{0.6158}$$

For all pump station cost estimate equations, y equals construction cost in dollars, and x equals pump station capacity in MGD.

2) Swan Island Dewatering Pump Station: City of Portland (220 mgd capacity, 150 ft deep); based on correspondence with Corollow Engineers. *Limitations: unknown cost type (bid, bod, etc), unknown year of cost (construction started 2002, ended 2006) assumed 2001.*

3) IIS Pump Dewatering Pump Station: Milwaukee (180 mgd capacity, approx. 300 ft deep); based on Dec. 14, 2007 Black and Veatch Report titled: IIS Pump Station Upgrade Conceptual Design Report Contract NO. J01009E01. *Limitation: basis of design cost.*

4) Upper Rogue Dewatering Pump Station: Detroit (100 mgd capacity, 185 ft deep); based on conceptual design costs determined by CDM in 2005. *Limitation: basis of design cost.*

5) Mainstream Pump Station: Chicago TARP (2 levels of pumps: 710 MGD High TDH, 320 MGD Low TDH; used 710 MGD as the representative capacity); cost estimated from highest of the three lowest bid prices (dated 1979) provided by Chief Engineer at MWRDGC. *Limitations: unknown if costs include excavation and other geotech. unknown which bid won the job.*

Figure 2.3.6-3 Deep Tunnel Dewatering Pump Station Curves [ENRCCI 8551; RS MEANS 100]

Pump Station O&M Costs

Pump station O&M costs are calculated based on three cost components: energy costs, material costs and labor costs. Energy costs are calculated based upon user input values for the annual volume pumped (in mgd), the dynamic head (in feet), the "wire to water" efficiency, and electrical rate (in dollars per kilowatt-hour). The "wire to water" efficiency is the overall efficiency of the pump, motor and variable speed drive. This efficiency is the product of the efficiency percentages of these three components and is a percentage represented as a decimal value.

Three different options can be applied to calculate both material and labor costs for pump stations in the ACT. The first method is derived from USEPA document 430/9-78-009, *Innovative and Alternative Technology Assessment Manual* dated February 1980. This document includes cost curves for both materials and labor annual cost as a function of wastewater flow (in mgd).

The second option for determining costs of pump station material and labor in the ACT was derived from cost data provided by PWD. Labor and material costs were calculated for each of 13 pumping stations based on materials purchased, annual maintenance man hours (including overtime hours) and an average hourly labor rate including fringe benefits applied from actual laborer salary data for calendar year 2007. Also applied to the labor costs is a site specific work overhead percentage. The total annual labor and material costs were plotted individually against the rated pump station capacity (in mgd), and a linear line of best fit of these points determined the labor and materials cost equations.

The final option for calculating O&M costs for pumping stations in the ACT is for the user to input their own cost equation. The default configuration is for a linear cost equation with rated capacity (in mgd) as the independent variable. Figure 2.6.3-4 summarizes the pump station O&M cost curves based on pump station capacity and compares the PWD costs to EPA O&M cost data.

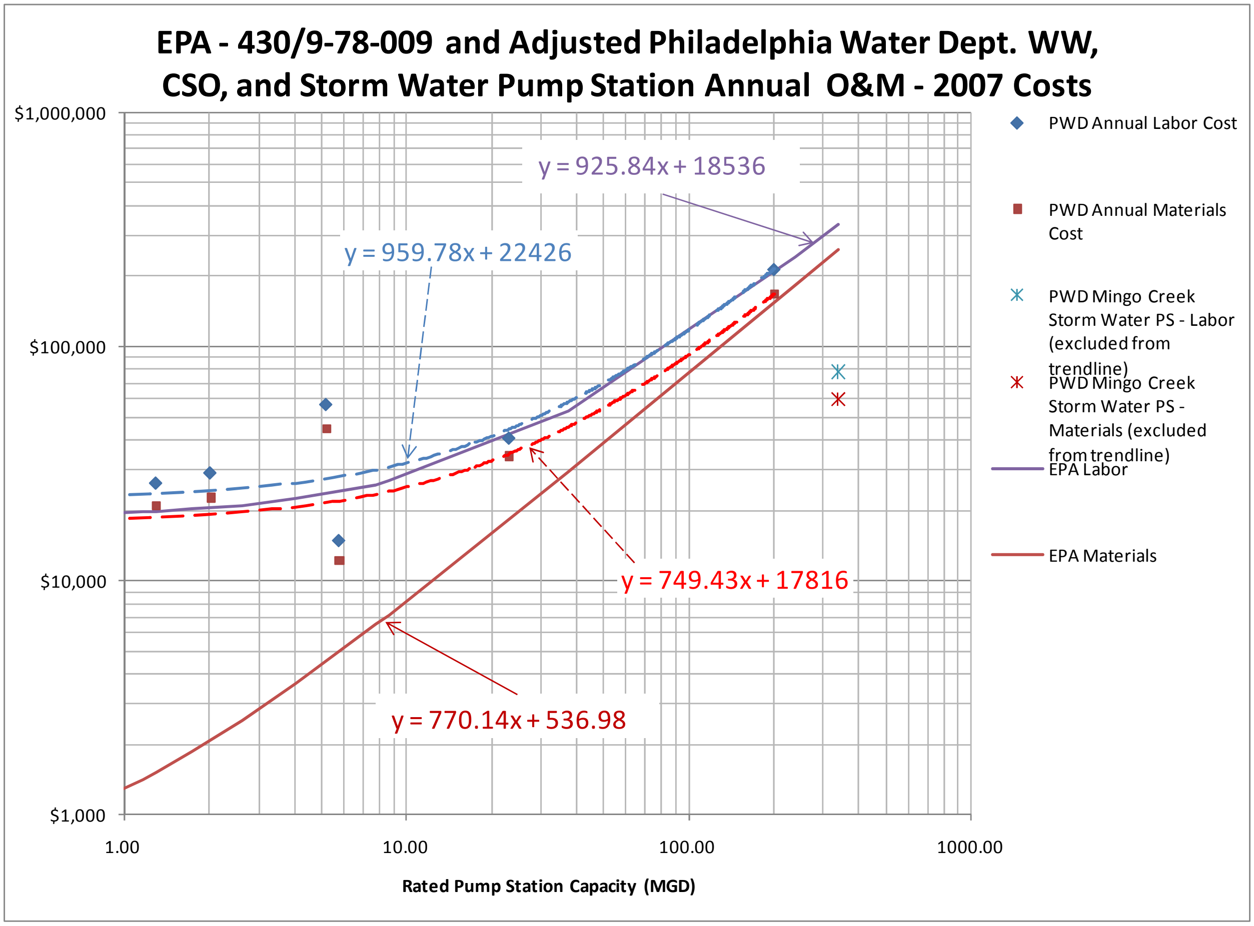

Figure 2.6.3-4 Pump Station Operations and Maintenance Costs [ENRCCI: 7939(PWD), 7966(EPA); RSMeans: 115.2 (PWD), 100.0 (EPA)]

2.3.7 Force Mains

There is not a separate control category for force mains in the ACT. Construction costs for force mains are to be calculated in the same manner as open-cut pipe, with the exception that the construction cost will assume installation of ductile iron pipe. Air release valves can be added as additional costs in the open-cut pipe cost estimate worksheet in the ACT.

2.3.8 Short-Bore Tunnel (Trenchless)

Trenchless methods of pipeline construction can be superior to open cut methods, or the only option for special applications. Trenchless methods result in less surface disturbance, minimize pavement damage, and reduce utility conflicts, which is important when working in urban areas. Trenchless methods should be used when crossing highways, railroads, and other obstacles that are poorly suited for open cut methods. Trenchless methods might be less expensive than open cut methods depending on various factors including pipe depth, pipe diameter, distance between pits, geology, the bidding environment, etc. Trenchless methods can be used for pipe depths deeper than what is feasible for open cut methods.

Many trenchless methods exist; however, the two most applicable methods were included in the ACT for cost estimating purposes: Microtunneling, and Pipe Jacking. These two methods work by pushing segments of pipe through the ground from a Jacking Pit. Microtunneling utilizes a micro-tunnel boring machine (MTBM) for advancement at the front of the pipe segments, whereas Pipe Jacking utilizes an open face. Pipe Jacking is typically a little less expensive, but because it utilizes an open face it should not be used below the groundwater table. Pipe Jacking is less favored than Microtunneling for diameters less than 48 inches and greater than 72 inches. For cost estimating purposes it is reasonable to not consider Pipe Jacking, and assume that Microtunneling will be used on all trenchless jobs. Both techniques require a Receiving Pit for retrieving equipment at the end of a pipe run. Significant cost savings can occur when two or more pipe runs share the same receiving or jacking pit.

Trenchless costs are sensitive to the geology at the pit locations and along the pipe run. For planning level cost estimation, basic geological conditions can be identified along the pipe run (e.g. soil, rock, and mixed), and in the pits (soil, rock). Mixed face conditions occur when both rock and soil conditions are experienced along the pipe run. Mixed face conditions should be avoided when possible, and will increase the uncertainty of the cost estimate. Steel pipe is recommended in mixed face conditions.

The ACT provides construction cost estimates for pipelines constructed by trenchless methods based on the following user inputs:

- Pipeline
    - Method (Microtunneling or Pipe Jacking)
    - Nominal Pipe Size (ranging between 24 to 144 inches, but extreme minimum and maximum sizes are not feasible for all applications)
    - Pipe Material (RCP, HOBAS, Composite FRP, Steel)
    - Pipe Length (distance between pits)
    - Ground Type (Soil, Rock, Mixed)
- Jacking and Receiving Pits

  - Depth of Soil (i.e. depth from the ground surface to the bottom of excavation in soil)
  - Depth of Rock (i.e. depth from the bottom of excavation in soil to the bottom of excavation in rock)
  - Manhole at Pit (yes, or no)

Planning level trenchless unit costs are presented in Tables 2.3.8-1 through 2.3.8-10 and are in terms of direct construction costs (i.e. materials, labor, and equipment), and do not include contractor's overhead and profit and indirect costs.

The total direct construction cost estimate for a trenchless pipeline is determined by the summation of the following cost groups: piping, pits, and manholes or just backfill. The piping costs listed by the soil group are complete and include the pipe material costs. Pit costs are determined by summing the Set Floor, Thrust Wall & Jacking Frames cost, cost per vertical foot in soil, and additional cost per vertical foot in rock. More specifically, costs per vertical foot are calculated separately for each depth group. When in rock, the cost per vertical foot in soil and additional cost in rock is summed together. The manhole costs per vertical foot are complete. If a manhole is not built the backfill cost per vertical foot should be used.

Trenchless tunneling costs ultimately depend on site specific and local geotechnical conditions, and other factors; the planning level unit costs presented in Tables 2.3.8-1 through 2.3.8-10 represent optimum conditions and other assumptions:

- Planning level classifications of geotechnical soil conditions were used: soil, rock, mixed face.
- Ground improvement costs were not included.
- Production rates reflect work in urban streets with timely delivery of materials.
- Jacking and receiving pits were estimated using soldier piles and lagging for earth support.
- Rock was assumed to be below 15,000 psi compressive strength.
- Risk of boulders and manmade obstructions were not considered.
- Dewatering costs were excluded.

The planning level unit costs presented in Tables 2.3.8-1 through 2.3.8-10 were developed by summing numerous direct unit construction costs (e.g. pipe material costs, equipment and labor costs for soil excavation). The logic for assembling the costs was based on engineering judgment and current industry practices. Unit cost sources and methods include:

- Labor Costs
  - Labor rates for Philadelphia.
  - Workman's compensation, liability insurance, and taxes were included in the labor rates.
  - Provisions for some overtime were included.
  - The following were excluded: stewards, surveyors, costs for off-shift, 10 hour shifts, and weekend work.
  - Crew size based on assumed collective bargaining coverage for this type of work.

- Equipment and operating costs represent compiled "owned" equipment rates for the Northeast area of the country.
- Material quotations were solicited from various vendors and represent budget estimates.

General guidelines for using the trenchless unit costs include the following:

- Mixed face areas should be avoided if possible; tunneling at a deeper depth in rock is preferred.
- Tunneling in "mixed face" conditions if necessary, should be limited to steel pipe as the machine tends to deflect in the interface areas, thus stressing the joints on concrete or Hobas type pipes.
- Pipe runs with diameters less than 36 inches should be limited in length to less than 500 feet, due to the inability to remove intermediate jacking stations.
- Small diameter concrete or clay pipes should be limited to 400 feet.
- Hobas discourages pipes larger than 84 inches from being used for direct microtuneling or jacking as the bell / gasket bank will deform on the larger sizes.
- Diameters greater than 108 inches should not be "jacked" using open face machines, TBM's should be employed and segments should be considered.
- Shafts deeper than 30 feet to 50 feet should be constructed using circular caissons, which can ultimately be used as the permanent access.
- Tunneling in rock should be limited to machines 60 inches and above in diameter, this is due to face access for cutter head replacement and the limited power of the smaller machines.

Table 2.3.8-1 Microtunneling: Reinforced Concrete Non-Pressure Pipe Unit Costs used in the ACT [ENRCCI 8578; RS MEANS 113.2]

2.3.9 Conventional Tunnel - Storage/Conveyance

The term Conventional Tunnel refers to large diameter tunnels created by tunnel boring machines (TBM) that are advanced from the TBM location, unlike Short-Bore Tunnels (Trenchless) that are advanced from the pit location.

Supplemental materials outside of the ACT were used to determine key components of a complete CSO storage tunnel alternative cost, including cost estimates for Conventional Tunnels in Rock and Primary Tunnel components, and some Secondary Tunnel Alternative components. The following sections document the supplemental materials and ACT modules used to determine a complete CSO storage tunnel alternative cost.

The Primary Tunnel components include the following:

- Shafts
  - Work
  - Maintenance
  - Vent
  - Access
- CSO Tunnel Components
  - CSO vortex near surface structure
  - CSO drop shaft structure
  - Adits (tunnel connecting CSO drop shafts to the storage tunnel)

The Secondary Tunnel Alternative components include the following:

- New or modified CSO regulating structures
- Consolidation piping – near surface piping that directs flow from the CSO regulators to the CSO vortexing/drop structures
- Tunnel dewatering pump station

Supplemental Materials - Conventional Tunnel in Rock and Primary Tunnel Components

A tunnel costing spreadsheet was developed to estimate the cost of conventional rock tunnels and primary tunnel components. The key user inputs used for determining a tunnel cost estimate include:

- Tunnel
  - Tunnel Inside Diameter
  - Tunnel Length
  - Lining Type (Cast in place, or Segmental)
  - Corrosion Protection Liner (Yes, or No)
- Shafts (numerous types)
  - Number of shafts
  - Shaft diameter
  - Depth in soil
  - Depth in rock

- CSO Tunnel Components
    - Design flowrate

It should be noted and emphasized that there is no industry standard cost estimating tool for rock tunnel construction available at this time (i.e. equivalent of RS Means®, Mining Cost Services® etc.). This is due to the highly sensitive nature of the cost of tunneling relative to geology, depth, groundwater issues, the end use and application of the structures, among many other labor, finance and risk allocation issues. The result is that there is no uniform way of evaluating the cost across the industry.

Therefore, the user of the spreadsheet should be extremely careful and cognizant of the implication of each factor on the tunneling method and related cost. As such, the program can render a reasonable planning level estimate of the potential tunnel cost if it is used within the ranges specified herein. For variations beyond these values, the formulas will need to be revised.

The estimated cost is based on the assumption of using a tunnel boring machine (TBM) (open or shielded) as the tunneling method. The TBM deep tunnel drilling will be assumed to be in full rock face, which offers two choices of ground support, including temporary support plus cast in place (CIP) as well as Concrete Segmental lining. Most of the tunnel cost elements were based on a conventional tunnel in New York, detailed cost estimate for a conventional tunnel in St. Louis, MO, and general rule of thumb values for tunnel construction.

The formulas used to adjust the estimated cost of tunnel are empirical and in general vary by using power functions. The adjustment for diameter is considered to be proportional with tunnel diameter or linear function (power of 1) with the ratio of tunnel diameters. The adjustment for tunnel length is done based on a power function to account for the spread of the fixed cost items over the longer tunnel, meaning a gradual decrease in estimated cost per foot as the tunnel gets longer. Although these powers are variable and can be changed, they have been set to 0.3-0.25 for excavation and final lining, respectively. The values used are based on personal judgment of the overall trend in the adjustment curve.

Costs associated with site Mobilization/Demobilization are estimated based on the tunnel diameter and length. The length of the tail or starter tunnel in rock can be selected as needed and again a rule of thumb for this level of planning is to use a minimum of 10 times the tunnel excavated diameter to allow for assembly of the machine and its back up system. Cost per unit for hand mining of the starter/tail tunnel is calculated by the spreadsheet and the length is deducted from the length of the bored tunnel.

A short list of assumption behinds the conventional tunnel cost estimate is listed as follows:

- Construction of main tunnel to be performed by TBMs.
- Tunnel cost varies proportional to tunnel diameter.
- Tunnel cost will decrease with tunnel length within a certain range. The rate of decrease is estimated by using a power function (power of 0.25-0.3).

- Tunnel is in uniform ground. Mixed face conditions are not accounted for and it is recommended to choose the vertical alignment to stay within rock.
- Variation of rock types is acceptable.
- Tunneling is done with a circular profile and by a tunnel boring machine.
- Open hard rock TBMs will be used for excavation of rock while installing temporary support, and followed by CIP concrete lining. Alternatively, one pass system can be used with double shield machine and concrete segmental lining. Additional cost of tunneling is reflected in the cost per foot of segments.
- Access to the tunnel is through the work shaft and not portals.
- No exceptional or extraordinary complications exist in the ground, normal variation of lithology and some structural features are included. Unusual conditions with high groundwater pressure, abnormal in situ stresses, extended area of fault zones, contaminated ground, encountering high volume of methane, etc. is not considered in the costs.
- Normal contracting practice with design-bid-build is assumed to be used for the project.
- Operations are based on 24 hour activities and full access to the site 7 days a week.
- Cost of tunneling comprises labor, equipment, and consumables, with 1/3 rule.
- Geographical impact is primarily in terms of labor cost, and can impact the 1/3 contribution of the labor.
- Shaft depths in the range of around 200 ft can be estimated based on unit price of excavation. Deeper shafts may require special provisions.
- Shaft diameters of 10-75 ft can be estimated based on unit prices, larger shafts may need special provisions.
- Excavation cost includes transportation of muck in the tunnel and off the site within reason. Additional cost of muck haulage to a long distance or special provisions of dump sites was not accounted for.

CSO vortex drop shaft costs were determined by using Sage Timberline software to estimate the cost of numerous structures, based on basis of design drawings, designed to handle specific flow rates.

ACT - Conventional Tunnel Module

The cost estimate from the supplemental materials can be input into the Conventional Tunnel module. The user input parameters are listed as follows:

- Length of Tunnel
- Inside Diameter of Tunnel
- Unit Cost of Tunnel ($/gal)

Supplemental Materials - Secondary Tunnel Alternative Components

Cost estimates for new or modified CSO regulator structures were determined by using Sage Timberline software to estimate the cost of numerous structures, based on basis of design drawings, designed to handle specific flow rates.

ACT - Secondary Tunnel Alternative Structures Components

Consolidation piping was costed with unit costs from the open cut pipe module of the ACT.

Deep CSO storage dewatering pump stations were costed with unit costs from the pump station module of the ACT. Specifically the deep tunnel dewatering pump station costing curve was used.

Supplemental Materials - CSO Storage Tunnel O&M Costs

Supplemental materials were used outside of the ACT to determine O&M costs for CSO storage tunnels. Conventional CSO storage tunnel O&M was largely based on two WEFTEC 2007 Session 8 references:

- Murphy, S. Operations and Maintenance Requirements for Storage Tunnels and In-System Storage Facilities
- Sherrill, J. Fujita, G. Budget Development for Operations/Maintenance Requirements For CSO/SSO Control Facilities

These references provided a general framework to perform O&M cost estimates. Tunnel storage O&M activities were broken into two groups: event (operations), and non-event (maintenance). Non-event activities are maintenance activities on the tunnel, dewatering pump station, and associated structures, that occur when the tunnel is not being operated. Event activities are operations activities that occur immediately before a CSO storage event, while the tunnel is filling, and while the tunnel is being dewatered and flushed. Guidelines for estimating event and non-event labor hours were provided, along with a breakout of labor hours per labor classification. Guidelines for marking up labor hours to include training, vacation, and other benefits were included. In addition, estimates for materials and electrical costs were provided.

Several modifications to the cost estimating approach were performed. The primary consumer of electricity was the dewatering pump station, and was calculated directly. Additional cost markups for tunnel length and dewatering pump station capacity was included in the estimate.

The following inputs were used to estimate an annual O&M cost:

- Estimates of annual event duration
- Labor rates for specific labor classifications
- Pump station electrical consumption
    - Annual Volume Pumped

    - Total Dynamic Head
    - Wire to Water Efficiency
    - Electrical Rate
- Tunnel Length
- Pump Station Capacity

ACT – Conventional Tunnel O&M

Upon completion of a CSO storage tunnel O&M cost estimate from the supplemental materials, the cost can be input to the Conventional Tunnel Module of the ACT in terms of dollars per gallon. From this value, the ACT will provide a present worth analysis of the conventional storage tunnel alternative for comparison with other planning alternatives.

2.3.10 Tank Storage

Off-line tank storage within the collection system can be used to reduce combined sewer overflows (CSOs) or sanitary sewer overflows (SSOs) by storing wet-weather flows. After an event, the stored combined sewage and flushed solids would be conveyed to the existing interceptor system (by gravity or pumping) for treatment at the treatment plant.

A costing curve for tank storage was developed for the ACT based on tank storage costing curves used for other CSO control programs around the nation, as well as cost data of completed storage tanks in varying CSO and SSO storage applications. The following items are included in the cost estimation equation for surface storage facilities:

- A below-grade, cast-in-place, covered storage tank between 0.1 and 30 MG of storage.
- Each tank includes an automated flushing system.
- Odor control is required.
- A control building is required.

If pumping into the surface storage facility is required or if it must be dewatered via pumping, the pump station is to be provided in a separate structure, and its costs are accounted for separately in the ACT. Dewatering pumping is required if gravity dewatering time exceeds 48 hours from the end of an event.

Conveyance from the existing collection system to the storage facility or from the facility to the interceptor will be accounted for separately in the ACT.

Figure 2.3.10-1 displays the plot of the data used for determining the storage tank cost curve for the ACT. The user must input the tank storage to calculate the initial facility cost. The equation for the storage tank costing curve is:

$$y = 3.48x^{0.826}$$

Where y equals cost in million dollars and x equals the storage volume in MG

O&M Costs for CSO storage tanks were estimated based on the WEFTEC07 approach for CSO/SSO facility O&M. This methodology is used for Retention Treatment Basins as well.

Figure 2.3.10-1 Storage Tank Cost Curve [ENRCCI 8551; RS MEANS 100]

2.3.11 Screening

While screens serve as a pre-treatment device in several types of high rate treatment facilities, fine screens can also serve as a stand-alone CSO control measure with disinfection. With screen sizes ranging from 4 to 6 mm, these facilities can be very effective at removing floatables, including sanitary trash.

Screening facility costs are estimated as a standalone technology within the ACT. However, since screening facilities are not designed to remove fecal solids, disinfection generally must be achieved via chlorination and dechlorination. Chlorination/dechlorination facilities are included in the ACT as a separate control technology, and described further in Section 2.3.15 of this manual. For disinfection at screening facilities, the use of sodium hypochlorite for chlorination and sodium bisulfite for dechlorination will be the default assumptions. Any wastewater pumping required as part of the screening facility will be accounted for separately in the ACT; Section 2.3.6 details pump station cost estimation within the ACT.

The cost curve equation for screening was developed from construction cost data provided by the PM, BC, and BPs, as well as cost curves from other CSO control programs around the nation. The curve is displayed in Figure 2.311-1. The equation of the selected curve for screening is:

$$y = 0.0834x^{0.843}$$

Where y equals construction cost in million dollars, and x equals treatment capacity in MGD

From the equation of the selected curve, the user is to input the design flow rate in MGD.

O&M costs for screening facilities are estimated based on the WEFTEC07 approach for CSO/SSO facility O&M. An example O&M calculation for a screening facility is provided below.

Example Calculation for Determination of O&M Costs for Screening Facilities

Notes:

2.3.12 Vortex Separation

Vortex separator capital cost and operations and maintenance costs were assumed to be similar whether they are built at an existing water pollution control plant or at satellite locations. Planning-level estimates of their costs are described in Analysis of Wet Weather Alternatives for Southeast WPCP, Supplemental Documentation Volume 10.

2.3.13 Retention Treatment Basins

Retention treatment basins (RTBs) are satellite HRT facilities designed to provide screening, settling, skimming (with a fixed baffle) and disinfection of combined sewer flows before discharging to the receiving water. RTBs serve to capture combined sewage during small wet weather events and are gradually dewatered after the event for treatment at a wastewater treatment plant. In larger events, RTBs will begin to overflow and discharge treated effluent, but the captured volume left at the end of the event is also dewatered for treatment.

RTBs can be designed with a variety of screen types, disinfection methods and basin geometries. The surface loading rates can also vary but are typically higher than rates used for design of primary clarifiers. RTBs can be constructed above or below grade but typically require at least an above-grade process/control building. If pumping of the combined sewer flow is required, the pump station may be integral to the RTB facility or constructed as a separate structure.

For planning purposes, all RTBs will be assumed to be configured as described below. The RTB facilities are assumed to include:

- Coarse, mechanically cleaned bar screens at the headworks of the facility.
- Disinfection via chlorination using sodium hypochlorite with sodium bisulfite dechlorination. The basins are sized to achieve the design chlorine contact time at the design flow rate with no additional volume for pre-disinfection settling. The tool allows for an assumed design contact time of 10 to 30 minutes at design flow.
- A settling/contact basin with flushing provisions. Assumed rectangular basin configuration with side water depths to approximately 20 ft.
- Captured volume including solids are dewatered to the interceptor.
- A fixed baffle located just upstream of the effluent weir to provide skimming.
- Provisions to dewater the facility to the interceptor system, including pumping if required.
- An option for an above or below ground facility, which will be covered with odor control.
- A building for screenings removal, chemical storage, electrical and process control.
- A basin divided into two parallel compartments just below grade, with an effluent weir and geometry based on a design surface overflow rate of 6,000 gallons per day (gpd)/square foot (sf).
- If pumping is required, it will be provided in a separate structure. Its costs will be accounted for separately in the ACT.

Design factors to be input into the ACT by the user will include:

- Design flow rate

- Chlorine contact time

Figure 2.3.13-1 displays the selected retention treatment basin facility cost estimating curve and equation, and is considered a construction cost with overhead, profit and indirect costs included.

Given the unique nature of RTBs, actual facility construction costs from around the country are a good source for developing planning level costs. In the mid to late 1990's, a number of retention treatment basins were constructed in Michigan as part of the Rouge River National Wet Weather Demonstration Project. Due to the readily available actual construction cost data for each of these RTBs, nine were selected to serve as the basis for deriving planning level construction costs.

The verified data was plotted with facility volume as the dependant variable. As a test of fit, a USEPA cost curve[1] for tank storage capital costs was plotted to determine any fit with the RTB actual construction cost data. The EPA curve was used due to the similar structural configurations among tank storage and RTBs, and that this particular cost curve was based on a large, wide ranging data set. The curve was updated for time, and modified by a factor of 50% for a more complete fit with the verified data points. The resulting curve fit well enough to render it the selected curve for costing RTB capital costs. All verified points are displayed in Figure 2.3.13-1 along with the selected costing curve. The cost equation from the selected curve is:

$$y = 9.72x^{0.826}$$

Where y equals construction cost in million dollars, and x equals facility volume in MG

2.3.14 High Rate Clarification

High rate clarification capital cost and operation and maintenance costs were assumed to be similar whether they are built at an existing water pollution control plant or at satellite locations. Planning-level estimates of their costs are described in Supplemental Documentation Volumes 9 through 11.

2.3.15 Disinfection

Disinfection is assumed to be a component of all high rate treatment (HRT) facilities. All costs for disinfection (including contact tanks or conduits) will be included in the cost estimates for applicable alternatives, with sizing scaled to appropriate design flows.

As a default assumption, the equipment and appurtenance costs for chlorination using sodium hypochlorite and dechlorination using sodium bisulfite. However, it is recognized that UV disinfection may be a viable alternative for HRC, and an option to select UV disinfection is included in the ACT.

The users are to select a disinfection type, and input the design flow rate for the disinfection alternative into the ACT.

Figure 2.3.15-1 displays the selected disinfection cost estimating curve and equation.

Chlorination/Dechlorination Construction Costs

The construction cost curve equation for chlorination / dechlorination facilities was developed from the 1993 USEPA report *Combined Sewer Overflow Control*. It was compared to construction cost data provided by other CSO control programs around the nation. The equation of the selected curve for chlorination / dechlorination facilities, displayed in Figure 2.3.15-1 is:

$$y = 0.223x^{0.464}$$

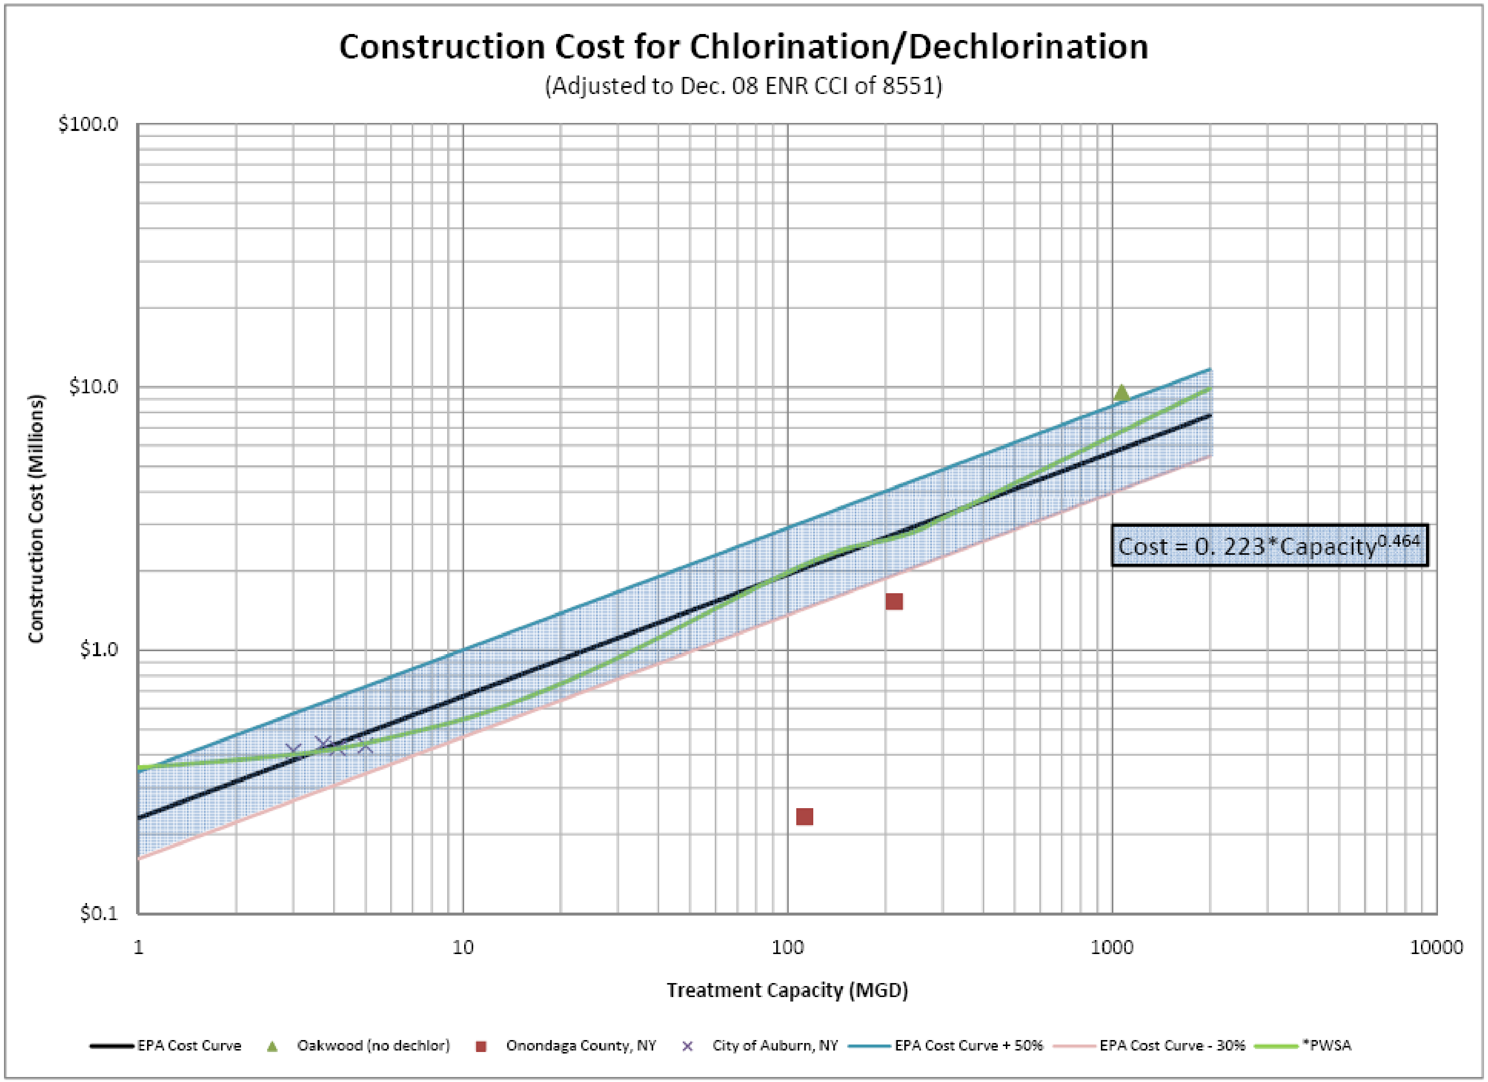
Where y equals construction cost in million dollars, and x equals treatment capacity in MGD.

Ultraviolet Disinfection Construction Costs

The cost curve equation for UV disinfection facilities was developed from the City of Indianapolis *CSO Control Cost Estimating Procedures Memo* which modified a chlorination cost curve found in the 1993 USEPA report *Combined Sewer Overflow Control*. It was compared to cost curves from other CSO control programs around the nation. The equation of the selected curve for ultraviolet disinfection, displayed in Figure 2.3.15-3 is:

$$y = 0.719x + 0.540$$

Where y equals construction cost in million dollars, and x equals treatment capacity in MGD



* Source: PWSA *Basis of Cost for CSO Control Technologies* , March 2007

Figure 2.3.15-1 Chlorination / Dechlorination Construction Cost Curve [ENRCCI 8551; RS MEANS 100]

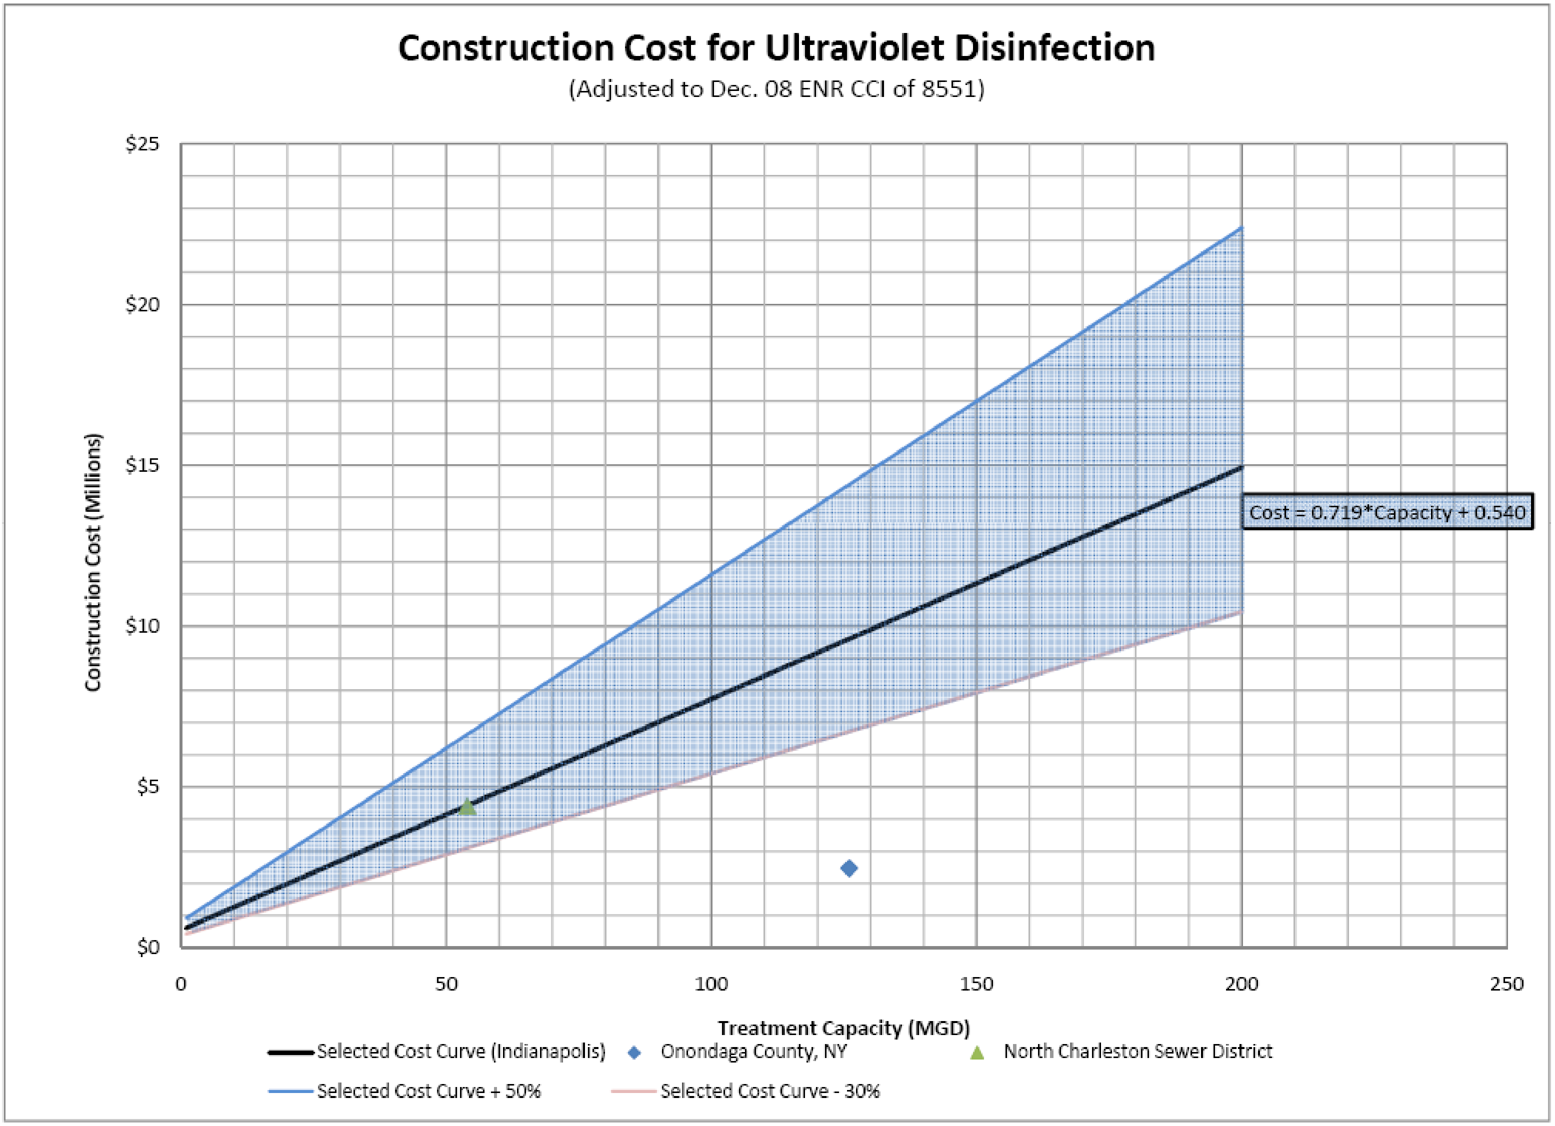


Figure 2.3.15-3 Construction Cost Curve for Ultraviolet (UV) Disinfection [ENRCCI 8551; RS MEANS 100]

Chlorination/Dechlorination & Ultraviolet Disinfection O&M Costs

Disinfection facility O&M cost equations are provided for both ultraviolet disinfection and chlorination/dechlorination facilities. These equations were developed from the City of Indianapolis CSO Program[2], and are based on USEPA curves adjusted to the proper ENRCCI value.

O&M costs for chlorination / dechlorination facilities were derived from the City of Indianapolis *CSO Control Cost Estimating Procedures Memo* which modified a chlorination cost curve found in the 1993 USEPA report *Combined Sewer Overflow Control*. For the ACT, the curve was updated to a base period of December 2008. The resulting cost curve, displayed in Figure 2.3.15-2, is:

$$y = (\text{Current ENRCCI}/6635) * 12.531 * x^{0.614}$$

Where y equals construction cost in $Thousands, and x equals facility capacity in MGD.

O&M costs for UV disinfection facilities were derived from the City of Indianapolis *CSO Control Cost Estimating Procedures Memo* which modified a chlorination cost curve found in the 1993 USEPA report *Combined Sewer Overflow Control*. For the ACT, the curve was updated to a base period of December 2008. The resulting cost curve, displayed in Figure 2.3.15-4, is:

$$y = (\text{Current ENRCCI}/6635) * 5475 * x$$

Where y equals construction cost in dollars, and x equals facility capacity in MGD.

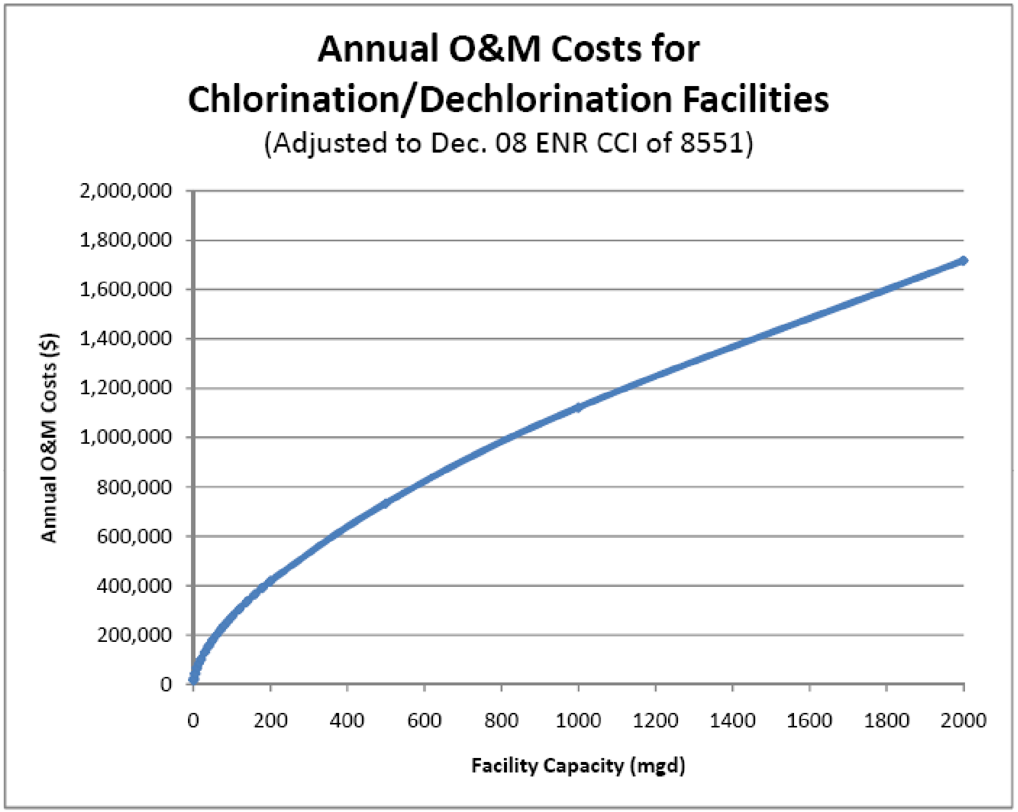
Base ENRCCI: **8,551**

Cost Table for New CSO Chlorination/Dechlorination Disinfection Treatment Facilities

Facility Capacity (mgd)	Annual O&M Cost ($)
1	16,149
2	24,716
5	43,383
10	66,398
15	85,167
20	101,622
30	130,348
40	155,531
50	178,370
60	199,498
70	219,303
80	238,040
90	255,893
100	272,994
120	305,331
140	335,642
160	364,320
180	391,643
200	417,817
500	733,366
1000	1,122,415
2000	1,718,000



The cost table above is based on the following conditions:

1. Annual O&M costs are derived from the USEPA construction cost curves using the current ENRCCI, which is an acceptable estimate between a range of 1 and 2000 mgd.
2. Curve defined by the equation below is based on the use of sodium hypochlorite and sodium bisulfite.

Annual O&M Cost Equation:

Cost ($Thousands) = (Current ENRCCI / 6635) * 12.531 * $Q^{0.614}$

*6,635 was the ENRCCI from March 2003.

*Q = Facility Capacity (mgd)

3.0 LIFECYCLE COSTS

3.1 Introduction to Lifecycle Costs

The user will be evaluating alternative control elements (e.g., storage vs. satellite treatment) and control alternatives. Control alternatives are arrays of control elements (e.g., a relief interceptor and one 5-mg storage tank at the bottom of the sewershed vs. two 2-mg tanks along the existing interceptor) to provide the same level of watershed-wide wet-weather control.

The various control elements and control alternatives will be compared economically based on comparative life cycle costs. Lifecycle costs are the total costs of building, operating and maintaining a control element for the planning period of the WWP.

3.2 Planning Period and Temporal Framework

The ACT allows for user-specified construction end dates and construction duration periods for each control implemented.

3.3 Present Worth Analysis

Lifecycle costs of alternative control elements will be compared based on their respective present worth. The ACT will calculate the present worth of control elements based on the design parameters entered by the user.

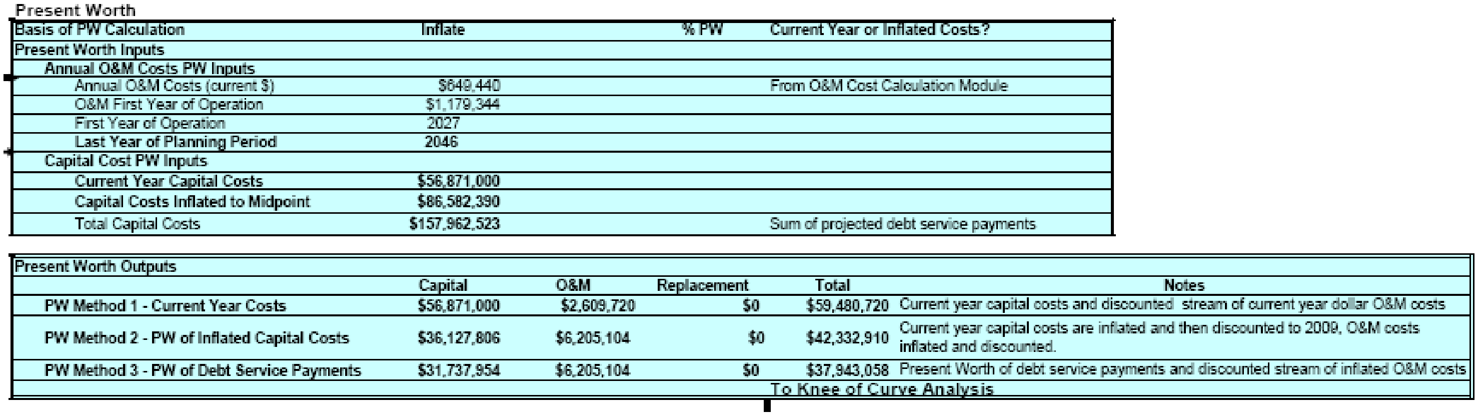
Present worth is the value, expressed in present dollars of the capital costs and the stream of future O&M costs generated by a control element. Calculating the present worth of alternative control elements allows for comparisons between various mixes of capital and O&M costs over the planning period.

The ACT calculates present worth for capital costs, O&M and replacement costs in three different ways. For analysis of alternatives, The City of Philadelphia's Long Term Control Plan Update describes costs and benefits derived using method 2.

> **Method 1** – **Current Year Costs –** Costs are not inflated under Method 1. Capital costs are expressed in current dollars. O&M costs are expressed in current dollars. The current year value of the future stream of O&M payments are discounted back to the current year, as are future replacement costs. This methodology is simplistic but obviates the complexities involved in predicting inflation rates and the mid-point of construction.
>
> **Method 2** (default in ACT)– Under Method 2, current year capital costs are inflated to the mid-point of construction at the input capital costs inflation rate and then deflated back to current year using the discount factor. O&M costs are inflated to the years of implementation and the inflated stream of costs is discounted back to the current year. Replacement costs are inflated to the replacement year and then discounted back.
>
> **Method 3** – Method 3 recognizes the reality of bond financing for major capital projects such as wet weather controls and addresses the current value of the future stream of

debt service payments. Capital costs are inflated to midpoint of construction. Debt service payments, based on the inflated capital costs are then discounted as a stream of future payments back to current year. O&M costs are inflated to the years of implementation and the inflated stream of costs is discounted back to the current year. Replacement costs are inflated to the replacement year and then discounted back.

An example of the results of these three methodologies is shown below on Figure 4.3-1 excerpted from the ACT Schematic diagram, provided in Appendix A to this document.



Present Worth

Basis of PW Calculation	Inflate	% PW	Current Year or Inflated Costs?
Present Worth Inputs			
Annual O&M Costs PW Inputs			
Annual O&M Costs (current $)	$649,440		From O&M Cost Calculation Module
O&M First Year of Operation	$1,179,344		
First Year of Operation	2027		
Last Year of Planning Period	2046		
Capital Cost PW Inputs			
Current Year Capital Costs	$56,871,000		
Capital Costs Inflated to Midpoint	$86,582,390		
Total Capital Costs	$157,962,523		Sum of projected debt service payments

Present Worth Outputs					
	Capital	O&M	Replacement	Total	Notes
PW Method 1 - Current Year Costs	$56,871,000	$2,609,720	$0	$59,480,720	Current year capital costs and discounted stream of current year dollar O&M costs
PW Method 2 - PW of Inflated Capital Costs	$36,127,806	$6,205,104	$0	$42,332,910	Current year capital costs are inflated and then discounted to 2009, O&M costs inflated and discounted.
PW Method 3 - PW of Debt Service Payments	$31,737,954	$6,205,104	$0	$37,943,058	Present Worth of debt service payments and discounted stream of inflated O&M costs

To Knee of Curve Analysis

Figure 4.3-1 – Example of Present Worth Methodologies within the ACT

Land Costs

Land acquisition costs will be entered into the present worth calculations at current (2009) values and will be inflated by the ACT if the inflation function is activated. As discussed more fully in Section 2.1.4 of this document, estimated land acquisition costs will be provided by the user due to the location specific nature of the potential cost, and inputted by the user into the ACT for the specific alternative run. Where the control element may reasonably be contained within an existing ROW or if the land requirements for various alternatives are substantially identical, it might be reasonable to omit land acquisition costs from the present worth analysis.

Salvage Value

The ACT does not account for the salvage value of control elements.

3.4 Replacement Costs

Because of the long planning period, mechanical equipment and depending on the initiation of operation, potentially structural facilities will be at the ends of their respective useful lives prior to the end of the planning period. Therefore, replacement costs for equipment or structural facilities requiring replacement or substantial rehabilitation prior to 2048 must be included in the present worth analysis.

The user has the option of inputting a replacement cost and a renewal/replacement frequency for applicable equipment in an alternative. The ACT calculates the present value of these replacement costs given the user input values and the default planning period.

Hydrologic and Hydraulic Modeling

Updated: September 1, 2009

V4.1 BASELINE MODEL DEVELOPMENT

Development of the baseline model for the LTCPU was significantly important. The baseline model is the foundation from which all alternatives were built and resulting data compared against. Accurately simulating the current hydrologic conditions and hydraulic infrastructure was essential to producing valuable and reliable results. The methods and input data utilized in order to create the baseline model with respect to the hydrology, hydraulics and the calibration and validation, are discussed in the subsections following. Detailed analyses of the Water Pollution Control Plants (WPCP) for the Southeast, Northeast and the Southwest Drainage Districts (SEDD, NEDD and SWDD) were performed to determine the WPCP treatment capacities, pumping rates, WPCP piping and head works. The WPCPs exiting conditions were used for each of the baseline models. The maximum treatment rate for the SEDD WPCP (SEWPCP), NEDD WPCP (NEWPCP) and SWDD WPCP (SWWPCP) used for the baseline models were 280 mgd, 435 mgd and 480 mg respectively. Please refer to the supplemental documentation volume numbers 6, 7 and 8 for stress testing of the WPCPs.

v4.1.1 Hydrologic Model Development

The baseline model was developed using the EPA-SWMM4 software. The RUNOFF module in SWMM4 requires the input of several physical parameters to determine the rainfall-runoff response from modeled combined-sewer and separate sanitary sewer subcatchments.

- Subcatchment area
- Subcatchment width (used to determine overland flow length)
- Percent directly connected impervious area (effective impervious area)
- Subcatchment ground slope
- Manning’s roughness coefficient for both pervious and impervious areas
- Depression storage for both pervious and impervious areas (initial abstraction)
- Soil infiltration parameters
- Rainfall dependent inflow and infiltration parameters
- Baseflow ranges
- Precipitation input data
- Evaporation input data

Each parameter is discussed in greater detail in the following subsections.

Subcatchment Area

Natural stormwater drainage subcatchment area can be determined by constructing drainage divides on topographic maps and is dependent upon the detail of the topographic information. Combined sewer subcatchment area is determined based on detailed sewer plans within the City and the topographic maps needed to determine surface drainage to sewer inlet locations. The delineation of sanitary sewer subcatchment area inside the City is based on detailed sewer plans. Subcatchment areas outside of the City were delineated with a tool in ArcView using USGS 30-meter DEMs to identify drainage divides. Subcatchment areas within the City were defined based on detailed sewer plats. The RUNOFF model represents all stormwater runoff subcatchments as rectangular areas defined by the subcatchment width parameter. RUNOFF simulates surface runoff from drainage areas using three "planes" of overland flow. One plane represents all impervious surfaces directly connected to the hydraulic system and include initial abstraction or surface detention storage (puddles, cracks, etc.) which do not permit immediate runoff. A second plane represents all pervious areas and impervious areas not directly connected to the hydraulic system. The third plane is defined as the fraction of the directly connected area that provides no detention storage and thus produces runoff immediately. The runoff from the drainage area is the sum of the flow off the three planes. The complete hydrologic model consists of 2098 subcatchments representing the entire PWD service area.

Subcatchment Width

The width of the subcatchment is the physical width of overland flow. Since real subcatchments are not rectangular with properties of symmetry and uniformity, it is necessary to adopt other procedures to obtain the width for more general cases. This is important because if the slope and roughness are fixed, the width can be used to alter the hydrograph shape. For the PWD combined sewer system (CSS) models, width was initially taken to be double the square root of the subcatchment's area and later treated as a calibration parameter.

Directly Connected Impervious Area (DCIA)

The percent imperviousness of a subcatchment is a parameter that can be reasonably estimated from aerial photos or land use maps. However, not all of the impervious area is directly connected to the drainage system, or is "effective" when simulating a hydrologic response from these areas. For example, if a rooftop drains onto a pervious area, this should not be included as directly connected. The total percent impervious area was used as the initial effective impervious area and then reduced during the calibration process to best simulate the observed hydrologic response over a range of precipitation events.

In generating initial estimates of gross impervious cover the following method was employed. For all areas within the City of Philadelphia, GIS coverage of impervious areas derived from 2004 orthodigital photographs was used. This coverage delineates all land use in the City into pervious or "natural surfaces," comprised of lawns, parks, marshes, golf courses, wooded areas and cemeteries, as well as several different classifications of impervious areas. Impervious land uses were broken down into the following types:

- Alleys
- Buildings
- Building Centers
- Concrete/Asphalt Slabs/Patios
- Ditches (Asphalt or Concrete)
- Driveways
- Institutions
- Lakes
- Medians
- Parking
- Pedestrian Bridges
- Parking Islands
- Pond
- Pools
- Railroad Ballast
- Railroad Bridges
- Reservoirs
- Rivers
- Sidewalks
- Shoulders
- Streams
- Tanks
- Travel Bridges
- Travelways

For each RUNOFF subcatchment, the area of these land uses was summed to generate a total impervious area. Impervious areas in each subcatchment were summed and divided by the total area in order to get the first estimate of subcatchment "effective" impervious area.

For residential land uses outside of the City for areas contributing stormwater and do not have any flow monitoring data , population densities were developed using 2000 census and block area data. Two equations, Stankowski (1974) and Manning et al (1987) that use population density as the independent variable to define percent impervious were selected for this modeling application. The equations are expressed as:

Stankowski, $I = 0.117D^{0.792 - 0.039 \log D}$

Manning, $I = 10v4.95\text{-}81.27(0.974)^{PD}$

Where I = Percent impervious
PD = Population density per acre
D = Population density per square mile

Percent impervious estimates for each census block were calculated with both equations. For population densities less than 35 persons per acre (ppa), the Stankowski and Manning equations were averaged. However, only the Manning estimate was used when the population density was greater than 35 ppa. This distinction was made because the Stankowski equation is less accurate for high density urban areas.

Each land use classification was assigned a percent impervious cover based upon regional averages and/or population density. If monitoring data was available for the shed monitoring data was used to reach upon a percent impervious number.

Slope

The subcatchment slope should reflect the average slope along the pathway of overland flow to inlet locations. For a simple geometry, the calculation is the elevation difference divided by the length of flow. Subcatchments containing highway ramps underwent a more technical slope procurement procedure in order to prevent distortion of the slopes due to the grade of the ramp.
ArcGIS was utilized in order to calculate the slopes for these subcatchments. Generally, the topographic lines representing the ramps were removed and new raster layers were created. From the new raster layers, slopes were calculated using the remaining topographic lines.

Manning's Roughness Coefficient

Manning's roughness values must be estimated for both pervious and impervious overland flow. Manning's roughness for impervious surfaces was set to 0.013 and for pervious surfaces to 0.1 or 0.05. Roughness is an empirical value and may be treated as a calibration parameter when necessary.

Depression Storage

Depression (retention) storage is the rainfall abstraction volume that must be filled prior to the occurrence of runoff on both pervious and impervious areas. In RUNOFF, every subcatchment is divided into three subareas: Pervious area with depression storage, impervious area with zero depression storage and impervious area with depression storage. By default, the model assumes 25% of the impervious area has zero depression storage. This default value was not altered in the LTCPU model setup. In the model, water stored as depression storage on pervious areas is subject to infiltration and evaporation. Water stored in depression storage on impervious areas is depleted only by evaporation therefore replenishment of the retention storage typically takes longer when compared to pervious areas. Depression storage is an empirical value and may be treated as a calibration parameter when necessary. Following calibration, impervious depression storage was set as 0.02, 0.05, or 0.1 inches and pervious depression storage was set at 0.15 or 0.1 inches. These values were selected based on literature review and past modeling experience with the City's existing hydrologic models of combined sewer areas.

Pervious Area Infiltration Parameters

The rate of infiltration is a function of soil properties in the drainage area, ground slopes and ground cover. RUNOFF computes the rate of infiltration into the soil using either the Horton method or Green-Ampt method, as selected by the user. In each method, a set of infiltration parameters is required to represent soil properties. For the LTCPU hydrologic model, the Green-Ampt method is used to estimate infiltration rates. The Green-Ampt equation for infiltration has physically based parameters that can be estimated based on soil characteristics. The soil parameters used in this method are:

- Average Capillary Suction
- Saturated Hydraulic Conductivity
- Initial Moisture Deficit

Soil information for the Philadelphia watersheds was obtained at the beginning of the PWD CSO program in the early 1990s. Information was obtained from the U.S. Department of Agriculture's (USDA) Natural Resources Conservation Service (NRCS), which is responsible for collecting, storing, maintaining and distributing soil survey information for privately owned lands in the United States. Initial infiltration parameters were assigned to each subshed based on soil texture classification. Saturated hydraulic conductivity was treated as a calibration parameter.

Flow Routing

Subcatchments are divided into three subareas that represent impervious area with and without depression (detention) storage and pervious area with depression (detention) storage. Overland flow is generated from each of the three subareas by approximating them as non-linear reservoirs. When inputs to the non-linear reservoir (rainfall/snowmelt) exceed the outputs (evapotransporation & infiltration) for any of the three subareas, outflow is generated using the Manning's equation.
The kinematic wave approximation is used as the basic flow routing algorithm across the three planes of flow. This approximation assumes the friction slope is equal to the ground slope of the plane. This flow routing algorithm is applied sequentially to the impervious (with detention) plane, the pervious plane and the impervious (without detention) plane.

Hydrologic routing techniques that apply the kinematic wave approximation algorithms are used to route the overland flow through the pipe, culvert, channel and lake networks as required.

Rainfall Dependent Inflow and Infiltration (RDI/I)

Rainfall-Dependent Inflow and Infiltration (RDI/I) into sanitary sewer systems has long been recognized as a major source of operating problems, causing poor performance of many sewer systems. The three major components of wet-weather wastewater flow into a sanitary system - base wastewater flow (BWF), groundwater infiltration (GWI) and RDI/I are illustrated in Figure v4.1.1 below.

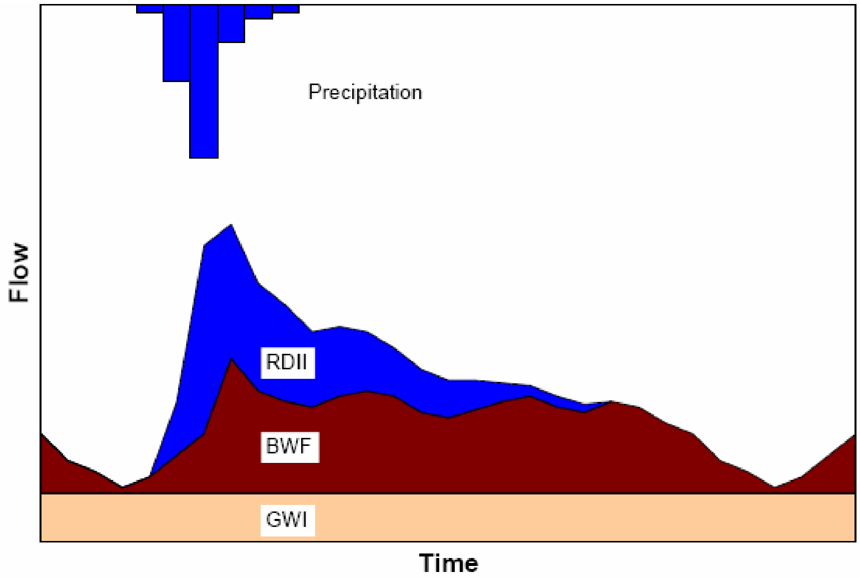

Figure v4.1.1 Three components of wet-weather wastewater flow (EPA, 2007)

The RTK hydrograph generation method to define the RDI/I response for the sanitary sewer systems has two steps. The first step is to define RTK parameters in response to one unit of rainfall over one unit of time. Three unit hydrographs are typically used because the shape of an RDI/I hydrograph is too complex to be well represented by a single unit hydrograph. The RDI/I hydrograph can be generated using less than three sets of R, T and K. However, experience indicates that it often requires three unit hydrographs to adequately represent the various ways that precipitation becomes RDI/I. The first triangle represents the most rapidly responding inflow component and has a T of one to three hours. The second triangle includes both rainfall-derived inflow and infiltration and has a longer T value. The third triangle includes infiltration that may continue long after the storm event has ended and has the longest T value. In this first step, the RTK parameters for each of the three triangles are defined for each unit rainfall over one unit time frame. The sum of the R values for each of the three unit hydrographs (i.e., R1, R2 and R3) must equal the total R value for the rainfall event. Figure v4.1.2 below depicts a summation of three unit hydrographs into a total RDI/I hydrograph in response to one unit rainfall over one unit time frame. This unit hydrograph is described by the following parameters:

- R - The fraction of rainfall volume that enters the sewer system and equals the volume under the hydrograph
- T - The time from the onset of rainfall to the peak of the unit hydrograph in hours

- K - The ratio of time to recession of the unit hydrograph to the time to peak
- A - Sewered area
- P - Rainfall depth over one unit time
- Volume - Volume of RDI/I in unit hydrograph
- Qp - Peak flow of unit hydrograph

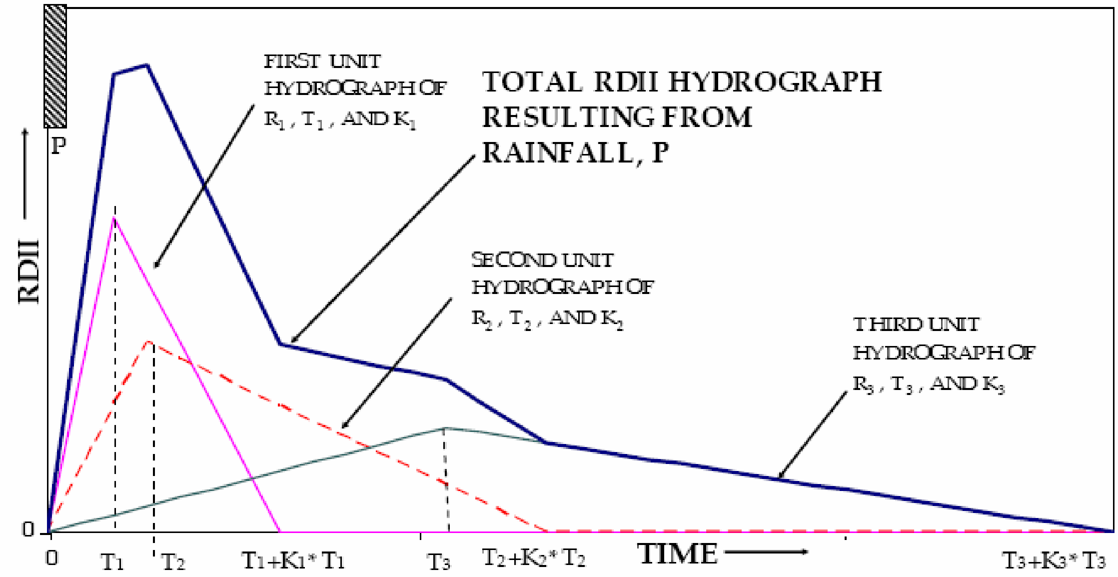

Figure v4.1.2 Summation of three unit hydrographs (EPA, 2007)

RDI/I analysis was performed on sewersheds with separate sanitary sewers contributing to the combined sewer system. This analysis was performed to more accurately account for the excess rain water entering the sanitary sewers through a combination of inflows from directly connected downspout pipes, sump pumps, foundation drains, manhole openings and large defects along streams and infiltration through saturated soils and an elevated groundwater table into small leaks in degraded sewer pipes and joints. RDI/I decrease the available sewer capacity available to convey stormwater runoff through the trunks and into the interceptor. The RUNOFF module uses three sets of unit hydrographs defined by R, T and K values to represent the shape of the RDI/I hydrograph. Please refer to the Model Calibration and Validation section for details on RDI/I parameters used in the model.

Evaporation Input Data

Evaporation data is required by the model in the form of average monthly evaporation rates, although finer time increments may be input as negative flows by creating an evaporation time series. Evaporation data usually can be obtained from the NWS or from other pan measurements.

Limited long-term daily evaporation data exists for the Philadelphia area. Neither the Philadelphia Airport nor the Wilmington Airport records evaporation data. Average monthly evaporation (inches per day) are used for all SWMM4 models determined from New Castle County, Delaware recorded daily evaporation data from 1956 through 1994.

Temperature Input Data and Snowmelt

Temperature time series input data can be used to run a snowmelt routine in SWMM4. The average snowfall volume and frequency for Philadelphia, however, does not account for a significant portion of the average annual precipitation. Therefore, the snowmelt routine was not employed. Instead several snowfall events that occurred during the year 2005, which was selected as the basis for the typical year, were modified to represent snowmelt time series based on PWD non-heated raingage observations, Philadelphia International Airport observed hourly snowfall, daily snow cover and daily maximum temperatures.

The RUNOFF hydrographs are saved in binary format for input to the EXTRAN block of SWMM to perform hydraulic routing in sewer and/or open channel system networks.

v4.1.2 Hydraulic Model Development

This section describes the process by which the Hydraulic models of PWD's combined and separate sanitary sewer system has been developed. The hydraulic model was developed using the EXtended TRANsport (EXTRAN) block of the U.S. EPA's Storm Water Management Model Version 4 (SWMM4; Huber and Dickinson, 1998). The Tier 2 models were developed by refining and adding hydraulic elements to the Tier 1 EXTRAN models. The Tier 1 EXTRAN models in combination with the U.S. Army Corps of Engineers' Storage, Treatment, Overflow, Runoff Model (STORM; Hydrologic Engineering Center, 1977) were used to represent the hydraulic elements and evaluate alternatives for the 1997 LTCP (for more information refer to System Hydraulic Characterization June 27 1995).

The EXTRAN module of SWMM is used to analyze and simulate flow through the combined sewer system. EXTRAN uses a link-node description of sewer and open channel systems facilitating the physical prototype and the mathematical solution of the gradually-varied unsteady flow (St.Venant) equations, which forms the mathematical basis of the model. The links transmit the flow from node to node. The primary dependant variable for the links is discharge. The primary dependant variable for the nodes is head, which is assumed to be changing in time, but constant throughout any one node. To reiterate the list of elements required by SWMM to calculate the flow in the sewers, values for the following variables are necessary:

- Pipes
- Junctions
- Orifices
- Weirs
- Pumps
- Outfalls

The information required to accurately represent these elements within the model were obtained from the return plans (as-built), contract drawings and drainage plats available through the Engineering Records Viewer (ERV) developed by the City of Philadelphia. Values which did not match the drawings were modified to bring them current with plan drawings. Individual descriptions of how these elements are modeled follow below.

Pipes

Pipes are the conveyance element in the EXTRAN models. For the EXTRAN model the following pipe information is required.

- Pipe name.
- Pipe's upstream and downstream nodes
- Initial flow in the pipe.
- Shape of the pipe (the pipes that can be modeled circular, rectangular, horseshoe, egg, basket handle, trapezoidal channel, parabolic/power function channel, irregular (natural) channel, horizontal ellipse, vertical ellipse, arch, bridge).
- Pipe dimensions (depth, width, area, side slopes, power function parameters and natural section data).
- Offsets of pipes (if the pipe does not begin or end at the invert (bottom) of the upstream or downstream node an offset value describing the difference from the bottom of the upstream and or downstream node and the pipe bottom needs was provided).
- Manning's roughness coefficient, the manning's coefficient is usually the property of the pipe's building material. The manning's coefficient may be changed in to account for additional sediment depositions and unintended restriction like rubble in the pipe.
- Minor losses (entrance, exit and additional losses).
- Sediment depth in the pipe.

Very short pipes can cause mathematical instabilities in the model. Short pipes are converted to equivalent pipes that have lengths that will satisfy the courant condition while maintaining the same head loss as the original (this is achieved the manipulating the Manning's roughness coefficient). The following procedures were followed to represent the pipes in the model. Pipes in a branch with the same shape, slope and make material may have been combined together to hydraulically represent one single equivalent pipe. If necessary, minor expansions may have been ignored if occurring between two pipes of the same diameter, slope and same material so as to combine all the section in to one longer stable section. If the need arose to combine pipes of varying capacities, slopes, shapes and make material; the diameter of the resulting section was set equal to the most constricting pipe in the series and the manning's coefficient was adjusted so as an equivalent flow was conveyed and head loss was maintained as the original section. Some of the offsets when the pipe invert is not the same as the node invert may cause mathematical instabilities; if such instabilities were seen a minimal storage was provided to remove the instability and if the problem still persisted the last resort was to change the slope of the pipe so as the pipe invert matched the water surface at the node if the problem still persists then pipe slope was changed to set pipe invert equal to the node invert (when ever the slope of the pipe is changed the manning's coefficient should be changed so that the flow and head loss would match the original section of the pipe). Broadly the pipes in the waste water collectors system can be separated in to 4 categories; trunk sewers that collect sanitary and wet weather flow from house lateral branches, street inlets etc. and bring them to the regulators, the dry weather flow pipes that take all of the dry weather sanitary and a percentage of the wet weather flow to interceptor, the interceptors that collect the flows from the dry weather flow pipes and deliver the flows to downstream interceptor system or the WPCPs, the wet weather overflow pipes that convey the flow that cannot be accommodated in either the dry weather pipes or interceptor to the receiving water.

Junctions (Nodes)

Nodes are the connection points for the pipes. The primary dependant variable for the nodes is head, which is assumed to be changing in time, but constant throughout any one node. Flow and volume continuity are calculated at nodes in the EXTRAN model. The nodes in the model can be actual manholes and places where there is pipe size and or slope and or pipe material change or there is a hydraulic control structure in the pipe network. Nodes at locations where a manhole does not exist were simulated in a manner so as they do not flood out. The following information is required to model a node in EXTRAN:

- Junction Name
- Ground elevation/Top of the node, for manholes with bolted down covers an increase in top of the node higher than the actual top may be provided to mimic the excess head built up that can be handled by the node before the mode floods.
- Invert elevation (Bottom of the junction)
- Constant inflow if any in to the junction, this can be the average dry weather flow that the junction receives from the surrounding sewer sheds (More description about the baseflow distribution can be found in the hydrology section above).
- Initial water depth in the junction above invert
- Junction location data (x,y) for spatial location.
- Junction volume calculation parameters (either default plan surface area (12.6 ft^2) or fixed plan surface area other than default value or power function defining the plan surface areas or set of depth and plan surface area pairs). The volume other than default volumes is required for junctions that mimic storage elements or non-standard manholes or chambers.

In sections where multiple pipes may be combined in to one longer section it is important to keep track of the node that has the lowest top elevation. If flooding occurs in a section of pipes, the hydraulic grade line will be controlled by the node with the lowest top elevation. In these situations the node with the lowest top elevation should be correctly represented so as to get the correct hydraulic representation. The information required to accurately represent the junctions within the model were obtained from the return plans (as-built), contract drawings and drainage plats available through the Engineering Records Viewer (ERV) developed by the City of Philadelphia. Values which did not match the drawings were modified to bring them current with plan drawings.

Orifices

Two types of orifices are used within the LTCPU model, static and variable. Static orifice opening sizes remain constant over the length of a simulation. The variable orifices opening cross-section is controlled by either a set of time closure rules or head level in a control node (this can be any node in the model). EXTRAN internally converts the orifices to equivalent pipes of 200 feet and a manning's coefficient representing the same head loss as the orifice. Following are the parameters necessary to define an orifice in EXTRAN:

- Upstream and Downstream nodes

- Type of orifice (side outlet circular, bottom outlet circular, side outlet rectangular, bottom outlet rectangular, time-history side outlet circular orifice with gated controls, time-history bottom outlet circular orifice with gated controls, time-history side outlet rectangular orifice with gated controls, time-history bottom outlet rectangular orifice with gated controls, side outlet circular orifice with timed closure with gated controls, bottom outlet circular orifice with timed closure with gated controls, side outlet rectangular orifice with timed closure with gated controls, bottom outlet rectangular orifice with timed closure with gated controls, side outlet circular orifice with head-dependent gated control, bottom outlet circular orifice with head-dependent gated control, side outlet rectangular orifice with head-dependent gated control, bottom outlet rectangular orifice with head-dependent gated control)
- Orifice coefficient
- Orifice offset from the bottom of the junction invert.
- Dimensions of the orifice (depth, width area).
- Orifice control information (time history data for timed closure orifices, node from which the controls are based on, orifice completely open cross-sectional area, orifice completely closed cross-sectional area, rate of orifice closure and flow direction restrictions.)

If the static orifice causes mathematical instabilities then they may be modeled in the EXTRAN model as equivalent pipes that mimic the same flow characteristics and head loss as the orifice. The information required to accurately represent the orifices within the model were obtained from the return plans (as-built), contract drawings and drainage plats available through the Engineering Records Viewer (ERV) developed by the City of Philadelphia. Values which did not match the drawings were modified to bring them current with plan drawings.

Weirs

For all EXTRAN models used in LTCPU analyses all weirs were modeled as equivalent pipes with the head loss and flow characteristics simulating those that would be produced from a weir. The information required to model a weir is:

- Upstream and downstream junctions for the weir.
- Type of weir
- Weir length and height to the crest of the weir
- Weir coefficient.

The information required to accurately represent the weirs within the model were obtained from the return plans (as-built), contract drawings and drainage plats available through the Engineering Records Viewer (ERV) developed by the City of Philadelphia. Values which did not match the drawings were modified to bring them current with plan drawings.

Pumps

Pumps in EXTRAN are modeled to lift the flows to a higher head at a pre-specified rate. Pumps can be offline pumps that pump flow based on the volume in the pumped junction. The pump curve is defined by three pump rates and three corresponding pump volumes measured at the pumped junction. The pump rates remain constant between each volume in the pumped junction. Another type of pump is the inline pump where the pump rate depends on the head level in the pumped junction. Three sets of head level and respective pump rates are provided with the pump rate remaining constant between each head level. EXTRAN allows simulation of a three-point head discharge pump. The pumping rate depends on the water level difference between the pumped junction and the discharge junction. A set of differential head and pump rate pairings is provided and the pump rate varies linearly between each head and pump rate pair. The fourth type of pump that can be modeled is the variable speed inline pump. In this type of pump the pump rate is based on the depth in the pumped junction. Pumping rate varies linearly between input depth in the pumped junction and the pump rate pairs. Lastly, a lift station type pump may be simulated. This pump type more realistically simulates the operation of a typical pump station. The pump rates are provided for each of the pumps and each one turns on at a given depth and stays on until the depth goes below the "pump-off" depth. Pump station and WPCP data, wet well depths and corresponding pumping rates were studied to determine the type of pump and curves used for the EXTRAN model. For all the models used in the LTCPU analysis the variable speed inline pump mentioned above was used. To model a pump the following information is required:

- Pump Type
- Pumped junction name
- Pump discharge junction name
- Pairs of pumped junction depth and corresponding pump rates
- Volume of wet well (for the offline pump)
- Pump on and off water levels in the pumped junction.

The information required to accurately represent the pumps within the model were obtained from either pump station monitoring data or pump manufacturer's specification sheets.

Outfalls

Outfalls are the discharge points in the EXTRAN models. The outfalls can either have a boundary condition that the head has to overcome for outflow to occur or the outfalls can be free outfalls without any boundary conditions. For most of the sections in the EXTRAN model where the outfalls are in the tidal sections of the rivers (Schuylkill and Delaware) the outfalls have boundary conditions equal to the mean tide (-4.89 ft). For the non-tidal sections in the model the outfalls do not usually have outfall boundary conditions. For special conditions like the gravity flow into the WPCPs, where the plant boundary had to be overcome to reach the WPCP, the appropriate boundary conditions are applied. Another special condition is the computer controlled outflows where the outflow only occurs once a predetermined head has been reached and the appropriate head boundary conditions are applied.

To model the outfall in EXTRAN the following information was needed:

- Name of the outfall
- Boundary condition to be applied.

Regulators

Regulators are structures in the CSS that prevent flow from going to the receiving waters in dry weather and control the flow that reaches the WPCPs in wet weather. Significant differences in design approaches and philosophies can be observed from system to system. The various types of regulators include weir diversions into side or bottom orifices, float-controlled gates, tipping-plate gates, vortex drop shafts, leaping weirs, motor-operated sluice gates and a number of other configurations. A brief description of the modeling approaches for the types of regulators used for the LTCPU analyses is mentioned below. The PWD system includes a variety of regulator types. A regulator's function is to divert all the dry weather and part of the wet weather flow (e.g. storm flow) into a dry weather outlet pipe (DWO) that feeds the interceptor pipes, delivering the flows to the WPCPs. Any excess wet weather flow that can not be accommodated in the DWO goes in the storm over flow pipe (SWO) and overflows in to the receiving water by way of an outfall. There are 5 types of common regulators simulated in the EXTRAN models:

- Slot regulators
- Sluice gate regulator
- Water hydraulic
- Computer controlled
- Brown and Brown regulators (B&B)

Other than the above listed regulators, two types of additional structures are used for storm relief:

- Dams
- Side overflow weirs
- Tide Gates

Slots

The slot-type regulators divert dry weather flow into the DWO conduit through an orifice constructed at the bottom of the combined trunk sewer. During storms, the wet weather flow can exceed the capacity of the orifice and/or the DWO and rise above the orifice and flow over a dam (where static dam are constructed to enhance the DWO capacity) to a SWO and onto the receiving water. Adjustable plates are utilized in some instances to allow for changes in the diverted flows. At a minimum, this orifice opening is sufficiently large to convey dry weather flow plus a certain percentage of the storm flow. In some locations, static dams are constructed to work in conjunction with the slot in order to enhance the capture of both dry and wet-weather flow. For this type of regulator structure in EXTRAN, the regulator is modeled as a node with inflow from trunk(s) and the flow into the DWO from the regulating chamber is modeled as a fixed orifice (orifice dimensions equal the slot opening) and if the flow from the regulating chamber does not pass through tide gates, then the section representing a dam leading to the SWO is modeled as a weir (weir dimensions are made to represent the dam section). If the flow from the regulating chamber to the SWO passes through a tide gate then the dam section leading to the SWO is modeled as an orifice (orifice dimensions simulate the opening above the dam).

Sluice gates regulators

Sluice gates located in the regulating chambers manage flow to the DWO by controlling the size of the opening from the trunk sewer. Typically, this type of regulator consists of a dam constructed in the invert of the trunk sewer downstream of the sluice gate opening. The dam diverts flow into the regulator chamber under dry weather conditions. During storms, the sluice gate may be lowered to a predetermined height and the tide gate (if present) on the SWO is opened. When flows return to normal dry weather conditions, the sluice gate returns to the fully opened position and the tide gate is closed. The sluice gate may be operated manually or automatically either by computer controls or based on water hydraulics. For this type of regulator structure in EXTRAN, the regulator is modeled as a node with inflow from trunk(s) and the flow in to the DWO from the regulating chamber is modeled as a fixed orifice (orifice dimensions equal the sluice gate opening) if the DWO opening is static. If the flow in to the DWO passes through an automated opening that change based on levels in a control node then the opening is modeled as a variable orifice with controls mimicking the actual sluice gate controls. If the flow from the regulating chamber does not pass through tide gates, then the section representing dam leading to the SWO is modeled as a weir (weir dimensions are made to represent the dam section). If the flow from the regulating chamber to the SWO passes through a tide gate then the dam section leading to the SWO is modeled as an orifice (orifice dimensions are set to represent the opening above the dam).

Water Hydraulic Control

There were regulators in the CSS originally designed to operate under City-water hydraulic control. These systems no longer operate in that mode, but now function as static dams. The regulator gates are fixed in the full open position and the tide gates are fixed in a fully closed position. CSOs occur when the water level in the trunk exceeds the top of the tide gates. In their current operating mode, these structures create a large (or near optimum) amount of storage in the trunk sewer during wet weather. This condition minimizes overflows to the receiving waters. For this type of regulator structure in EXTRAN, the regulator is modeled as a node with inflow from trunk(s) and the flow into the DWO from the regulating chamber is modeled as a fixed orifice (orifice dimensions equal the sluice gate opening). Flow from the regulating chamber does not pass through tide gates, so the section leading to the SWO is modeled as a weir (weir dimensions are made to represent the dam section).

Computer controlled

Computer controlled regulators use level monitors and Programmable Logic Controllers (PLCs) to locally regulate the opening and closing of the regulator and tide gates to achieve in-system storage. This is accomplished through the monitoring of the trunk sewer water level relative to a storage set point. During wet-weather flow, the trunk sewer water level will rise above the dam elevation and flow will begin to store behind the gate. When the set point depth is reached, the PLC lowers the regulator gate and actuates the tide gate to maintain the water level at the storage set point. For this type of regulator structure in EXTRAN, the regulator is modeled as a node with inflow from trunk(s) and if flow into the DWO passes through an opening that changes based on water levels in a control node, the orifice is modeled as a variable orifice with controls mimicking the actual gate controls based on control node depths. If the tide gate openings leading to the SWO are also based on levels then they are also represented as variable orifice(s) to mimic the actual controlled openings.

Brown and Brown regulators (B&B)

Brown and Brown regulators B&B regulators are float operated regulators with controls on the openings into the regulator chamber and the DWO. The opening at the gate from the combined sewer trunk to the regulating chamber is variable and is controlled by a float in the chamber. For this type of regulator structure in EXTRAN, the regulator is modeled as a node with inflow from trunk(s) and if the flow into the DWO passes through an opening that changes based on water levels in a control node then the orifice is modeled as a variable orifice with controls mimicking the actual orifice gate controls. If the orifice gate is chained open and acts as a static orifice then it is modeled as a static orifice. If the flow from the regulating chamber does not pass through tide gates, the section representing the dam leading to the SWO is modeled as a weir (weir dimensions are made to represent the dam section). If the flow from the regulating chamber into the SWO passes through a tide gate, the dam section leading to the SWO is modeled as an orifice (orifice dimensions are set to represent the opening above the dam).

Dams

The static dams utilized in the storm relief systems operate in the same manner as the static dams in the combined sewer system. In the relief system, static dams divert wet weather flows from the trunk sewer into the storm relief sewer. For this type of structure in EXTRAN the structure is modeled as a node with inflow from trunk(s) and if the flow from the regulating chamber does not pass through tide gates, then the section representing the dam leading to the SWO is modeled as a weir (weir dimensions are made to represent the dam section). If the flow from the regulating chamber into the SWO passes through a tide gate then the dam section leading to the SWO is modeled as an orifice (orifice dimensions are set to represent the opening above the dam).

Side Overflow Weirs (SOW)

SOWs operate in a similar manner to dam-type regulators except SOWs are constructed on the side of the trunk sewer, parallel to direction of flow. When the hydraulic grade line in the trunk sewer exceeds the weir crest elevation, the storm flow spills laterally over the top of the weir into the relief sewer and ultimately into the receiving water. With the weir crest constructed parallel rather than perpendicular to the direction of flow, the hydraulic capacities in the trunk are not restricted due to downstream control. In a few isolated cases, the side-discharge control function is accomplished through a conduit rather than a weir. In these cases, while the sewer may be circular, baskethandle or another standard sewer shape, the geometry of the flow to the discharge is otherwise identical to the SOW. For this type of structure in EXTRAN the structure is modeled as a node with inflow from trunk(s) and the SOW is modeled as a weir with an offset and an opening that represent the SOW dimensions and offset.

Tide gates

Tide gates are one-way gates that allow the flow to go to the receiving water but prevent the backwater from the receiving water body to enter the combined sewer system. Tide gates are installed in combined sewer systems to prevent back-flooding of the combined sewer system by high tides or high stages in the receiving waters. This back-flooding can cause flooding of regulator structures and introduce the receiving water to the interceptor system. In combined systems, tide gates are installed in the outfall sewer just beyond the regulator or between the regulator and the receiving water. Tide gates can be differentiated into two categories: (1) vertical tide gates; and (2) horizontal tide gates.

Vertical tide gates are hinged at the top and designed to permit discharge with a small differential head on the upstream side of the gate and to close tightly with a small differential head on the downstream side of the gate. Vertical tide gates can be further classified depending on the material used for their flap: (1) Cast iron; (2) pontoon; and (3) timber. Cast iron gates are comprised of solid iron while pontoon gates are fabricated of layered sheet metal which forms air cells in the gate, increasing its buoyancy. Generally, cast iron gates are used for smaller sizes and timber or pontoon gates for larger sizes. Sluice gates are also present in the PWD sewer system. These are classified as horizontal tide gates. Opening and closing of horizontal tide gates is governed by a predetermined water level in either the regulating chamber or combined trunk sewer. Sluice gates are generally comprised of cast iron. The tide gates are represented in the EXTRAN model as one-way equivalent pipes, the flow from which can only flow in the downstream direction.

v4.1.3 Model Simplification

Once all the information is compiled into the model the models are simulated and error checks performed to find mathematical and implementation problems. The models were put through a thorough Quality Assurance procedure. The EXTRAN model gets inflow information from the preceding hydrologic and or hydraulic model runs. After creating the model, it was simplified by reducing the amount of nodes and pipes within the network. The goal of the simplification process was to increase the efficiency by decreasing run-time, while keeping the integrity of the model results. A simplification process was completed to increase the computational speed of the model, effectively decreasing the model run-time. The simplification process followed the steps outlined below:

- Increase the minimum length of the pipes for all feasible situations to 1000 feet.
- Most branches shorter than 1000 feet were identified and eliminated.
- All pipes in a branch with the same shape and slope were combined.
- Expansions were ignored if occurring between two pipes of the same diameter.
- Branches having pipes of varying capacities and shapes and not having a series of similar pipe sizes to combine to a length of 1000 feet were combined regardless and the diameter was set equal to the most constricting pipe in the series.
- If slopes were changed to meet the 1000 foot pipe length requirement, the Manning's coefficient was adjusted accordingly.
- If baseflow existed at a node to be eliminated, the baseflow was transferred to the downstream node if less than 500 feet from the eliminated node, otherwise it was loaded to the upstream node.
- Equivalent pipes were avoided where possible to conserve volumes.

The resulting simplified model allowed for a larger time step (20 seconds) to be used without violating the Courant conditions and, thus, decreasing the computational burden of the model. Continuous simulations were performed using the RUNOFF and EXTRAN models and the results from the simulations were directly or indirectly used to evaluate effects of various alternatives for LTCPU.

v4.1.4 Model Calibration / Validation

Development of the SWMM model for the LTCPU was followed by a calibration and optimization of the parameters for both modules. During the calibration of any model, it should not be expected that simulated results will match perfectly the measured data, since the measured data is subjected to some degree of error, while the model is an approximation of the system hydrology and hydraulics. Therefore, the measured data must be thoroughly reviewed and any limitations must be identified before adjusting calibration parameters. Note that the model calibration is accomplished by finding the best comparison between simulated and measured runoff characteristics over a range of storm events.

Model calibration is accomplished by adjusting initial estimates of the selected variables, within a specified range, to obtain a satisfactory correlation between simulated and measured flow and volume. The variables selected to adjust or calibrate were parameters that typically cannot be measured accurately (e.g., percent impervious, soil infiltration parameters, etc) and which have the greatest affect on the accuracy of the results. The calibration parameters were prioritized according to their influence on the model results, which can vary from one drainage system to another and on several model simulations (sensitivity analysis) on the PWD LTCP.
For the hydrologic calibration, the following data was assessed:

- Precipitation Data
- CSS Trunk Monitor Data
- DCIA Calibration
- RTK Distribution

For the hydraulic validation, the following elements were considered:

- WPCP Inflow and Pumping Data
- Validation Results

Simulations were performed using different model settings and compared using a combination of quantitative and qualitative measures. These combinations are detailed in Table v4.1.1 below with the characteristics for each specific presentation outlined next to each measure.

v4.1.5 Hydrologic Model Calibration

Calibration of the hydrologic model was an iterative process by which RUNOFF module parameters were changed, within acceptable ranges based on available data, from initial estimated values to ones that quantitatively provide the best match between modeled results and observed data.

Table v4.1.1 Details and characteristics of the measures to define the "goodness-of-fit" for calibration and validation results.

Event Volume		
Measure	**Type**	**Basis**
slope of regression line, scatter plot of simulated vs. observed data	Quantitative	A slope equal to 1 represents equality between simulated and observed event volumes. transformation for use in performance spreadsheet: absolute value of (1 – slope) A lower number is better.
probability value for t-test of slope equal to 1, scatter plot of simulated vs. observed data	Quantitative	null hypothesis: slope is not significantly different from 1 alternative hypothesis: slope is significantly different from 1 Reject the null hypothesis for small p-values. transformation for use in performance spreadsheet: none A higher number is better.
intercept of regression line, scatter plot of simulated vs. observed data	Quantitative	An intercept equal to 0 is ideal. transformation for use in performance spreadsheet: absolute value of intercept A lower number is better.
probability value for t-test of intercept equal to 0, scatter plot of simulated vs. observed data	Quantitative	null hypothesis: intercept is not significantly different from zero alternative hypothesis: intercept is significantly different from zero Reject the null hypothesis for small p-values. transformation for use in performance spreadsheet: none A higher number is better.
r-squared value about equal-fit line, scatter plot of simulated vs. observed data	Quantitative	measures scatter transformation for use in performance spreadsheet: none A higher number is better.
slope of regression line, double mass plot of cumulative simulated and observed data over time	Quantitative	A slope equal to 1 represents equality between simulated and observed event volumes. transformation for use in performance spreadsheet: absolute value of (1 - slope) A lower number is better.
intercept of regression line, double mass plot of cumulative simulated and observed data over time	Quantitative	An intercept equal to 0 is ideal. transformation for use in performance spreadsheet: absolute value of intercept A lower number is better.
simulated and observed cumulative frequency distributions of data, small events	Qualitative	*Small events are defined as those where rainfall volume does not exceed depression/interception storage, and no runoff takes place. This distinction is left to the best judgment of the person reviewing the graph. A rating of L or H indicates that more calibration is required.* L: simulated event volumes are lower than observed event volumes M: simulated event volumes are approximately equal to observed event volumes H: simulated event volumes are higher than observed event volumes transformation for use in performance spreadsheet: L=H=1; M=2 A higher number is better.
simulated and observed cumulative frequency distributions of data, medium events	Qualitative	*Medium events are defined as those where runoff occurs from impervious cover, but not from pervious cover. This distinction is left to the best judgment of the person reviewing the graph. A rating of L or H indicates that more calibration is required.* L: simulated event volumes are lower than observed event volumes M: simulated event volumes are approximately equal to observed event volumes H: simulated event volumes are higher than observed event volumes transformation for use in performance spreadsheet: L=H=1; M=2 A higher number is better.
simulated and observed cumulative frequency distributions of data, large events	Qualitative	*Large events are defined as those where runoff occurs from pervious cover. This distinction is left to the best judgment of the person reviewing the graph. A rating of L or H indicates that more calibration is required.* L: simulated event volumes are lower than observed event volumes M: simulated event volumes are approximately equal to observed event volumes H: simulated event volumes are higher than observed event volumes transformation for use in performance spreadsheet: L=H=1; M=2 A higher number is better.

Event Peak Flow

Measure	**Type**	**Basis**
slope of regression line, scatter plot of simulated vs. observed data	Quantitative	A slope equal to 1 represents equality between simulated and observed peak flows. transformation for use in performance spreadsheet: absolute value of (1 - slope) A lower number is better.
probability value for t-test of slope equal to 1, scatter plot of simulated vs. observed data	Quantitative	null hypothesis: slope is not significantly different from 1 alternative hypothesis: slope is significantly different from 1 Reject the null hypothesis for small p-values. transformation for use in performance spreadsheet: none A higher number is better.
intercept of regression line, scatter plot of simulated vs. observed data	Quantitative	An intercept equal to 0 is ideal. transformation for use in performance spreadsheet: absolute value of intercept A lower number is better.
probability value for t-test of intercept equal to 0, scatter plot of simulated vs. observed data	Quantitative	null hypothesis: intercept is not significantly different from 0 alternative hypothesis: intercept is significantly different from 0 Reject the null hypothesis for small p-values. transformation for use in performance spreadsheet: none A higher number is better.
r-squared value about equal-fit line, scatter plot of simulated vs. observed data	Quantitative	measures scatter transformation for use in performance spreadsheet: none A higher number is better.

Time to Peak

Measure	**Type**	**Basis**
time when event peak flow occurs, simulated and observed event time series plots	Qualitative	*The reviewer looks at all time series plots and makes a qualitative determination whether, on balance, simulated event peaks are different from observed event peaks. A rating of E or L indicates that more calibration is required.* E: simulated event peaks occur earlier than observed event peaks M: simulated event peaks occur at approximately the same time as observed event peaks L: simulated event peaks occur later than observed event peaks transformation for use in performance spreadsheet: E=L=1; M=2 A higher number is better.
volume under the recession limb, simulated and observed event time series plots	Qualitative	*The recession limb is defined as the portion of the event after the last peak. The reviewer looks at all time series plots and makes a qualitative determination whether, on balance, simulated volumes are different from observed volumes. A rating of L or H indicates that more calibration is required.* L: simulated recession limb volumes are lower than observed event volumes M: simulated recession limb volumes are approximately equal to observed event volumes H: simulated recession limb volumes are higher than observed event volume transformations for use in performance spreadsheet: L=H=1; M=2 A higher number is better.

Precipitation data

The main goal in acquiring precipitation data was to get the most detailed and consistent (temporally and spatially) data available for the periods in which hydraulic data were available for the Philadelphia CSS service area. It was determined after extensive review and QA assessment that the PWD 24-raingage network data required bias adjustment and normalization to provide the spatial and temporal consistency necessary for the calibration process. Details of the precipitation data analyses and adjustment procedures are presented in Supplemental Documentation 5: Precipitation Analysis.

The SWMM RUNOFF module requires assignment of an input rainfall time series for each stormwater runoff or sanitary sewer RDI/I basin in the model. Inverse distance-squared weighting is used to estimate rainfall in areas between rain gauges. A one-square-kilometer grid is imposed over the PWD service area. Next, a rainfall value for every time step is assigned to each grid element by inverse distance-squared weighting of the rainfall values from three nearby surrounding gages. Finally, the gridded precipitation values are area-weighted to provide average rainfall values for each individual sewershed in the model. In this manner, the bias adjusted 15-minute accumulated rainfall data for the PWD 24-raingage network is distributed to RUNOFF model basin areas using the Inverse Distance Weighted (IDW) method. Details of this distribution procedure may be found in Supplemental Documentation 5: Precipitation Analysis.

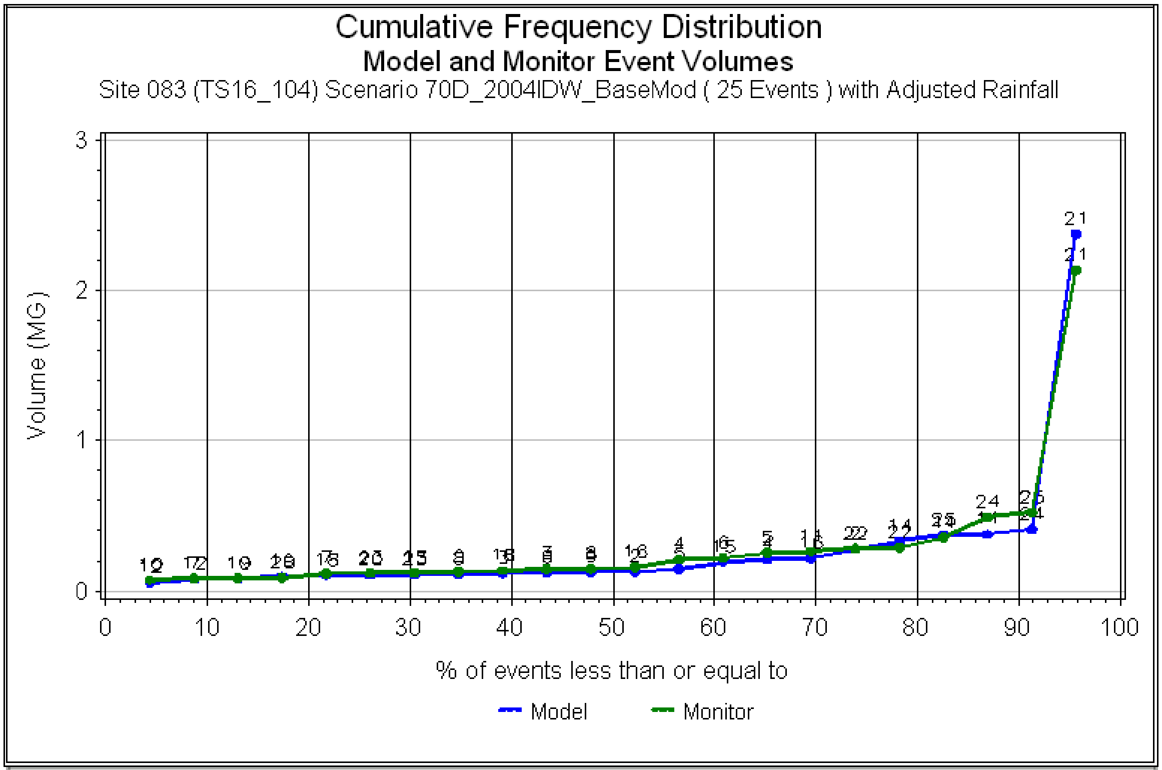
Combined Sewer System Trunk Monitor Data

Flow data taken from flow monitors located in trunk sewers throughout the combined sewer area were analyzed and then used to adjust calibration parameters for the hydrologic models. There were six combined trunk sewer monitors having sufficient usable data to perform calibration analyses. These six flow monitors are presented in Table v4.1.2 below. Included in the table are the model pipe names of the monitor location, the area draining to the monitor, the calibration period and corresponding drainage districts.

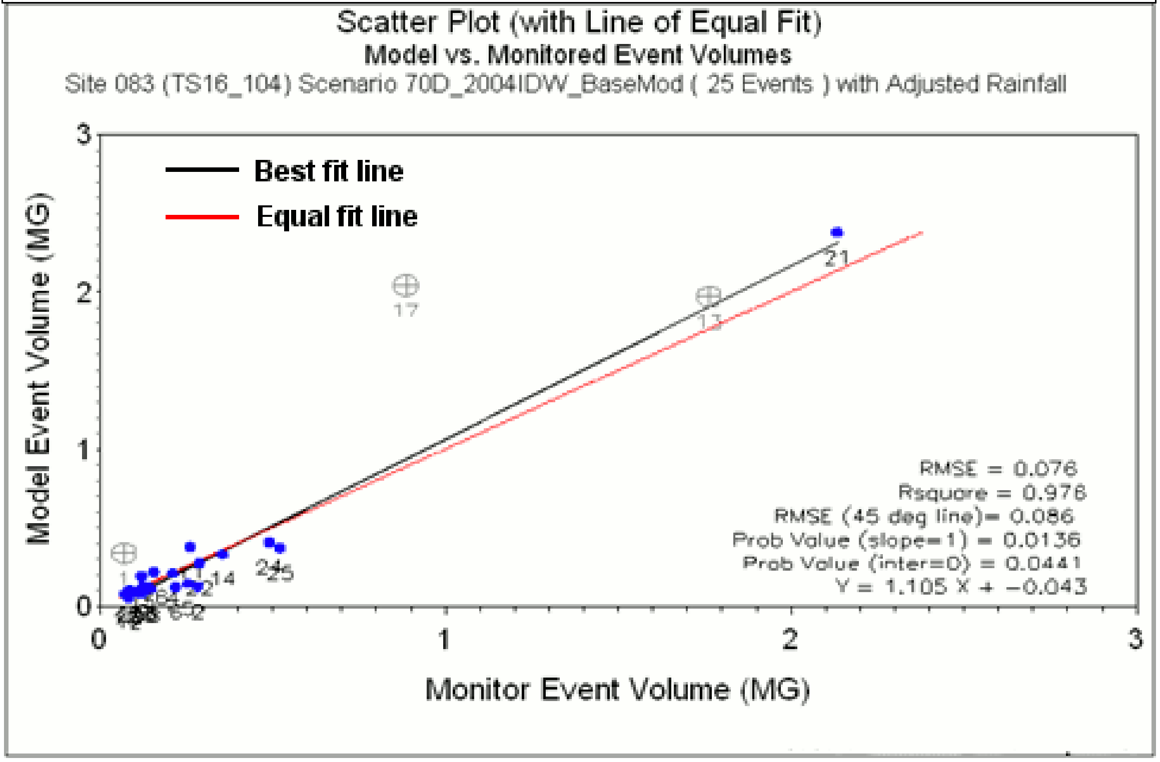
Table v4.1.2 Trunk monitor calibration information.

Monitor	District	Pipe Name	Data Range	Drainage Area (ac)
79	SW	TS27-3308	1/1/2002-9/2/2002	4.33
83	SW	TS16-104	1/1/2004-12/31/2004	19.65
84	SW	TS13-108	1/13/2004-5/2/2006	25.11
85	SW	TC06-112	10/25/2002-7/28/2004	98.56
S42-130	SW	TR25-104	4/26/2006-9/19/06	73.05
D54-15	SE	TD54-604	5/26/2006-9/15/2006	167.19

Hydrograph decomposition was performed on the data from the above flow monitors to extract the wet weather portion. This flow was used to compare to the simulated model flow. To assess the goodness of fit of the model output to observed data a series of plots were created including scatter plots of event volumes, time to peak and peak flows, Cumulative Frequency Distributions (CFDs), Cumulative mass regression plots and timeseries plots for each event. A selection of result plots for monitor 83 is presented collectively as Figure v4.1.3 below. The r-squared, slope, intercept and the equal fit line from the scatter plots and the qualitative assessment of the timeseries plots were used to determine the level of fit for model output compared to observed data.



Cumulative Frequency Distribution
Model and Monitor Event Volumes
Site 083 (TS16_104) Scenario 70D_2004IDW_BaseMod (25 Events) with Adjusted Rainfall



Scatter Plot (with Line of Equal Fit)
Model vs. Monitored Event Volumes
Site 083 (TS16_104) Scenario 70D_2004IDW_BaseMod (25 Events) with Adjusted Rainfall

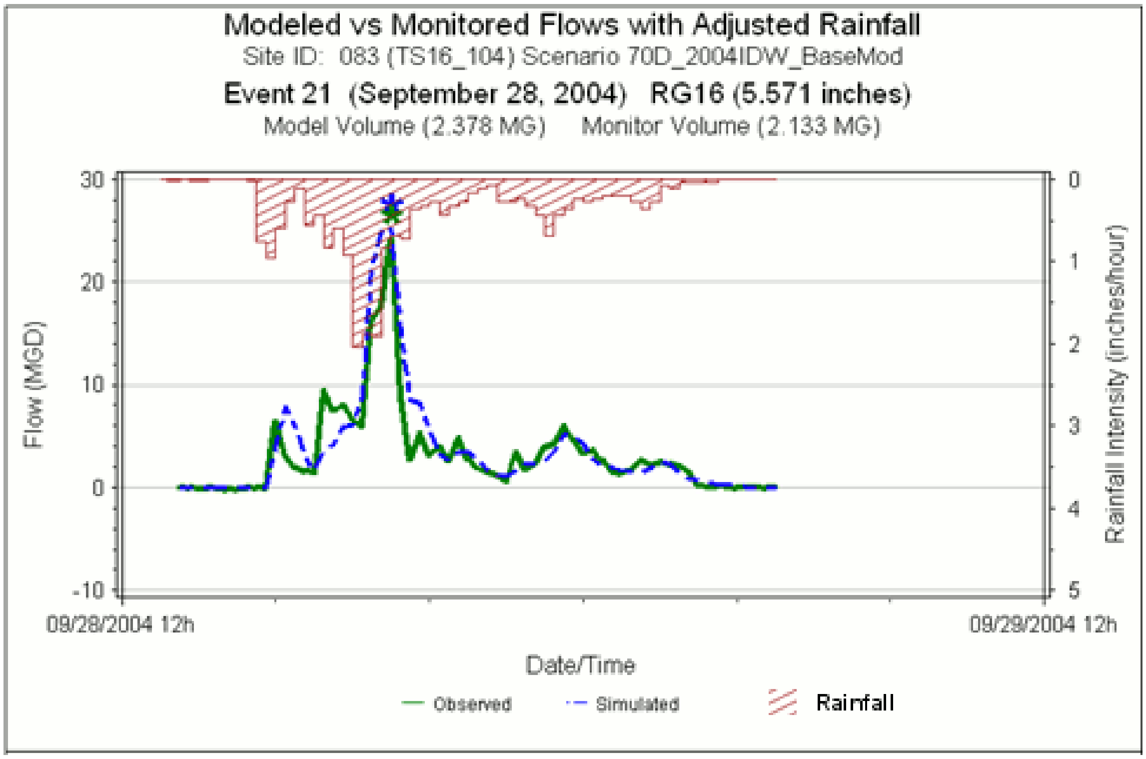


Figure v4.1.3 Result plots for Site 83 including the CFD, event volume scatter plot and the September 28, 2004 event timeseries plot.

The results for each model run were organized into a performance spreadsheet and model parameters that provided the best fit calibration scenario were chosen.

Parameters Adjusted

Model calibration is accomplished by adjusting initial estimates of the selected variables, within a specified range, to obtain a satisfactory correlation between simulated and measured flow and volume. The variables selected to adjust or calibrate were parameters that typically cannot be measured accurately (e.g., percent impervious, soil infiltration parameters, etc) and which have the greatest affect on the accuracy of the results. The calibration parameters were prioritized according to their influence on the model results, which can vary from one drainage system to another and on several model simulations (sensitivity analysis) on the PWD LTCP.

Directly Connected Impervious Area (DCIA)

For all sewersheds with monitored trunk sewers, directly connected impervious area (DCIA) in the best-fit model was lower than gross impervious cover derived from aerial photography. The ratio of DCIA to total gross impervious area ranged from 50% to 100%. Because the majority of sewersheds are unmonitored and the measurements themselves have uncertainty associated with them, it is reasonable to present this value as a range. Presented below are ranges associated with specific areas in the drainage district.

- 5 monitors in trunk sewers: Adjustments in the best-fit model range from 50% to 95% of gross impervious cover.

- Cobbs Creek watershed model: Adjustments were made watershed-wide based on USGS streamflow records. Adjustments were made in combined and separate areas and in areas inside and outside the City. This calibration process had a higher level of uncertainty than the trunk monitors. Adjustments ranged from 50% to 100% of total impervious cover.
- Tookany/Tacony-Frankford Creek watershed model: Adjustments were made watershed-wide based on USGS streamflow records. Adjustments were made in combined and separate areas and in areas inside and outside the City. This calibration process had a higher level of uncertainty than the trunk monitors. Adjustments ranged from 50% to 75% of total impervious cover.

Based on the histogram shown below (Figure v4.1.4), the mean and most common adjustment is 70% of DCIA. This value is used in the best-fit model, with the exception of monitored sheds. To account for the uncertainty that exists in the monitoring data a high and low range of DCIA were chosen for the LTCPU models. The high estimate for DCIA for the unmonitored shed was assumed to be 80 percent of the gross impervious and for the low estimate it was assumed as 60 percent of gross impervious. For the calibrated sheds an increment of 10 percent in calibrated DCIA was used to account for the high uncertainty estimate and a 10 percent decrease from the Calibrated DCIA was used to represent the low estimate of the uncertainty.

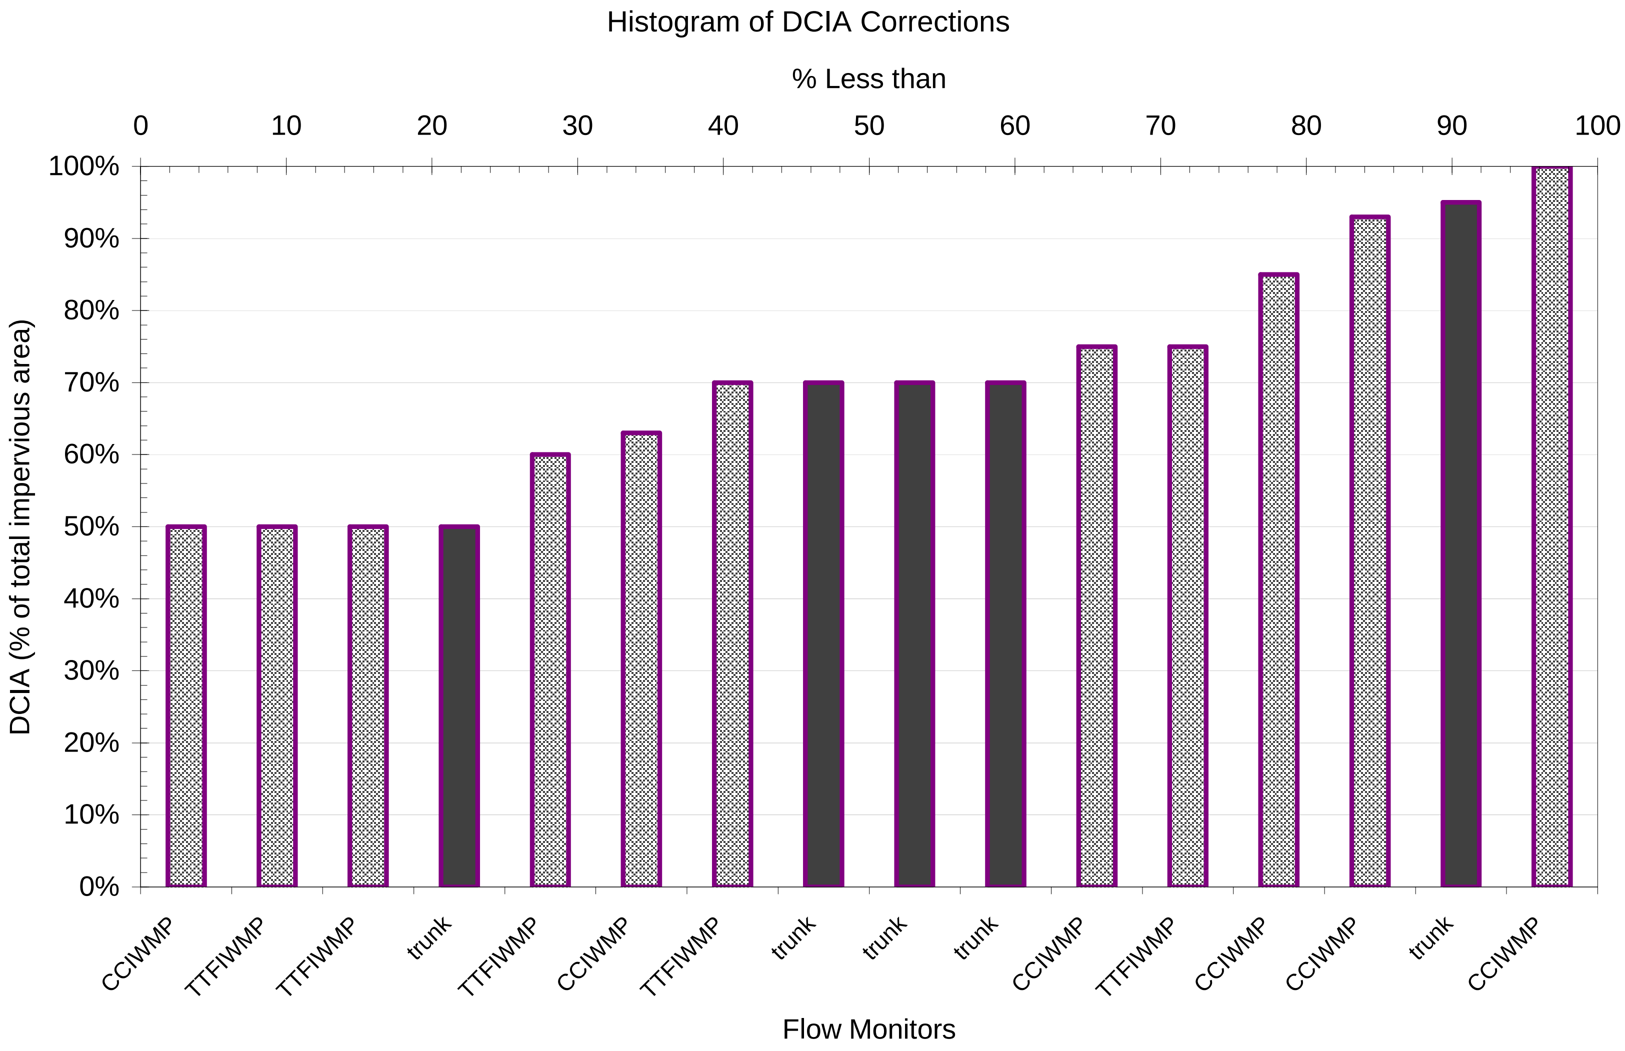

Figure v4.1.4 Histogram of resulting calibrated DCIA percentages of gross impervious area for available monitors within the drainage district.

RTK Distribution

The purpose of this task was to determine an acceptable average R-value range within the simplified SWMM model to represent rainfall dependent inflow and infiltration volumes (RDI/I) across all un-monitored separate sanitary sewer area. The existing RDI/I values from the 39 flow monitoring sites discussed previously were used in this process. The full range of R-Values showed no apparent correlation to population density, geographic location or size of monitored shed, therefore, the analysis included:

- Ranking of the 39 sites based on R-value.
- Creation of a histogram and cumulative frequency distribution plot.
- Upper (80 percentile) and lower (20 percentile) limit determination based on the central tendency about the median.

The resulting histogram is presented as Figure v4.1.5 below. The final median R-Value to represent the watershed area is 0.0401.

An in-depth RDI/I analysis was conducted for the city of Philadelphia to account for the contribution to the CSS within the LTCPU models. The first step in the process was data collection (described in section 2.1) and assessment. To define the RTK values for the city, a selection of flowmeter sites was made from the 39 sites available. Selection of the flowmeter sites was based on the quantity and quality of data existing at each site and of the 39, 13 provided a satisfactory amount of observed flow data. The selected flowmeter site ID, contributing area and the location (district) are shown below in Table v4.1.3.

Table v4.1.3 Sites chosen for full RTK analysis.

Site ID	Contributing Area (Acres)	Drainage District	Data Date Range
5	9361	NE	6/2000 to 9/2001
27	674	NE	8/1999 to 4/2000
29	656	NE	9/1999 to 10/1999
40	4557	SW	8/1999 to 9/2001
44	1986	NE	11/1999 to 4/2000
49	1784	SE	5/2000 to 8/2002
57	164	SW	6/2000 to 9/2001
70	276	NE	6/2000 to 9/2001
72	301	NE	3/2001 to 5/2005
75	179	NE	6/2001 to 7/2004
77	162	NE	9/2000 to 7/2002
95	3540	NE	6/2004 to 5/2006
96	12594	NE	6/2004 to 5/2006

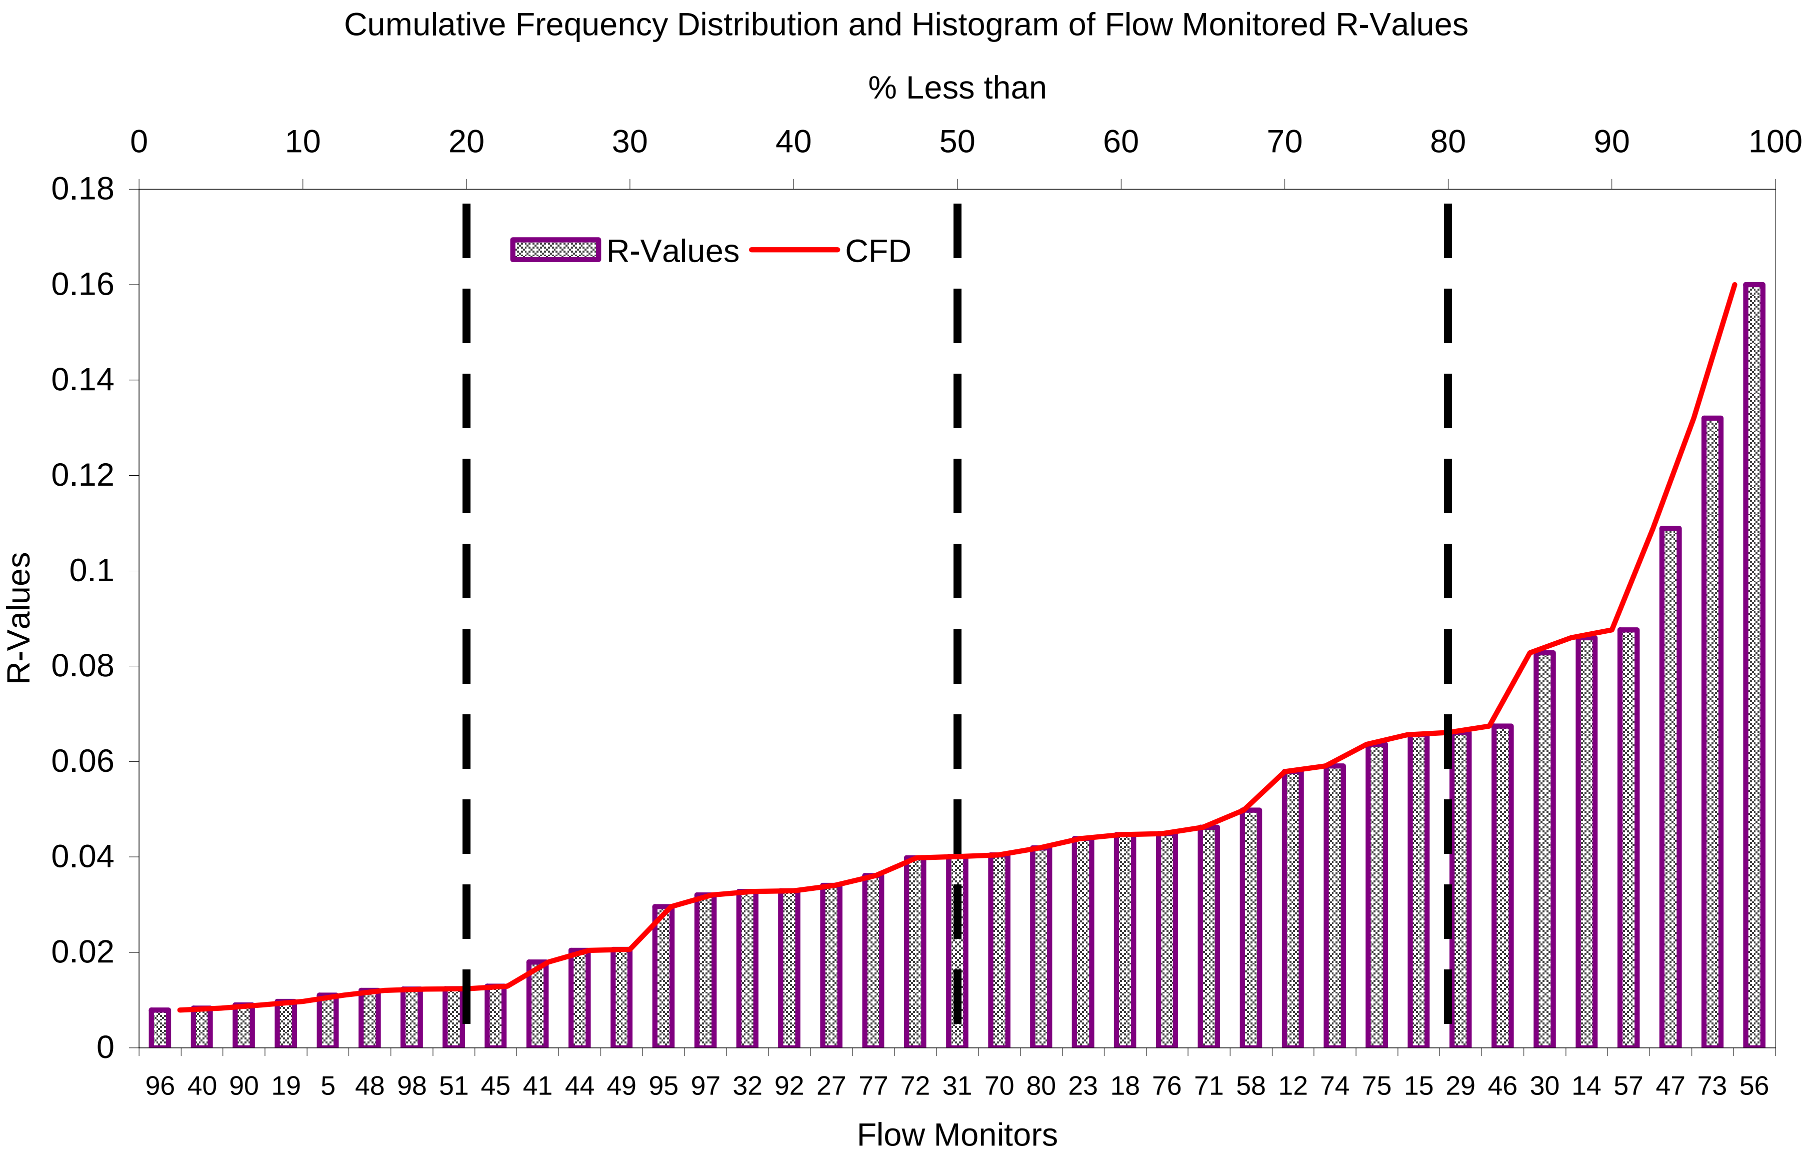

Figure v4.1.5 Histogram of resulting calibrated R-values for selected monitors within the drainage district.

1. Quality assurance procedure carried out on above selected sites. The raw flowmeter data was formatted and imported into a QA template. Data was checked for date/time inconsistencies, unusable data due to flowmeter malfunctions or missing data. Data was flagged at each timestep to identify data as good, missing, unusable or interpolated. Flags were used to help calculate statistical information on the data and to facilitate understanding of anomalous data in subsequent data processing steps (e.g., SHAPE analysis). If previous Quality checks had been done to older data sets, those data were re-evaluated and brought up to current quality standards
2. After quality assurance of the data, it was formatted and imported into CDM SHAPE software. Rain data from the Allflows.mdb database was generated specific to each flowmeter site (i.e., raingage ID and time frame). Within the SHAPE software, weekday and weekend dry-weather flow patterns were determined. Hydrograph decomposition was performed by adjusting groundwater points through the entire time frame of the data. During groundwater adjustment, wet-weather event boundaries were delineated. R-values and inflow and infiltration values for each flowmeter site were calculated and exported.
3. The exported data for all events were further assessed for anomalies (i.e., events affected by snow, holiday patterns or extreme events) that may skew analysis results. If events existed fulfilling any of these criterion, they were removed from the event list and were not included in subsequent analyses.

4. The R-Values (calculated for each event) are summarized to get average values for each month. The events are sorted based on month, year and then day. The average for each month was calculated two ways:
    1. The arithmetic average
    2. The volume weighted average calculated using the I/I depth and rainfall depth for each event

   The method chosen to use in further analyses was determined by how well the data flowed from month to month (i.e., which showed smoother transitions)
5. Exported parameters from SHAPE and the calculated average R-values are inserted to a Microsoft EXCEL spreadsheet created to analyze the fast (RTK1), medium (RTK2) and slow (RTK3) response of rainfall dependent inflow and infiltration (RDII). The RDII volume from observed and simulated data is calculated and plotted for each event at each flowmeter site. Based on volume comparison, the R, T and K values are manipulated to produce a more closely matched comparison of volumes. Adjustment of RTK values followed these guidelines:

   i. Divide the R value exported from SHAPE analysis three ways (fast, medium and slow response R-values) for each month
   ii. For first run arbitrarily choose T and K values for one month
      a. The month with the most data was chosen
   iii. Run the program
      a. The resulting hydrograph produced by summing the three response hydrographs equals the total simulated RDII response
   iv. Adjust RTK values based on how well the simulated RDII response matches the observed RDII response
   v. Once the RTK values produce an acceptable match to the observed hydrograph, the RTK values are placed in another Microsoft EXCEL

spreadsheet to check the shape of each unit hydrograph corresponding to the fast, medium and slow responses

        a. Adjustments are made (if necessary) to make transitions between the three phases smooth (i.e., without dips)

    vi. Once adjusted (or fine-tuned), the TK values are applied to all other months.
    vii. R-values are adjusted for each month to create matching hydrographs while the TK values remain static

Final values for RTK at each flowmeter site were distributed to all sheds contributing to that flowmeter in the simplified runoff master sheet

6. A second EXCEL spreadsheet was utilized to check the unit hydrographs resulting from the RTK values specific to each site. This was done to make certain the transitions between the response curves remained fluid, without disruption due to dips. If there are disruptions, the values are adjusted slightly and distributed to the remaining months. For the remaining months the TK values remain static, while the R-values are adjusted.
7. The R, T and K values from the last step were used for the RUNOFF simulation. Runoff results produced from SWMM were plotted with SAS for verification and observed versus simulated responses compared
    a. If hydrographs did not produce an acceptable match, refinement of the RTK parameter values was done and the data re-imported to the SWMM runoff input file
    b. The SWMM model was re-run and data plotted
    c. The process was repeated until an acceptable match was created

An example of an acceptable matching hydrograph and corresponding best-fit volume scatter plot are shown in Figure v4.1.6.

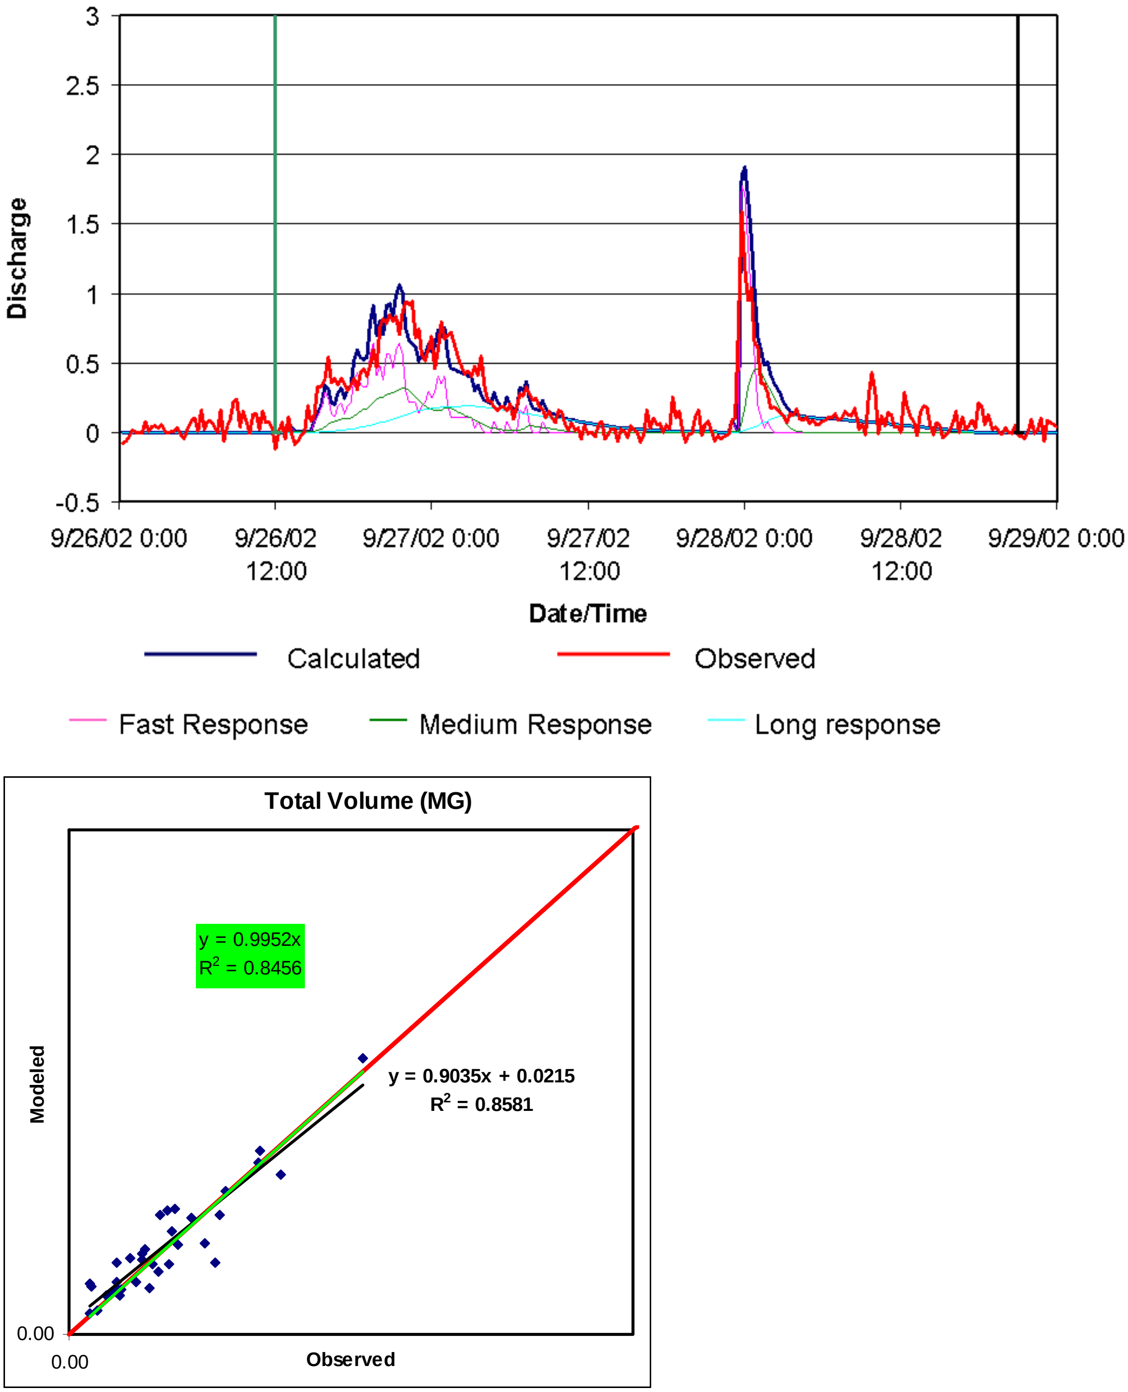

Figure v4.1.6 Examples of an Acceptable Observed to Simulated Data Hydrograph and Best-Fit Volume Scatter Plot Match from the RTK Template Analysis Spreadsheet Tool.

During this process, four sites were chosen as templates for the remaining 26 flowmeter sites and all remaining un-metered sanitary sewer shed loading points. Selection of the four sites to use as templates was based on flowmeter data consistency, accuracy and precision of observed hydrographs compared to estimated hydrographs. The size of the contributing area to the flowmeter was used as the criteria for distributing the templates to the un-metered sheds. Table v4.1.4 outlines the four sites selected as templates.

Table v4.1.4 Listing of the sites chosen as templates and the corresponding ranges of application.

Site ID	Contributing Area	Area Range to Apply
75	179	area < 300 acres
70	276	300 acres ≤ area ≤ 1000 acres
40	4557	1000 acres ≤ area ≤ 5000 acres
5	9361	area > 5000 acres

Distribution among un-metered sheds

The distribution of template RTK values to un-metered sheds was based on the contributing drainage area to each outlet node. The un-metered shed names were searched respective outlets identified. The contributing area to each outlet was totaled. Based on the total contributing area to each outlet, template IDs were assigned to each shed draining to that outlet. The template IDs associated RTK parameters to each shed. The RTK templates and boundary conditions are those outlined in Table v4.1.4 above.

Outlying Community User Input Hydrographs

The outlying community areas chosen for direct time series input are DELCORA, Bucks County (MB-1) and Lower Southampton Township (MSH-1). These areas were selected based on the magnitude of the contributing flows and the availability of acceptable quality data for the period of interest.

The procedures described herein were used to create SWMM4 EXTRAN K3-line timeseries input data for selected outlying community sanitary sewer connections to the Philadelphia combined sewer system (CSS). The timeseries data are to be used to define wet weather flow response from these areas in continuous simulations performed for the 2005 representative year selected for LTCPU project evaluations. Filling missing or errant data is required in order to generate continuous timeseries over the one-year simulation period. The outlying community areas chosen for direct timeseries input are DELCORA, Bucks County (MB-1) and Lower Southampton Township (MSH-1). These areas were selected based on the magnitude of the contributing flows and the availability of acceptable quality data for the period of interest.

Bucks County and Lower Southampton Township timeseries flow data source is the 2.5-minute permanent billing meter data obtained from the PWD real-time unit (RTU) database. Quality assurance and quality control (QAQC) procedures including inspection of monthly timeseries plots were used to flag errant or missing data. The accepted data is then averaged to 15-minute intervals.

DELCORA flow data is obtained from hourly Southwest WPCP influent flow data measured at the plant. Quality assurance and quality control procedures including inspection of monthly timeseries plots were used to flag errant or missing data. The accepted data is then interpolated to 15-minute intervals.

Data Gap Filling Procedures

Identification and filling of data gaps are required in order to generate continuous timeseries data needed for performing the typical year model simulations for 2005 data. First, all data gaps and their durations are identified. Next, each data gap is characterized as either wet weather or dry weather flow with the corresponding procedures used for gap filling as described below.

The procedure for Dry Weather Flow is as follows. For small data gaps of less than 1 hour, linear interpolation was performed. Missing or errant data over one or more hours was filled using the nearest previous day's dry weather flow (DWF) data.

The procedure for Wet Weather Flow is as follows. For small data gaps of less than 1 hour, linear interpolation was performed. Wet weather events with missing or errant data periods of one hour duration or more were filled for the entire wet weather event boundaries as defined by the RDI/I analysis. Model simulation results using RDI/I RTK shape parameters previously calibrated for these areas were used to generate the wet weather flow by subtracting baseflow. The calculated wet weather flow for each timestep was added to the timeseries nearest previous day's DWF data.

The continuous flow timeseries generated for the year 2005 that contained diurnal and seasonal time varying baseflow patterns. In contrast, RUNOFF model generated hydrographs used for all other model areas simply have wet weather hydrograph responses added to a constant average baseflow. In order to represent the wet weather responses from the K3 line timeseries input areas more consistently with the modeled areas from the RUNOFF module, hydrograph separations were performed on the K3 timeseries data using CDM SHAPE software to extract the wet weather response hydrograph. The final timeseries was constructed by adding a constant average baseflow to the separated wet weather response K3 timeseries

High and Low Baseflow Estimates

Average monthly dry weather flow rates are determined from WPCPs hourly influent flow data based on days with complete records of average hourly flow data and for which there is no rainfall recorded at any of the PWD rain gages on that day or the previous two days. Annual average dry weather flow (baseflow) rates are determined from these monthly values. Average annual dry weather flow rates for each WPCP over the period 1999 through 2005 are presented in Figure v4.1.7. Average annual flow rates for the period 1999 through 2005 have been standardized dividing by the 7-year average in order to better compare relative changes in inter- annual baseflow rates between drainage districts and are presented by the time series plots in Figure v4.1.8. Note: the time period from 1999 through 2005 is selected because significant reductions from dry weather flow rates prior to this period are generally observed as a result of tidal inflow eliminations.

High and low average annual dry weather flow rates are used to establish upper and lower estimates of available wet weather treatment capacity (worst and best case scenarios) for LTCPU project evaluations. Cumulative frequency distribution plots of average monthly dry weather flow rates over the period 1999 through 2005 are presented for each WPCP in Figure v4.1.9. The values representing the 80th and 20th percentiles for each WPCP, presented in Table v4.1.5, are selected for determining high and low baseflow estimates, respectively. These low, median and high baseflow estimates are expressed as a fraction of current SWMM EXTRAN model dry weather WPCP influent flow. These baseflow multiplication factors are presented in Table v4.1.6 for each drainage district model.

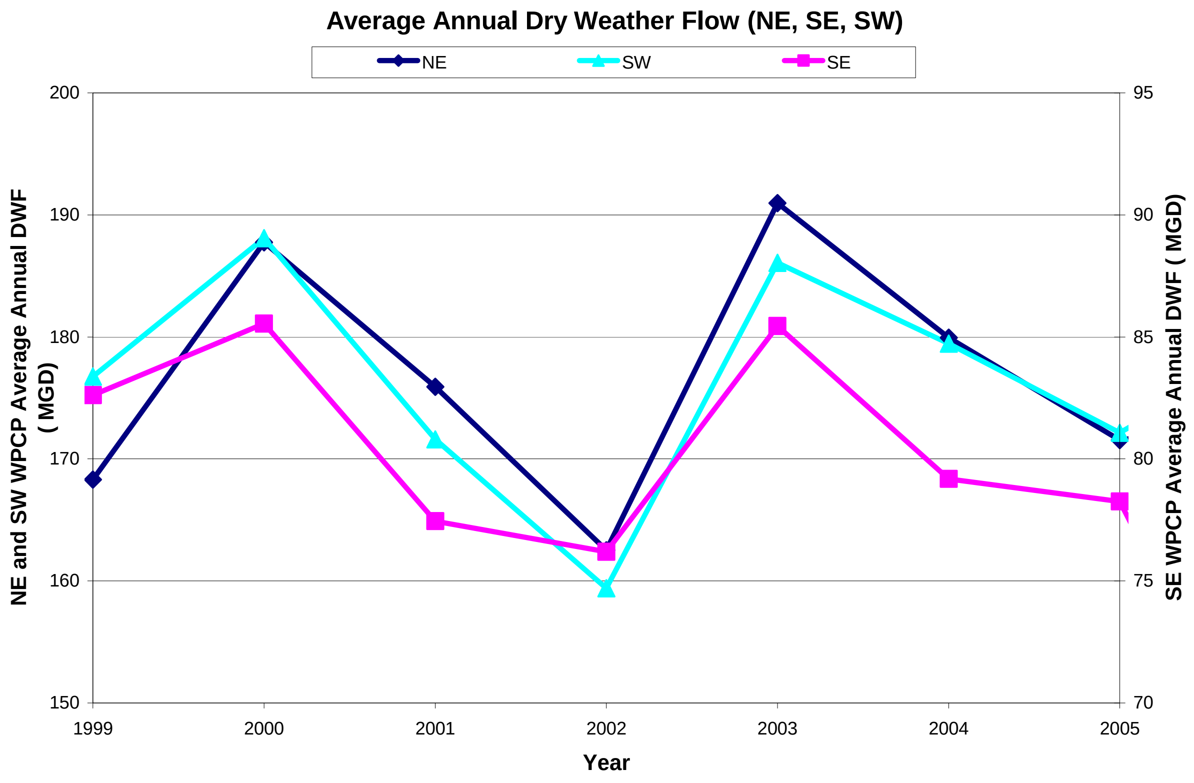

Figure v4.1.7 Average annual dry weather flow rates for each WPCP over the period 1999 through 2005.

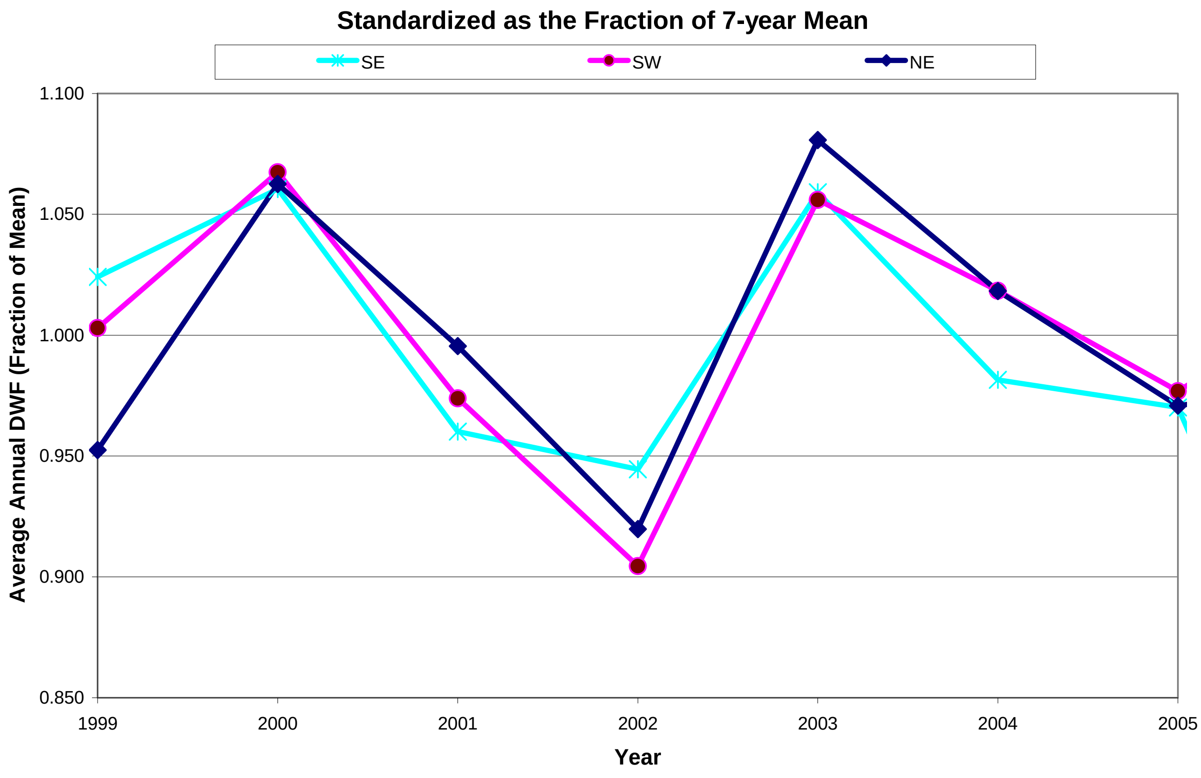

Figure v4.1.8 Standardized **a**verage annual flow rates for the period 1999 through 2005.

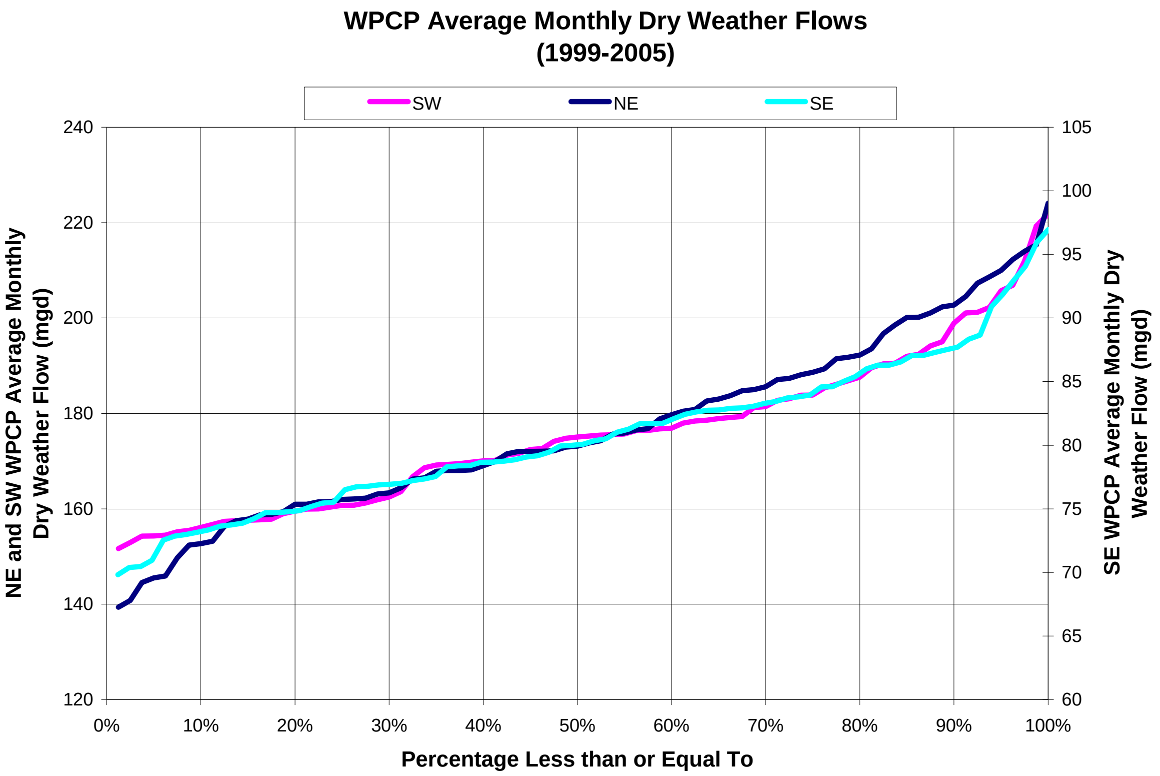

Figure v4.1.9 Cumulative frequency distribution plots of average monthly dry weather flow rates over the period 1999 through 2005.

Table v4.1.5 Average Monthly Baseflow Statistics (1999 - 2005)

WPCP	DWF Percentiles (mgd)		
	20th	50th	80th
SE	75	80	86
NE	161	173	192
SW	160	175	188

Table v4.1.6 SWMM EXTRAN Model Baseflow Multiplier Factors for Low, Median and High Flow Scenarios

WPCP	SWMM EXTRAN Baseflow Multiplier Factors		
	Low	Median	High
SE	0.938	1.003	1.073
NE	0.911	0.980	1.088
SW	0.892	0.979	1.049

v4.1.6 Hydraulic Model Validation

Once the hydrologic models have been calibrated based on combined trunk and sanitary sewer monitoring data, the system hydraulic models were validated against observed pollution control plants (WPCP) influent flow and level data for the calendar year 2005. The results for each drainage district are subsequently discussed using the quantitative and qualitative best-fit measures outlined in Table v4.1.1 as a guide for model result accuracy.

WPCP Inflow and Pumping Data

PWD monitors level and inflow at its three water pollution control plants. These flows were compared to simulated flows for a range of storm events during the calendar year 2005. WPCP influent flow and pump wet-well level data are stored in average hourly time intervals. A QA process was performed on the flow data, during which errant or missing data were removed. The observed flow time increments were interpolated to a 15-minute time interval before being imported into the SHAPE program along with the rainfall data for analysis. The data underwent hydrograph decomposition and the wet-weather portion of the flow coming to the plant was extracted.
The model parameters adjusted to best match the monitored WPCP influent flow and level data included plant head boundaries, pump curves, metering head losses and QA of regulator gate settings.

Southeast Drainage District

The results of final Southeast Drainage District (SEDD) hydraulic model validation, performed using SE WPCP influent hydrograph separated wet-weather flow data, are presented in Figures v4.1.10 through v4.1.12. Linear regression analysis is performed comparing model estimated SE WPCP influent wet weather flow volumes (y-axis) to monitored event volume (x-axis) using IDW rainfall data for the calendar year 2005. The events that have been excluded from the regression analysis based on the protocols described previously are presented in the scatter plots with different symbols and shading so they can be distinguished from those events included in the regression. Ideally the plots would reveal a one to one relationship, meaning the model simulated exactly the monitored runoff volume for each event.

Figure v4.1.10 is a scatter plot with the linear regression analysis results used to determine quantitatively how well the model simulated total event volumes treated at the SE WPCP. The red-dashed line is the 45-degree line that would indicate a perfect fit with an r-squared value of 1. Figure v4.1.11 is an overlay of model and monitored SE WPCP influent wet-weather event volume cumulative frequency distribution (CFD) plots. Figure v4.1.12 is an overlay of model and monitored hydrograph time-series plots for the October 22, 2005 storm event. The plots display a good correlation between observed and simulated event volumes over the full range of events analyzed. Any significant systematic deviation between simulated and observed data would indicate events of a certain volume range were not being adequately simulated by the model.

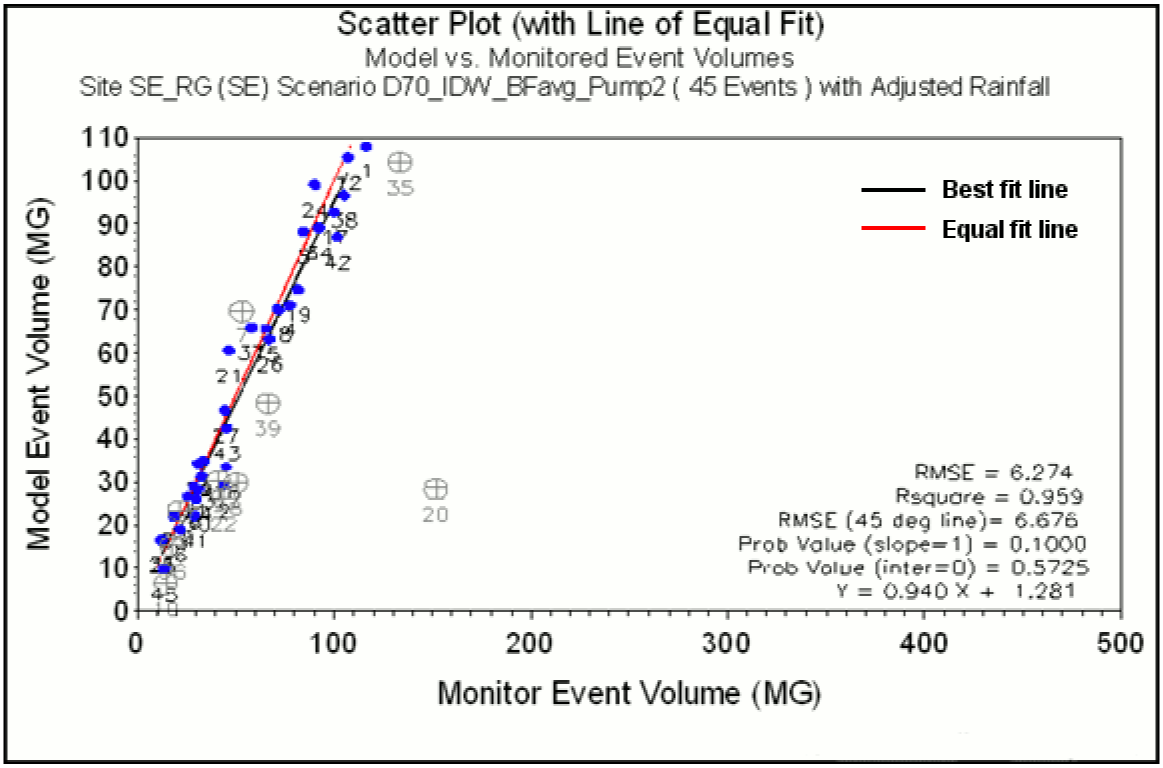

Figure v4.1.10 SE WPCP linear regression of modeled versus monitored event volumes

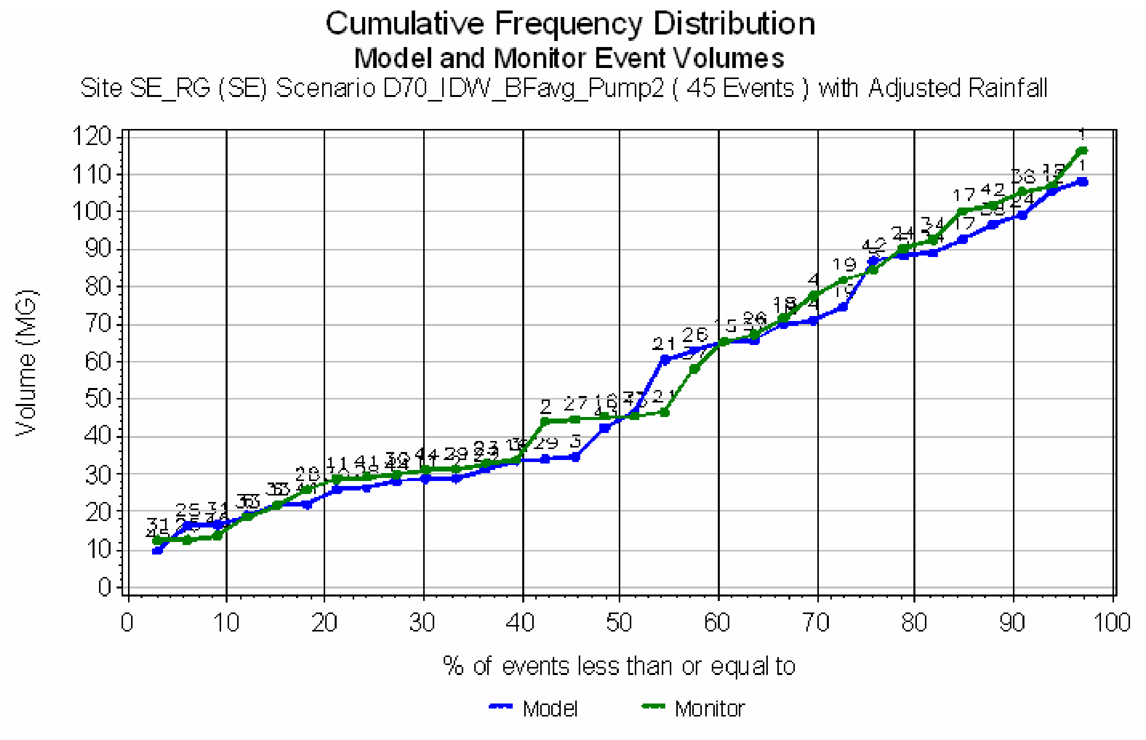

Figure v4.1.11 SE WPCP CFD plots of monitored and modeled event volumes

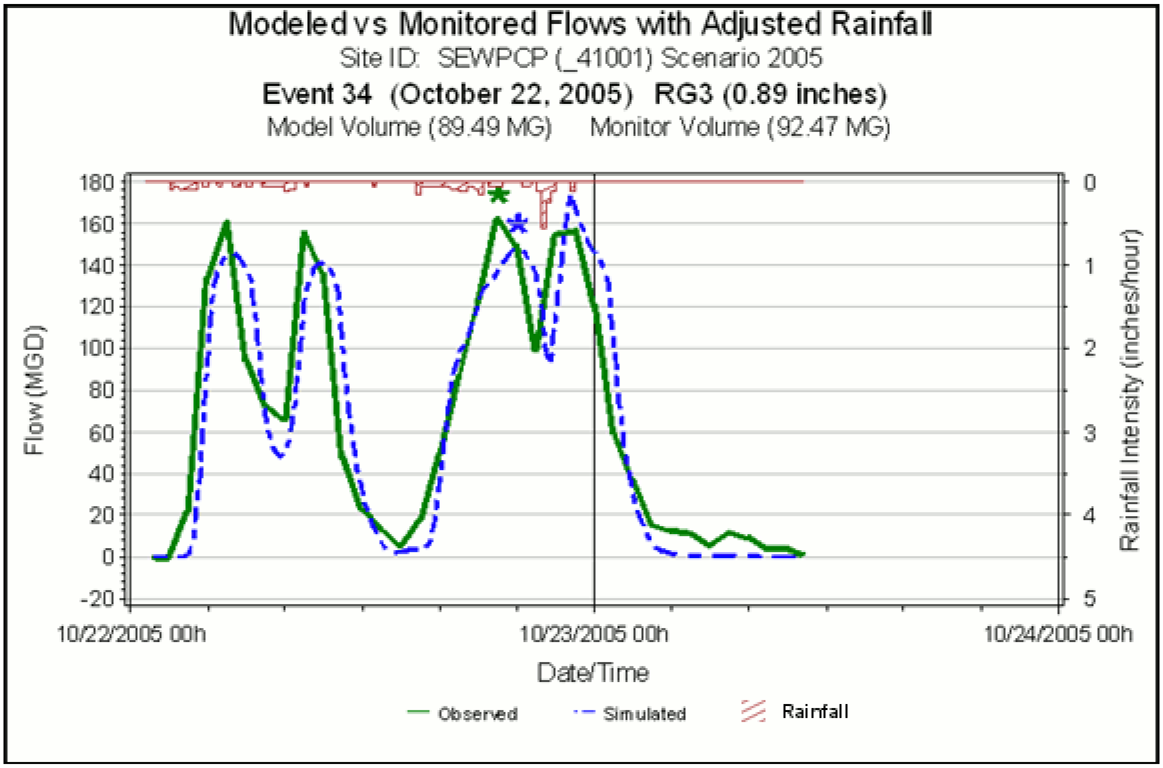

Figure v4.1.12 SE WPCP model and monitored wet-weather flow time-series plot for the October 22, 2005 event

Southwest Drainage District

Final validation plots for the Southwest drainage district (SWDD) hydraulic model are presented in Figures v4.1.13 through v4.1.16. The plots are presented separately for the two interceptor systems that feed the Southwest Water Pollution Control Plant (WPCP), the Southwest High Level (SWHL) and the Southwest Low Level (SWLL). The events that have been excluded from the calibration analyses, using the set of protocols described previously, are presented in the scatter plots with different symbols and shading so they can be distinguished from those included in the regression analyses.

Figure v4.1.13 shows the linear regression analysis used to determine quantitatively how well the SWHL simulated the wet-weather event volumes. The monitored wet-weather event volumes are on the horizontal axis and the modeled event volumes are on the vertical axis. (The red-dashed line is the 45-degree line that would indicate a perfect fit with an r-squared value of 1.0). Figure v4.1.14 shows the cumulative frequency distribution (CFD) plots of the monitored and the modeled wet-weather volume from the SWHL. This plot is used to check if the wet-weather volumes being simulated are different from the observed for various sized storms. Similarly figure v4.1.15 and v4.1.16 show the linear regression analysis and the cumulative frequency distribution plots for the SWLL interceptor system. The curves at the SW interceptors match each other reasonably well with no significant deviation for each plot.

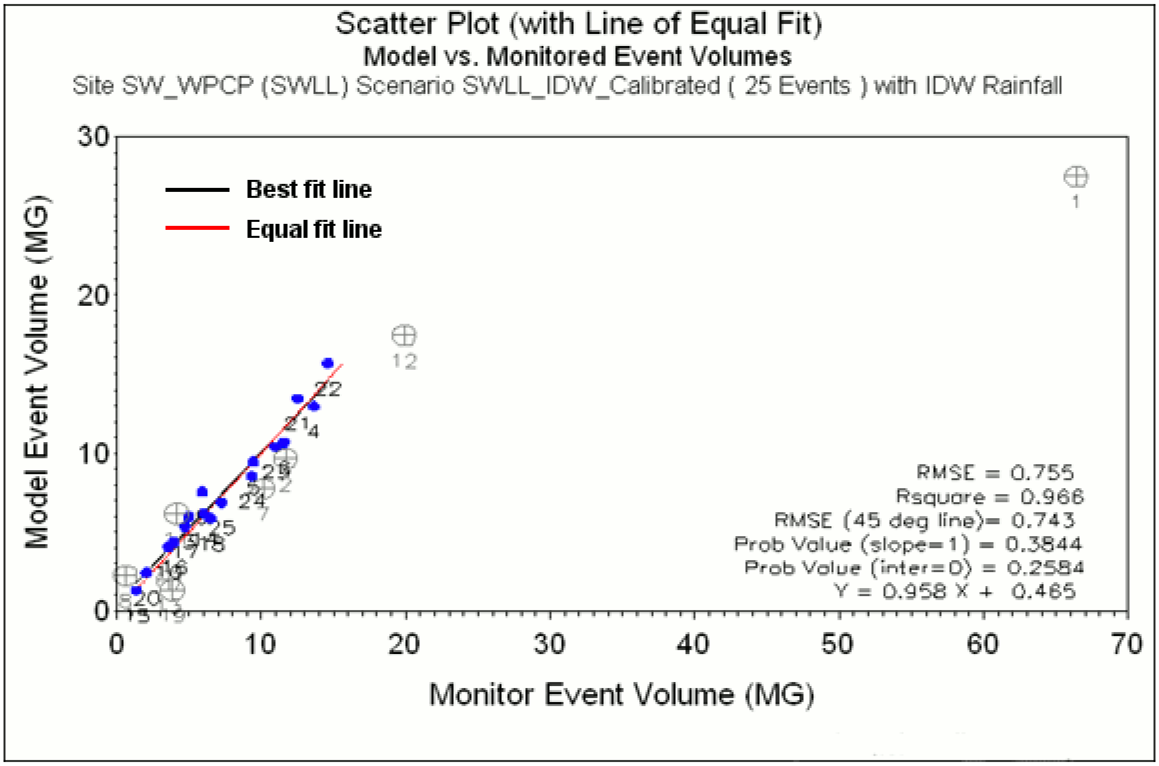

Figure v4.1.15 SWLL linear regression of modeled versus monitored event volumes

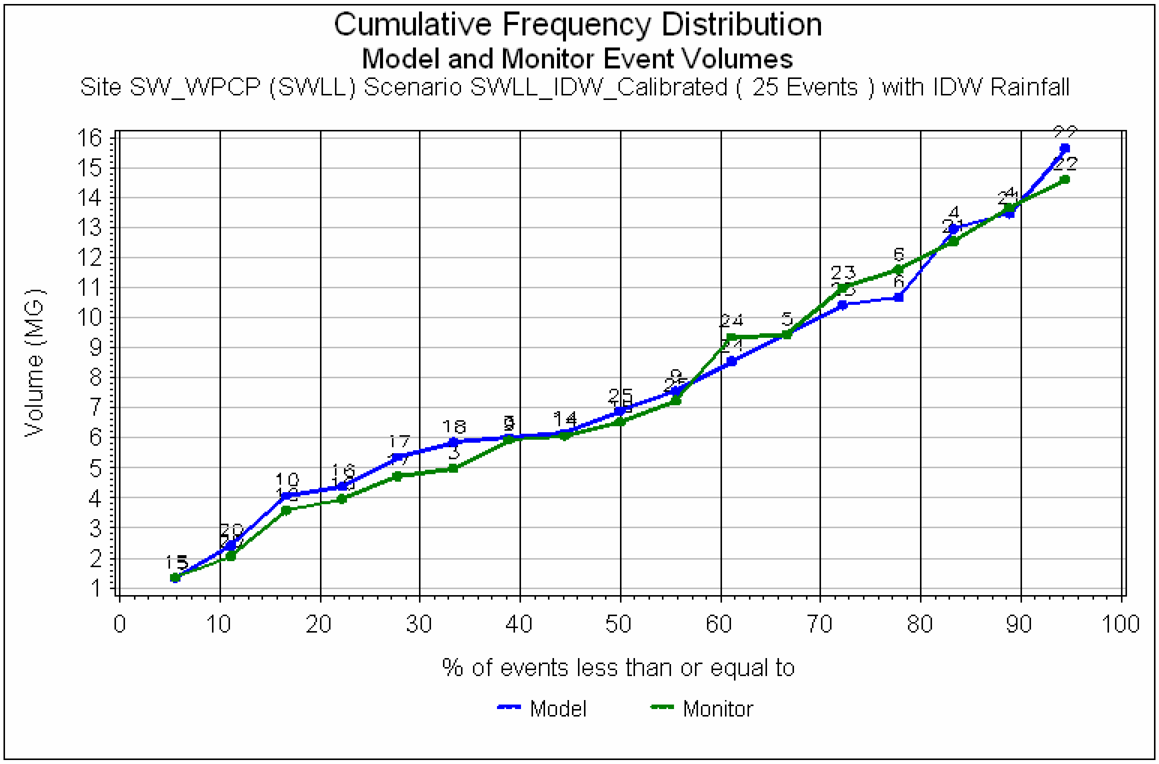

Figure v4.1.16 CFD Monitored and Modeled event volumes SWHL

Northeast Drainage District

The Northeast Water Pollution Control Plant (NE WPCP) receives combined sewer flows by gravity from the Northeast High-Level system (NEHL) and through pumping from the Northeast Low-Level system (NELL). These two drainage systems connect at the NE WPCP and can be modeled separately or as a single combined model. The NEHL system is comprised of two interceptor systems: the Frankford High Level (FHL) and the Tacony (T). The NELL system is comprised of five interceptor systems: the Somerset Low-Level (SOM), the Upper-Frankford Low-Level (UFLL), the Lower Frankford Low-Level (LFLL), the Upper Delaware Low-Level (UDLL) and the Pennypack (P).

Final validation plots for the Northeast drainage district (NEDD) model are presented in Figures v4.1.17 through v4.1.30. These plots include scatter plots of model versus monitored WPCP influent wet-weather event volumes showing linear regression analysis results, cumulative frequency distribution plots of model and monitored WPCP influent wet-weather event volumes and selected model and monitored influent wet-weather flow hygrographs. Plots are first presented for the total NE WPCP and the combined NELL. Calibration plots are also presented for each of the following three metered plant influent lines, FHL, the combined SOM and UFLL and the UDLL which also includes flow from the LFLL. The same event list is used for all analyses. Events are excluded from the calibration analyses based on the set of protocols described previously and are distinguished from those included in the regression plots by use of different symbols and shading.

The plots generally display a good correlation between observed and simulated event volumes over the full range of events analyzed. Any significant systematic deviation between simulated and observed data would indicate events of a certain volume range were not being adequately simulated by the model.

Significant systematic under-estimation of the combined SOM/UFLL influent wet-weather event volumes is indicated by the linear regression and CFD as presented in Figure v4.1.25 and Figure v4.1.26. However, inspection of individual influent wet-weather flow hygrographs for the January 7 and July 1, 2005 rainfall events presented in Figure v4.1.27 and Figure v4.1.28, respectively, reveal a very close overall correlation between modeled and monitored hydrographs. In fact, the correlation between modeled and monitored hydrographs for the combined SOM/UFLL appears to be much better than that for the UDLL, as illustrated in Figure v4.1.29 and Figure v4.1.30, which shows a higher correlation in the linear regression and CFD plots than the combined SOM/UFLL.

4.2 CHARACTERIZATION OF BASELINE CONDITIONS – SYSTEM RESPONSE TO WET WEATHER

The response of the CSS to wet weather conditions is detailed for each WPCP drainage district through model simulations of calibrated LTCPU baseline models using typical year rainfall and the median range of estimated hydrologic parameters. Statistics for each rainfall event causing a CSO are presented for each drainage district in Table v4.2.1 through Table v4.2.3. These tables include a list and count of regulators overflowing and estimates of rainfall, runoff, and overflow volumes for each event.

Table v4.2.1 NEDD Response to Wet Weather Conditions

Rainfall Events			CSO Regulators Overflowing		NEDD Rain Gage Rainfall Depth Statistics					Flow Depth Values		
Start Time	End Time	Duration (hrs)	List	Count	Average Depth (inches)	Max Depth (inches)	Min Depth (inches)	Max Intensity (in/hr)	Min Intensity (in/hr)	RDI/I (inches)	Runoff (inches)	Overflow (inches)

4.3 ALTERNATIVE MODEL DEVELOPMENT

The alternative model was built using the baseline model as its foundation. Some changes were made to the baseline models to represent the projects that are in the process of being implemented. The alternative models that were developed with these changes in them form the basis of various analyses that were performed for the LTCPU.

v4.3.1 WPCP Expansion

LTCPU Section 8 Infrastructure-Based Control Measures describes the WPCPs and their expansion scenarios. More information on the stress testing of the WPCPs can be found in Supplemental Documentation Volumes 6, 7 and 8. More information on the WPCP Wet Weather Treatment Alternatives can be found in Supplemental Documentation Volumes 9, 10 and 11.
Based on these studies the WPCP capacities for each of the drainage district were chosen.

For the alternative model the WPCP treatment rates 330 mgd, 650 mgd and 540 mgd were chosen for the SEWPCP, NEWPCP and SWWPCP respectively.

For the SEDD and SWDD these treatment rates can be delivered to the respective WPCP with minor improvements. For the SEDD the treatment rate at SEWPCP can achieved by process improvements and improvements to the influent pumping at SEWPCP. For the SWDD the treatment rate at SWWPCP can achieved by improvements at the SWWPCP. For the NEDD two additional barrels would need to be built to deliver the flow from the high level interceptor system to achieve peak flow of 650 mgd at the NEWPCP.

The alternative models were developed to include the above changes so as to achieve the peak treatment flow at each of the WPCPs.

v4.3.2 Infrastructure Improvements

The following infrastructure improvements have been included in all alternatives evaluated as part of the LTCPU.

Indian Creek Daylighting In-System Storage

The project is located in the Cobbs Creek Watershed at the confluence of the East Branch Indian Creek and the West Branch Indian Creek. Currently the West Branch Indian Creek flows into a culvert within which the outfall of CSO regulator C_05 discharges before merging with the East Branch Indian Creek to form the main stem of Indian Creek. The proposed project will divert the creek out of the culvert and restore the surrounding stream channel. The approximately 700 feet of 6’ x 6’ culvert will now be over-sized for conveying CSO flows from regulator C_05 and will be modified to allow storage of a majority of this flow during wet weather and release to the collection system for treatment at the SW WPCP as capacity becomes available.

T14 Real-Time-Control In-System Storage

CSO outfall T14 is a very large sewer (21' by 24') that discharges into the Tacony Creek during periods of moderate to heavier rainfall. The T14 combined trunk sewer has a volume of approximately 10 million gallons upstream of the regulator chamber. To use as much of this storage as possible, a control structure is needed in the sewer. Installation of a crest gate is proposed in order to retain flow within the sewer. This gate will reduce CSO discharges to the creek by utilizing the sewer for in-system storage. This control technology provides an additional margin of protection against wet weather discharges while maintaining flood protection for upstream communities. The crest gate retains the stored flow in the sewer and a new connector pipe and control gates drain the stored flow for treatment at the NE WPCP as capacity becomes available.

Rock Run Relief Real-Time-Control In-System Storage

The Rock Run Relief Sewer provides flood relief to combined sewersheds in PWD's Northeast Drainage District (NEDD). The Rock Run Relief structure, R15, is a side overflow weir which diverts wet weather flows into the Rock Run Relief Sewer at R15 once flow levels exceed the diversion weir height. This proposed project will utilize approximately 2.3 MG of the 11 ft diameter relief sewer for storage of combined sewer flows through a control structure, inflatable dam or hydraulic gate, constructed within the outfall pipe along with a new connector pipe to the Tacony Interceptor and control gate to drain the flow for treatment at the NE WPCP as capacity becomes available.

v4.3.3 Waterfront Disconnection

Currently, stormwater runoff from the two interstate highways (I-95 and I-76) along Philadelphia's riverfronts is discharged to the combined sewer system, using wet weather capacity and increasing overflow from sewersheds along the waterfronts. The area represented by I-95 is approximately 2.1% of impervious area in the Delaware Direct watershed. Currently, the Pennyslvania Department of Transportation has plans to expand the capacity of a portion of I-95 by adding new lanes. This major construction project provides an opportunity to incorporate a stormwater management component concurrently with the transportation component. In this concept, stormwater runoff from new and existing lanes will be diverted from the combined sewer system. New separate storm sewers will be constructed from I-95 to the waterfront, with appropriate stormwater quality treatment included as appropriate. This infrastructure can be sized to accommodate not just runoff from the highway, but runoff from future redevelopment projects along the waterfront.

Interstate Highways and Waterfront Land

ArcGIS was used to identify the areas between the highway and the river. The highway area was also identified. Properties located close to the Delaware and Schuylkill waterfronts present opportunities for sewer separation, appropriate pretreatment of stormwater and direction of stormwater to public or private permitted outfalls. It is important to note the same land-based stormwater management techniques being considered for the combined sewer system can function as pretreatment for runoff entering a separate storm sewer system. This runoff would no longer be included in PWD's CSO management program but would continue to be managed through PWD's larger stormwater and watershed management programs.

Table v4.3.1 lists the "waterfront" drainage area currently draining to combined sewers. Waterfront can be defined in one of two ways. Defined as all land between interstate highways and rivers, it comprises approximately 4% of combined drainage area. This percentage is highest in the southeast drainage district at 7%. Defined more narrowly as the area between combined sewer regulator structures and the river, the waterfront area comprises approximately 2% of drainage area. There is also a long-term potential to disconnect the interstate highways themselves from the combined sewer system.

Table v4.3.1 Distribution of Waterfront Land

Land Location	Combined-Sewered Impervious Area (ac)				Combined-Sewered Impervious Area (% of total)			
	City-Wide	SED D	NED D	SWD D	City-Wide	SED D	NED D	SWD D
Non-Waterfront	43,414	8,700	20,060	14,654	95.8	91.5	98.4	94.9
Between Regulator Structures and Rivers	681	157	245	279	1.6	1.8	1.2	1.9
Between Major Highways and Rivers	1,507	578	234	695	3.5	6.6	1.2	4.7
Highway	315	165	94	56	0.7	1.9	0.5	0.4
Waterfront + Highway	1,822	743	327	752	4.2	8.5	1.6	5.1

v4.3.4 Green Stormwater Infrastructure Model Details

Philadelphia's stormwater regulations require a minimum level of performance from post-construction stormwater management structures. Rather than focusing on differences in structure between different land-based practices, we will assume that an appropriate practice or mix of practices can be designed to meet this level of performance. We will model a generic structure that meets management goals through some combination of storage, infiltration and slow release.

To improve modeling efficiency, stormwater management will be modeled separately from combined sewer system hydraulics. Outflow hydrographs from stormwater management structures will be used as inflow hydrographs for the sewer system. This section describes sizing and configuration of model elements that will approximate the requirements of the Philadelphia stormwater regulations.

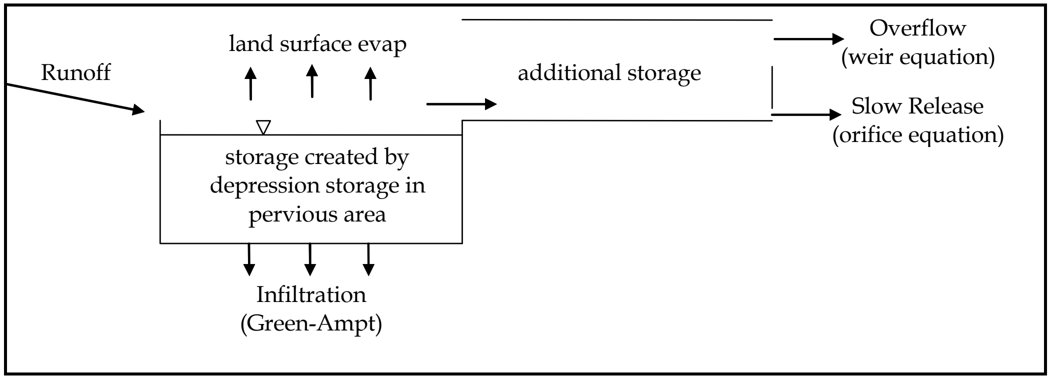

Figure v4.3.1 Conceptual Diagram of Modeling Approach

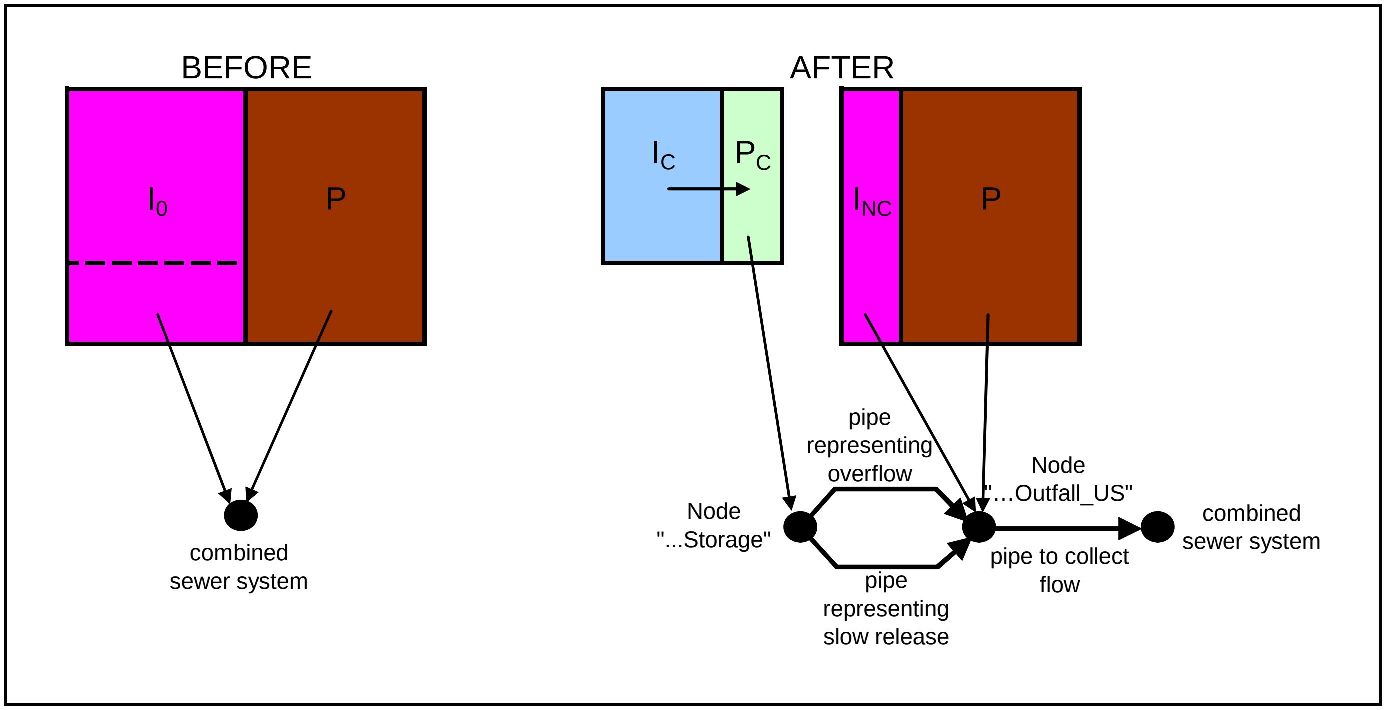

Figure v4.3.2 Schematic Diagram of Modeling Approach

Identified in the schematic diagram above, portions of the subcatchments are divided up and labeled as follows:

I_0 = impervious area of original model subshed (ac)
P = pervious area of original subshed (ac)
I_C = impervious area draining to stormwater controls (ac)
P_C = bottom area of stormwater controls (ac)
I_{NC} = impervious area not draining to controls (ac)

The portion of the impervious drainage area to be controlled is calculated. The area to be occupied by stormwater control structures is included in this area.

$$(I_C + P_C) = I_0 \text{ x } X$$

Where X = percentage of original impervious area to be controlled, designated by the user

Next, the bottom area of stormwater controls and the impervious drainage area can be calculated.

$$P_C = (I_C + P_C) / (R + 1)$$
$$I_C = R \text{ x } P_C$$

Where R = ratio of controlled impervious area to stormwater control bottom area , designated by the user

Next, the impervious area not draining to controls is calculated.

$$I_{NC} = I_0 - I_C - P_C$$

In SWMM, these numbers are entered as percent impervious and total area.

Total area (controlled) = $I_C + P_C$
Total area (not controlled) = $I_{NC} + P$
Percent impervious (controlled) = $I_C / (I_C + P_C)$
Percent impervious (not controlled) = $I_{NC} / (I_{NC} + P)$

The Philadelphia Stormwater Regulations require control of a water quality volume equal to 1.0 inch of runoff from the directly connected impervious area. This volume includes two components, an infiltration volume and a treat-and-release volume. The infiltration volume is the minimum of the water quality volume or the volume that can be infiltrated in an acceptable period.

$$V_I = \min\left[\left(V_{WQ} \text{ x } I_c \text{ x } (43{,}560 \text{ ft}^2 / \text{ac}) \text{ x } (1 \text{ ft}/12 \text{ in})\right), \left(P_C \text{ x } K_{sat} \text{ x } T \text{ x } (43{,}560 \text{ ft2/ac}) \text{ x } (1 \text{ ft}/12 \text{ in})\right)\right]$$

Where V_I = infiltration volume (ft^3)
V_{WQ} = water quality volume = 1.0 in
K_{sat} = saturated vertical hydraulic conductivity of soil under stormwater control (in/hr)
T = allowable time for standing water to infiltrate soil, designated by user (hr)

The infiltration volume determines depression storage in the pervious area representing stormwater controls.

$$D_C = [V_I / (P_C \times 43{,}560\ ft^2/1\ ac)] \times (12\ in/1\ ft)$$

Where D_C = depression storage in pervious area representing stormwater controls (in)

The treat-and-release volume is the difference between the water quality volume and infiltration volume, if any. This volume is represented in the model as a storage node, with orifice and weir controls on its outflow, which will only receive runoff after depression storage is full. The weir height (difference between invert and overflow elevation) of this pipe is designated by the user and the cross-sectional area is calculated to give the required storage volume.

$$V_{TR} = (V_{WQ} \times I_C \times 43{,}560\ ft^2/ac \times 1\ ft/12\ in) - V_I$$
$$A_N = V_{TR} / H_w$$

Where A_N = surface area of storage element (ft^2)
V_{TR} = treat-and-release volume (ft^3)
H_W = weir height in storage node, designated by user (ft)

A weir control is added to allow larger storms to overflow the storage element. This discharge is assumed to receive no significant detention or water quality treatment. The total height of the storage element is set at an arbitrary value greater than the weir height to allow high flows to exit the storage element unimpeded.

The stormwater regulations designate an allowable release rate for the treat-and-release volume in combined-sewered areas, based on 24-hour detention of a reference volume equal to runoff from a 1-year, 24-hour storm. The average allowable release rate is calculated as this volume released over 24 hours:

$$Q_{ave} = [(2.64\ in) / (24\ hrs)] \times (1\ ft/12\ in) \times (43{,}560\ ft^2/ac) \times (1\ hr/3600\ s) = 0.11\ cfs/ac$$

Where Q_{ave} = allowable average controlled release rate per acre of impervious drainage area

It is assumed that with a submerged orifice control, the peak release rate is approximately twice the average:

$$Q_{peak} \sim 2 \times Q_{ave} = 0.22\ cfs/ac$$

Where Q_{peak} = maximum allowable controlled release rate per acre of impervious drainage area

An orifice control sufficient to provide this level of detention can be estimated by solving the submerged orifice equation.

$$D_O = (4\ A_O / \pi)\ \hat{}\ (1/2)$$

Where A_{ref} = cross-sectional area of the storage node if it were required to store this volume (ft^2)
A_O = area of orifice to release reference volume in targeted time (ft^2)

C_D = submerged orifice discharge coefficient, designated by user (dimensionless)
g = gravitational constant (ft/s^2)
D_O = orifice diameter (ft)

EXTRAN converts the slow-release orifice to an equivalent pipe with a diameter equal to the orifice diameter. The model automatically lowers the invert of this pipe to approximately simulate a bottom-discharge orifice and calculates a roughness coefficient (assuming flow given by Manning's equation and slope equal to the change in head divided by the change in length) to provide approximately the same head loss that would have been provided by an orifice. To prevent backwater affects on the orifice from non-LID sheds loading to the downstream node of the storage pipe, the invert elevation of the upstream storage node is increased by 30' and an offset equal to the increase is added to the downstream node of the storage pipe to keep the slope parameters intact. Any offset existing at the upstream storage node was removed. The orifice control is modeled as a static orifice without gated controls.

The stormwater regulations require management of a channel protection volume on some sites. Management of this volume does not require storage of the entire volume and management of the water quality volume meets part of this requirement. The approach below is based on a practical interpretation of how these controls might be designed by site engineers, assuming a relatively lenient interpretation of the requirement.

Runoff during the most intense 30 minutes of a 1-yr, 24-hour NRCS Type II event will be approximately as follows:

$$Q_{runoff} = (0.306) / (0.5 \text{ hrs}) = 1.62 \text{ in/hr} = 1.63 \text{ cfs/ac}$$

The NRCS approximate method of reservoir routing (Urban Hydrology for Small Watersheds, Figure 6-1) suggests that a storage volume equal to 52% of the runoff volume will be needed to reduce the peak runoff to the allowable peak release rate. This storage volume is calculated and the water quality volume is subtracted to determine additional storage needed to meet the channel protection requirement. This volume is added to the volume in the storage element. The orifice control is not changed.

Total storage volume required = 52% x 2.64 in = 1.37 in
$V_{ch\text{-}add} = (1.37 \text{ in} – 1.00 \text{ in}) \times (1 \text{ ft}/12 \text{ in}) \times I_C \times (43{,}560 \text{ ft}^2/1 \text{ ac}) \times I_{ch}$
$A_{ch\text{-}add} = V_{ch\text{-}add} / H_W$

Where $V_{ch\text{-}add}$ = additional volume to be added to storage element (ft^3)
I_{ch} = portion of controlled impervious area subject to channel protection requirement (%)
$A_{ch\text{-}add}$ = additional cross-sectional area to be added to storage element (ft^2)

In the special case where infiltration is sufficient to manage the entire water quality volume and no additional channel protection volume is required, the surface area of the storage pipe is set arbitrarily to 50 ft^2 and the orifice diameter is set to 10 ft. These settings should be sufficient to allow effectively uncontrolled flow through the storage element.

Validation of Prototype EXTRAN Model

Single-Subshed, Constant-Inflow Case

RUNOFF and EXTRAN elements were set up for a single subshed ('47TH-ST') according to the equations in the previous section, with 50% of impervious cover served by LID. Based on impervious cover (1.15 ac), the peak allowable slow release flow was calculated (0.22 cfs/ac x 1.15 ac = 0.253 cfs). A constant flow of 0.300 cfs was introduced to the storage element. Once the storage element reached equilibrium under this condition, flow in the controlled release orifice was 0.253 cfs. Overflow reached a constant value of 0.047 cfs (0.300 cfs – 0.253 cfs) as expected.

Single-Subshed, Single-Event Comparison to Spreadsheet Solution

A hydrologic model and the same hydraulic model from the single-subshed, constant-inflow case was run with 25-yr, 24-hour NRCS Type III rainfall distribution. This distribution was chosen to test the model response to a variety of runoff intensities. At lower intensities, runoff intensity does not exceed slow release orifice capacity. When runoff intensity exceeds slow release capacity, storage begins to fill. When depth in the storage element exceeds the overflow elevation, flow occurs in the pipe representing an overflow weir.

The table below shows the SWMM RUNOFF water balance before and after application of stormwater BMPs serving all impervious cover in a subshed. As expected, infiltration increases and surface runoff decreases by approximately the same amount.

Table v4.3.2 RUNOFF Water Balance

	pre-LID		post-LID	
	cu.ft.	in	cu.ft.	in
Total Precipitation (Rain plus Snow)	117,990.00	6.501	117,990.00	6.501
Total Infiltration	40,035.60	2.206	50,269.60	2.770
Total Evaporation	357.05	0.020	388.67	0.021
Total Surface Runoff from Watersheds	77,622.50	4.277	67,347.50	3.711
Impervious Area Runoff from Watersheds......	58,654.30	6.463	0.00	0.000
Pervious Area Runoff from Watersheds........	18,968.00	2.090	18,968.00	1.941
Impervious to Pervious Area Runoff..........	0.00	0.000	54,077.40	2.979
Infiltration over the Pervious Area...	40,035.60	4.412	50,269.60	5.144

A time series of runoff was input to a spreadsheet model of a stormwater control structure that performs a mass balance of storage volume, controlled release and overflow on a one-minute time step. The algorithm followed for each time step was as follows:

1. Controlled runoff is taken from SWMM RUNOFF output.
2. Storage volume = storage volume (from previous time step) + runoff – slow release volume (from previous time step).
3. Overflow volume is the difference between storage volume and the volume of the storage element. If storage does not exceed volume of the storage element, overflow volume = 0.
4. Storage volume = storage volume (from step 2) – overflow volume.
5. Depth = storage volume (from step 4) divided by storage element cross-sectional area.
6. Slow release is calculated using the orifice diameter and submerged orifice equations discussed in the previous section.

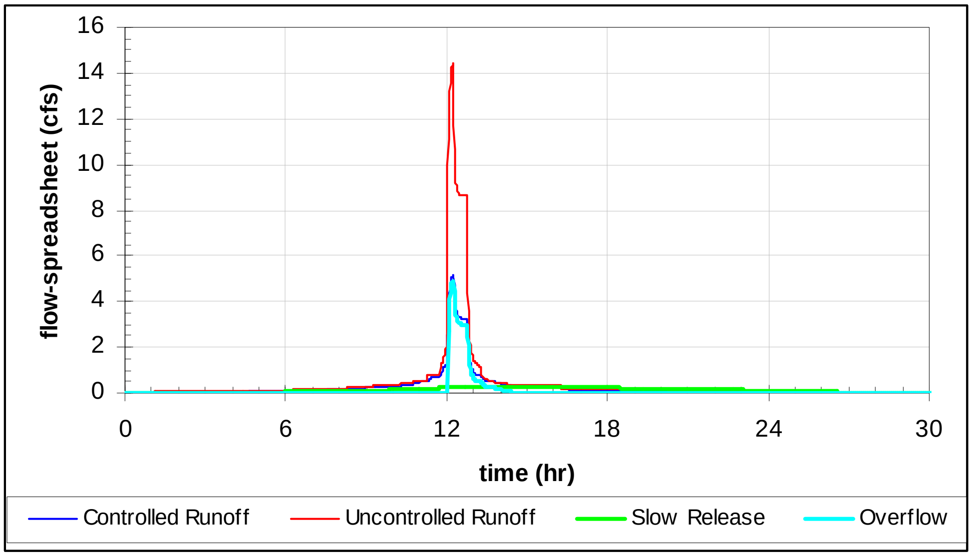

Figure v4.3.3 Spreadsheet Solution

An EXTRAN model was constructed with the same dimensions, same hydrologic input and same time step as the spreadsheet model. For the purpose of validating the SWMM model, the spreadsheet solution was assumed to be exact. In other words, the SWMM model is considered valid if it matches the spreadsheet model within a reasonable tolerance. The figure and table below compare results of the two models. Volumes and peak flows match within 1% or less, an acceptable margin of error for the application.

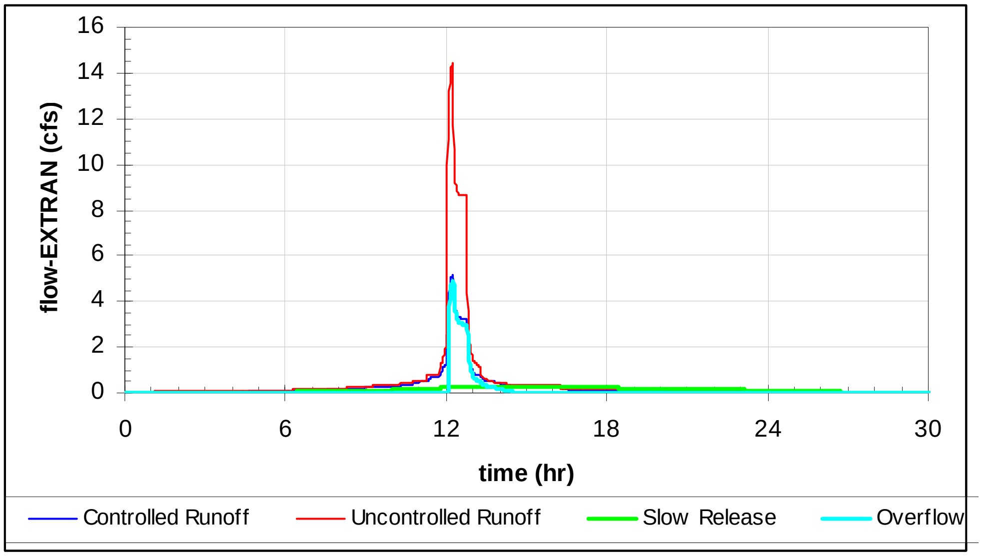

Figure v4.3.4 EXTRAN Solution

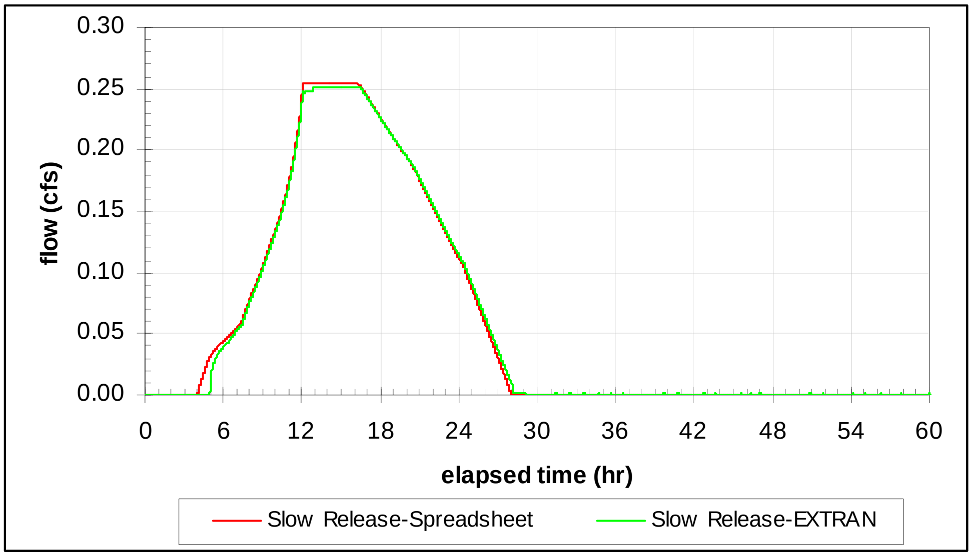

Figure v4.3.5 Comparison of Slow Release

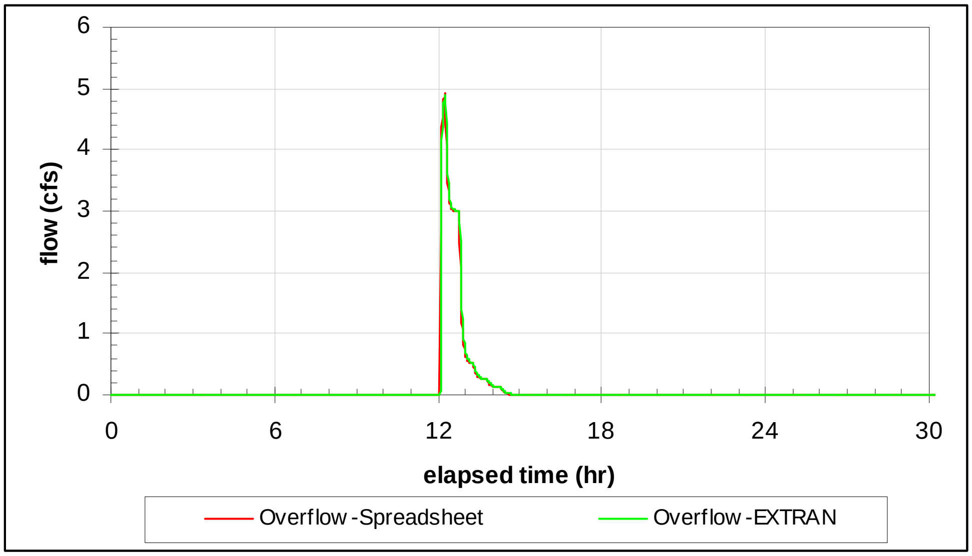

Figure v4.3.6 Comparison of Overflow

Table v4.3.3 Comparison of Volumes and Peak Flows

	spreadsheet	EXTRAN	Difference
Slow release volume (cu.ft.)	12,629	12,557	-0.57%
Overflow volume (cu.ft.)	11,565	11,587	0.19%
Peak slow release (cfs)	0.254	0.252	-0.80%
Peak slow release (cfs/ac)	0.203	0.201	-0.80%
Peak slow release (cfs/ac imperv.)	0.221	0.219	-0.80%
Peak overflow (cfs)	4.91	4.90	-0.32%
Peak overflow+slow release (cfs)	5.17	5.14	-0.44%

v4.3.5 LID Model Runs

Scenarios

- A: storage/infiltration/treatment = 1" over all impervious area not excluded
- B: storage/infiltration/treatment = 1" over all impervious area not excluded, plus 20% DCIA reduction for parcels over 1 ac and not classified as "direct drainage" as defined by stormwater program
- C: storage/infiltration/treatment = 1" over all impervious area not excluded, plus channel protection requirement for parcels over 1 ac and not classified as "direct drainage" as defined by stormwater program
- sensitivity runs
  - D: infiltrate 1" or maximum that can be infiltrated in 24 hours, whichever is less
  - E: store and slow release 1" everywhere, no infiltration
  - F: increase infiltration/water quality volume to 1.5"
  - H: partial failure – reduce infiltration rates by 50%, remove 50% of slow release orifices

Combinations

[(A, B, C = 3) x (# of runs needed to define a curve ~ 10)] + (D, E, F, H) ~ 34

Interpretation of Results

- Determine an area (or range) to be affected by the stormwater ordinance over the planning horizon.
- Adjust acreage affected by ordinance for practices that may provide a lower level of performance than the ordinance (green roofs and trees). (i.e., perform an analysis to estimate X ac served by bioretention provides the same function as Y ac covered by a green roof).
- Determine an area (or range) to be affected by incentives for private land not subject the ordinance.
- Determine an area (or range) of public land to be targeted for stormwater management.
- Evaluate results of sensitivity runs.
- Choose a single run (or set of runs) to represent source controls and produce a baseline model to be used for infrastructure evaluation projects.

v4.3.6 Deep Tunnels

For a tunnel storage alternative, CSO flows in excess of the interceptor capacity are diverted via a modified or new diversion structure to a series of secondary tunnel structures that convey flow into the storage tunnel. The approach to model the tunnels for all three districts was to simulate the tunnels as storage nodes. To model the tunnels as a storage node, the length of the tunnel to be modeled is obtained by doing a preliminary tunnel alignment. Once the length is determined models are set up for varying tunnel diameters. The tunnel is assumed to be circular.

The diameters range from 15 to 35 feet and are increased by an interval of 2.5 feet for each simulation. Using the tunnel length and the diameter a volume is calculated. Using eighty percent (80%) of the calculated volume, a storage node 20 feet deep with constant surface area is simulated.

The storage section representing the tunnel volume itself has a plan surface area that will satisfy the tunnel volume requirements. The maximum tunnel drain down rate was set so that the tunnel would drain down in 24 hours when the capacity of the WPCP is available. All the outfalls that will contribute to the tunnel are connected to the storage node. Figure v4.3.7 shows a visual representation of the tunnel in the models.

The following steps were followed to setup the models.

1. The tunnel model is built on top of the model that has all the alternatives in the LTCPU.
2. Any flow that goes over the dam in a regulator connected to the tunnel is assumed to go in the tunnel. The only exceptions are the regulators that have the computer controlled overflow gates; in these cases the flows that currently go to the receiving water are assumed to go to the tunnel.
3. All the overflows from the regulator are conveyed to the tunnel using additional conveyance conduits. The conveyance conduits were sized to not cause any backwater conditions at the regulators.
4. The bottom of the tunnel storage junction is a 10 feet high section with small plan surface area so that the tunnel volume can be drained with out causing long tails towards the end of the drain down.
5. The storage section representing the tunnel volume itself is 20 feet deep and has a plan surface area that will satisfy the tunnel volume requirements
6. There is an overflow pipe just above the storage section representing the tunnel volume (Figure v4.3.7).
7. The tunnel drain down pipe is rated to only allow a maximum flow. This maximum flow is set so that the tunnel can be drain down in 24 hours, at this rate.
8. The tunnel drain down pipe is connected to another downstream pipe that conveys the flow from the tunnel drain down and the interceptors that convey flow to the WPCP in the given drainage district. The pipe that combines both these flows is rated to deliver a maximum flow to which each of the WPCPs will be expended to. This final pipe is also setup in a way that the flow from the interceptors is given priority over the tunnel drain down.
9. The tunnel will only drain down when there is capacity left over at the WPCP after the flows from the existing interceptors are treated.

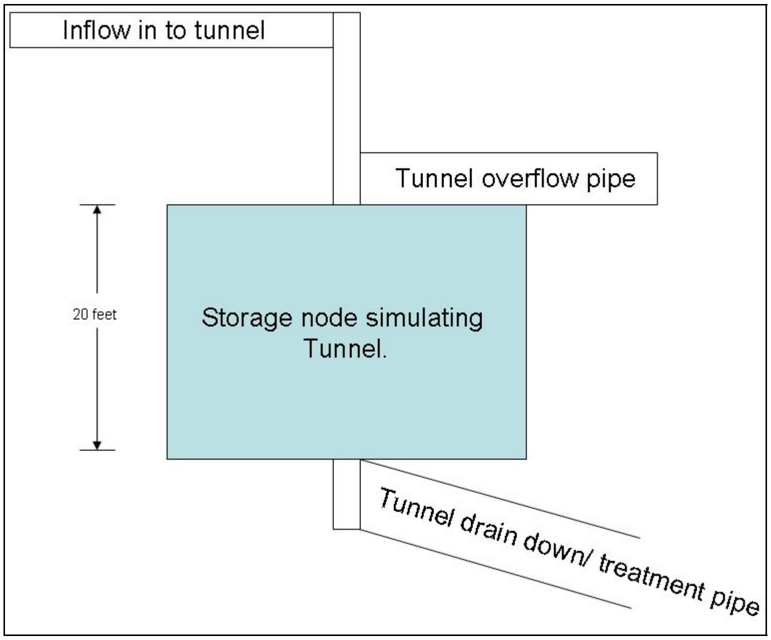

Figure v4.3.7 Storage depicting the tunnel

The volume captured by the tunnel over the course of a one-year simulation was calculated as the difference between the overflow produced from the simulated tunnel scenario and the corresponding baseline scenario. There are two baseline scenarios, each representing the upper and lower boundary of an uncertainty range for DCIA, baseflow and RDI/I watershed characteristics. Each baseline scenario has the interceptors draining to the plant with pumping boundary conditions limiting the high level interceptors' inflow into the WPCP. The baseline plant capacities for the SEDD, NEDD and SWDD are 280, 435 and 480 MGD, respectively.

SEDD Tunnel

The SEWPCP was assumed to be expanded to treat 330 MGD. The total length of the tunnel, excluding the drain down section, is 5.9 miles. The inflow into the tunnel model is the total flow produced from each regulator's outfall. Table 4.3.4 presents the tunnel length and corresponding volume of the storage node for the SEDD tunnel. The volumes shown in the first row represent the total tunnel volume and the second row shows the 80% tunnel volume that was used for the simulations.

Table v4.3.4 Length Volume and Drain down Data for the SEDD Tunnel Model

	Tunnel Diameter (ft)								
	15	17.5	20	22.5	25	27.5	30	32.5	35
	Tunnel volume (Million Gallons)								
Tunnel Volume	41.4	56.4	73.7	93.2	115.1	139.3	165.8	194.6	225.6
Volume used For simulation	33.2	45.1	58.9	74.6	92.1	111.4	132.6	155.6	180.5
Peak Tunnel Drain Down rate (MGD)	33.2	45.1	58.9	74.6	92.1	111.4	132.6	155.6	180.5

NEDD tunnel

It was assumed the NEWPCP will be expanded to treat 650 MGD. The total NEDD tunnel length is estimated to be 10 miles. The tunnel length along the Delaware was estimated as 5.3 miles and along Tacony as 4.7 miles. The tunnel for the NEDD was simulated as one storage node as it is also assumed that the tunnel along the Tacony and Delaware in the NEDD are interconnected. Table v4.3.5 presents the tunnel length and corresponding volume of the storage node. The volumes shown in the first row are the total volumes of the tunnel and the 80% volume used for simulations is presented in the second row.

Table v4.3.5 Length Volume and Drain down Data for the NEDD Tunnel Model.

	Tunnel Diameter (ft)								
	15	17.5	20	22.5	25	27.5	30	32.5	35
	Tunnel volume (Million Gallons)								
Tunnel Volume	70.1	95.4	124.6	157.7	194.7	235.6	280.3	329	381.6
Volume used For simulation	56.1	76.3	99.7	126.2	155.7	188.5	224.3	263.2	305.3
Peak Tunnel Drain Down rate (MGD)	56.1	76.3	99.7	126.2	155.7	188.5	224.3	263.2	305.3

The NEDD also includes all regulators draining to the Upper Frankford Low Level (UFLL), Lower Frankford Low Level (LFLL) and the Pennypack (PP) interceptor systems in addition to the regulators draining to the UDLL, SOM and TAC interceptor systems. The overflow from the regulators along these interceptor systems were conveyed to the tunnel.

SWDD tunnel

It is assumed the SWWPCP will be expanded to treat 540 MGD. The total SWDD tunnel length is estimated to be 13.7 miles. The tunnel length along the Schuylkill was estimated as 6.4 miles and along Cobbs Creek as 7.3 miles. The tunnel for the SWDD was simulated as one storage node; it is also assumed that the tunnel along the Cobbs Creek and Schuylkill River in the SWDD are interconnected. Table v4.3.6 presents the tunnel length and corresponding volume of the storage node. The volumes shown in the first row are the total volumes of the tunnel and the 80% volume used for simulations is presented in the second row.

Table v4.3.6 Length Volume and Drain down data for SWDD Tunnel.

	Tunnel Diameter (ft)								
	15	17.5	20	22.5	25	27.5	30	32.5	35
	Tunnel volume (Million Gallons)								
Tunnel Volume	95.9	130.5	170.4	215.7	266.3	322.2	383.4	450	521.9
Volume used For simulation	76.7	104.4	136.3	172.5	213	257.8	306.7	360	417.5
Peak Tunnel Drain Down rate (MGD)	76.7	104.4	136.3	172.5	213	257.8	306.7	360	417.5

The SWDD includes all regulators draining to the Central Schuylkill East Side (CSES), Central Schuylkill West Side (CSWS), Lower Schuylkill West Side (LSWS), Southwest Main Gravity (SWMG), Cobbs Creek High Level (CCHL) and the Cobbs Creek Low Level (CCLL). The overflow from the regulators along these interceptor systems were conveyed to the tunnel.

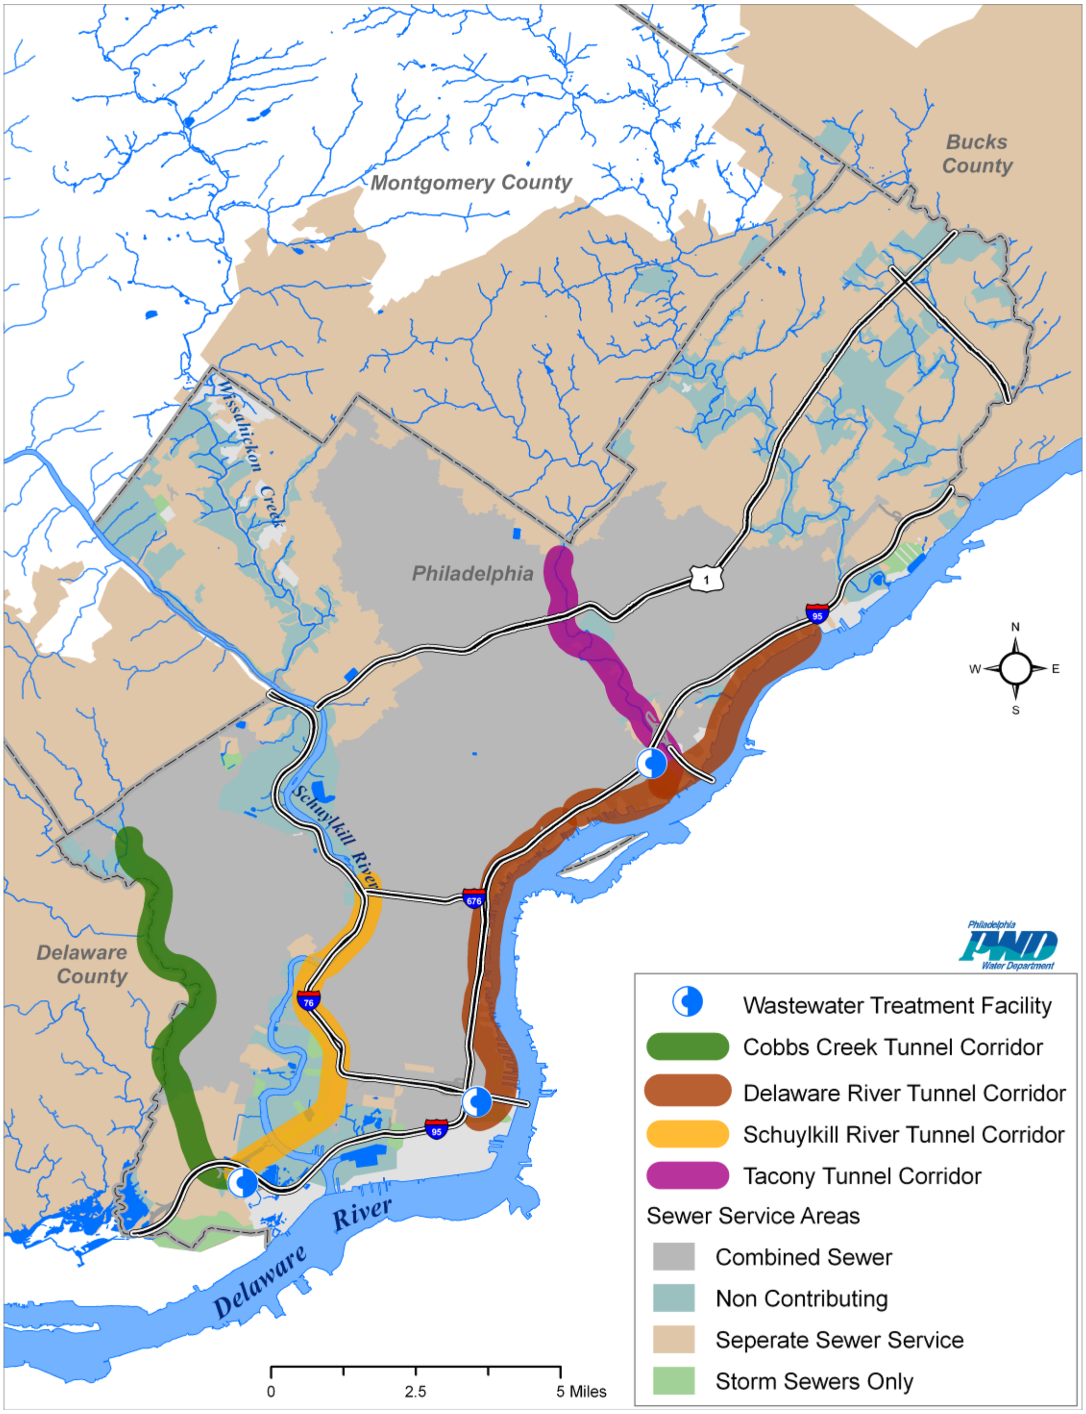

Figure v4.3.8 Potential Tunnel Alignment.

v4.3.7 Spreadsheet Analysis Procedure for the "All Transmission" and Satellite Treatment Unit Alternatives

Prior to building a model representing parallel interceptor systems and satellite treatment facilities, spreadsheet tools were created to align a parallel conveyance system to capture and convey flow to the respective WPCP of the existing interceptor system being paralleled. In this section, parallel transmission and treatment alternatives are referred to as "all transmission". Output from a SAS processing tool served as input to the spreadsheets. The SAS tool identifies a peak flow value and overflow volume for each overflow goal at every regulator in the system having an outfall. The spreadsheet analyzes each regulator producing an overflow for each green stormwater infrastructure implementation scenario for all overflow goals 1 through 25 events per year.

All Transmission Alternative and Satellite Treatment Alternative Descriptions

Building a conveyance sewer to capture and deliver overflow from the regulators in the existing interceptor system is the foundation from which these alternatives have been created. Using the estimated peak overflow numbers produced from the SAS program – discussed in further detail below – as input to the preliminary spreadsheets provides a preview into the effectiveness of building a parallel interceptor system. The spreadsheets are designed to size parallel interceptors using a targeted overflow frequency and corresponding overflow rate with the sizing limited to an assumed constructability limit (12 ft x 12 ft box sewer). Once the constructability limit has been reached or exceeded, either another parallel system is required to continue conveying flow to the WPCP or a satellite treatment unit must be built.

In the case of building a satellite treatment unit, another spreadsheet tool was developed to appropriately size and place the unit. The input to this particular spreadsheet is the same as the all transmission spreadsheet. The satellite treatment spreadsheet is automated to place units at regulators where half the total interceptor system overflow rate to convey to the WPCP or the constructability limit has been reached or exceeded. For some watersheds and interceptor systems, the location of a satellite treatment unit has been predetermined based on availability of land. In these situations, the automated process is manually overridden and pipe dimensions are calculated based on the predetermined location.

The processes and details of each spreadsheet and an overview of the SAS program algorithm used to generate the overflow numbers used as input to the spreadsheets are presented below.

Conveyance Logistics

The loading priority within both spreadsheets for parallel interceptor conveyance to the plant is based on spatial logistics. The assumption was made that the amount of flow delivered by the existing interceptor systems modeled under free outfall (no restrictions at the plant) conditions is the maximum flow that can be treated at the plant. For the Northeast drainage district the plant capacity is 650 MGD, for the Southeast drainage district the plant capacity is 330 MGD and the Southwest drainage district is 540 MGD. Any flow delivered by the parallel interceptor conveyance pipes to the WPCP that exceeds the capacities above would have to be treated using high-rate treatment trains, which would be located at the WPCP.

It is important to understand that each parallel interceptor system is analyzed independently of the others within the same watershed. For instance, the Schuylkill watershed contains regulators along five (5) interceptor systems and regulators in each interceptor system was sized and underwent satellite treatment unit analysis without being affected by analyses done on the regulators in the other interceptor systems. This is mainly due to the possibility that building the parallel interceptor and/or satellite treatment placement alternatives may not be feasible for all – or any – of the interceptor systems within a watershed and therefore, these systems should be analyzed as independent operations to determine which interceptor systems show the most benefit from the parallel system. This also allows for flexibility in choosing the best "package" of options to create the most appropriate alternative to mitigate the overflows in any particular watershed. This analysis process is applied to all systems throughout the city until the overflow target has been met and delivered to the plant or the constructability limit for a single open cut conveyance sewer has been reached in order to determine which interceptor systems are best suited for the all transmission and/or satellite treatment unit alternative.

SAS Tool Description

The inputs to the SAS program are the capture dataset for each regulator (described in section v4.3.12), land-based control model simulation output and an outfall list. The program uses these three inputs to determine the corresponding peak event overflow treatment rate required to satisfy targeted overflow frequencies between 1 and 25 overflows per year.

The SAS program analyzes the treatment rates required at each of the outfalls in the Combined Sewer System (CSS) so that a targeted overflow frequency is achieved. For instance, if an outfall overflows fifty (50) times a year and the treatment capacity exists to treat the third largest overflow among the fifty (50), then there will be only two (2) storm events that will cause an overflow. The rest of the 48 events can be treated. This is the premise under which the program was written. The steps outlined below were followed in order to calculate targeted overflow numbers for each regulator:

1. The overflow data from the EXTRAN model for each regulator having an outfall is loaded into the SAS program. The input data is in 15-minute average wet weather flow data.
2. One of the options in the program is averaging of the 15-minute input flow data to 30 minutes or 1 hour flow.
    a. For the purposes of the all transmission and satellite treatment spreadsheet analyses the 15-minute flow data was averaged over the hour.
3. SAS uses the regulators' generated event lists contained in the capture input data file to retain only events that produced overflows.
4. The type of processed flow data – raw 15 minute or averaged 30 minute or 1 hour flow data – is selected and merged with the overflow event list from step 3. For each regulator, the peak overflow rate for each of the events is extracted and then ranked in descending order.
5. The program steps through each ranked regulator dataset and determines the number of events overflowing, the respective total overflow rate, untreated volumes and treated volumes.
    a. For example, for a given regulator, the second peak overflow treatment rate produced from a given event in the sorted list from step 4 is set equal to the available treatment capacity. Referring to Table v4.3.7 below, this value equals 14 cfs.

b. All overflow events that have peak overflows equal to or less than this value are considered treated – or captured as labeled in Table v4.3.7.
c. The number of events with peak overflow values greater than the available treatment capacity value is determined, which for this example is equal to 1 as there is only one event that is ranked as having a greater peak overflow rate. This overflow frequency number represents one of the targeted overflow goals that will be analyzed within the all transmission and satellite treatment analysis spreadsheets.
d. The regulator's untreated volume for the respective overflow frequency is calculated by summing the residual overflow rate and converting it to a volume.
e. The treated volume – or captured volume – is the difference between the total ranked overflow volume for all events and the untreated volume as calculated in the previous step.
f. The SAS program steps through each ranked event comparing and calculating the overflow numbers as described above for target overflow frequencies 1 through 25.

All Transmission and Satellite Treatment Spreadsheet Descriptions

Of the two spreadsheets, the all transmission spreadsheet is the more straightforward and least complex as it essentially follows the alignment and slopes of the existing interceptor without exception. Implementing the algorithm to place the satellite treatment units made the second spreadsheet inherently more difficult to build and maintain. Additional factors that came into consideration as the satellite treatment spreadsheet was being built included the calculation of reverse grade interceptor conveyance pipes to deliver flow upstream to the satellite treatment units and manual overrides to the automated selection of satellite treatment unit locations because of predetermined land availability. As a result, the satellite treatment unit spreadsheet was built to only analyze 1, 4, 10 and 25 overflows per year for each green stormwater infrastructure implementation level, as opposed to the all transmission spreadsheet which calculates pipe dimensions for all targeted overflows from 1 through 25 for each green stormwater infrastructure implementation level.

All Transmission Analysis Methodology

The spreadsheet analysis for the all transmission alternative is developed to exactly mimic the existing parallel systems. The slope and segment length is taken to be that of the existing interceptor segment it is paralleling. The spreadsheet also provides the depth of cover in order to estimate the amount of excavation necessary for each pipe segment.

The dimensions of the conveyance pipes are estimated using the existing interceptor pipe segment slope and the cumulative overflow rate captured at the nearest upstream regulator outfall, prior to any loading from the nearest contributing downstream regulator's outfall. These numbers are used within the Manning equation – representing full flow conditions – to determine the box sewer dimensions.

The parallel interceptor collects and conveys overflow by moving upstream from the plant through interceptor systems until the sum of target peak overflow rates exceed the assumed constructability limit for open cut conveyance sewers – set to be a 12 ft x 12 ft box sewer. The spreadsheet also summarizes the total system wide untreated overflow volume and total peak overflow rates for each scenario.

Satellite Treatment Location Analysis Methodology

Generally, the satellite treatment location spreadsheet is setup to calculate the total overflow rate for all regulator outfalls contributing overflows to the system and at the regulator where half of that flow is reached or exceeded, the spreadsheet places a satellite treatment unit. Manual overrides were necessary for some interceptor systems where locations were known to have sufficient land available to build a treatment unit.

Because the algorithm places the satellite treatment unit at the regulator where half the total overflow of the interceptor system is reached or exceeded, at least part of the parallel system will have to be built at reverse grade as compared to the corresponding existing interceptor system segments. Due to the potentially high variability of satellite treatment locations for interceptor systems where predetermined locations do not exist – e.g. the interceptor systems within the Schuylkill watershed – the reverse grade pipe segment dimensions, slopes and depth to cover calculations were extensive and had to be done for each scenario and each interceptor system independently. Also, depending on the target overflow rate, the size of the satellite treatment units varied. All these numbers are summarized within the satellite treatment analysis spreadsheets.

Table v4.3.7 The example below assumes the second event's peak treatment rate – 14 cfs – set as the available treatment capacity. The residual overflow rates, used to calculate the overflow untreated and treated volumes are included and the resulting overflow event number.

Time	Event Overflow Rate (cfs)	Total Event Overflow Volume (cu.ft)	Ranked Overflow Event Number	Event Peak Overflow (cfs)	Total Overflow Volume for All Ranked Events (cu.ft)	Total Available Treatment Rate (cfs)	Event Residual Overflow (cfs)	New Overflow Event Number	Overflow Volume After Treatment (cu.ft)	Treated Volume (cu.ft)

v4.3.8 Street Trees

Concepts

Street trees are desirable, but by themselves provide a level of control lower than the level defined by Philadelphia's stormwater regulations. Therefore, an "equivalency ratio" was determined defining the relative benefits of these measures and other stormwater management measures. For example, "1.0 ac of impervious surface covered by tree canopy results in the same runoff volume reduction as 0.X ac of impervious surface draining to an infiltration bed meeting the level of performance defined by PWD's stormwater regulations."

Under PWD's regulations and demonstration programs, trees are often used in combination with other practices such as bioretention and tree trenches under sidewalks. We can assume the level of performance for these facilities will meet the regulations. This section is only applicable to trees functioning as a green stormwater interception mechanism independently.

For the purposes of this study, it was assumed that pervious surfaces do not need to be managed. This approach applies only to street trees over impervious surfaces, typically street trees. As the city becomes greener in the future, street trees by themselves could be viewed as a temporary solution that can be implemented relatively quickly on a large scale, while more comprehensive street greening solutions such as tree trenches and infiltration inlets will take longer to implement. If a more pessimistic (but still green) view is taken, it can still be thought that in some areas, street trees can be seen as being the only desirable controls.

Ideal Model

In forestry research, trees and soils are being modeled as the complex three-dimensional systems they are. This is beyond the scope and appropriate level of detail for the LTCPU, but it is worth examining the processes to determine which can be simplified.

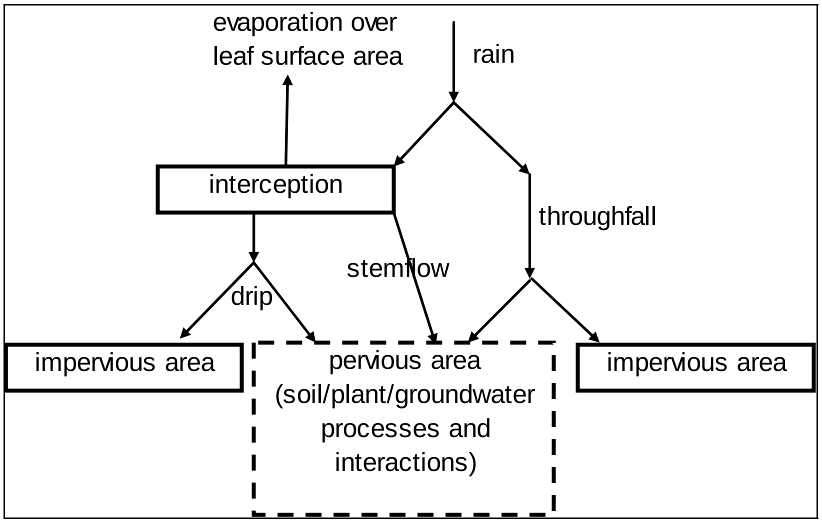

Figure v4.3.9 Conceptual model of tree canopy interception, storage and stemflow.

- Throughfall: Rain falls directly through the tree either because there is no leaf in its path or because it strikes hard enough to move the leaves out of its way. Throughfall may fall on a pervious surface (tree well) or impervious surface (pavement). This can happen at any time during the storm.
- Interception: Rain either ponds on curved leaf surfaces, or "sticks" to leaves through surface tension. Together, these two phenomena comprise canopy storage. When canopy storage is exceeded, water either drips off the tree or flows down the stem.
- Stemflow: For a street tree or other tree planted in impervious cover, all stemflow flows to the pervious area or tree well. A portion of drip falls on pervious cover and a portion on impervious cover, since part of the tree canopy covers both types of surfaces.
- Canopy evaporation: Water stored in the canopy is exposed to the air over the entire leaf surface, not just over the ground projection ("footprint") of the tree.
- Infiltration/Evaporation/Transpiration from soil: Once water reaches the soil, it can continue downward by gravity to recharge groundwater, evaporate through contact with air in soil pores, or be taken up by tree roots and transpired into the atmosphere.

Typical Model

Many modeling studies model trees simply as a storage value, or "initial abstraction". Once this storage is exceeded, any excess stormwater flows immediately to a sewer inlet or receiving water.

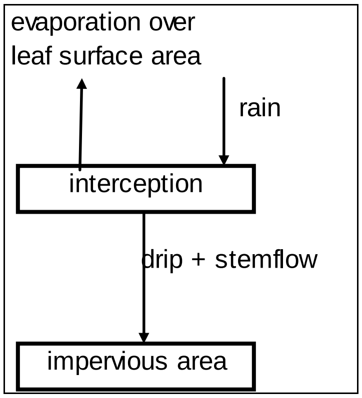

Figure v4.3.10 Typical simplistic model setup to represent tree canopy interception

Compromise Model

The model developed for this study is a good compromise between the ideal and typical models and can be implemented in SWMM. A strong basis for distinguishing between throughfall, drip and stemflow cannot be built without a lot more research. Therefore, a simplifying assumption was made that when canopy storage over pervious cover is exceeded, the excess will drip to pervious cover and vice versa. The dynamics of the unsaturated soil zone are not simulated for the LTCPU.

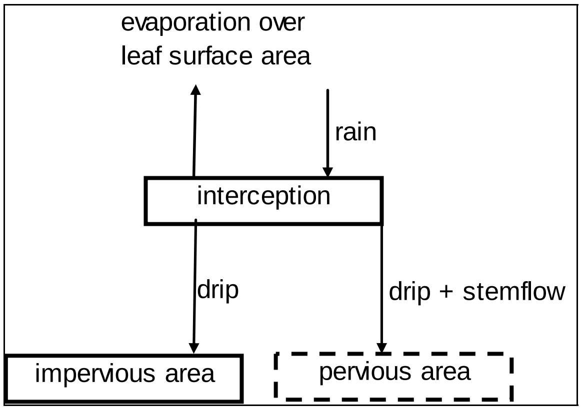

Figure v4.3.11 Visualization of the model setup for the LTCPU to represent tree canopy dynamics.

Model Assumptions and Setup

- Model a hypothetical acre of impervious cover equal to the leaf area.
- Canopy storage = 0.10 inches. This value is conservative compared to the Vanaskie and Xiao (2002) studies and roughly equivalent to the Xiao (2000) study. The CaseyTrees/Limno-Tech value of 0.032 inches seems overly conservative (see additional discussion below).
- Divide into 5 subsheds. Use SWMM 4 subshed routing options to route flows as shown in the diagram.
  - Two impervious sheds representing the leaf area and canopy storage (change SWMM default of 25% area with no depression storage); shed area = leaf area (tree canopy area times mean leaf area index (LAI) from Vanaskie study); divide rainfall and canopy storage (0.10 inches) by LAI; one drains to the impervious shed and one drains to the pervious shed
  - one shed representing pervious area under trees; no rainfall
  - one shed representing impervious area under trees; no rainfall
- Calculate and use the median and mode of the soil properties over the entire CSO area for the pervious area soil shed properties.
- Assuming mean crown diameter from the Vanaskie study, determine how many trees can be planted on the hypothetical acre if all canopies are touching.
- Assume each tree has a 16 sq.ft. (4 ft x 4 ft) tree well.
- A leaf on period of April 1 to October 31 is proposed. During the leaf off period, no canopy storage will be simulated.

Interpreting model results:

- Determine an equivalent acreage of green stormwater infrastructure that will result in the same reduction of uncontrolled runoff volume as the acre of trees. For example, "1.0 ac of impervious cover covered by street trees results in the same runoff volume reduction as 0.X ac draining to an infiltration bed meeting the level of performance defined by PWD's stormwater regulations."
- This approach assumes tree canopy covers all impervious cover on the site.

- With street trees, an added complication is that a fair level of implementation already exists; The resulting ratio will be adjusted based on an estimate of existing tree canopy and available area to implement new tree canopy.

Research/Previous Studies of Leaf Area and Canopy Storage

The CaseyTrees/LimnoTech Green Buildout study assumed a canopy storage volume of 0.032 inches over the ground projection. They conducted a literature review of twelve sources. CDM reviewed some of these sources and the results of an unpublished internal study by Matt Vanaskie. All storage depths are expressed over the tree's ground projection ("crown projection", "footprint"), not over the leaf area. Key results are summarized below:

Table v4.3.8 Literature review summary table for urban tree canopy research

Source	Study	Storage Min (in)	Storage Max (in)	Reviewed?	Urban/Open Grown	Deciduous	Species in Philadelphia "Top 30"?
Agricultural Runoff Manual, 1978	Casey Trees	0.138	0.197	No	No	?	?
Aston, 1979	Casey Trees	0.008	0.031	Yes	No	No	No
Blyth, 2002	Casey Trees	0.027	0.027	No	?	?	?
Crockford and Richardson, 1990	Casey Trees	0.067	0.079	No	?	No	No
Keim, 2006	Casey Trees	0.038	0.038	No	No	No	No
Link et al., 2004	Casey Trees	0.140	0.140	No	?	?	?
Pypker, 2005	Casey Trees	0.055	0.131	No	No	No	No
Schellekens, 1999	Casey Trees	0.045	0.045	No	?	?	?
Liu, 1998	Casey Trees	0.017	0.037	No	No	No	No
Wang, 2006	Casey Trees	0.027	0.027	No	?	?	?
Xiao, 2002	Casey Trees	0.340	0.563	Yes	Yes	Yes	Yes
Xiao, 2000	Casey Trees	0.106	0.106	Yes	Yes	Yes	Yes (similar)
Nowak/Von Hoyningen-Huene/USDA	Vanaskie	0.070	0.348	Yes	Yes	Yes	Yes

Green – results should apply to Philadelphia street trees
Yellow – unknown/not reviewed by CDM
Red – results do not apply to Philadelphia street trees

- Summary statistics on range of canopy storage in CaseyTrees literature review:
    - range: 0.008-0.563 in
    - median: 0.042 in
    - mean: 0.089 in
    - 95% confidence interval: (0.035, 0.143)

- CaseyTrees chose to simulate canopy storage at 0.032 inches. They arrived at this value based on assumptions in USDA's UFORE model, referenced in Wang 2006 above. According to CaseyTrees, UFORE assumes a value of 0.2 mm (0.0079 inches) over the leaf area. Using a leaf area index of 4.10 for District of Columbia street trees, this value works out to 0.032 inches over the ground projection.
- Many of CaseyTrees' sources are based on evergreen species, which are not commonly used as street trees on the east coast.
- Studies of interception in forest canopy may be useful, but the two recent studies by Xiao specifically consider urban, open grown, deciduous trees. These studies also report some of the highest values in the literature review.
- The unpublished Vanaskie study uses data from USDA specifically on trees in Philadelphia. It estimates leaf area and storage depths using regression approaches in the literature.
  - The USDA Forest Service provides data on species, sizes, condition and age of trees in Philadelphia (some documentation on data set in USDA Forest Service, 2007). Of the 31 most common types of trees, Matt found sufficient information to estimate storage for 14 of them.
  - Matt applied a regression approach reported by Nowak (1996) to estimate leaf area for species specific to Philadelphia. Leaf area is related to diameter at breast height and to shading factor. Nowak's study was specifically for urban, open grown, deciduous trees with species and sizes similar to Philadelphia street trees.
  - Matt applied a regression approach reported by Von Hoyningen-Huene (1981, reported in Schulze and George 1987, original reference available only in German). Storage is related to leaf area index. This equation is also applied by USDA's UFORE model and was used by Casey Trees.
  - After applying this regression approach to species and size data specific to Philadelphia, trees in the Vanaskie study had a mean LAI of 11.29 and a storage volume of 0.23 inches. Mean crown diameter was 24.5 ft.
  - Estimated LAIs were higher in the Vanaskie study than the mean found by Casey Trees of 4.10. Applying the Von Hoyningen-Huene regression with an LAI of 4.10 yields canopy storage of 0.113 inches.

Table v4.3.9 Summary of Unpublished Vanaskie Study Results

Common name	Genus	Species	% Population (% of trees)	Height (ft)	Crown Diameter (ft)	Shading factor	Ground Projection (ft^2)	Leaf Area (ft^2)	Leaf Area Index	Canopy Storage (in)

v4.3.9 Tree Canopy Coverage Adjustment Methodology

Street Tree Planting Research

A short literature review of Philadelphia and other cities' documents addressing street tree planting provided an outline of important restrictions for tree placement. A summarized outline of these documents is included in this memorandum following the results section. A list of specific considerations produced from this literature review affecting the city-wide tree canopy analysis is below.

- Distance from intersection to tree centerlines
- Distance between tree centerlines
- Distance from street lighting
- Distance from curb edge
- Distance from buildings

Other factors listed in the attachment were assumed to have minimal if any significance on calculating the amount of possible tree canopy coverage. For example, distances from parking meters or fire hydrants were assumed to have no affect on tree canopy coverage because 1) the objects do not impair tree canopy size and 2) the required distance from the tree is less than the mean tree canopy radius and does not limit the available area.

Distances from intersections, however, do limit available tree canopy area because the required distance may be greater than the mean tree canopy radius. The distance in this particular situation is the limiting factor, not the tree canopy (as in the parking meter and hydrant scenario). Figures v4.3.12 and v4.3.13 below are visual representations of these concepts. These figures also show a comparison of tree centerlines and the edge of tree canopy, which is a significant point for calculations that follow. Distance requirements (Table v4.3.10) are measured from the tree centerline and not the edge of tree canopy. When distance calculations are being performed, however, the edge of tree canopy is taken into account and therefore having an understanding of the distinction between the two is necessary.

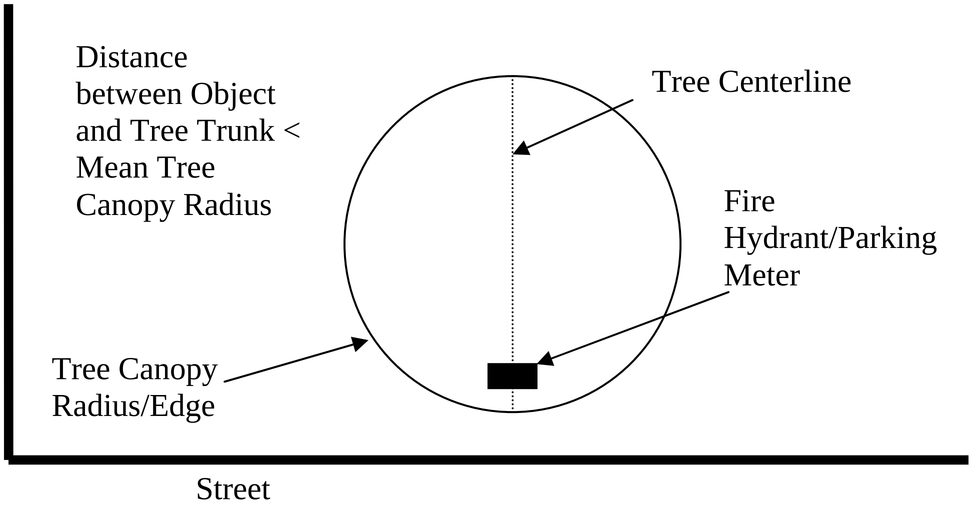

Figure v4.3.12 Visualization of the physical placement of an object with a required distance less than the mean tree canopy radius that does not obstruct the tree canopy area coverage.

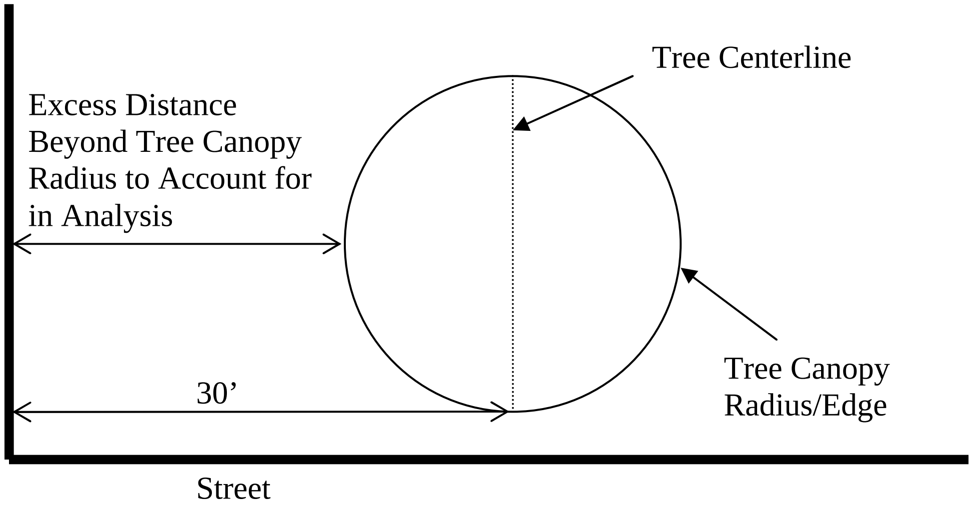

Figure v4.3.13 Excess distance to subtract from available tree canopy coverage area to fulfill distance requirements for tree center to the intersection.

In Figure v4.3.13, the area beyond the mean tree canopy perimeter needs to be subtracted from the available area for street tree canopy coverage. Based on the required distance from the tree center and height of the object, any distance less than the mean tree canopy radius will not affect the coverage of the tree canopy. Table v4.3.10 summarizes the final distance ranges found during the literature review used to calculate an adjusted equivalency ratio for the Philadelphia LTCPU.

Table v4.3.10 Distance Ranges for Specific Urban Elements Measured from Tree Center Line Based on Literature Review.

Distance from Intersection to Tree Center (ft)	30
Distance from Street Lighting (ft)	25
Distance between Tree Centerlines (ft)	30
Distance from Building Face to Edge of Canopy (ft)	5
Distance from Curb Face to Tree Center (ft)	1
Distance between Street Lights (ft)	150

Derivation of Available Coverage Area

It is inappropriate to extrapolate the unadjusted runoff reduction equivalency ratio to the entire city because it assumes an unrestricted availability of area for tree canopy coverage. Street tree canopy is limited by distance requirements due to such things as street lighting, buildings and intersections, as described previously. An adjustment based on these limitations is necessary. A ratio of the allowable area of tree canopy within the city versus the total city-wide sidewalk and street area is calculated and then adjusted to account for the limitations listed above. This value is multiplied with the preliminary equivalency ratio to determine the relative city-wide runoff benefit of street trees as compared to the runoff reduction from the model representing the city meeting the stormwater regulations.

Assumptions and Input Data

Assumptions were required in order to calculate an estimate of available urban area for tree canopy coverage. The main assumptions are as follows:

- Mean Tree Canopy Area = 527 square feet
- Total City-Wide Sidewalk and Street Area = 10,774.34 acres
- Required Distances affecting Available Area (found in Table v4.3.10)

These and other input data were produced from the literature review discussed in the previous section, the impervious cover master table spreadsheet (ImperviousAnalysis_071107_SKR.xls) and the tree canopy simulation results table and database (Parameter_adjmts_071102_SKR.xls, TREE_CANOPY_DATA_071119_932.mdb).

GIS sidewalk data provided by the Impervious_Surfaces_PHILA_2004 shapefile was used to estimate the total sidewalk area for the city. This data contained the area and perimeter length of sidewalk per square block and was the foundation from which all subsequent calculations were created. For the purposes of this analysis and the duration of this memo, the definition of a square block encompasses the length of sidewalk existing on all four sides of a block and does not include street length or width.

Calculations

The data from the Impervious_Surfaces_PHILA_2004 shapefile was imported into a database where all length, width and area calculations were performed. Within the database, each record represents a square block. The perimeter length of each square block was reduced by half to estimate the total sidewalk length. The given sidewalk area for each square block was divided by its respective calculated total sidewalk length to determine a width. The data was filtered to include only sidewalk widths greater than or equal to 6 feet (d_{smin}). Sidewalk widths less than 6 feet do not offer enough space to fulfill the building and curb edge distance requirements (required distances are listed in Table v4.3.10).

For the remaining data records, the distance between street lights was divided into the total square block length to determine the number of street lights per square block. Because the intersection distance requirement will compensate for street lighting at the corners of each square block, the total number of street lights per square block (n_{SL}) was reduced by 4. The length to remove to account for street lighting (L_{SL}) was determined using the equation below with the calculated number of lights per square block ($n_{SL} - 4$). Basically, the length to subtract for street lighting consists of the excess sidewalk area existing between the street light and the mean tree canopy perimeter. Each light will have two occurrences of this situation, assuming a tree exists on either side of the light and then it must be multiplied by the calculated number of street lights minus the occurrences on the corners ($n_{SL} - 4$).

$$L_{SL} = 2(d_{SL} - r)(n_{SL} - 4)$$

The sidewalk length to remove to fulfill the distance from an intersection requirement (d_I) was calculated as 240 feet. This was based on the required distance from an intersection (30 feet) and the number of instances (2 lengths per corner) of subtraction for a square block.

If the total calculated sidewalk length for a square block was less than the total length to subtract calculated from summing the excess street light (L_{SL}) and intersection (d_I) distance, the total distance to remove was set equal to the total sidewalk length for that square block. In these situations, the square block does not have enough space to allow for street tree coverage. Otherwise, the total distance to subtract was equal to the sum of the two calculated lengths (L_{SL} and d_I). The preliminary available length of sidewalk ($L_{Available}$) for tree canopy coverage was calculated by subtracting the summed distance requirement lengths (L_{SL} and d_I) from the total calculatedsidewalk length per square block.

Oftentimes, the tree canopy is obstructed by building interfaces. Therefore, only a portion of the tree canopy is active in intercepting rainfall. For each square block, the amount of tree canopy affected by the building interface was calculated using the equations that follow. The equations were taken from the Equv-pipes-RR-GM (version 3c) spreadsheet.

$$d_s = (Width + r) - d_{curb}$$

$$Width\ of\ Active\ Tree\ Canopy\ (W_{ATC}) = diameter - d_s$$

$$Angle\ Subtended = 2(Acos(r-W_{ATC}))\ /\ r$$

$$Active\ Tree\ canopy\ Area\ per\ Tree = (1/8(Angle\ Subtended - Sin(Angle\ Subtended)))*\ diameter^2$$

Where *diameter* = The Diameter of the Tree Canopy (feet)
r = The Radius of the Tree Canopy (feet)
d_s = The Length of Tree Canopy Unobstructed by Objects (feet)
d_{curb} = The Distance Required to the Curb Edge Measured from Tree Center Point (feet)

For larger sidewalk widths that do not impede the tree canopy the average tree canopy area of 527 square feet was applied.

The number of trees feasible per square block (n_B) was calculated by dividing the eligible length of sidewalk ($L_{Available}$) by the distance between tree center points requirement. For each square block the number of trees was multiplied by the active tree canopy area per tree to determine the estimated total tree canopy area available for each square block. The values for each square block were summed to determine the eligible city-wide tree canopy area. The ratio of calculated tree canopy area to total city-wide street and sidewalk area was calculated and then applied to the preliminary tree canopy total runoff reduction equivalency ratio of 0.875.

Results

A final runoff reduction equivalency ratio was developed based on required distances found in Table v4.3.10. Tables v4.3.11 and v4.3.12 contain all input parameters, assumptions and calculated values. The final ratio may be found in Table 3 and represents the percent city-wide tree canopy total runoff reduction as compared to the total runoff reduction produced from the model meeting the required stormwater regulations requirements. Ultimately, the ratio states that 1 acre of impervious surface covered by tree canopy results in the same total runoff volume reduction as approximately 0.287 acres of impervious surface draining to an infiltration bed meeting the stormwater regulations requirements.

Table v4.3.11 Static Input Variables used in Calculating Adjusted Tree Canopy Equivalency Ratios.

Variable Description	Values	Units
Total Combined Shed Area	43414.05	acres
Mean Tree Canopy Ground Projection Area	527	sq.ft
Percent of Combined Area without Trees	85%	
Runoff Reduction Equivalency Ratio	87.5%	
Diameter of Mean Tree Canopy Ground Projection Area	25.90	ft
Radius of Mean Tree Canopy Ground Projection Area	12.95	ft

Table v4.3.12 Varying Calculated Inputs and Outputs Used to Determine the Adjusted Equivalency Ratio.

Variable Description	Values	Units
Required Distance from Tree Center point to Building Face	5	ft
Required Distance from Tree Center point to Curb Edge	1	ft
Distance from Intersection to Tree Center (from curb to tree center)	30	ft
Distance Between Tree Centerlines	30	ft
Distance from Street Lighting	150	ft
Minimum Sidewalk Width where Tree Canopy is not Affected by Building Face	13.95	ft
Total Street/Sidewalk Area	4.69E+08	sq.ft
Total Area of Available Tree Canopy Coverage	1.54E+08	sq.ft
Adjusted Total Area of Available Tree Canopy Coverage	1.31E+08	sq.ft
Percent of City Area Available for Tree Canopy	32.78%	
New Tree Canopy Equivalency Ratio	**28.68%**	

v4.3.10 Outlying Community Flow Timeseries Analysis

Background

The procedures described herein were used to create SWMM4 EXTRAN K3-line timeseries input data for selected outlying community sanitary sewer connections to the Philadelphia combined sewer system (CSS). The timeseries data are used to define wet weather flow response from these areas in continuous simulations performed for the 2005 representative year selected for LTCP project evaluations. Filling missing or errant data is required in order to generate continuous timeseries over the one-year simulation period. The outlying community areas chosen for direct timeseries input are DELCORA, Bucks County (MB-1) and Lower Southampton Township (MSH-1). These areas were selected based on the magnitude of the contributing flows and the availability of acceptable quality data for the period of interest.

Data Sources

Bucks County and Lower Southampton Township timeseries flow data source is the 2.5-minute permanent billing meter data obtained from the PWD real-time unit (RTU) database. Quality assurance and quality control procedures including inspection of monthly timeseries plots were used to flag errant or missing data. The accepted data is then averaged to 15-minute intervals.

DELCORA flow data is obtained from hourly Southwest WPCP influent flow data measured at the plant. Quality assurance and quality control procedures including inspection of monthly timeseries plots were used to flag errant or missing data. The accepted data is then interpolated to 15-minute intervals.

Data Gap Filling Procedures

Identification and filling of data gaps are required in order to generate continuous timeseries data needed for performing the one-year (2005) model simulations. First, all data gaps and their durations are identified. Next, each data gap is characterized as either wet weather or dry weather flow with the corresponding procedures used for gap filling as described below:

Dry Weather Flow
For small data gaps (< 1 hour), linear interpolation was performed. Missing or errant data over one or more hours was filled using the nearest previous day's dry weather flow (DWF) data.

Wet Weather Flow
For small data gaps (< 1 hour), linear interpolation was performed. Wet weather events with missing or errant data periods of one or more hour duration were filled for the entire wet weather event with model simulation results using RDII RTK shape parameters previously calibrated for these areas. The model generated wet weather flow, obtained by subtracting the constant model baseflow from the simulated response, is added to the nearest previous day's DWF data.

Wet Weather Flow Separation

The continuous flow timeseries generated for the year 2005, as described above, contain diurnal and seasonal time varying baseflow patterns. In contrast, RUNOFF model generated hydrographs used for all other model areas simply have wet weather hydrograph responses added to a constant average baseflow. In order to represent the wet weather responses from the timeseries input areas more consistently with the Runoff modeled areas, hydrograph separations were performed on the timeseries data using CDM SHAPE software to extract the wet weather response hydrograph. The final timeseries was constructed by adding a constant average baseflow to the separated wet weather response timeseries.

v4.3.11 Capture Methodology

Capture calculations are performed in two steps. In the baseline condition, captured volume is the volume of combined sewer flow that is sent to the WPCPs during wet weather. In the LTCPU baseline wet weather is defined as when the flow in the dry weather pipe, connecting the regulator to the interceptor, increases more than 5 percent of the dry weather baseflow. In alternatives with CSO controls in place captured volume includes volume sent to the WPCPs and the volume prevented from reaching the CSS by source controls. Percent capture is calculated as the ratio of the captured volume to the sum of captured volume and volume overflowed to receiving waters.

The capture calculations are performed at each regulator. Each of the regulators is assigned to an interceptor system and the capture results from each regulator can be aggregated for that interceptor system. These results from the interceptors can be further aggregated by WPCP drainage district and by watershed

Capture calculation steps

For the Baseline capture calculations the following approach is used.

Requirements to calculate capture.

1. The capture formula is "Percentage Capture at a given regulator = 100 * [Total Volume through the dry weather pipe at the regulator / (Total Volume through the dry weather pipe at the regulator + Total volume that overflows to receiving water from the regulator)]".
2. For each regulator in the CSS, the dry weather flow pipe (DWO) and wet weather overflow pipe (SWO) is identified.
3. Flow for all the pipes identified in the last step is generated from the SWMM models. Another set of flow for the same pipes as above are generated for the same period as the wet weather simulation except using 0 (zero) precipitation. The zero precipitation simulation is performed to obtain the dry weather flows for the period of interest.
4. Using each of the regulators' DWO and SWO pipe flows calculations are performed.
    a. A tolerance is set for the baseflow for all the regulators which when exceeded indicates the regulator is in wet weather conditions (This tolerance is set at 5% for the LTCPU, when flow in the DWO pipe exceeds above 5% of baseflow, regulator is assumed to be in wet weather). Based on the baseflow tolerance the wet weather events are identified for the regulator. Capture calculations are performed for the wet weather events (using formula in step 1).
    b. If overflows from one regulator (Regulator "A") are re-regulated at another regulator (Regulator "B"), the overflow from A will be ignored when the capture result is aggregated to interceptor system.
    c. If a regulator (Regulator "C") re-regulates flow from upstream regulator's DWO (Regulator "D", Regulator "E"), all the DWO flows from D and E are ignored and only DWO flow from C is used when capture result is aggregated to the interceptor system.
    d. Negative flow through DWO (flow being relieved) pipes is subtracted when the capture calculation is performed. This accounts for regulators relieving other regulators.
5. The result from the CAPTURE program is summarized for yearly totals and aggregated by interceptor systems.

v4.3.12 Alternative Capture Calculation Methodology: Green Stormwater Infrastructure, Traditional Infrastructure and Large Scale Centralized Storage

Capture calculations for the alternatives that have been analyzed in the LTCPU – Green Stormwater Infrastructure, Traditional Infrastructure (Transmission to the WPCP) and Large Scale Centralized Storage (Tunnel) – are performed using the baseline model capture values as the foundation. The approach described below assumes that the overflow volume reduction, as compared to the baseline values, due to implementation of the alternatives is captured.

Steps included in alternative capture calculation

1. The overflow volume (SWO_0) to the receiving waters and treated volume (DWO_0) from the baseline models are obtained. This may be aggregated to the interceptor level or further aggregated to the WPCP drainage district level or the watershed level depending on the alternative for which effective capture calculations need to be performed.
2. The alternative scenario's overflow volume (SWO_1) aggregated to the interceptor level or further aggregated to the WPCP drainage district level or the watershed level depending on the alternative (representing Green Stormwater Infrastructure, Traditional Infrastructure or Large Scale Centralized Storage) are obtained.
3. The treated flow that accounts for reduction in volume that overflows to the receiving water due to implementation of the alternatives when compared to the baseline is inferred by the water balance to be: $[(SWO_0 + DWO_0) - (SWO_1)]$
4. The alternative capture formula is: $100*[(SWO_0 + DWO_0) - (SWO_1)] / (SWO_0 + DWO_0)$

VOLUME 5 PRECIPITATION ANALYSES

v5.1 METEOROLOGIC CHARACTERIZATION

The United States Environmental Protection Agency (US EPA) CSO Control Policy (1994) requires the characterization of the CSS area and evaluation of control measure performance in terms of system-wide average annual hydrologic conditions. The identification of an average annual precipitation record, therefore, is critical for the evaluation of CSS performance.

v5.1.1 Long-Term Meteorologic Conditions

The hydrologic conditions over the Philadelphia CSS area are characterized using the long-term historic hourly precipitation record, 59-year period (1948-2006), for the National Weather Service Cooperative Station located at the Philadelphia International Airport (PIA) (WBAN#13739). Statistical analyses of the long-term record are performed to determine the average frequency, volume, and peak intensity of rainfall events.

Identification of long-term average hydrologic conditions over the CSS is based primarily upon average annual and monthly precipitation volumes determined from the long-term record at the PIA. Comparisons are made between the individual annual precipitation volumes and the long-term average to identify relatively 'wet' and 'dry' years.

Figure v5-1 presents total annual precipitation volumes at the PIA for the years 1948-2006 along with one standard deviation from the mean. By this measure, 1983 and 1922 are the wettest and driest years on record, respectively. Furthermore, it is seen that during the past 15-years (since 1990) one year, 1996, is characterized as being wet and five individual years are characterized as being dry by having a total annual precipitation volume greater than one standard deviation from the mean.

Figure v5-2 shows the average monthly precipitation volumes relative to a range of plus and minus one standard deviation from the mean based upon the PIA historical record. Table v5-1 presents accompanying historical monthly precipitation volume statistics. Long term seasonal variation in monthly precipitation volumes can readily be seen between summer and winter.

The PIA long-term empirical cumulative distribution function of hourly rainfall intensity is presented in Figure v5-3.

Event Based Precipitation Analyses

Event based analysis of the long term precipitation record is used to best represent average annual CSO frequency and volume statistics needed for presumptive measurement of collection system performance. These event statistics are specific for a given minimum inter-event time (MIT) used for event definition.

A minimum inter-event time (MIT) is chosen for event definition so that the coefficient of variation (the ratio of the standard deviation to the mean) of inter-event times most closely approximates unity. This follows an exponential distribution of inter-event times for which the mean equals the standard deviation, and is based on the results of National Urban Runoff Program (EPA 1993). A six-hour minimum inter-event time is selected on this basis for the PIA using hourly precipitation data for the period 1948-2006 as seen in Table v5-2.

v5.1.2 Local Meteorologic Conditions

The average spatial distribution of precipitation over the CSS areas is characterized using the 17-year rainfall record for the PWD 24-raingage network collected over the period 1990-2006, along with 15 months of gage calibrated radar rainfall data. Extensive analyses of non-climatic gage biases based on inter-gage comparison and radar rainfall data are performed leading to the creation of a bias adjusted rainfall dataset for the PWD 24-raingage network over the 17-year period of record (1990-2006). The detailed analyses are presented in Section v5.2 Normalizing Rain Gage Network Biases Using Calibrated Radar Rainfall Estimates.

v5.1.3 Identifying a Representative 12-Month Period in Precipitation Record

The characterization of long-term system-wide average hydrologic conditions across the CSS is necessary in order to identify a continuous short–term period contained within the PWD 24-gage fifteen-minute rainfall record (1990-present) that simulates long-term average annual CSO statistics needed for performance evaluation of CSO control measures.

CSO occurrence is considered to be a complex function of storm-event characteristics such as total volume, duration, peak intensity, and length of antecedent dry period or inter-event time (IET). In order to identify short-term continuous periods likely to generate CSO statistics representative of the long-term record, continuous 12-month periods selected from the recent 17-year PWD 24-raingage record (1990-2006) were evaluated against the long-term record based on the following storm-event characteristics:

- Annual number of storm events
- Total annual rainfall volume
- Best fit cumulative distribution function (CDF) plot of event peak hourly rainfall intensity

Manipulation of the rainfall data is performed using Statistical Analysis System (SAS) code. SAS is a high-level programming language that is particularly well suited to processing large amounts of data with relatively simple programming code.

The first step in the analyses is to parse the bias adjusted and inverse distance-squared weight (IDW) filled 17-year precipitation record (1990-2006) for each gage location into continuous 12-month periods beginning with January 1, 1990 and progressing with 1-month increments to the final continuous 12-month period beginning on January 1, 2006. Each continuous 12-month period is thereby identified by the starting year and month.

Next, event statistics, including total volume, average duration, average peak intensity, and average inter-event time (IET) are determined, based on a minimum inter-event time (MIT) of 6 hours, for each 12-month period. Small events, defined as events with total volumes less than 0.05 inches, are removed from further analysis. Similarly, average annual event statistics are determined for each gage location over the s17-year period of record (1990-2006). The differences in average event statistics between each continuous 12-month period and the period of record are determined for each gage location. The absolute value of the average difference across all gage locations is then determined for each continuous 12-month period, and the result is then ranked in order of ascending magnitude as a measure of goodness of fit to the long term average for each event statistic.

The cumulative frequency distribution of event peak rainfall intensity is considered to be a critical measure for identifying rainfall periods that produce average long-term CSO statistics. Event peak hourly rainfall intensities are ranked and a left-continuous empirical CDF is generated with fractional ranks computed by dividing each rank by the denominator n+1, where n is the number of events. In this manner empirical cumulative distribution functions are generated for each continuous 12-month period and the 17-year period of record for each rain gage. The sum of the absolute differences in peak hourly rainfall intensity between the 12-month period and the 17-year period of record, determined for each event within the 12-month period based on its fractional rank, is used to measure the goodness of fit for each rain gage and 12-month period. This measure, referred to here as the total deviation, is averaged across all rain gages for each 12-month period and ranked in ascending order.

A final ranking is performed based on total deviation of peak hourly rainfall intensity, average annual rainfall volume, and average annual number of rain events. The top results from this ranking are presented in Table v5-4. The 12-month period beginning January 1, 2005 is chosen to represent long-term average hydrologic conditions for Long Tern Control Plan CSO performance evaluations based on the additional criteria that it is a recent calendar year.

Table v5-4 Ranking of Recent Representative Continuous 12-month Periods Based on the Best-Fit Distribution of Event Peak Hourly Rainfall Intensity, Average Annual Rainfall Volume, and Annual Number of Events

Start Year	Start Month	Average Event Peak (in/hr)	Annual Rainfall Volume (in)	Average IET (hrs)	Average Event Duration (hrs)	Annual Number of Events	Rank
1990 - 2006		0.11	42.80	76.54	9.74	76	
1992	3	0.10	43.57	74.48	10.33	79	1
1996	11	0.09	41.66	81.47	10.57	69	2
1992	8	0.10	44.08	76.52	9.95	78	3
1995	7	0.10	41.45	77.67	9.06	80	4
2004	12	0.11	43.51	77.27	10.63	76	5
1992	2	0.10	42.32	76.16	10.04	81	5
1992	1	0.10	41.36	78.87	10.15	79	5
2003	4	0.10	43.17	62.09	9.98	83	8
2005	3	0.11	43.02	82.31	10.00	75	9
2005	**1**	**0.11**	**44.06**	**78.76**	**10.26**	**79**	**10**
2000	8	0.11	41.43	77.65	9.34	73	11
1998	11	0.09	43.20	83.60	9.42	69	12
2002	7	0.08	41.67	72.39	11.85	76	13
1998	12	0.09	43.93	79.20	9.43	70	13
1997	7	0.09	43.09	71.39	11.92	80	15
1994	3	0.12	43.11	73.77	9.01	79	16
1997	8	0.09	41.87	71.42	11.77	80	17

* Only continuous periods with annual rainfall volumes within +/- 1.5 inches of the 17-year average annual rainfall volume (41.30 to 44.30 inches) were considered. Only rainfall events with total volume >= 0.05 inches, based on a 6-hour M.I.T. are included in the analysis

Table v5-5 compares selected PIA precipitation event statistics for the calendar year 2005 to PIA long-term historic median values. Events with total volumes less than 0.05 inches were excluded from the analysis because they are not expected to significantly influence CSO statistics.

Table v5-5 Seasonal Precipitation Event Statistics Comparing Long-Term Historic Record to Calendar Year 2005[*]

Statistic	2005		1948-2006

v5.1.4 Modifying the Selected 12-month Precipitation Record

Initial selection of the calendar year 2005 to represent long-term average hydrologic conditions for CSO LTCP project evaluations was based on the annual number of storm events, the total annual rainfall volume, and the best fit CDF plot of event peak hourly rainfall intensity, with preference given to more recent calendar years to better represent current conditions.

The calendar year 2005, however, contains the extreme event of October 8, 2005 which recorded an average rainfall volume across the PWD 24-gage network of 5.40 inches between October 7 at 12:15 PM and October 9 at 8:45 AM. This rainfall event has the third largest annual peak rainfall volume recorded at the Philadelphia International Airport (PIA) station over the long-term period of 1948-2006. Because the extreme rainfall event of October 8, 2005 accounts for a disproportionately large fraction of the total annual overflow volume the results of CSO LTCP project evaluations may be unintentionally skewed to minimize the long-term effectiveness of certain alternatives in favor of others.

In response to these concerns, a decision was made to adjust the rainfall record for the calendar year 2005 to better represent long-term average hydrologic conditions by scaling down the October 8 rainfall event so that the average rainfall volume across the PWD 24-gage network for this event is equal to the median peak annual rainfall volume estimated for the network over the long-term period of 1948-2006.

After scaling down the October 8 event, several other events are selected to be scaled up so that the average total rainfall volume across the PWD 24-raingage network is equal to the long-term average annual rainfall volume estimated across the network for the long-term period 1948-2006.

Time Series Modification Procedures

Median Peak Annual Rainfall Volume

The median peak annual rainfall volume is estimated for the PWD 24-raingage network over the long-term period of 1948-2006 by scaling the PWD median peak annual rainfall event volume for the 17-year period of 1990-2006 by the ratio of PIA median peak annual rainfall event volume for the long-term period of 1948-2006 to that for the period 1990-2006. The result is an estimated average peak annual rainfall event volume across the PWD 24-gage network of 3.40 inches based on a 6-hr Minimum Inter-event Time (MIT) as presented in Table v5-6.

Table v5-6 Median Annual Peak Rainfall Event Volumes (MIT = 6 hrs)

	1948-2006	1990-2006
	(inches)	(inches)
PIA	3.18	2.78
PWD	**3.40**	2.97

October 8, 2005 Rainfall Event Scaling

The October 8, 2005 extreme rainfall event is scaled down by multiplying the time series data for each of PWD rain gages by the factor 0.630. This scaling factor is determined as the ratio of the average median peak annual rainfall volume estimated for PWD 24-raingage network over the long-term period of 1948-2006 (3.40 inches), to the average rainfall volume for PWD 24-raingage network during the October 8, 2005 event (5.40 inches).

Average Annual Rainfall Volume

The average annual rainfall volume across the PWD 24-raingage network for the recent period 1990-2006 is scaled up by a factor of 1.03 to estimate the average for the long-term period (1948-2006) based on the ratio of averages at the PIA for these periods. Simply stated, the PIA long-term average annual rainfall (1948-2006) is 3% greater than that for the more recent period 1990-2006.

Average annual rainfall volumes for the PIA and the PWD 24-raingage network are presented for each time period in Table v5-7. The long-term average annual rainfall volume across the PWD network is estimated to be approximately 44.79 inches.

Table v5-7 Average Annual Rainfall Volume Comparison

Rainfall Dataset	Average Annual Rainfall (inches)
PIA (1948-2006)	41.05
PIA (1990-2006)	39.84
PWD (1990-2006)	43.48
PWD (1948-2006) estimated	**44.79**
PWD 2005	44.53
PWD 2005 w/ Oct 8 Scaled Down	42.53
PWD Oct 8 Event	5.40
PWD Oct 8 Event Scaled Down	3.40

Scaling Representative Year to Match Long-Term Average Annual Rainfall Volume

The average annual rainfall volume across the PWD network for the year 2005, after scaling down the October 8 event, is 42.533 inches - approximately 2.25 inches less than the long-term average annual rainfall estimated for the PWD network of 44.785 inches. The 2.25 inches of rainfall are distributed back into the annual time series by selecting events to scale up based on the CDF of total event rainfall volumes.

The CDF plots of total event rainfall volume for each gage are considered in order to identify a range of event frequencies that have lower event volumes in the calendar year than in the long-term record (17-yrs).

The first step in this process is to generate a master event list based on the sum of the rainfall from all 24 PWD raingages using a 6-hr MIT. This allows the rainfall time series data for all rain gages to be scaled within the same selected set of event boundaries. The 18 events selected for distributing the 2.25 inches of rainfall needed on average to match the long-term average annual rainfall volume are presented in Table v5-8.

Table v5-8 Event Boundaries Selected for Scaling Up

Master Event No.	Start Time	End Time
2189	1/7/05 21:30	1/9/05 0:00
2190	1/11/05 15:00	1/12/05 1:15
2195	1/25/05 13:00	1/25/05 18:15
2204	2/4/05 9:00	2/4/05 16:00
2214	3/1/05 11:15	3/1/05 18:30
2215	3/8/05 4:15	3/8/05 14:15
2217	3/20/05 3:00	3/21/05 4:15
2228	4/23/05 6:30	4/24/05 1:45
2252	6/10/05 11:15	6/10/05 16:15
2257	7/1/05 16:00	7/1/05 19:00
2259	7/5/05 16:15	7/5/05 18:00
2280	8/8/05 6:30	8/9/05 11:15
2283	8/16/05 12:30	8/17/05 8:15
2287	8/27/05 8:15	8/27/05 19:30
2307	10/12/05 23:00	10/15/05 7:15
2328	12/9/05 7:45	12/10/05 0:00
2335	12/25/05 13:00	12/26/05 12:00
2337	12/29/05 7:00	12/29/05 23:30

A scaling factor is determined so that when multiplied by the time series data within the selected event boundaries for each gage then the average annual rainfall volume across all gages is equal to the long-term average. This factor for each gage is one plus the ratio of the total volume being added to the sum of the volumes of all events being selected for scaling. The total volume to be added for each gage is determined as the total annual volume for the gage excluding the volume for the October 8 event multiplied by the ratio of the average volume added to the average annual volume excluding the average volume for the October 8 event. The ratio of average volume added to average annual volume excluding the October 8th event is shown to be equal to (2.25 inches) / (44.53 inches – 5.4 inches) = 0.0576. Therefore, the scaling factor for each gage is determined by the formula:

$$\left[1 + 0.0576 \times \left(\mathrm{V}^{RG}_{\mathrm{Annual}} - \mathrm{V}^{RG}_{Oct8}\right) \Big/ \sum \mathrm{V}^{RG}_{SelectedEvents}\right]$$

The scaling factors applied to the selected events are presented for each gage in Table v5-9.

Results

The final results of the modification of the calendar year 2005 rainfall record is illustrated through the CDF plots of event rainfall volume produced for PWD RG-5 comparing the PWD period of record (1990-2006) and one of the following: calendar year 2005; modified calendar the year 2005. The two CDF plots produced for PWD RG-5 are presented in Figure v5-9 and Figure v5-10.

Table v5-9 Factors for Scaling Selected Rainfall Events for Each Raingage

RG	Factor	RG	Factor
1	1.32	13	1.348
2	1.304	14	1.35
3	1.362	15	1.337
4	1.331	16	1.347
5	1.334	17	1.364
6	1.329	18	1.348
7	1.354	19	1.372
8	1.359	20	1.351
9	1.313	21	1.384
10	1.356	22	1.325
11	1.344	23	1.301
12	1.335	24	1.383

In addition, Philadelphia International Airport (PIA) hourly rainfall data were used to generate CDF plots of total event rainfall (for events greater than or equal to 0.05 inches with MIT = 6hrs). These plots are presented in Figure v5-11 through Figure v5-13 comparing the following three time periods: 59-year period (1948-2006); 17-year period (1990-2006); calendar year 2005.

Comparing the CDF plots for each PWD gage indicates that event volumes corresponding to percentiles between 40% and 70% are generally lower for the calendar year 2005 before modification than for the 17-year average. Although these event volumes are increased after modification, they appear to be generally lower than the 17-year average. The same general relationship between calendar year 2005 and the 17-year average is seen at the PIA in Figure-4. Furthermore, PWD rain gage event volumes corresponding to percentiles between 70% and 90% are generally higher than the 17-year average before modification, and are increased further above the average after modification. A similar pattern is observed for the PIA.

Figure v5-14 and Figure v5-15 present cumulative frequency distribution plots of 15-minute rainfall intensities pooled for all 24 PWD rain gages over the period 1990-2006 for frequencies of occurrence less than or equal to 50% and greater than or equal to 50%, respectively .

Figure v5-16 presents a relative rainfall distribution map based on Inverse Distance Squared (IDS) weighting of 1-km square grid cells from bias adjusted PWD 24-raingage Network data for the modified representative year 2005. This IDS grid rainfall record is basin averaged and used as input for all hydrologic models as part of the LTCPU as described in Section v5.3.

v5.2 NORMALIZING RAIN GAGE NETWORK BIASES USING CALIBRATED RADAR RAINFALL ESTIMATES

The identification and adjustment of precipitation time series data for non-climatic changes in recording bias among rain gages can be instrumental in controlling uncertainty in hydrologic models. Hydrologic models depend upon the reliability of precipitation and flow monitoring data sets used for calibration and simulation. Consistent precipitation and flow monitoring measurements clearly can be important when attempting to characterize rainfall runoff relationships over time. Hydrologic models require rain gage networks to represent the spatial distribution of precipitation across a drainage basin and benefit from the normalization of relative rain gage biases across the network.

Calibration of large urban sewer system models, using a moderately-dense basin-wide rain gage network and continuous flow monitoring data, is improved by creating continuous homogeneous rainfall records with normalized spatial biases.

Double-mass regression and cumulative residual time series analysis techniques are used to evaluate and adjust historical rain gage network data to correct for non-homogeneity of individual rainfall records and to normalize spatial bias across the network. Homogeneity of rainfall time series data is evaluated and adjusted by comparison to the rain gage network mean over a 13-year period of record. Spatial bias across the network, then, is normalized by comparison to continuous calibrated radar rainfall estimates obtained over a 15-month period. Cumulative residual time series analysis techniques also are applied to evaluate the homogeneity of flow monitoring data used in model calibration. The benefits of normalizing the rain gage network biases to model calibration are illustrated by comparing model results using gage data with and without bias correction.

v5.2.1 Introduction

v5.2.1.1 Homogeneity of Rain Gage Station Records

Hydrologic model calibration of lumped runoff parameter estimates depends on consistent rather than precise absolute precipitation and flow monitoring measurement over time. Homogeneity of a rain gage record refers to the consistency of non-climatic bias in precipitation measurements at a gage location over its period of record. Changes in the method of measurement, location of the gage, or conditions immediately surrounding the gage, can cause the readings to differ systematically from prior readings and are indications of a need for correction (Easterling *et al.*, 1995). Homogeneity adjustment of rain gage data is performed to create a consistently scaled rainfall record at each gage location.

Adjustment of gage data to form homogeneous time series depends upon the ability to identify times when changes in measurement conditions may have occurred (Alexandersson 1986). Meta-data, a gage history record documenting changes in equipment and site conditions, often is used as the primary means for identifying changes in rain gage measurement conditions (Guttman 1998). Meta-data alone, however, is often insufficient for identifying non-homogeneity of gage records. Major reported equipment or station location changes can have little if any effect on the gage record, whereas seemingly minor adjustments and undocumented changes in site conditions may result in profound changes in the rainfall record as identified by analytic methods (Peterson *et al.*, 1998).

Time series analysis methods used for evaluating homogeneity and adjusting rain gage records depend upon comparison of gage data to a homogeneous reference time series. An appropriate reference time series is created by averaging measurements from several highly correlated nearby gages (Guttman 1998, Peterson *et al.*, 1998). It is also found valuable to include gages with short and incomplete data series in the reference value (Alexandersson 1986).

v5.2.1.2 Normalizing Rain Gage Network Biases

Representing precipitation spatially across a water or sewer-shed depends upon consistent recording among gages in a rain gage network. Once homogeneous rain gage records are created, it is important that all gages in the network be scaled to combine data for use in filling missing records. The goal is to develop a continuous rainfall record for each gage location, and to determine spatial bias adjustment factors to consistently represent the spatial distribution of rainfall across the network.

Normalizing rain gage network biases in this manner depends upon a reliable reference precipitation data set that represents spatial variation across the region with a uniform bias over a sufficiently long period of record. Calibrated radar rainfall estimates are used for this purpose.

v5.2.1.3 Background

The Philadelphia Water Department (PWD), as part of the City of Philadelphia's combined sewer overflow (CSO) permit compliance program, developed system hydraulic models of its separate sanitary and combined sewer systems that contribute flows to each of its three water pollution control plants, draining nearly 140 square miles of the city. The City maintains a network of 24 tipping bucket rain gages as part of this program. In addition, the City has obtained 18 months of largely continuous historical gage calibrated radar rainfall estimates provided by NEXRAIN Corporation, in order to further refine calibration of its large complex hydraulic system models. A map of Philadelphia showing approximate locations of PWD rain gages, radar rainfall grid, as well as, the combined and sanitary sewer service areas is presented in Figure v5-17.

Comparison of long term rainfall accumulations at neighboring gages revealed potentially significant systematic differences in non-climatic biases. Double mass and cumulative residual analyses of gage station records against the gage network mean value have further revealed non-homogeneity of station records due to changes in equipment operation or site conditions. Adjustment of rain gage data, therefore, was applied to create a consistently scaled precipitation record at each gage location. In addition to creating consistent (homogeneous) gage records over time, it also is important to scale all the gages consistently within the network to one another in order to combine data from different gages, for use in filling missing records, and representing spatial variation.

The goals of this investigation are to develop procedures to evaluate and adjust the historic PWD rain gage network record to produce homogeneous rain gage records at each gage location and to normalize rain gage network biases using radar rainfall estimates.

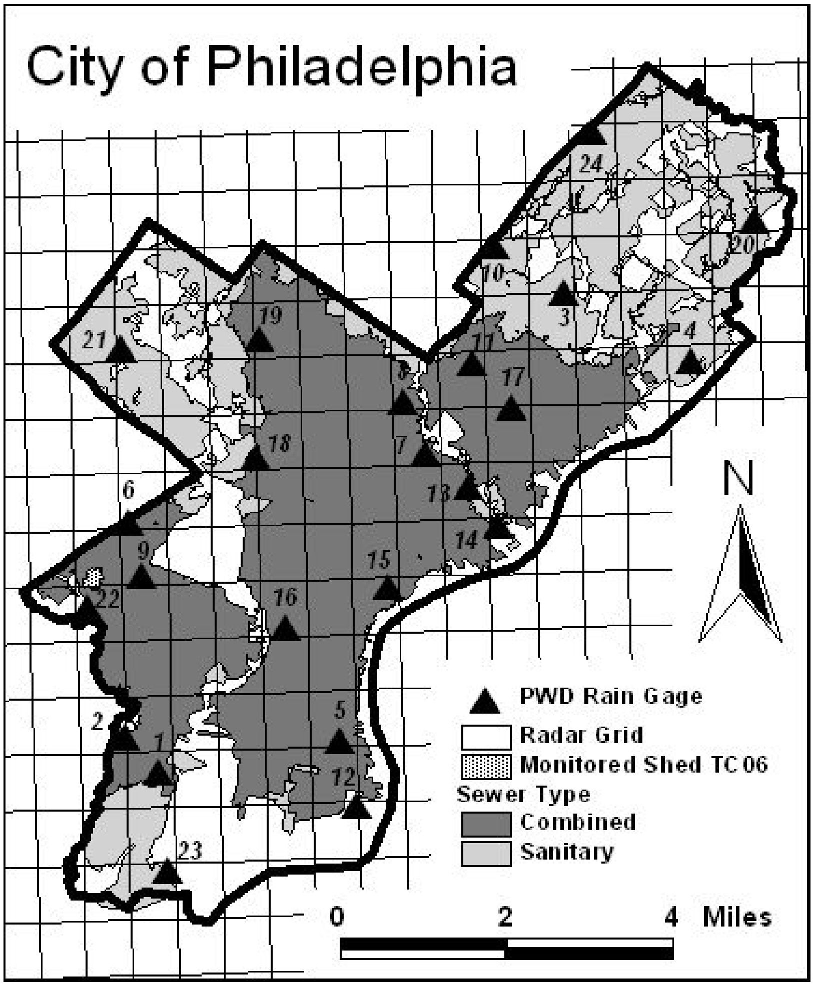

Figure v5-17 City of Philadelphia Showing the Approximate Locations of PWD Rain Gages, Radar Rainfall Grid, as Well as in City Combined and Sanitary Sewer Service Areas

v5.2.2 Homogeneity of PWD Rain Gage Station Records

This section describes the methods used to evaluate and adjust PWD rain gage records to create continuous homogeneous rainfall records at each location in the network for use as hydrologic model input.

v5.2.2.1 Data Set

The PWD maintains a database of 15-minute accumulated precipitation totals collected from its 24 tipping bucket rain gage network for the period 1990 to the present. The uncorrected, 2.5-minute accumulated, 0.01 inch tip count, rain gage data are subjected to preliminary quality assurance and quality control procedures. Identification and flagging of bad or missing data are performed for each rainfall event on a monthly basis by visual inspection of 15-minute accumulated data comparing measurements at nearby gages and looking for patterns of obvious gage failures, including plugged gages and erratic tipping. Flagged data for each gage subsequently are filled with data from the five nearest gages using inverse distance squared weighting. Neighboring gage data that are flagged are removed prior to weighting.

Daily rainfall volumes were totaled for each gage. Daily gage totals containing any filled data were removed from further analysis. A daily mean total was calculated for each gage as the average of all daily gage totals excluding the total at the gage itself. The resulting dataset consisted of daily gage totals, and daily mean totals (mean of all the other gages) for each gage.

v5.2.2.2 Double Mass Regression and Cumulative Residual Time Series Analysis

Double mass regression and cumulative residual time series analysis methods were used for evaluating the homogeneity and adjusting PWD rain gage records. These methods, like other reliable analytical methods of homogenizing rainfall time series, depend upon comparison of gage data to a homogeneous reference series. A reference series can be created using the average of a collection of nearby gages, or a homogeneous record at a single nearby gage (Allen *et al.*, 1998). The rain gage network mean value, calculated as described above, was selected as the reference series for homogenization of PWD rain gage data.

Evaluating the homogeneity of PWD rain gage records, and identifying dates when apparent changes in measurement conditions may have occurred, was performed using double mass and cumulative residual time series analysis techniques. A series of graphs was produced comparing gage to mean daily rainfall totals for each gage in the network. An example of the output generated is presented for PWD rain gage 22 in Figures v5-18 and v5-19.

A double mass plot of gage to mean cumulative daily rainfall totals was produced for each gage. The slope of the linear regression line passing through the origin is referred to as the double mass regression slope, DMRS, as shown in Figure v5-18. Potential heterogeneities are identified by visual inspection of the double mass plot as seen by systematic departures from the trend line. These departures can be identified more easily by plotting the accumulated residual from the simple linear regression of gage against mean daily rainfall totals over time (Craddock 1979) as shown in the cumulative residual plot in Figure v5-19.

Evaluation of potentially significant gage record non-homogeneity was aided by the addition of an objective graphic analytic tool to the cumulative residual plot. An ellipse was drawn on the plot to contain the residual of a homogeneous time series for a given probability of the standard normal variate (Allen *et al.*, 1998, Henriques et al 1999). The 80% probability level, commonly used by others according to Allen *et al.*, 1998, was chosen for this data evaluation program. Because the cumulative residual time series plot in Figure v5-19 is not contained within the ellipse, we reject at the 80% confidence level the hypothesis that the rainfall record at PWD rain gage 22 is homogeneous with respect to the mean. The parametric equation defining the probability ellipse is given by (Allen *et al.*, 1998)

$$x = \alpha Cos(\theta) + \alpha$$
$$y = \beta Sin(\theta)$$

with

$$\alpha = n/2$$
$$\beta = nZ_p S_{y,x} / \sqrt{(n-1)}$$
$$S_{y,x} = S_y \sqrt{(1-r^2)}$$

where:

n = the number of observations
S_y = the sample standard deviation
r = the Pearson correlation coefficient
Z_p = the standard normal variate at 80% probability
θ = an angle in radians varying from 0 to 2π

Cumulative residual analysis reveals even subtle change in gage bias often undetected by routine inspection of precipitation data and gage history records. Furthermore, subjective evaluation of the cumulative residual plot enables effective identification of the approximate dates abrupt changes in the relationship between the gage and its neighbors occur (Craddock 1979). In this manner, a set of adjustment periods are determined that contain continuous, relatively homogeneous segments of each gage record. Objective statistical methods are used by others to identify significant break points in gage record homogeneity (Peterson *et al.*, 1998). These methods have not been used here, however, like the subjective method of defining homogeneous periods used in this data homogenization program, they rely on comparative evaluation of time series data from a moderately dense and highly correlated gage network.

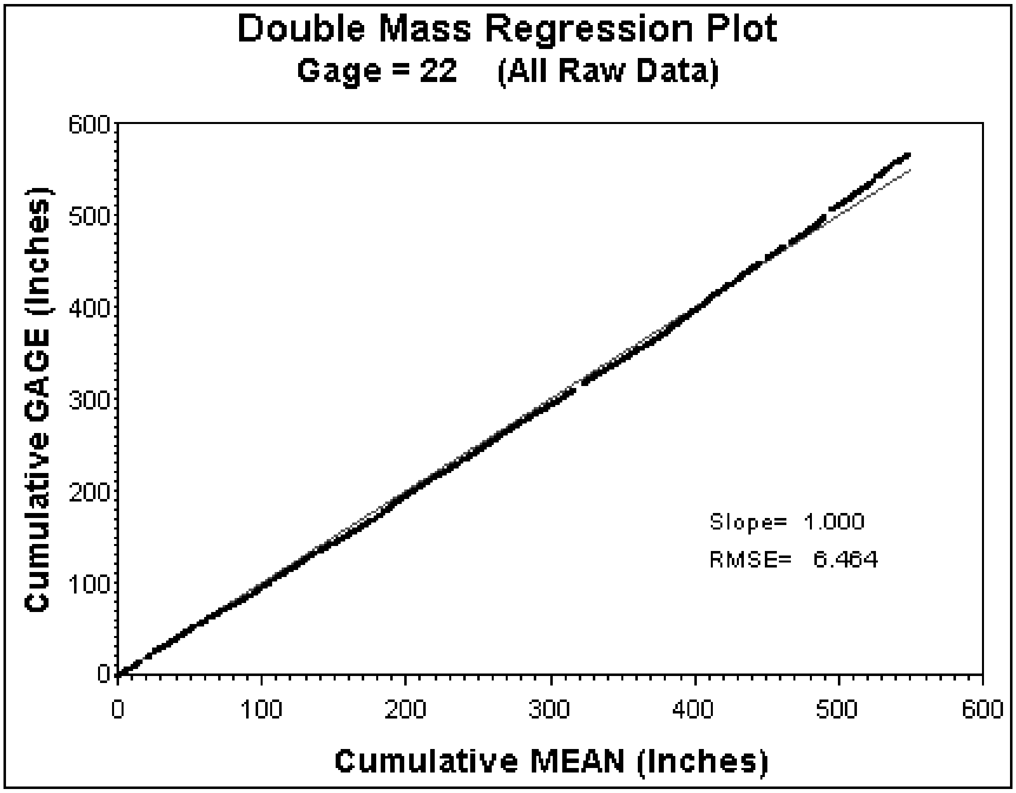

Figure v5-18 Double Mass Regression Plot of Cumulative Daily Rainfall at PWD Rain Gage 22 Against Mean Using All Raw Data for the 1990-2006 Period of Record

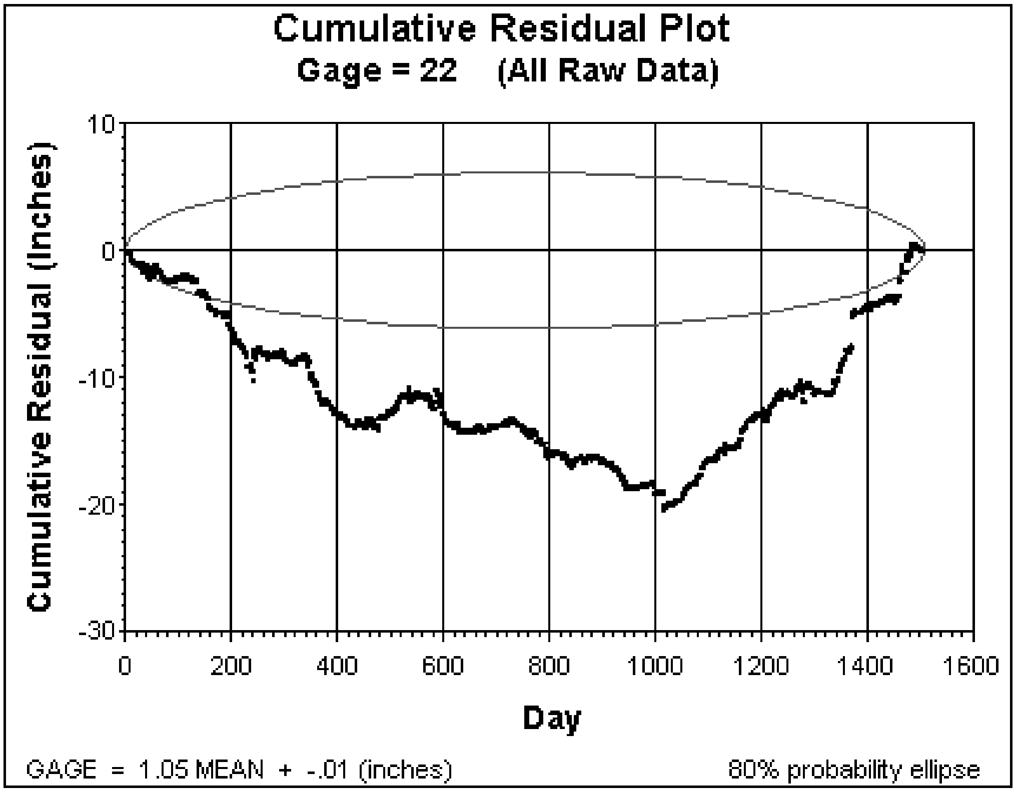

Figure v5-19 Cumulative Residual Time Series Plot from the Linear Regression of Daily Gage Against Mean Rainfall Totals at PWD Rain Gage 22 Using All Raw Data for the Period 1990-2006

v5.2.2.3 Adjusting Heterogeneous Gage Records

Once significant non-homogeneity of the gage record is determined, and the limits of homogeneous adjustment periods have been identified, adjustment factors are computed for these periods to form a homogeneous data record.

Homogeneity adjustment factors are viewed as the ratio of the average gage biases between a reference period and the period to be adjusted (Guttman 1998). Several methods of calculating adjustment factors are investigated. Each method employs a different form of expressing the average bias at the gage relative to the mean. Three methods of estimating average biases for a gage period considered are:

1. Average Daily Ratio of rain gage value to the mean (high influence of small event outliers)
2. Double mass linear regression slope (most stable with respect to outliers)
3. Linear regression slope (high influence of large event outliers)

The double mass linear regression slope with y-intercept = 0 was found to be the most stable with respect to outliers and was chosen for this study to determine homogeneity adjustment factors for selected periods of the rain gage record.

Rain gage record homogeneity adjustment factors were calculated for each interval by dividing the double mass regression slope (DMRS) of the entire unadjusted data record (Figure v5-18) by the DMRS for the adjustment period. This calculation is performed for each adjustment period identified and all raw data within the adjustment periods then is multiplied by these factors to generate the corrected rain gage record.

The results of homogeneity adjustment are presented for PWD rain gage 22 with the double mass regression plot in Figure v5-20 and the cumulative residual plot in Figure v5-21. Comparison of these plots to those presented in Figures v5-18 and v5-19 for the raw data reveal a significant improvement in homogeneity of rain gage bias relative to the network mean over the period of record for this gage.

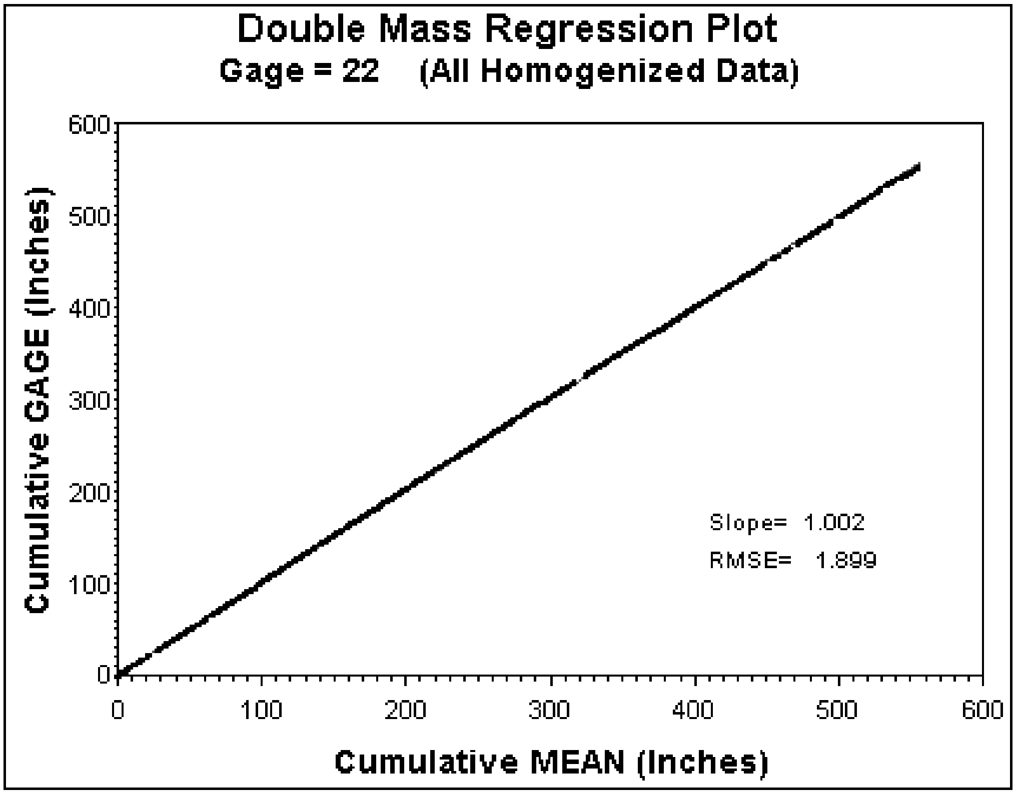

Figure v5-20 Double Mass Regression Plot of Cumulative Daily Rainfall at PWD Rain Gage 22 Against Mean Using Homogenized Data for the 1990-2006 Period of Record

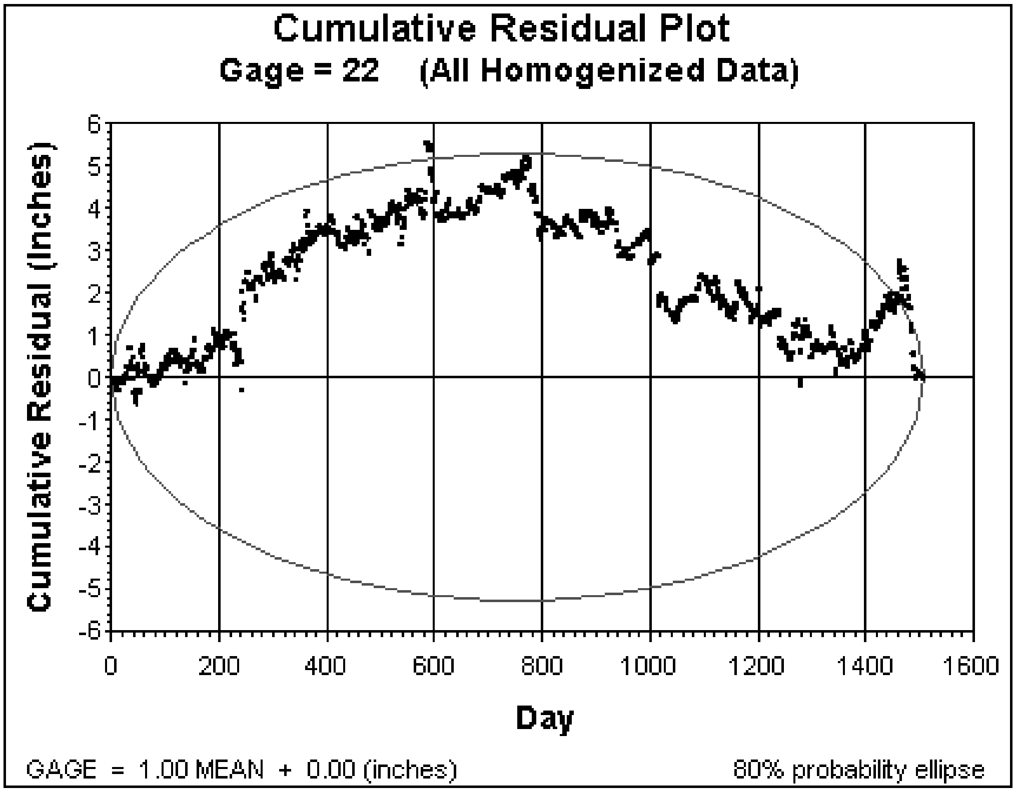

Figure v5-21 Time Series Plot of the Cumulative Residual from the Linear Regression of Daily Gage Against Mean Rainfall Totals at PWD Rain Gage 22 Using Homogenized Data for the Period 1990-2006

v5.2.3 Normalizing Spatial Biases in Rain Gage Data Using Calibrated Radar Rainfall Estimates

Once homogeneous gage records are created, all gages then are adjusted for consistent net systematic biases resulting from differences in gage equipment, gage site conditions, and previous homogeneity adjustments.

The second major goal of this investigation is to adjust all the gages in the PWD network to the same average bias, so the gage network more reliably represents spatial variation across the region. To achieve this goal a reliable reference series is needed to represent spatial variation of rainfall across region with a uniform bias, over a sufficiently long and homogeneous period of record. Calibrated radar rainfall estimates are used for this purpose.

v5.2.3.1 Data Set

Radar rainfall estimates provided by NEXRAIN Corporation are derived from a 2km x 2km National Weather Service level 3 radar mosaic product, corrected for ground clutter and other anomalies, and calibrated to the PWD 24 rain gage network using a mean field bias adjustment. The 15-minute calibrated radar rainfall estimates for a 15-month period including two relatively recent intervals: October, 1999 through August, 2000 and March, 2002 through June, 2002 are used for this analysis. The radar rainfall estimates are calibrated to the PWD rain gage network using a mean field bias adjustment method where the mean event accumulation for the radar pixels containing the

PWD rain gages is set equal to the mean event accumulation measured at the gages. In this way the total volume of rainfall reported within the network is conserved, while the spatial variation represented by radar data is retained.

v5.2.3.2 Bias Adjustment Using Double Mass Regression

Double mass regression analysis is used to correlate PWD rain gage measurements to calibrated radar rainfall data. In this way, overall spatial bias adjustment factors are determined that best represent the spatial distribution of rainfall over the full period of record for each rain gage in the network.

Before determining the overall bias of a rain gage record relative to the calibrated radar rainfall estimates, the homogeneity of the data sets is verified. The verification is performed by examining the time series plots of the cumulative residual from the linear regression of daily radar against rain gage rainfall totals, as shown for PWD rain gage 22 in Figure v5-22. Once an acceptable degree of homogeneity between the datasets is determined for the 15-month radar study period, the spatial bias adjustment factor is calculated for the complete gage record. The program developed for determining overall site bias factors at each gage is a two-part process using the same techniques developed for homogenization of the gage record.

The first step in determining the overall spatial bias adjustment factor, once the homogeneity of all datasets is established, is to determine the bias at each gage using the double mass regression slope,of radar to rain gage daily rainfall totals for the 15-month radar study period as presented in Figure v5-23 for PWD rain gage 22.

Next, the gage bias for the radar study period is related to the overall bias of the gage record to determine spatial bias adjustment factors that are applied to adjust the entire period of record for the gage, not just the 15-month radar period. This is done by determining the average gage bias for the 15-month radar period using the DMRS of the daily gage versus the mean rainfall for this period as shown by Figure v5-24. The DMRS for the entire period of record was previously determined using all homogenized data as shown by Figure v5-20. Then the ratio of the DMRS for the entire period of record (all data) to that of the radar study period (15-month) is calculated. This ratio is multiplied by the DMRS radar to rain gage bias from Figure v5-23, to yield the overall spatial bias adjustment factor for each gage.

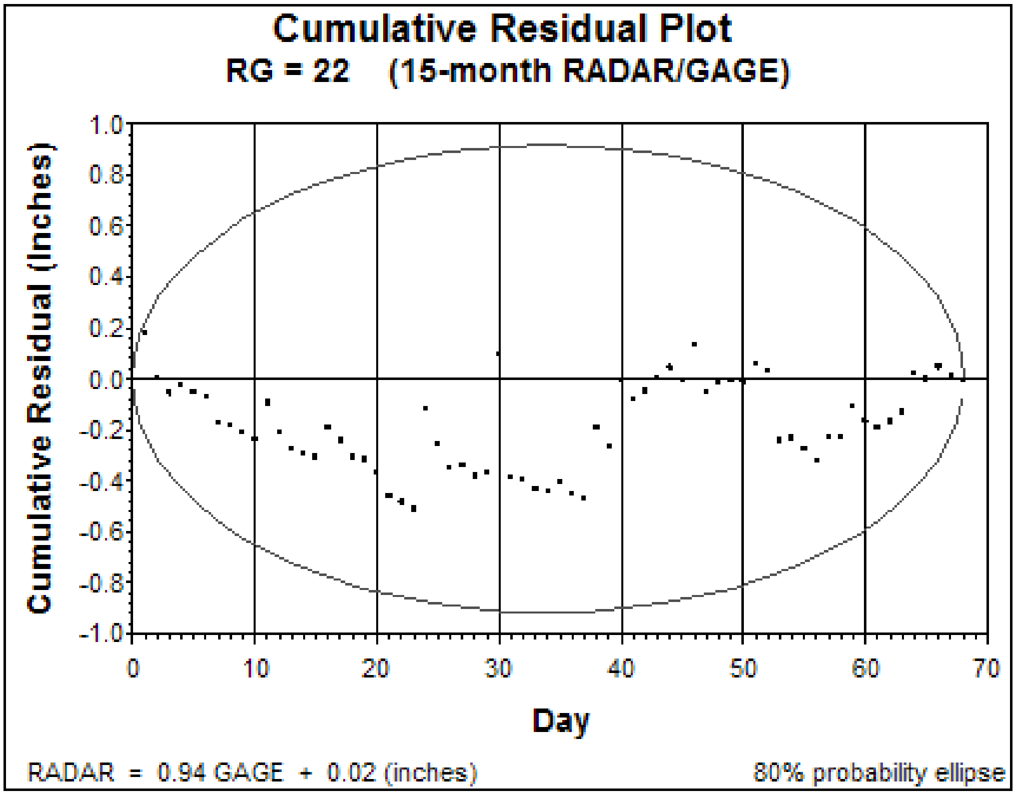

Figure v5-22 Cumulative Residuals: Linear Regression of Daily Radar Rainfall Estimates Against Rain Gage Totals at PWD Rain Gage 22 for the 15-Month Radar Study Period

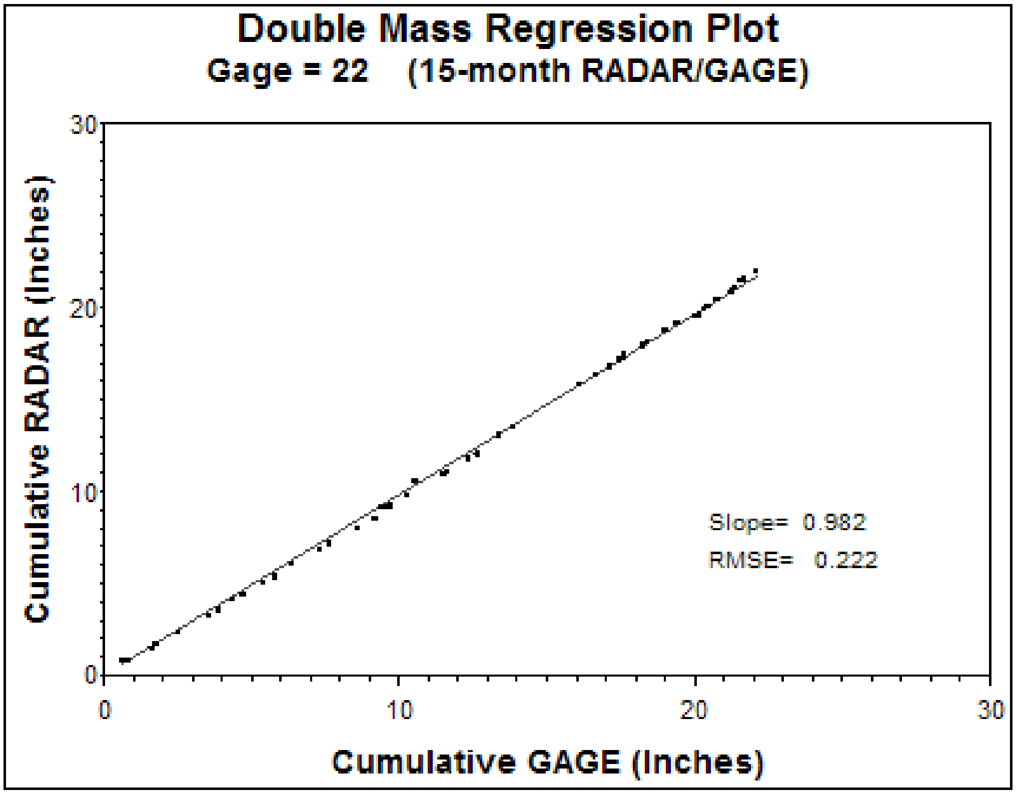

Figure v5-23 Double Mass Regression Plot of Cumulative Daily Radar Against Gage Rainfall Totals at PWD Rain Gage 22 for the 15-Month Radar Study Period

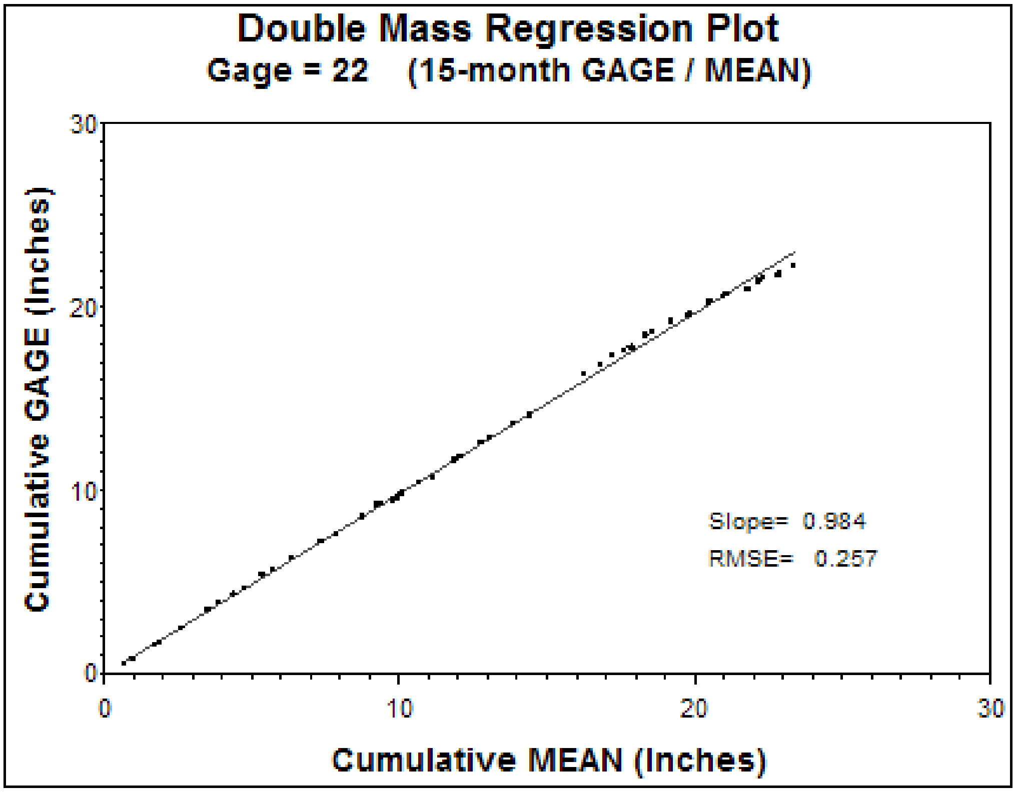

Figure v5-24 Double Mass Regression Plot of Cumulative Gage to Mean Daily Rainfall Totals at PWD Rain Gage 22 for the 15-Month Radar Study period

v5.2.3.3 Results

The overall spatial bias adjustment factors determined for each of the PWD rain gages is presented in column 8 of Table v5-10. PWD rain gage 14 is removed from the analysis because it lacks a sufficient number of daily measurements corresponding to the 15-month radar rainfall study period.

Inspection of column 3 in Table v5-10 reveals that across the network PWD rain gages 18 and 21 exhibit the greatest overall biases in raw gage data relative to the mean with overall biases of negative 8% and positive 9% respectively. These two rain gages are located among five PWD stations covering an approximately four square mile region of North West Philadelphia. This represents an average difference in rainfall between these two gages of approximately 15% over approximately a two mile distance.

The spatial distribution represented by radar rainfall data in column 10 of Table v5-10, however, reveals an average bias relative to the mean at gages 18 and 21 of positive and negative 3%, respectively. The spatial bias adjustment factors for PWD gages 18 and 21 are the greatest in the network. The final results of homogenization and spatial bias adjustment, given by the gage to mean double mass regression slopes presented in column 9 of Table v5-10, represent the long term average relative rainfall distribution across the region.

To better visualize the spatial distribution of rainfall represented by the final and intermediate results presented in Table v5-10, surface contour plots were generated using the DMRS for all rain gage locations relative to the network mean. The long term average distribution of rainfall over the Philadelphia area illustrated in Figure v5-25 is determined from the double mass linear regression slope, column 3 of Table v5-10, using all raw data for the 1990-2006 period of record.

Isometric contours lines are generated from this data using the kriging method of spatial interpolation provided by Surfer™ for Windows Notes V6 ©Golden Software Incorporated, 1993-97.

The average rainfall distribution relative to the network mean over the 15-month radar study period is presented in Figure v5-26 for raw, homogenized but not spatial bias adjusted, rain gage data. This figure reveals gage locations with significant long and short term differences in rainfall from nearby gages, as well as the regional average.

The final overall spatial bias adjustment factors for all homogenized PWD rain gage data over the 1990-2006 period of record are given in column 8 of Table v5-10 expressed as differences from the mean. These factors are graphically presented in Figure v5-27. Note that bias adjustment factors range from plus-to-minus seven percent.

The average relative distribution of rainfall observed from the radar rainfall data over the 15-month study period (Figure v5-28) compares favorably to that of the final adjusted PWD rain gage data determined over the 1990-2006 period of record (Figure v5-7).

v5.3 INVERSE DISTANCE SQUARED WEIGHTING AND BASIN AVERAGE RAINFALL CALCULATIONS

Much of the uncertainty in a carefully constructed hydrologic and hydraulic model is derived from uncertainty in the rainfall record. Therefore, increasing the level of detail of the rainfall input, both spatially and temporally, increases the accuracy and precision of the model results. Careful attention to rainfall collection and analysis is critical to the modeling effort.

The Runoff module of US EPA's Storm Water Management Model (SWMM) is used to simulate the hydrology of the separate and combined sewersheds in the service area. The service area is subdivided into a number of smaller sewersheds that each drain to a particular point in the collection system. Input data, including imperviousness, slope, and precipitation data, are entered for each sewershed. A rainfall value is required for each sewershed at each date and time for which a simulation will be run. These values must be derived from some combination of rain gage rainfall data and a method of estimating rainfall at points where no gages exist.

Bias adjusted 15-minute accumulated rainfall data for the PWD 24-raingage network are used for the weighting analysis. No filling of missing data is performed prior to the inverse-distance-square weighting. Bias adjustments are performed on the data as documented in Section v5.2.

There are a number of methods of estimating rainfall in areas between rainfall gages, including Thiesson polygons and inverse distance-squared weighting. An inverse distance-squared weighting procedure is chosen as described below.

A one-square-kilometer grid is imposed over the PWD service area, and the results of the weighting calculations are applied to this grid. Thus, each of the cells on the grid is assigned a rainfall value at each date and time. These grid values are later used to provide area-weighted average 15-minute rainfall values for each individual sewershed.

Manipulation of the rainfall data is performed by Statistical Analysis System (SAS) code. SAS is a high-level programming language that is particularly well suited to processing large amounts of data with relatively simple programming code. The algorithm includes five steps that apply to each date and time. These steps are listed and discussed in further detail below.

1. Read in gage rainfall data, areas, and coordinates
2. Populate the grid center points with rainfall values
3. Area-weight cell data to create a rainfall value for each sewershed
4. Output the results

Step 1: Read in raw data, areas, and coordinates.
Data input to the program include the following:

- Raw (bias-adjusted) rainfall data
- Results of GIS intersect between grid cells and sewersheds
- Rain gages assigned to each grid cell by earlier GIS analysis
- State plane coordinates of rain gage locations and grid cell centroids

Rain gages are assigned using the following logic:

- For grid cells other than those close to the edge of the service area, the three closest gages surrounding the cell are identified, forming a triangle that contains the grid cell centroid
- For some grid cells close to the edge of the service area, only two gages are assigned. For example, cell centroids contained in triangular polygon "010203" in Figure v5-29 are assigned gages 1, 2, and 3; cell centroids in irregular polygon "0102" are assigned gages 1 and 2
- Each assigned rain gage is assigned a backup gage to be used in cases where measurements at the primary gage do not pass quality assurance. In this case, data from the backup gage replace data from the primary gage. However, since the backup gage is further from the cell centroid, its data ultimately get a lower weight than data from the primary gage would have

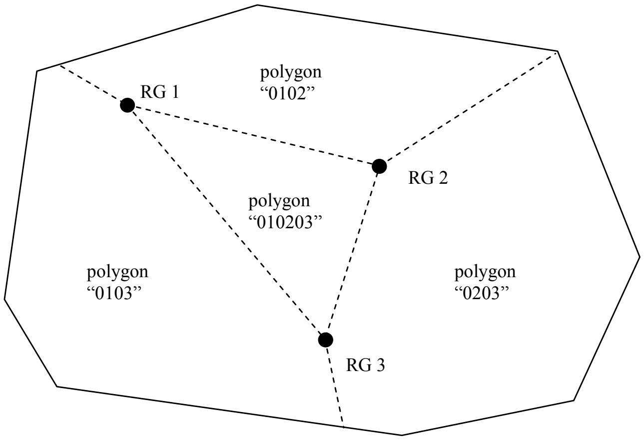

Figure v5-29 Schematic Diagram of Gauge Assignment Process

Step 2: Populate the grid center points with rainfall values.
After reading in the necessary data, the program uses it to populate the radar grid with rainfall values. Each point on the grid is assigned a value by inverse distance-squared weighting of 2 to 3 nearby rain gages. This process is depicted in Figure v5-30.

Rainfall for cell *j*, at a particular date and time, is given by the following equation:

$$P_j = \sum_{i=1}^{n} (f_{i,j} P_i)$$

Where P_j is the calculated precipitation at cell j,
j is the cell number,
i is the rain gage number,
n is the number of rain gages assigned to the cell (3 in the example),
$f_{i,j}$ is the rainfall weighting factor give by

$$f_{i,j} = \frac{(D_{i,j})^{-2}}{\sum_{i=1}^{n} (D_{i,j})^{-2}}$$

$D_{i,j}$ is the distance between gage i and cell j (by the Pythagorean Theorem), and P_i is the measured precipitation at rain gage i

Rules for missing data are as follows:

- A careful distinction is made between zero values and missing data due to quality control. Zero values are treated as zeros in the mathematical equations
- When a value is flagged as missing due to quality assurance, a value from a backup gage is substituted. If the backup gage data is also flagged, data assigned to the grid cell are based on data from the remaining 1-2 assigned gages, with backup gage values substituted as necessary. There were no instances in which none of the primary or secondary gages assigned had quality-assured data

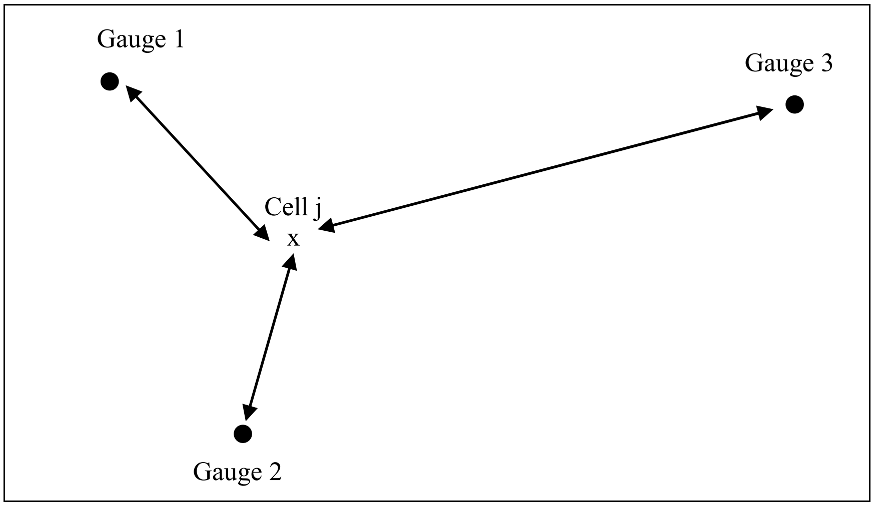

Figure v5-30 Conceptual Diagram Showing Gage Cell Assignments

Step 3: Area-weight cell data to create a rainfall value for each sewershed.
The final step in the calculations is the area-weighting of cell data to derive rainfall values for all sewersheds at all dates and times. This process is described by Figure v5-31.

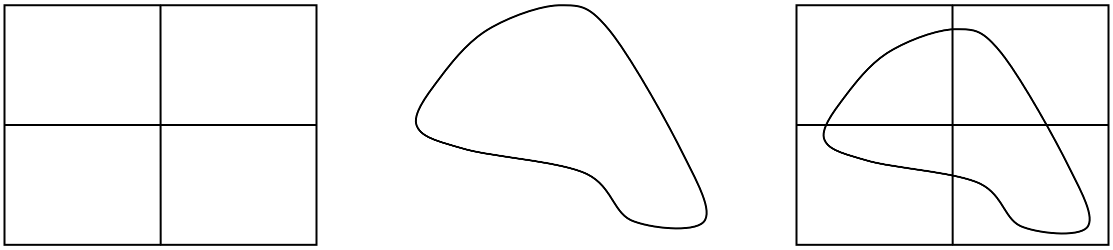

Figure v5-31 Conceptual Diagram of the Cell-Sewershed Relationship

At a given date and time, the precipitation for a sewershed is given by the following equation:

$$P_k = \sum_{j=1}^{n} \left(\frac{A_{j,k} P_j}{\sum_{j=1}^{n} A_{j,k}} \right)$$

Where P_k is the calculated rainfall for sewershed k,

j is the cell number,

n is the number of cells contained all or partially within sewershed k,

$A_{j,k}$ is the area of cell j within sewershed k, and

P_j is the calculated rainfall at cell j.

Step 4: Output the results.

The results of the calculations, consisting of rainfall at every sewershed, date, and time, are output in format that can readily be read by a SWMM model.

Quality assurance consists of verification of input parameters and verification of output with spreadsheet calculations. Scenarios for verification include some chosen at random and some chosen as special cases. Special cases include situations in which only one to two assigned gages provide usable data at a particular sewershed and time. Errors found through this process have been corrected, and it has been repeated until the project team has a high level of confidence that the results are accurate.

INTRODUCTION

1. Introduction

1.1 Project Objectives and Methodology

As part of its obligations under the Federal Clean Water Act and the Pennsylvania Clean Streams Law, the City of Philadelphia Water Department (PWD) has initiated a program with an objective to minimize the impact of combined sewer overflows (CSOs) on local receiving waters. One of the proposed strategies for reducing the CSO volume is to maximize flow to be treated by the water pollution control plants (WPCPs) during periods of wet weather. To implement this strategy effectively, the PWD needs to have a clear understanding of the factors that affect how much flow each of the three WPCPs can effectively treat. With this knowledge, the PWD will be able to identify and prioritize plant upgrades and other system modifications that will allow it to meet their CSO minimization objectives in the most environmentally-sound and cost-effective manner.

The PWD contracted CH2M HILL to conduct stress testing at the three wastewater treatment plants that are owned and operated by the City. The objective of the stress testing was to determine the reliable maximum capacity of the existing facilities and identify cost-effective methods of increasing the ability of these facilities to treat peak hydraulic flows associated with wet weather conditions. The major tasks performed during the project are briefly described below.

Historical Data and Operations Review. The objective of the historical data and operations review was to evaluate the physical condition, current loading, and treatment efficiency provided by the existing unit processes. A tour of the plant was conducted, and the process equipment and facilities were examined. Operating records, design information, and engineering drawings were studied to develop a strong understanding of the operations and constraints. Technical Memorandum 1 – Historical Data Review was produced to summarize the results of the site visit and historical data analysis.

Short-Term Stress Test. CH2M HILL performed a series of capacity and diagnostic tests to determine the loading versus performance characteristics of specific unit processes at each facility. The short-term stress testing focused on determining the response of the primary and secondary clarifiers to increased hydraulic loading under different operating conditions. The short-term stress testing at the Northeast WPCP (NEWPCP) included primary clarifier stress tests, secondary clarifier stress tests, secondary clarifier dye tests, and flow meter calibration. The results of each test are summarized in a test description report in Technical Memorandum 2 – Short-Term Test Results.

Long-Term Stress Test (Online Monitoring). Online monitoring equipment was installed to quantify the dynamic load/response characteristics of the secondary treatment system to naturally-occurring storm events. The equipment was also used to monitor the effect that increased flows had on the solids inventory in the system and the secondary effluent quality. Online monitoring included total plant flow, return activated sludge (RAS) flow, mixed liquor suspended solids (MLSS) concentration, sludge blanket levels, and secondary effluent total suspended solids (TSS) concentration. The equipment was in place from March

1 to June 30, 1999 and recorded data on a 10-minute interval. The results of the long-term stress test are summarized in Technical Memorandum 3 – Long-Term Online Monitoring Results. The detailed online monitoring data and instrument calibration records are provided under separate cover.

Hydraulic Throughput Capacity Assessment. WinHYDRO, a computer model that facilitates complex analysis of plant hydraulics, was used to evaluate the hydraulic throughput capacity of the Northeast WPCP. Hydraulic and energy grade lines from the headworks to the plant outfall were developed for the average and peak flow conditions. Hydraulic bottlenecks, which limit the hydraulic throughput capacity of the existing facilities, and flow distribution problems were identified and evaluated. The hydraulic throughput capacity of each unit process was determined. The results of the hydraulic modelling performed are summarized in Technical Memorandum 4 – Hydraulic Throughput Capacity of Existing Facilities.

Evaluation of Potential Improvements. Based upon results on stress testing and hydraulic modeling, major bottlenecks that limit plant capacity were identified and potential solutions developed to increase peak instantaneous capacity. Budgetary cost estimates were developed for each potential solution. The results of this analysis are summarized in Technical Memorandum 5 – Budgetary Cost Estimates for Potential Plant Improvements.

1.2 Report Organization

The project notebook consists of a final report and a series of attachments. The main body of the report contains a summary of the results from the stress testing, plant data analysis, and the evaluation of process improvements and upgrade options. The detailed results from the historical data review, short-term testing (stress tests, dye tests and flow meter calibration), online monitoring, and hydraulic throughput capacity assessment are included in the project notebook as attachments. Tables describing the design criteria, scope of work, estimated capital costs for the potential process modifications and capital upgrades, and the current National Pollution Discharge Elimination System (NPDES) discharge permit for the site are also included as attachments.

FIGURE 2-1
FLOW SCHEMATIC
NORTHEAST WPCP

CITY OF PHILADELPHIA WATER DEPARTMENT

2.1.1 Preliminary Treatment

The NEWPCP receives wastewater from the Frankford high-level sewer and the Frankford, Somerset, and Delaware low-level sewers. The Frankford high-level sewer flows by gravity through the high-level screens to preliminary treatment and provides approximately 28 percent of the raw sewage flow to the facility. The remaining 72 percent of the raw sewage flows via gravity through the low-level screens into the raw sewage pump station where it is pumped to detritor tanks. The low-level screens are susceptible to blinding during high loadings (autumn leaf litter) due largely to the long travel time of the single rake mechanism. A new screen, with multiple rakes, has been installed and is not performing satisfactorily.

There are six raw sewage pumps with a rated capacity of 85 mgd at 55 of feet head, each equipped with variable speed drive. The pump operation is manually controlled based on the level in the pump station wet well. The maximum water surface level (WSL) in Junction Chamber "A" (before overflows could occur in the collection system) is 18.5 ft. Operators control the raw sewage pump operations to ensure the pump wet well remains below this level. The level in Junction Chamber "A" is maintained between 8 to 10 feet with the influent gate in the fully open position. Either modifying the influent gate position or allowing the water surface level in Junction Chamber "A" to increase above 18.5 feet is considered a flow restriction or flow throttling action. Flow restriction or throttling incidences when the total flow is less than 420 mgd must be reported under the current NPDES requirements. THIS REPORTING MECHANISM IS TIED TO INFLUENT HGL NOT FLOW

The NEWPCP has four rectangular detritor grit removal tanks. Under certain flow conditions the WSL can back up into the grit tanks causing the tanks to overflow and recirculate back through the plant drain system. The hydraulic bottleneck is associated with the piping to the primary clarifiers and is discussed in more detail in Section 3.2.

2.1.2 Primary Treatment

There are two sets of primary clarifiers. The south (Set 2 or old) primary clarifiers consist of four 250 by 125 feet rectangular basins with a side wall depth of 10 feet. Each tank has seven chain and flight mechanisms that move the primary sludge to the influent end of the basin. The tank influent channel has openings at the bottom of the channel. A venturi meter located between the grit tanks and clarifiers measures flow to the south clarifiers. Due to a hydraulic restriction, the maximum flow to the south primary clarifiers is approximately 180 mgd.

The north (Set 1 or new) primary clarifiers consist of eight 240 by 65 feet rectangular basins with a side wall depth of 10 feet. Each tank has four chain and flight mechanisms that move the sludge to the influent end of the basin. There are four gates into each clarifier from the common influent channel located at the bottom of the influent channel. Two venturi meters located between the grit tanks and clarifiers measure flow to the north clarifiers. Due to a hydraulic restriction, the maximum flow to the north primary clarifiers is approximately 240 mgd.

420MGD
TO SECONDARY

2.1.3 Secondary Treatment

The NEWPCP has seven four-pass step-feed aeration basins. The original design of the facility was based on the SURFACT process that used a combination of suspended and attached growth by mounting a series of rotating biological contractor (RBC) units on top of each aeration basin. The RBCs are plagued with mechanical and operational problems and have been taken out of service.

The four-pass aeration basins can be operated in sludge re-aeration or step-feed mode. In addition, the NEWPCP has incorporated a selector zone at the beginning of B and C passes to improve the settling characteristics of the mixed liquor. The facility has been operating in re-aeration mode for several years. However, starting in mid-December 1998, the operations staff observed an increase in the final effluent five-day biochemical oxygen demand (BOD_5) concentration and a resultant decrease in the facility BOD_5 removal efficiency. The cause of the increased final BOD_5 was an inefficiency of the selector caused by an excessively high dissolved oxygen level in the zone. Modifications to the selector zone were made and the problem has been resolved.

The mixed liquor from the seven aeration basins flow into a common mixed liquor channel which feeds three sets of secondary clarifiers. The flow distribution between the sets of secondary clarifiers is not measured and therefore cannot be adequately controlled. There are a total of 16 rectangular secondary clarifiers. Each clarifier has chain and flight mechanisms that transport the sludge to a central hopper located at approximately the mid-length of the clarifier. The RAS rate is flow-paced and is currently operating at approximately 15 percent of the through flow based on the RAS flow meters output. Plant operations staff believe the existing RAS meters underestimate the RAS flow. Based on the measured ratio between the mixed liquor and RAS TSS concentration, the plant operations staff believe RAS is approximately 30 percent of the through flow.

Set 1 consists of eight 75 by 214 feet rectangular clarifiers, with a side wall depth of 11 feet and a common aerated influent (mixed liquor) channel. The flow distribution between the clarifiers in Set 1 is not measured and the operations staff suspects there are some hydraulic and solids loading imbalances between the eight clarifiers, with the downstream clarifiers receiving a larger portion of the overall flow.

Set 2 consists of eight 70 by 231 feet rectangular clarifiers, with a sidewall depth of 13 feet, and the set arranged into two banks of four clarifiers each. Each set of four clarifiers has a common non-aerated mixed liquor and a common final effluent channel. The common effluent channel for the Set 2 clarifiers is a hydraulic bottleneck and under high flow conditions the clarifier launders become flooded.

2.1.4 Disinfection

Disinfection is provided by chlorine solution injected at the upstream end of the chlorine contact chamber. Each basin provides a three-pass serpentine flow pattern and an overflow weir located at the end of the third-pass controls the WSL. The outfall conduits provide additional chlorine contact time for disinfection.

2.1.5 Solids Handling

The NEWPCP has twelve dissolved air floatation tanks (DAFs) to thicken the waste-activated sludge (WAS). The thickened sludge is pumped to the sludge-mixing chamber where it is combined with the primary sludge. The underflow from the DAF units is used as dilution water. Excess underflow is recycled to the head of the plant. Occasionally the DAF units are not able to float the WAS and the underflow from the DAF units has a very high solids concentration. Fortunately this does not occur very often.

The NEWPCP has eight anaerobic digesters with a total volume of 17.9 million gallons. The combined primary sludge and WAS is pumped to the anaerobic digesters sequentially. The digested solids are transported to the Biosolids Recycling Center for composting, beneficial reuse and landfilling.

2.2 Regulatory Requirements

The NEWPCP National Pollution Discharge Elimination System (NPDES) permit limits include effluent BOD_5 and TSS concentrations, mass discharges, and percent removal for daily, weekly (calendar), and monthly averages. Table 2.2 summarizes the NPDES permit criteria for the facility in effect during testing. Compliance is based on the flow measured by the three venturi flumes located upstream of the primary tanks and a 24-hour composite sample collected daily at the chlorine contact chamber outfall.

TABLE 2.2
NORTHEAST WPCP – NPDES PERMIT REQUIREMENTS

Parameter	Units	Monthly Average	Weekly Average	Maximum Day	Peak Instantaneous
BOD_5					
Concentration	mg/L	30	45	-	60
Mass Loading	lbs/day	42,000	63,600		
Percent Removal	%	86			
TSS					
Concentration	mg/L	30	45		60
Mass Lading	lbs/day	52,540	78,810	-	
Percent Removal	%	85			
Flow	mgd	210		315	420

PWD has negotiated a new NPDES permit for this facility effective July 2000. The modifications to the NPDES permit are summarized below. As part of PWD's long-term combined sewer overflow (CSO) control program, PWD will be reducing the frequency and volume of untreated sewage discharges through the CSOs. In order to account for the increased loading due to the combined sewage flows that exceed the treatment plant's rated hydraulic capacity, the following methods may be used for calculating and reporting mass loadings and effluent concentrations on the monthly discharge monitoring reports.

- If a calendar month includes one or more days where flow exceed 315 mgd, a value of 85 percent may be used for those days for the purpose of calculating average monthly TSS percent removal. The actual TSS percent removal associated with those days shall be reported on the appropriate space provided on the DMR.

- If a calendar month includes one or more days where flow exceed 315 mgd, a value of 86 percent may be used for those days for the purpose of calculating average monthly $cBOD_5$ percent removal. The actual $cBOD_5$ percent removal associated with those days shall be reported on the appropriate space provided on the DMR.
- When daily flows exceed 315 mgd, the average monthly and average weekly TSS and $cBOD_5$ mass loadings for those days may be calculated by using the lesser of the actual load or the permit's allowable average monthly and average weekly limit, respectively. The actual TSS and BOD_5 loadings associated with those days shall be reported on the appropriate space provided on the DMR.

PWD has requested that $cBOD_5$ data be used to establish compliance with permit requirements. Analysis of the data collected over the previous permit cycle indicated that there is relatively little variation in the $cBOD_5/BOD_5$ ratio in the plant influent. Therefore, calculating the theoretical $cBOD_5$ loading based on historical BOD_5 data can be used to develop $cBOD_5$ limits for the site. The suggested $cBOD_5$ permit requirements for NEWPCP are:

	Concentration mg/L	Mass Loading lbs/day	Percent Removal %
Average Monthly	25	36,430	86
Average Weekly	40	54,645	
Instantaneous Maximum	50		

A copy of the new NPDES is located in the project notebook.

2.3 Current Loading and Performance Achieved

2.3.1 Unit Process Loading

Table 2.3 presents a summary of the current unit process loading over a three-year period from July 1995 to July 1998. The average and maximum daily flows were 199 mgd and 380 mgd, respectively. The maximum instantaneous flow was 430 mgd.

On September 16, 1999, the total plant flow was greater than 315 mgd from 4:30 a.m. to 10:00 a.m. the following morning. The peak flow was greater than 420 mgd for approximately 13 hours over that timeframe. The water surface level in Junction Chamber "A" was greater than 12 feet starting at 7:00 a.m. on September 16. However, the influent sluice gate was not throttled to restrict the flow to the plant.

TABLE 2.3

Notes:
[1] Maximum hydraulic loading based on instantaneous flow
[2] Maximum loading based on 95th percentile
[3] Based on all units in service
[4] Based on through flow only
[5] Based on RAS flow rated of 34 percent
[6] Including volume of outfall

The average raw sewage TSS and BOD_5 concentrations are 177 mg/L and 133 mg/L, respectively. The average organic loading to the treatment plant, calculated based on the raw sewage TSS and BOD_5 concentrations and the average flow for each day was 291,855 lbs/day and 217,282 lbs/day, respectively.

2.3.2 Primary Treatment Performance

The average and peak surface overflow rates (SORs) for the primary clarifiers were approximately 800 gpd/ft^2 and 1,700 gpd/ft^2, respectively. Typical overflow rates for rectangular clarifiers are between 1,000 gpd/ft^2 to 3,000 gpd/ft^2. The primary clarifiers at the NEWPCP are operating below their expected capacity based on typical surface overflow rates.

The removal efficiencies are slightly lower than expected considering the low hydraulic loading. The average TSS removal efficiency in the primary clarifiers was 61 percent and 63 percent, respectively for Sets 1 and 2. The Set 2 clarifiers performed slightly better than the Set 1 clarifiers given the hydraulic loading on Set 1 clarifiers was higher due to the hydraulic restriction between the Set 1 clarifiers and the preliminary treatment building. This difference in performance can be attributed to this hydraulic restriction. The BOD_5 removal efficiency in the primary clarifiers was 37 percent and 40 percent, respectively for Sets 1 and 2.

2.3.3 Secondary Treatment Performance

The average primary effluent TSS and BOD_5 concentrations were 87 mg/L and 96 mg/L, respectively. The average and 95th percentile total BOD_5 loadings to the secondary treatment system, calculated based on the primary effluent BOD_5 concentration and the average flow for each day were 142,600 lbs/day and 180,825 lbs/day, respectively.

The aeration basins are currently operating with a solids residence time (SRT) of 1.9 days. The food to microorganisms (F:M) ratio in the aeration basins averaged 0.82 day^{-1}. The F:M is slightly lower in the late summer/early fall due to a higher mixed liquor suspended solids (MLSS) concentration over this period. The average sludge volume index (SVI) between January 1998 and January 1999 was 99 mL/g. This is low for an activated sludge plant, indicating there are few filamentous organisms in the biomass. Operations created a selector zone in the beginning of B and C passes by controlling the air supply. The target SVI during the transition was 80 to 100 mL/g. Typically, the mixed liquor values for a well-settled activated sludge are between 100 mL/g and 150 mL/g. The aeration basin selector reduces the number of filamentous organisms in the mixed liquor and thereby improves the settling characteristics of the sludge. Operational staff reported that the effluent has been turbid in the winter months because of the absence of the "sweeping action" associated with filaments. Improvements to the selector zone being operated has not resulted in a reoccurrence of these turbid events. Current SVI's range from 80 to 100 mL/g.

Using average values, a mass balance around the secondary clarifiers was performed to check the reliability of the solids inventory data. The measured RAS flow was approximately 15 percent of the total plant flow. The error difference between the measured solids in, and the measured solids out of the secondary clarifier was approximately 194 percent. The expected level of accuracy for this type of analysis is +/- 10 percent. Based on the mass balance calculation, the RAS flow is approximately 34 percent of the flow into the aeration basin.

The average and peak SORs for the secondary clarifiers were approximately 770 gpd/ft^2 and 1,660 gpd/ft^2, respectively. Typical SORs for rectangular Gould-type clarifiers are between 800 gpd/ft^2 to 1,500 gpd/ft^2. The secondary clarifiers at the NEWPCP are operating at or beyond the expected maximum hydraulic capacity based on typical SORs.

The average and peak solids loading rates (SLRs) for the secondary clarifiers were approximately 9 lbs/day/ft^2 and 20 lbs/day/ft^2 based on RAS flows of 34 percent (result of mass balance calculation). Typical peak SLRs for rectangular Gould-type clarifiers are between 20 lbs/day/ft^2 and 40 lbs/day/ft^2. The secondary clarifiers at the NEWPCP are operating below the expected maximum hydraulic capacity based on typical solids loading rates.

The secondary clarifiers at the NEWPCP achieve a very good quality final effluent even though the hydraulic loading rates are close to the expected maximum capacity. The daily TSS and BOD$_5$ concentrations were below the NPDES criteria of 60 mg/L except for one day in October 1995 and three days in January 1996 when the TSS concentrations exceeded the discharge limit. Based on a 30-day running average, the final effluent TSS load to the receiving water and percent removal did not exceed the NPDES criteria of 52,540 lbs/day and 85 percent removal. However, the BOD$_5$ load to the receiving water and percent removal did exceed the NPDES criteria on one occasion in January 1996. The NPDES permit is based on the calendar month.

SECTION 3

CURRENT CAPACITY

3. Current Capacity

3.1 Treatment Capacity

The reliable treatment capacity of the unit processes at the NEWPCP was estimated using a combination of manufacturers information, standard engineering design loading and performance criteria, operations staff observations of previous performance, and field testing of specific unit processes.

The field testing conducted at the NEWPCP included the following:

Online Monitoring Data

- Secondary clarifier 7
- Plant flow, RAS flow, mixed liquor TSS, sludge blanket level, and effluent TSS from March 1 to June 30, 1999

Primary Clarifier Stress Tests

- Primary clarifier 12 – Set 2 clarifiers
- Primary clarifier 1 – Set 1 clarifiers normal sludge pumping operation
- Primary clarifier 1 – increased sludge pumping

Secondary Clarifier Stress Tests

- Secondary clarifier 2 – current mixed liquor concentration (approximately 1,000 mg/L)
- Secondary clarifier 2 – increased mixed liquor concentration (approximately 2,000 mg/L)

Secondary Clarifier Dye Tests

- Secondary clarifier 2 – Set 1 clarifiers
- Secondary clarifier 12 – Set 2 clarifiers
- Secondary clarifier 15 – installed longitudinal baffle and sludge hopper hat
- Secondary clarifier 16 – installed longitudinal baffle

Table 3.1 summarizes the estimated treatment capacity for each unit. The basis of the estimated capacity is discussed below. The detailed field test results are presented in Technical Memorandum 2 – Short-Term Test Results and Technical Memorandum 3 – Long-Term Online Monitoring Results.

TABLE 3.1
NORTHEAST WWTP TREATMENT CAPACITY ASSESSMENT

Unit Process	Estimated Capacity (mgd)	Criteria
Pumping and Screening	500 mgd – screening and raw sewage pumping capacity	
	Low-level interceptor[1] – 375 mgd	Observed capacity of pumps
	High-level interceptor – 125 mgd	Observed maximum flow
Grit Removal	525 mgd – grit removal [2]	SOR – 58,000 gpd/ft^2
Primary Treatment	460 mgd – existing	Based on allowable SOR
	505 mgd – modified inlet baffle	SOR – 2,500 gpd/ft^2
	567 mgd – improved sludge pumping	SOR – 2,800 gpd/ft^2
	710 mgd – potential	SOR – 3,500 gpd/ft^2
	Set 1[3] – 273 mgd (existing)	2,500 gpd/ft^2 – test results
	Set 2[3] – 187 mgd (existing)	2,000 gpd/ft^2 – test results
	Set 2 – 235 mgd (modified inlet baffle)	2,500 gpd/ft^2 – test results
Aeration Basins	N/A – no change to organic loading patterns	
Secondary Clarifiers	270 – 380 mgd – existing condition	Long-term monitoring results
	440 mgd – improved flow/solids distribution between clarifiers	Based on allowable SOR – 1,800 gpd/ft^2
	322 mgd – mixed liquor concentration 2,000 mg/L	Based on allowable SLR – 30 lbs/day/ft^2
Chlorine Contact Chamber	430 mgd – meeting disinfection requirements at current flows	
	800 mgd – volume of chlorine basin and plant outfall	HRT – 15 minutes

[1] Based on one pump and one screen out of service
Rated capacity of raw sewage pumps – 85 mgd at 55 feet TDH, Observed maximum capacity 75 mgd
Channel velocity of screens – 0.41 ft/s at 5 ft channel depth

[2] Based on removal of 60 mesh (0.25 mm) particles

[3] Based on one clarifier out of service

3.1.1 Preliminary Treatment

The estimated treatment capacity of the preliminary treatment system is 500 mgd. This is based on the observed capacity of 75 mgd of the existing pumps with five of the six pumps in service, plus an estimated capacity of 125 mgd for the Frankford high-level sewer. For peak flow conditions, the face velocity for the bar screens will vary from 0.2 ft/s to 0.4 ft/s. The face velocity is determined by the pump wet well level that controls the water depth through the bar screen channel.

The estimated treatment capacity of the grit removal tanks is 525 mgd. This is based on three of the four grit detritors being in service, with an allowable SOR of 58,000 gpd/ft^2. The expected removal efficiency of the grit removal system under peak flow conditions is 90 percent of particles greater than 60 mesh (25 mm).

3.1.2 Primary Treatment

Six primary stress tests were conducted at the three wastewater treatment plants owned and operated by the PWD. Table 3.2 summarizes the physical characteristics of the clarifiers at each site and the stress tests performed. The primary clarifiers at all three plants are hydraulically similar. Differences in behaviour are the result of differences in influent characteristics and minor differences in influent and effluent structures.

Three stress tests were performed on the primary clarifiers at NEWPCP. Figure 3-1 presents the measured TSS removal efficiency as a function of the SOR observed during the three stress tests. The test procedures and detailed results are described in Technical Memorandum 2; the main findings are summarized below.

Set 2 Primary Clarifiers. The stress test on primary clarifier 12 indicated that the clarifier performance began to deteriorate at a SOR of 2,000 gpd/ft^2, with an increase in effluent suspended solids and removal efficiency of less than 60 percent. At a SOR of 2,400 gpd/ft^2, the solids in the cross-collection channel were re-suspended, resulting in a short-term catastrophic failure of the clarifier. Clouds of black solids were observed in the influent end of the clarifier and the primary effluent TSS concentrations were greater than 100 mg/L for approximately 45 minutes. Catastrophic failure occurred again at a SOR of 2,700 gpd/ft^2. The sludge blanket in the clarifier rose throughout the test.

Set 1 Primary Clarifiers. The stress test on primary clarifier 1 indicated that the clarifier performance began to deteriorate at a SOR of 2,500 gpd/ft^2, with a TSS removal efficiency of less than 50 percent. The sludge blanket in the clarifier remained relatively constant through the test, rising slightly at the effluent end of the clarifier at the end of the test period. The re-suspension of solids from the cross-collection channel was not observed during this test. A second stress test on primary clarifier 1 was performed to quantify the improvement that could be achieved by increasing the primary sludge removal rate. The primary sludge pumps were operated for five out of every 20 minutes to simulate an underflow rate of 250 gpm for the test period. The TSS removal efficiency improved at all SORs tested. The removal efficiency was greater than 60 percent for a SOR of up to 2,800 gpd/ft^2. The clarifier performance deteriorated significantly at a SOR of 3,200 gpd/ft^2. The sludge blanket level remained below one foot throughout the test.

The estimated treatment capacity of the primary clarifiers is 460 mgd. This is based on two clarifiers being out of service (one clarifier in each set) and an allowable SOR of 2,500 gpd/ft^2 and 2,000 gpd/ft^2 for the Set 1 and Set 2 clarifiers, respectively. Modifications to the Set 2 clarifier inlet openings to direct the flow upward and away from the influent sludge hopper would result in an increase in primary treatment capacity of 505 mgd. Increasing the primary sludge pumping rate from the clarifiers would increase the primary treatment capacity to over 550 mgd. The primary stress test at SWWPCP indicated that these clarifiers are able to achieve 60 percent TSS removal efficiency at a SOR of 3,500 gpd/ft^2 with modifications to the inlet structures and improved solids removal. The potential maximum capacity of the primary clarifiers at the NEWPCP is 710 mgd with two clarifiers out of service based on an allowable SOR of 3,500 gpd/ft^2.

3.1.3 Secondary Treatment

Six secondary clarifier stress tests were conducted at the three wastewater treatment plants owned and operated by the PWD. Table 3.3 summarises the physical characteristics of the clarifiers at each site and the secondary clarifier stress tests performed. The secondary clarifiers at all three plants are very similar and performed similarly. Differences in performance were largely the result of differences in mixed liquor settling characteristics and solids loading during the tests.

Test performed				
Stress test	2	1	0	3
Target SOR (range) gpd/ft^2	860-2,000	600-2,100		1,000-2,100
Dye tests	1	0	3	1

Three stress tests were performed on the Set 1 secondary clarifiers. The test procedures and results are described in Technical Memorandum 2; the main findings are summarized below. Stress tests were not performed on the Set 2 clarifiers because of the difficulty in measuring flow to the test tank.

Four dye tests were performed on the secondary clarifiers. The dye tests included secondary clarifier 2 (Set 1), secondary clarifier 12 (Set 2), secondary clarifier 15 (with longitudinal baffle), and secondary clarifier 16 (longitudinal baffle plus sludge hopper hat). The test procedures and results are described in Technical Memorandum 2; the main findings are summarized below.

The performance of the secondary clarifier 7 was monitored over a four-month period using online instrumentation to quantify the dynamic performance of the clarifiers to naturally-occurring storm events. The online instrumentation recorded total plant flow, set 1 RAS flow, mixed liquor TSS concentration, sludge blanket levels, and effluent TSS concentration. The results of the online monitoring are summarized below; more detailed results are presented in Technical Memorandum 3.

Stress Test Results. Three stress tests were conducted on secondary clarifier 2. Figure 3-2 presents the effluent TSS concentration as a function of the SOR. The first test was conducted in the summer at current mixed liquor concentration. The second and third stress tests were conducted in September at current and elevated mixed liquor concentrations. The mixed liquor concentration of the Set 1 clarifiers was increased by modifying the RAS distribution to the aeration basins. Aeration basins 6 and 7 preferentially feed the Set 1 secondary clarifiers.

The stress tests conducted at current mixed liquor concentrations (Tests 1 and 2) indicated that the clarifier performance began to deteriorate at a SOR of 1,800 gpd/ft^2. The effluent TSS concentration remained below 25 mg/L throughout the test and catastrophic failure of the clarifier was not observed. The mixed liquor concentration and SVI during test 1 was 890 mg/L and 151 mL/g. The mixed liquor concentration and SVI during Test 2 were 970 mg/L and 103 mL/g, respectively. The clarifier performed slightly better during the second test. The SVI range corresponds to the range normally experienced at the facility. The mixed liquor concentrations were approximately 20 percent lower than the average mixed liquor for the facility.

The stress tests conducted at elevated mixed liquor concentrations (Test 3) indicated that the clarifier deteriorates rapidly at a SOR of 1,600 gpd/ft^2. Catastrophic failure of the clarifier was observed and the sludge blanket increased under the effluent launders and started to washout. The failure mechanism was a solids-flux-type failure and the test was terminated once failure was achieved. The mixed liquor concentration and SVI during Test 1 were 1,930 mg/L and 95 mL/g. The mixed liquor concentration was approximately 70 percent higher than the average mixed liquor for the facility.

Figure 3-3 presents the effluent TSS concentration as a function of solids loading rate (SLR) for the three stress tests conducted. The secondary clarifier failed at a SLR of approximately 30 lb/ft^2 per day. The estimated capacity of the secondary clarifiers will decrease with increasing mixed liquor concentrations.

Dye Test Results. Dye tests were used to evaluate the hydraulic efficiency of the secondary clarifiers. Four clarifier dye tests were performed; one dye test for each clarifier type and baffling configuration used at the facility. The test results from clarifiers 2 and 12 indicated that the hydraulic characteristics of the Set 1 and Set 2 clarifiers are very similar. The stress test results from clarifier 2 can be used to estimate the performance of the Set 2 clarifiers.

The test results from clarifiers 15 and 16 indicated that the longitudinal baffle does not improve the hydraulic characteristics of the clarifier. A more pronounced sludge density current was observed in the baffled clarifiers than in the unbaffled clarifiers.

Online Monitoring Results. The online monitoring recorded the response of secondary clarifier 7 to six storm events. Table 3.4 summarizes results of the online monitoring program. The secondary clarifier TSS concentration exceeded 60 mg/L for short periods of time during each storm. The effluent TSS concentration rose significantly at plant flow rates between 270 mgd to 380 mgd. The maximum SOR based on total plant flow and number of clarifiers in service during the storm events ranged from 1,310 gpd/ft^2 to 1,700 gpd/ft^2. This is significantly lower than the maximum allowable SOR observed during the secondary clarifier stress test. The difference between the stress test and long-term monitoring results indicates a significant imbalance in the flow and solids distribution between the secondary clarifiers.

TABLE 3.4

3.2 Hydraulic Throughput Capacity

The hydraulic throughput capacity of the unit processes at the NEWPCP was estimated using WinHYDRO, a computer model that facilitates complex analysis of plant hydraulics. Hydraulic and energy gradelines from the headworks to the plant outfall were developed for a number of flow rates. The hydraulic throughput capacity of each unit process was developed based on the assumption that the downstream hydraulic bottlenecks had been resolved. Table 3.3 summarizes the estimated hydraulic throughput capacity for each unit process. The detailed hydraulic modelling results are presented in Technical Memorandum 4 – Hydraulic Throughput Capacity of Existing Facilities.

TABLE 3.3
NORTHEAST WWTP CURRENT HYDRAULIC THROUGHPUT CAPACITY

Unit Process	Estimated Capacity (mgd)	Basis of Capacity Estimate
Chlorine Contact Basin	>800	• Flow path – from the chlorine contact basin weir to the chlorine contact flow distribution chamber • Hydraulic control section – chlorine contact chamber weir • Both chlorine contact basins in service with the flow control gates fully open • Hydraulic exceedance – secondary clarifier overflow weir elevation
Secondary Effluent Channel – Set 1	300	• Flow path – from the chlorine contact basin weir to the secondary clarifier 1 overflow weir • Hydraulic control section – chlorine contact chamber weir • Both chlorine contact basins in service with the flow control gates fully open, 50/50 flow split between Set 1 and Set 2 secondary clarifiers; all secondary clarifiers in service • Hydraulic exceedance – secondary clarifier overflow weir elevation
Secondary Effluent Channel – Set 2	190	• Flow path – from the chlorine contact basin weir to the secondary clarifier 9 through 16 overflow weir • Hydraulic control section – chlorine contact chamber weir • Both chlorine contact basins in service with the flow control gates fully open, 50/50 flow split between Set 1 and Set 2 secondary clarifiers; all secondary clarifiers in service • Hydraulic exceedance – secondary clarifier overflow weir elevation
Primary Effluent Channel – Set 1	330	• Flow path – from the secondary clarifier overflow weir to the primary clarifier 1 overflow weir • Hydraulic control section – secondary clarifier overflow weir • A 50/50 flow split between Set 1 and Set 2 secondary clarifiers, 50/50 flow split between Set 1 and Set 2 primary clarifiers; six aeration basins in service • Hydraulic exceedance – primary secondary clarifier overflow weir elevation
Primary Effluent Channel – Set 2	250	• Flow path – from the secondary clarifier overflow weir to the primary clarifier 12 overflow weir • Hydraulic control section – secondary clarifier overflow weir • A 50/50 flow split between Set 1 and Set 2 secondary clarifiers, 50/50 flow split between Set 1 and Set 2 primary clarifiers: six aeration basins in service • Hydraulic exceedance – primary clarifier overflow weir elevation
Primary Clarifier – Set 1	250	• Flow path – from the primary clarifier overflow weir to the grit chamber collection channel • Hydraulic control section – primary clarifier overflow weir • All primary clarifiers in Set 1 in service, four detritors in service • Hydraulic exceedance – top of concrete in the grit removal building

TABLE 3.3
NORTHEAST WWTP CURRENT HYDRAULIC THROUGHPUT CAPACITY

Unit Process	Estimated Capacity (mgd)	Basis of Capacity Estimate
Primary Clarifier – Set 2	180	• Flow path – from the primary clarifier overflow weir to the grit chamber collection channel • Hydraulic control section – primary clarifier overflow weir • All primary clarifiers in service, four detritors in service, butterfly gate valve in the fully open position • Hydraulic exceedance – top of concrete in the grit removal building
Raw Sewage Pump Station Discharge Channel	Version A – 410 Version B – 440	• Flow path – from the Set 1 primary clarifier overflow weirs to the raw sewage pump station discharge channel • Hydraulic control section – primary clarifier Set 1 overflow weir • Version A – flow to Set 2 clarifiers limited to 180 mgd Version B – 50/50 flow split between Set 1 and Set 2 clarifiers • Hydraulic exceedance – top of concrete in the raw sewage pump station

The hydraulic throughput capacity of the NEWPCP is greater than 500 mgd except in the following locations:

- **Primary Clarifier Influent** – The hydraulic throughput capacity of the channel between the preliminary treatment building (grit tanks) and primary clarifiers set 2 is limited to 180 mgd. The headlosses occur in the 5 ft by 7 ft channel section between the set 2 flume (venturi meter) and the primary clarifier influent channel. The hydraulic throughput capacity of the channels between the preliminary treatment building (grit tanks) and the primary clarifiers set 1 is limited to 250 mgd. Therefore, the total hydraulic throughput capacity between the preliminary treatment and primary treatment is 430 mgd. At flow rates above 430 mgd the detritor floor and walkways become flooded. Additionally, at times, the detritor floor has flooded at flows less than 430 mgd for unknown reasons.

- **Secondary Clarifier Set 2 Effluent Channels** – The hydraulic throughput capacity of the set 2 secondary effluent channel is limited to 190 mgd with all secondary clarifiers in service. Excessive headlosses occur in the clarifier discharge channel and common effluent channel due to entrained air escaping through the bottom slots which connect the upper and lower channel sections. The hydraulic restriction contributes to the hydraulic imbalance between the set 1 and set 2 secondary clarifiers. The hydraulic restriction also contributes to flooding of the set 2 secondary clarifier weirs and premature failure of the clarifiers due to localized velocity gradients at the effluent weir.

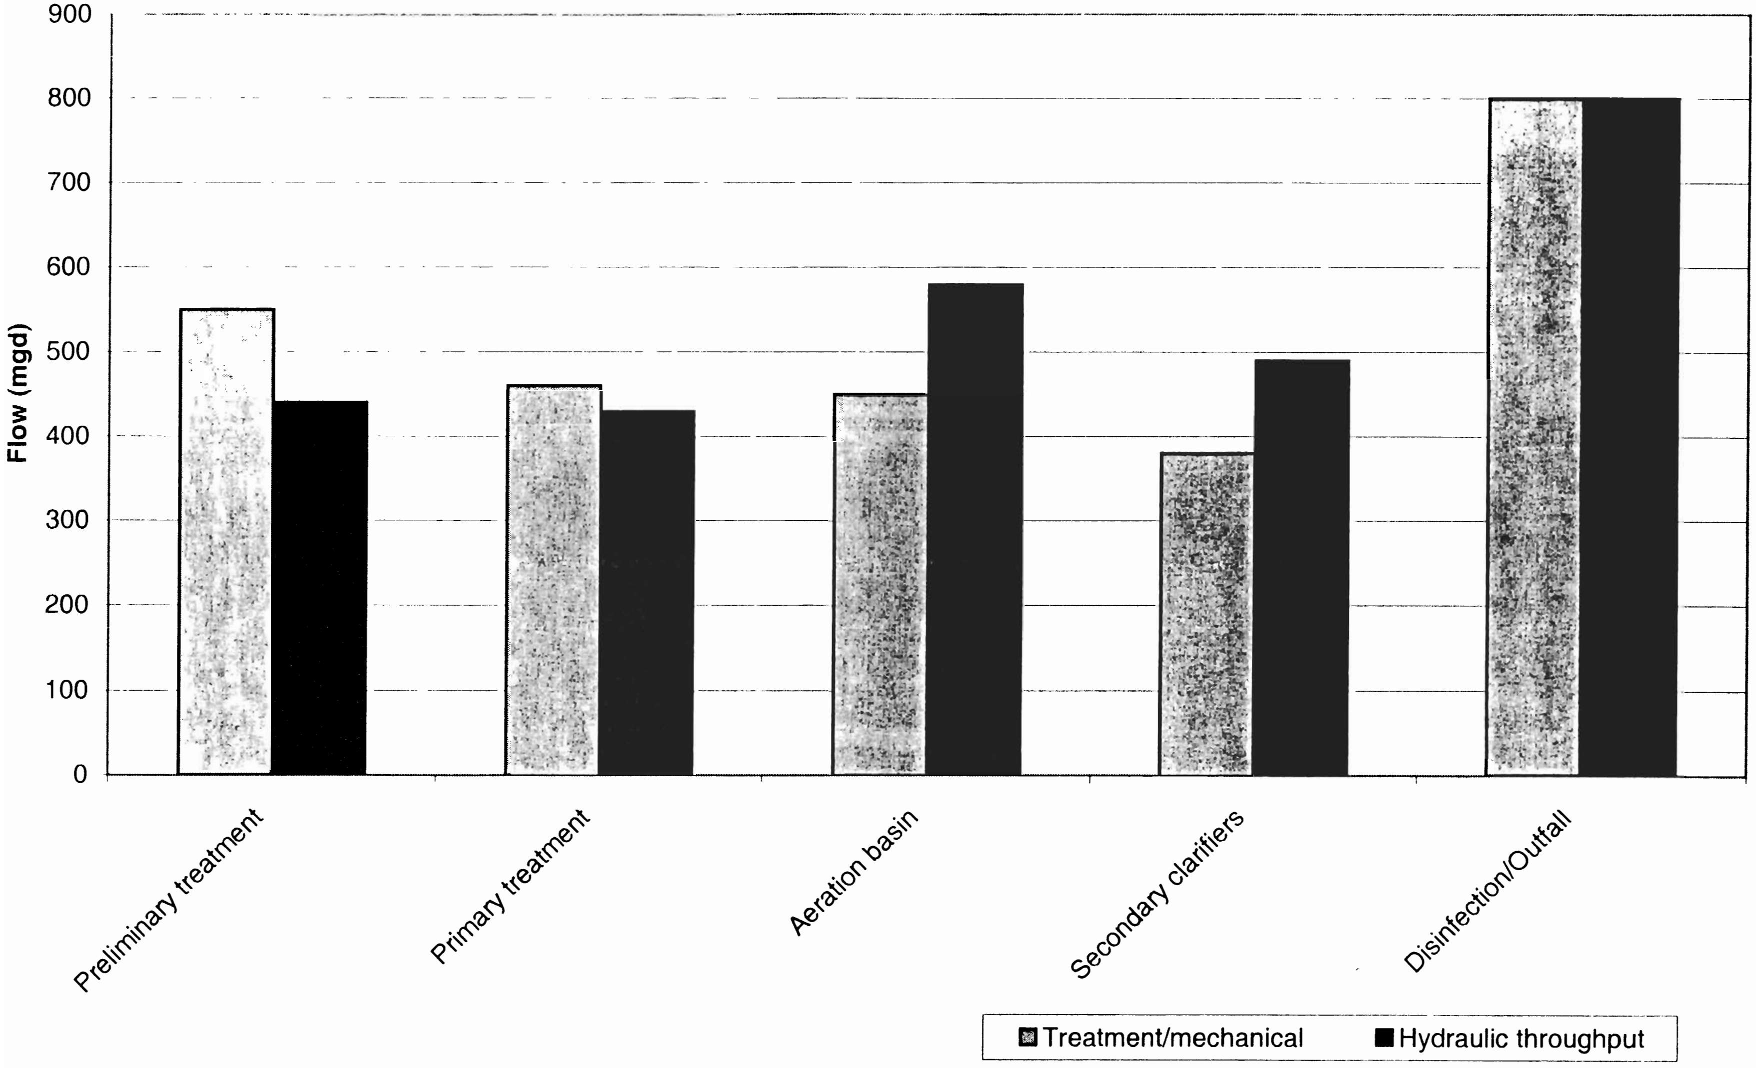
3.3 Capacity Limiting Factors

Figure 3-4 presents a summary of the estimated current capacity on a unit process basis for NEWPCP. The major capacity bottlenecks for the facility are:

- **Secondary Clarifiers** – The treatment capacity of the secondary clarifiers at the NEWPCP is reduced by the difficulties in controlling the hydraulic distribution between the set 1 and set 2 clarifiers and the hydraulic and solids loading between the clarifiers in each set.

- **Primary Clarifiers** – The hydraulic throughput capacity to the primary clarifiers limits the hydraulic throughput of the facility to 430 mgd. The hydraulic restriction between the set 2 primary clarifiers and the preliminary treatment building has a negative impact on the flow distribution between set 1 and set 2 primary clarifiers.
- **Primary Treatment** – The treatment capacity of the set 2 primary clarifiers is limited to 185 mgd due to high velocities caused by the inlet baffle resuspending solids in the clarifier cross collector channel.

Figure 3-4
Northeast WPCP - Estimated Current Capacity



SECTION 4

CURRENT SUSTAINABLE TREATMENT CAPACITY

4. Current Sustainable Treatment Capacity

4.1 Sustainable Treatment

The estimated treatment capacities summarized in section 3 of this report utilise maximum instantaneous limits currently in PWD's NPDES permits as the goal for the effluent quality. Since the maximum instantaneous and maximum daily limits are the same values, a process operation whose final effluent quality will meet the instantaneous maximum limits will also meet the daily maximum limits. However the current NPDES permits, based on expected performance for plants that intake substantial quantities of storm water, include maximum weekly and monthly limits which are significantly more stringent than the daily/instantaneous limits. Furthermore, strict compliance with maximum monthly concentration limits will not guarantee monthly compliance with other quality limits in the permit such as average monthly and weekly loading limits and percent removal requirements.

An important but difficult question remains regarding how long a facility (or process) can sustain high flows which allow effluent quality to meet all the permit effluent quality requirements.

The performance of the secondary clarifiers determines the final effluent quality from the NEWPCP. The data collected during the field-testing was used to predict final effluent quality as a function of flow rate. The predicted final effluent TSS and BOD_5 concentration for a given flow rate was used to determine the maximum flow which could be maintained for an infinite period of time with effluent quality meeting the monthly and weekly loading and percent removal requirements in the NPDES permit.

Secondary clarifier capacity is defined by either the clarification capacity, which is a function of surface overflow rate (SOR), or the solids flux capacity which is a function of solids loading rate (SLR). Clarifier performance as a function of both SOR and SLR was collected during the testing for a range of operating conditions. Data from the six secondary clarifier stress test was used to quantify the secondary clarifier performance as a function of hydraulic loading and to identify the maximum allowable solids loading rate for the clarifiers.

The historical data was used to determine the yield and mixed liquor concentrations required as a function of primary effluent quality. The data from the primary clarifier stress tests was used to determine the expected primary effluent quality as a function of flow rate. The mixer liquor required for the expected primary effluent quality determines the solids loading rate for the secondary clarifier.

4.2 Analysis Methodology

4.2.1 Predicting Secondary Effluent Quality as a Function of the SOR

In the stress tests of the secondary clarifiers, the TSS and BOD_5 concentrations in the secondary effluent were measured as a function of the surface overflow rate applied to the clarifiers. A linear regression was performed on the field testing data to establish the relationship between SOR and TSS and BOD_5 concentrations in the effluent. The intercept and slope values obtained for the regression were statistically analyzed to find the 95% confidence level associated with these two coefficients. Using the upper 95% confidence level interval provides a conservative description of the relationship between the SOR and effluent quality. The model is used to predict TSS or BOD_5 for a given SOR, the value generated using the linear regression will be lower than the actual value observed 95 out of 100 times.

The estimated effluent concentrations and discharge loads (which are equal to the effluent flow rate multiplied by the effluent concentration) can then be compared to permit levels to determine the sustainable treatment capacity of the facility on a SOR basis.

4.2.2 Effect of the SLR on Secondary Clarifier Performance

Failure of the secondary clarifiers may occur either due to clarification or thickening. An increase in the hydraulic loading to the primary clarifiers will result in an increase in organic loading to the aeration basin due to an increase in the amount of organic material entering the plant and deterioration in the primary clarifier performance. An increase in the organic loading to the aeration tanks results in an increase in the mixed liquor concentrations and therefore an increase in he solids loading for a given flow. Therefore the analysis done in terms of the SOR must be complemented with an analysis of the effect of influent flow rate versus SLR.

Stress tests were performed on the primary clarifiers and removal efficiencies as a function of the surface overflow rate in the primary clarifiers were documented. The data was used to predict the quality of the primary effluent as a function of the influent flow rate. This analysis, combined with analysis of historical data on solids production, was used to estimate the SLR as a function of flow, taking into account both the performance of the primary clarifiers and the increase in the organic loading associated with augmented flows.

The stress tests on the secondary clarifiers indicated that the maximum SLR that could be maintained before thickening failure occurs is 35 lb/(ft^2.day). The flow at which these solids loading rates are achieved are the maximum sustained flow that can be maintained in the plant before thickening failure occurs.

4.3 Analysis Results

4.3.1 Predicting Maximum Flows as a Function of the SOR

Figure 4.1 is a plot of the TSS in the secondary effluent and the SOR applied in the secondary clarifier from the six secondary clarifier stress tests conducted at the facilities owned and operated by PWD. The data from all six secondary clarifier stress tests were used in the preparation of this plot. Figure 4.2 presents the same analysis was done for the BOD_5 concentration in the secondary effluent.

The amount of TSS and BOD_5 discharged results from the product of the flow rate and the concentrations predicted by the 95% confidence level regressions. The discharge values were compared to the NPDES Permit values at the time of the test for the NEWPCP. The results of this analysis are presented in Table 4.1.

TABLE 4.1 NORTHEAST WPCP – TEST PERIOD NPDES PERMIT REQUIREMENTS AND RESULTS OF THE SUSTAINABLE FLOW ANALYSIS[1]

Parameter	Units	NPDES Limit	Maximum Sustainable Flow based on SOR		Maximum Sustainable Flow based on SLR
			TSS Limit	BOD5 Limit	
Maximum Day Limits	Mgd	420			375
Maximum Week Limits	Mgd		320	305	
BOD_5 Concentration	mg/L	45			
BOD5 Mass Loading	lbs/day	63,600			
TSS Concentration	mg/L	45			
TSS Mass Loading	lbs/day	78,810			
Maximum Monthly Limits	Mgd	210	260	235	
BOD_5 Concentration	mg/L	30			
BOD_5 Mass Loading	lbs/day	42,000			
BOD_5 Percent Removal	%	86			
TSS Concentration	mg/L	30			
TSS Mass Loading	lbs/day	52,540			
TSS Percent Removal	%	85			

[1] BOD_5 limits based on old permit, plant now monitors $cBOD_5$ for compliance.

The maximum sustainable flow at which the NEWPCP can meet the monthly NPDES TSS and BOD_5 effluent mass loading requirements are 260 and 235 mgd respectively. The maximum month sustainable capacities are slightly higher than the average design capacity of the facility.

Figure 4-1
Secondary Clarifier Stress Test - Effluent TSS Concentration as a Function of SOR

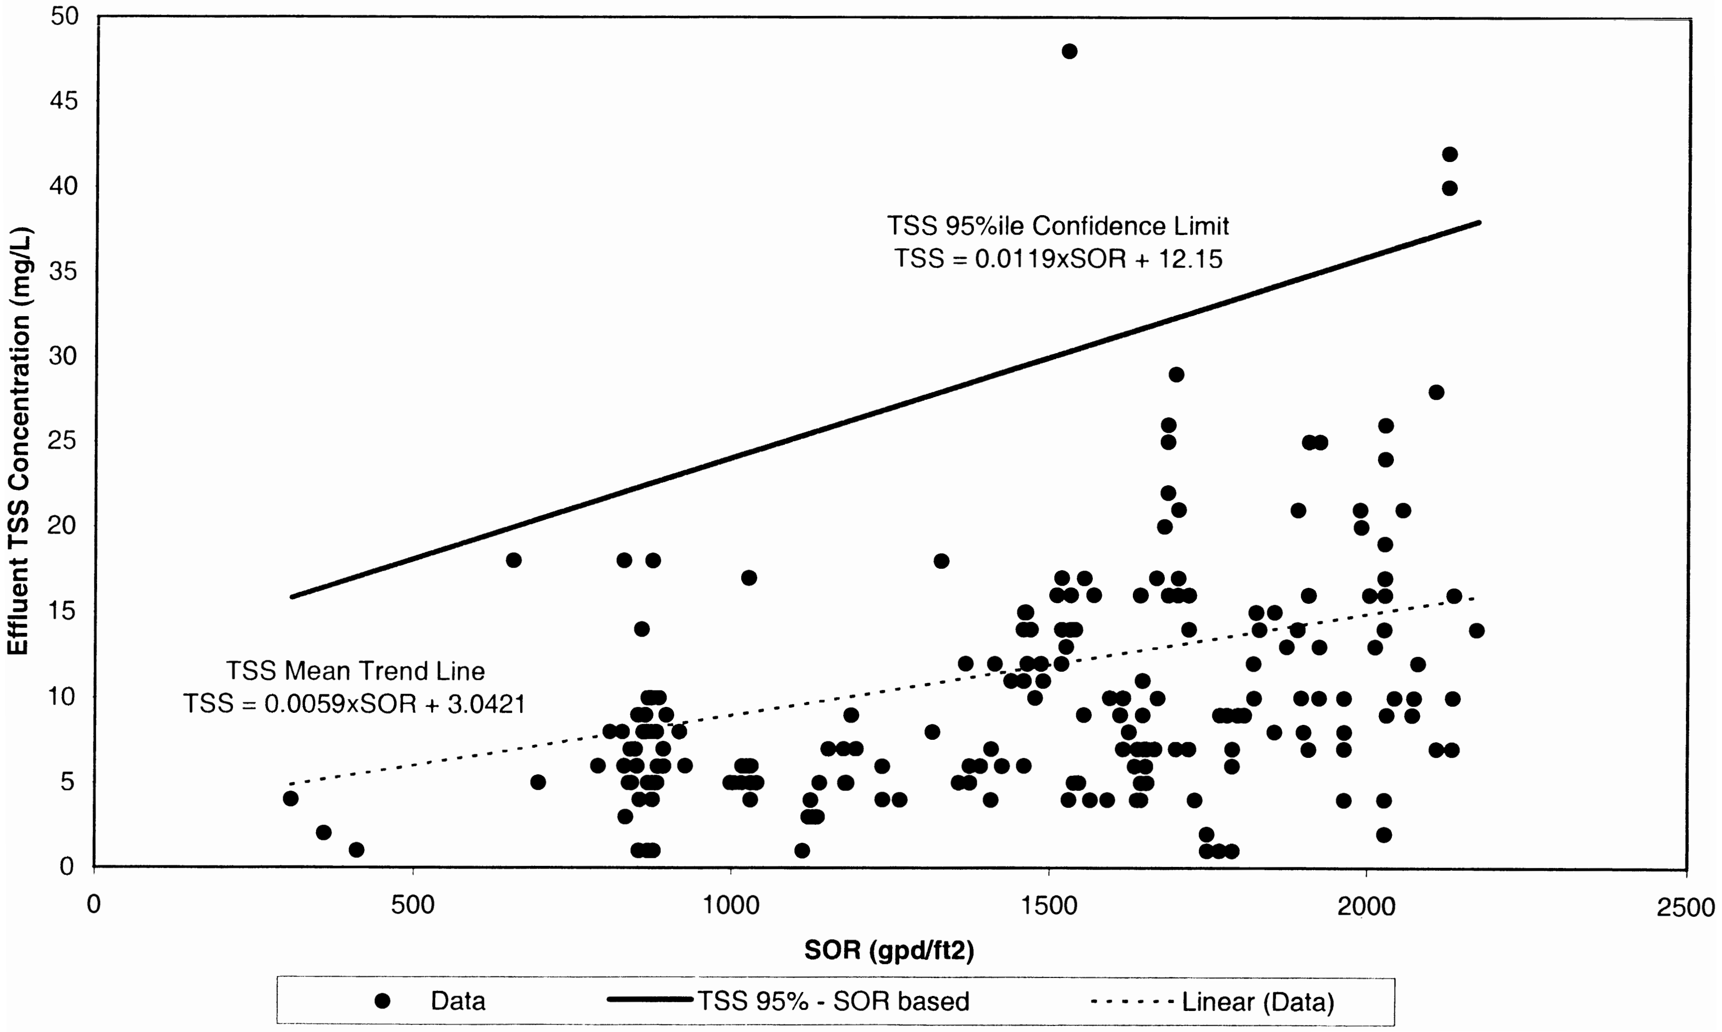


Figure 4-2
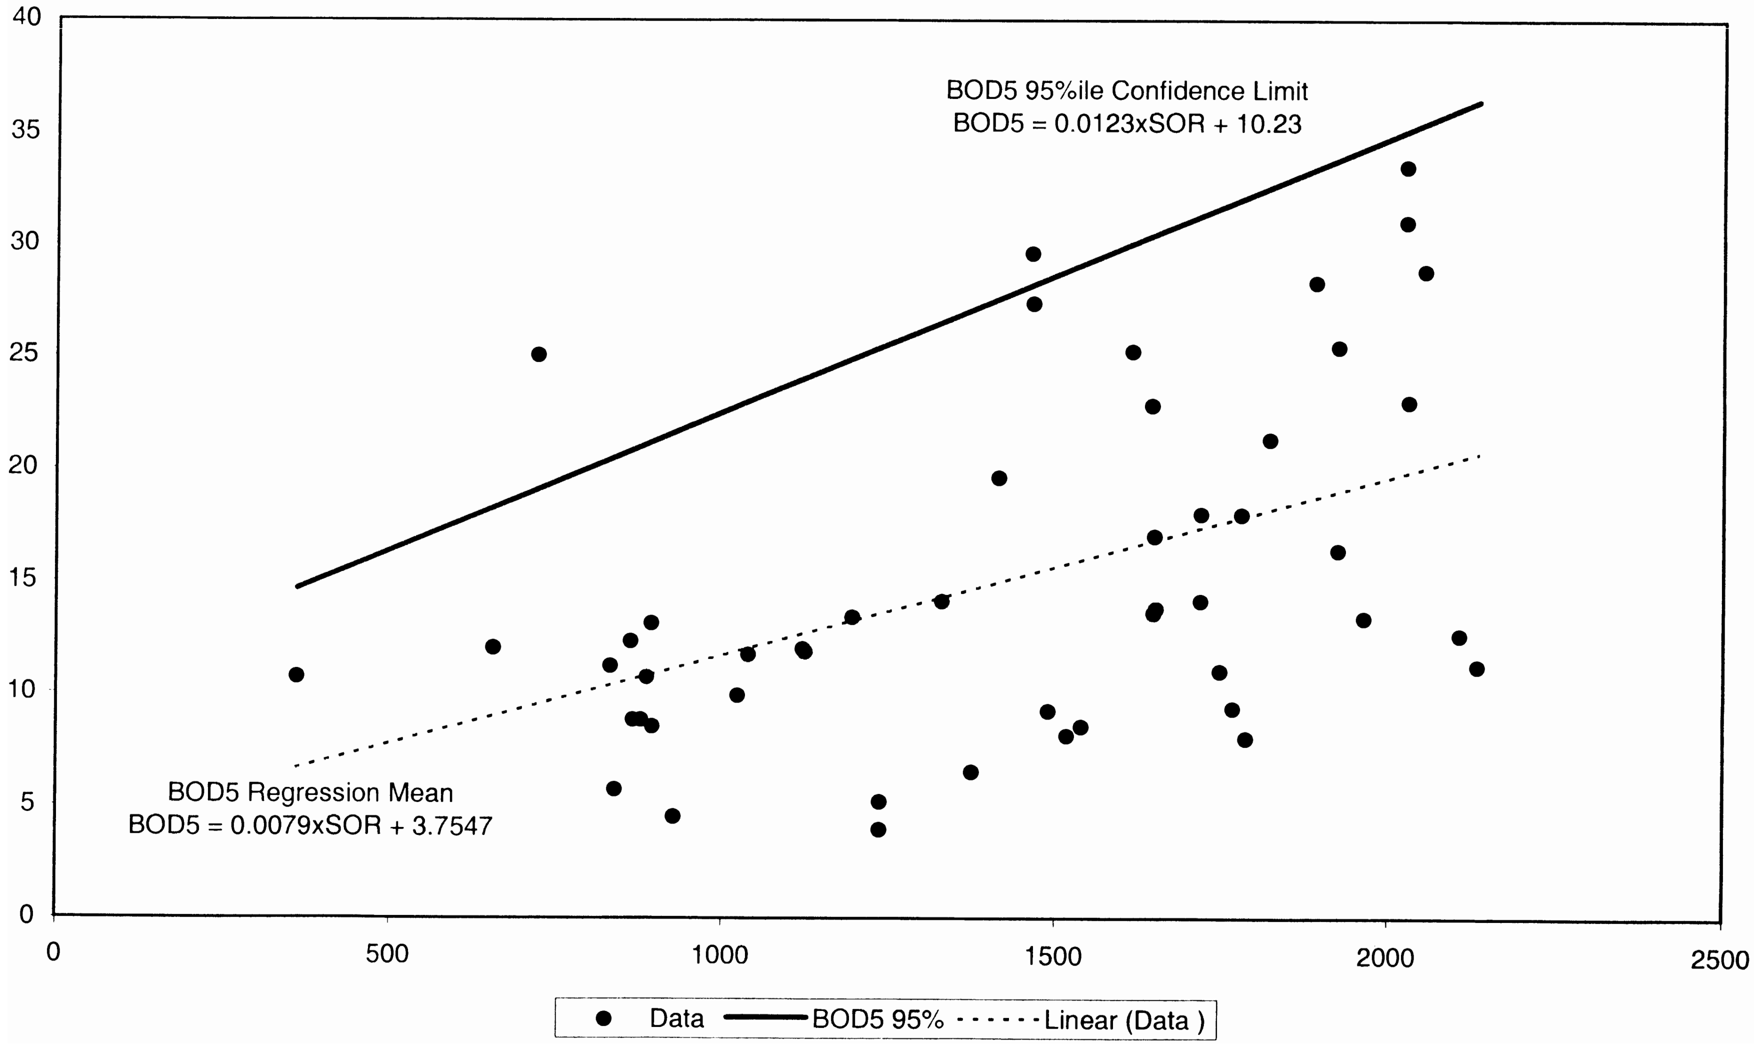
Secondary Clarifier Stress Test - Effluent BOD5 Concentration as a Function of SOR



4.3.2 Predicting Maximum Flows as a Function of SLR

The stress tests of the secondary clarifiers indicated that the maximum solids loading rate that could be sustained by the secondary clarifiers was 35 lb/(ft^2.day). The solids loading rate is a function of the MLSS concentration in the aeration basin and the influent and RAS flow rates. The MLSS concentration is dependent on the loading to the aeration basins, which in turn is dependent on the performance of the primary clarifiers as a function of the flow. The objective is to develop an overall correlation between the flow coming into the plant and the resulting solids loading rate into the secondary clarifiers.

The primary clarifier stress test results were used to determine the TSS percent removal in the primary clarifiers as a function of influent flow rate. A regression analysis of all stress test results performed in the primary clarifiers, except the test performed at the Southeast plant where the clarifier failed prematurely due to the hydraulic limitations of the launders, was performed and the lower 95% confidence levels associated with the regression parameters were calculated. Figure 4.3 presents the results of this analysis.

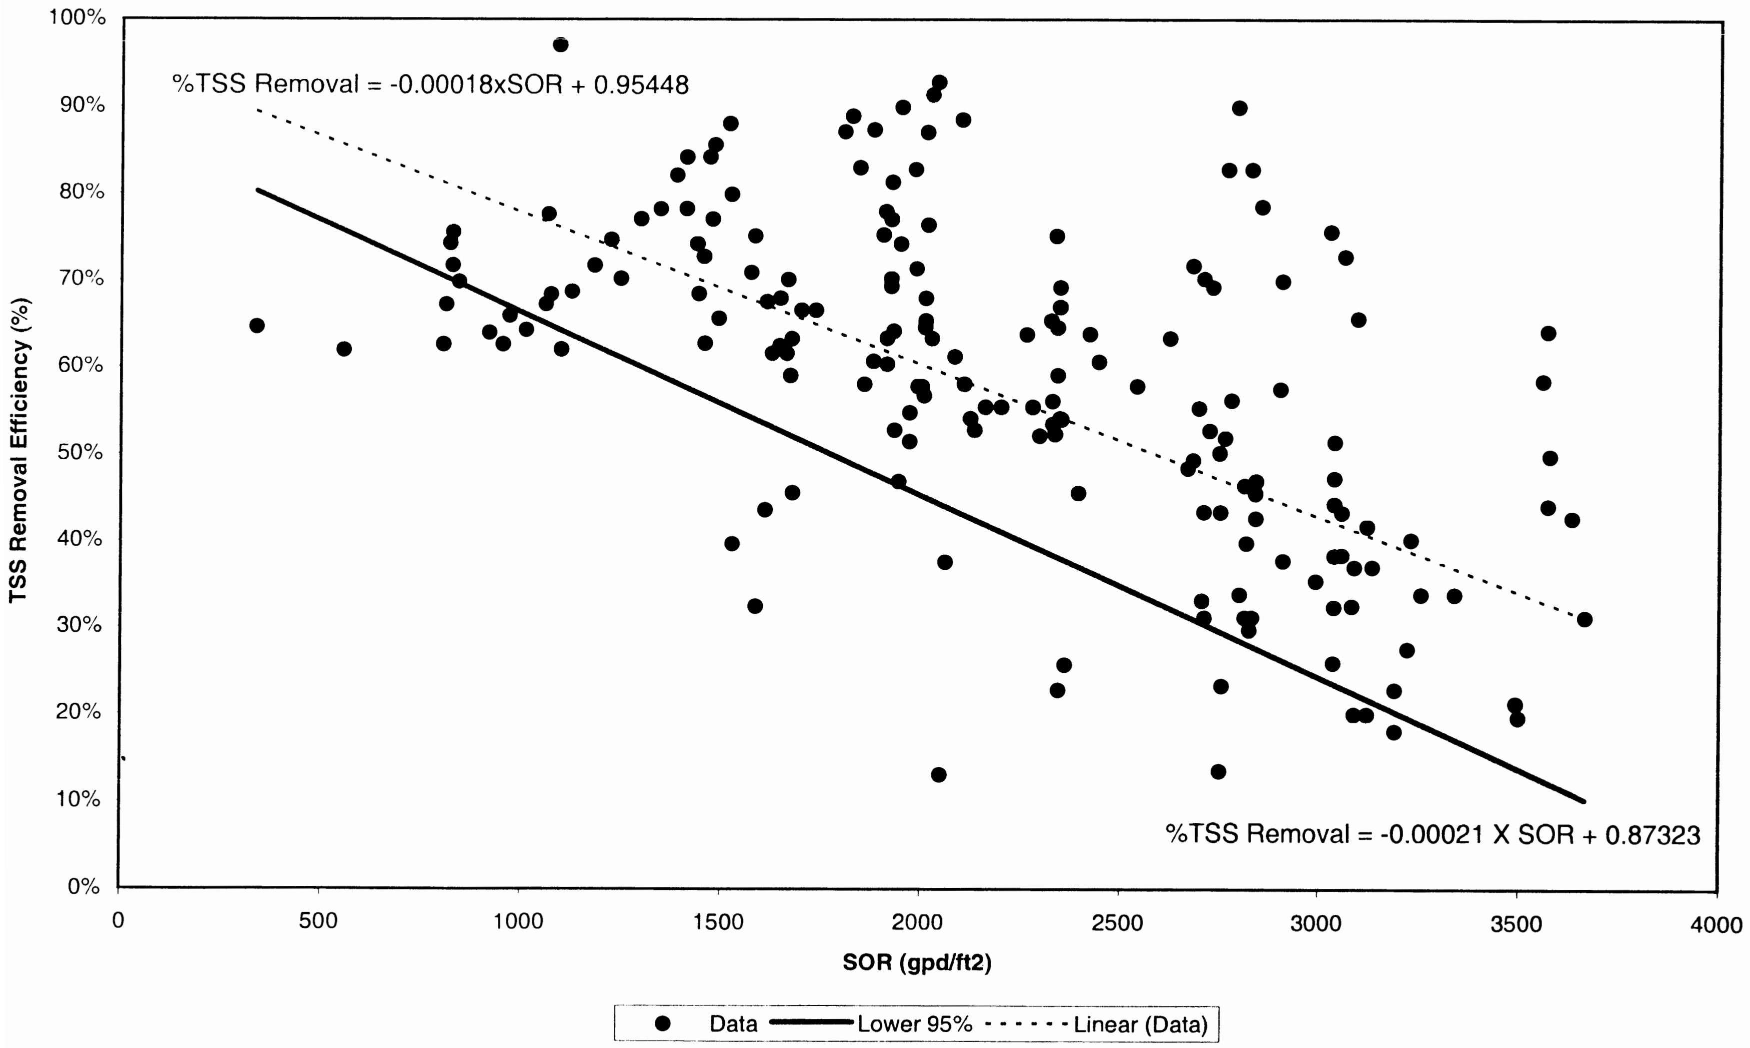
The yield for the NEWPCP was estimated based on the historical data of waste activated produced and the TSS and BOD$_5$ concentrations in the primary effluent. For the determination of the SLR limiting flow it was assumed that all of the primary clarifiers, secondary clarifiers and aeration basins are in service. This corresponds to current operating practice at the site.

The SLR becomes 35 lb(ft^2.day) at the NEWPCP when the sustained flow is equal to 375 mgd. At flow rates greater than 375 mgd thickening failure will occur unless measures are taken to reduce the solids loading rate to the secondary clarifiers. Preventative measures which can be readily implemented at the NEWPCP include modifing the step feed gate postions based on influent flow.

Improving the primary clarifier performance by providing "out of clarifier" primary sludge thickening or enhanced primary clarifier performance through chemical addition would also reduce the solids loading to the secondary clarifiers. These alternatives would require capital expenditure for additional facilities.

Improving the solids removal efficiency of the secondary clarifiers would effectively increase the allowable solids loading rate to the clarifier. This would require modifications to the existing RAS system.

Figure 4-3
Primary Clarifier Stress Test – Percent TSS Removal Efficiency as a Function of SOR



Upgrades to Increase Capacity of Secondary Treatment to 450 MGD

Currently NEWPCP secondary system capacity is limited to 430 mgd. A slight increase to this secondary treatment capacity could be achieved by modifying the Set 2 secondary effluent channel "double decker" structure to improve hydraulics and some modifications to the existing RAS collection and pumping system. Capital costs for these improvements are estimated at $2,410,000.

Increase Wet Weather Treatment Capacity

The NEWPCP has four unused secondary clarifiers on site. These tanks could be modified to provide stormwater treatment equivalent to primary treatment for an additional 100 mgd of flow. The estimated capital cost to modify these tanks is between $5,000,000 and $10,000,000. The estimated capital cost to increase the raw sewage pumping and preliminary treatment by 150 mgd is between $20,000,000 and $24,000,000.

The potential primary treatment capacity at the NEWPCP is 710 mgd. Increased primary sludge pumping would be required to achieve the additional primary treatment capacity. The estimated capital cost for primary sludge thickeing is $12,254,000. The estimated capital cost to increase the raw sewage pumping from 500 to 800 mgd to take advantage of all available tankage on site is between $36,000,000 and $40,000,000.

COST TO TAKE THICKENING/SLUDGE CAPACITY TO 550 MGD = ?

4.4 Control of High Flow Duration

Discussions with PWD managers directing PWD 's CSO program indicated that current CSO in line storage and draw down plans expect that stored combined sewerage would be released to the plant over a 12 hour period following a storm event. This is a volume of combined sewerage that PWD's plants have not received in the past. Furthermore, there is flexibility in the draw down strategy since the primary objective of the effort would be to return the storing sewer back to its original condition prior to the next storm event. It was clear that this is only a current plan and it would change should PWD be required in the future to provide additional combined sewerage storage to meet receiving water quality objectives.

From the wastewater treatment plants perspective, there are a number of factors that influence the ability of a plant to achieve weekly or monthly limits when the plant is being stressed by storm induced high influent flows. The number and distribution of rain events during the week/month together with plant effluent quality during non-rain event periods rank high on the list of influences. PWD's revised permit language provides effluent quality relief but only when the daily plant flow exceeds the permitted maximum daily flows currently stated in the permits. No such relief occurs for flows below the maximum daily flow limits.

Since the impact of stored combined sewerage on the NEWPCP performance is an unchartered experience, it is recommended that the duration of storage be no greater than a 24-hour period for each storm event. Should the CSO program's strategy for stored combined sewerage change beyond this 24 hour period, the issue of plant compliance for all monthly and weekly effluent quality requirements should be reviewed.

SECTION 5

POTENTIAL UPGRADES

5. Potential Upgrades

A list of potential upgrades was developed to increase the capacity or improve the performance of the NEWPCP. The potential improvements are based on the results of stress tests on unit process, long-term monitoring of the plant, and hydraulic modelling.

Each upgrade option has been prioritized based upon the following criteria:

- **Priority A – Existing Facilities Optimization.** Improvements that are easily implemented, low cost, high benefit, and will have an immediate positive impact upon normal operations. These are options that can be included in short-term capital budgets.
- **Priority B – Proactive Improvements.** Improvements that are moderate in cost and will have a small impact on plant capacity. This category also includes improvements that are necessary to maintain existing capacity for increased mixed liquor suspended solids (MLSS) in the aeration tanks. These are options that should be included in a long-term improvement plan.
- **Priority C – Improvements to Increase the Solids Handling Capacity of the Secondary Clarifier.** The stress tests identified that the solids handling capacity of the secondary clarifiers is very limited. This category includes improvements that are necessary to increase the secondary clarifier capacity with current mixed liquor concentration and/or to maintain exisitng capacity if increased mixed liquor suspended solids are required in the future.
- **Priority D - Capacity De-bottlenecking.** Improvements that have large costs associated with them and will greatly increase capacity above the current permitted peak flow. These options should be considered in an overall long-term wet-weather flow control program and in the long-term improvement plan if significantly more treatment capacity is required at the facility.

The list of potential upgrades, budgetary cost estimate, and their associated prioritization are summarized in Table 5.1 below. Detailed descriptions of each upgrade are presented in Technical Memorandum 5 – Budgetary Cost Estimates for Potential Plant Improvements.

The cost estimates shown here are based on preliminary costs and are for use as "budgetary" values only. The cost estimates are Class "C" cost estimates (order of magnitude costs) as defined by the American Association of Cost Engineers. The level of accuracy of the Class "C" cost estimates is +50 percent to –30 percent of the actual cost of construction. These costs can be used for decision-making to select those options that are most feasible from both a design and cost perspective for more detailed analysis.

Table 5.1
Potential Upgrade Options at Northeast WPCP

Option No.	Description	Priority Classification	Estimated Conceptual Cost
1	Improve mixing in mixed liquor channel to secondary clarifiers 9 through 16	A	$472,000
2	Polymer addition on Set 1 secondary clarifiers to maintain effluent quality	B	$22,000
3	Separate flow measurement of secondary effluent from sets 1 and 2	C	Currently undetermined
4	Automation of step feed operation for aeration tanks	A/B	$161,000
5	Modify Set 2 secondary effluent channels to reduce hydraulic restrictions under high flow conditions	B/D	$223,000
6	Modify the existing RAS system in the secondary clarifiers	C	$2,183,000
7	Provide a second conduit to the Set 2 primary clarifiers to convey additional flow to Set 2 Primary tanks	D	$3,312,000
8	Reduce losses and increase capacity between the grit tanks and Set 1 clarifiers by installing another conduit and venturi meter	D	$707,000
9	Provide a bypass from the primary effluent channels to the chlorine contact chamber	D	$8,291,000
10	Provide separate primary sludge thickening	D	$12,254,000
11	Reuse abandoned ABCD tanks as wet weather treatment facility	C	$5.0 – 10.0 million
12	Increase raw sewage pumping and screening	D	
	A - by 50 mgd	D	$10.0 – 12.0 million
	B - by 150 mgd		$20.0 – 24.0 million
	C - by 300 mgd		$36.0 – 40 million

Table 5.1 includes the final estimated cost for each improvement. Table 5.2 below presents a summary of the overall cost for improvements at the Northeast plant, broken down into alternatives that are dependant upon one another for an increase in capacity at the plant.

TABLE 5.2
SUMMARY OF BUDGETARY COSTS FOR POTENTIAL IMPROVEMENTS AT NORTHEAST WPCP

Improvement Alternatives	Total Costs for Improvements (Million $)	Cumulative Costs for Improvements (Million $)	Plant Peak Capacity (mgd)	New Plant Peak Capacity (MGD)		
				Primary	Secondary	Stormwater
Process optimization (Options 1,2, 4)	0.64	0.64	430	430	430	0
Upgrades required to increase capacity of the primary treatment to 550 mgd with secondary bypassing (Options 7, 8, 9, 12A)	23.31	23.95	550	550	430	0
Upgrades required to increase capacity of secondary treatment to 450 mgd (Options 5, 6)	2.41	26.36	550	550	450	0
Increase wet weather treatment capacity						
(Options 11, 12B)	34.00	49.36	650	550	450	100
(Options 10, 12C)	52.25	77.61	800	700	450	100

Process Optimization

The objective of this plan is to improve the performance of the NEWPCP under current wet weather flow conditions by implementing modest capital imrovements and operational changes.

The secondary clarifiers at the NEWPCP are susceptible to solids loading failure under high flow conditions. This project identified upgrades that improve the hydraulic and solids loading distribution between the clarifiers by improving the mixing in the mixed liquor channel and improving flow measurement between sets of clarifiers. Implementing step feed during high flow conditions will reduce the solids loading on the secondary clarifiers and therfore improve performance. The estimated capital cost of these upgrades is $640,000.

Upgrades to Increase Primary Capacity to 550 MGD with Secondary Bypassing

The NEWPCP has additional primary treatment capacity that is unavailable because of hydraulic limitations between the preliminary treatment building and the primary clarifiers. This bottleneck can be resolved by adding a new conduit and venturi meter, as well as a new conduit to the Set 2 primary clarifiers. A bypass channel from the primary effluent to ? WHY the chlorine contact chamber will be required for the additional flow. The estimated capital cost to increase the primary treatment capacity from 430 to 550 mgd, including secondary bypassing and upgrade to the raw sewage pumping, is $23,310,000.

SECTION 1

INTRODUCTION

1. Introduction

1.1 Project Objectives and Methodology

As part of its obligations under the Federal Clean Water Act and the Pennsylvania Clean Streams Law, the City of Philadelphia Water Department (PWD) has initiated a program with an objective to minimize the impact of Combined Sewer Overflows (CSO) on local receiving waters. One of the proposed strategies for reducing the CSO volume is to maximize flow to be treated by the water pollution control plants (WPCP) during periods of wet weather. To implement this strategy effectively, the PWD needs to have a clear understanding of the factors that affect how much flow each of the three WPCPs can effectively treat. With this knowledge, the PWD will be able to identify and prioritize plant upgrades and other system modifications that will allow it to meet the CSO minimization objectives in the most environmentally sound and cost-effective manner.

The PWD contracted CH2M HILL to conduct stress testing at the three wastewater treatment plants that are owned and operated by the City. The objective of the stress testing was to determine the reliable maximum capacity of the existing facilities and identify cost-effective methods of increasing the ability of these facilities to treat peak hydraulic flows associated with wet weather conditions. The major tasks performed during the project are briefly described below.

Historical Data and Operations Review. The objective of the historical data and operations review was to evaluate the physical condition, current loading, and treatment efficiency provided by the existing unit processes. A tour of the plant was conducted, and the process equipment and facilities were examined. Operating records, design information, and engineering drawings were studied to develop a strong understanding of the operations and constraints. Technical Memorandum 1 – Historical Data Review was produced to summarize the results of the site visit and historical data analysis.

Short-Term Stress Test. CH2M HILL performed a series of capacity and diagnostic tests to determine the loading versus performance characteristics of specific unit processes at each facility. The short-term stress testing focused on determining the response of the primary and secondary clarifiers to increased hydraulic loading under different operating conditions. The short-term stress testing at the Southeast WPCP (SEWPCP) included primary clarifier stress tests, secondary clarifier stress tests, secondary clarifier dye tests, and flow meter calibration. The results of each test are summarized in a test description report in Technical Memorandum 2 – Short-Term Test Results.

Long-Term Stress Test (Online Monitoring). Online monitoring equipment was installed to quantify the dynamic load/response characteristics of the secondary treatment system to naturally-occurring storm events. The equipment was also used to monitor the effect increased flows had on the solids inventory in the system and secondary effluent quality. Online monitoring included total plant flow, return activated sludge (RAS) flow, mixed liquor suspended solids (MLSS) concentration, sludge blanket levels, and secondary effluent total suspended solids (TSS) concentration. The equipment was in place from March 1 to June 30, 1999 and recorded data on a 10-minute interval. The results of the long-term stress test are summarized in Technical Memorandum 3 – Long-Term Online Monitoring Results. The detailed online monitoring data and instrument calibration records are provided under separate cover.

Hydraulic Throughput Capacity Assessment. WinHYDRO, a computer model that facilitates complex analysis of plant hydraulics, was used to evaluate the hydraulic throughput capacity of the SEWPCP. Hydraulic and energy grade lines from the headworks to the plant outfall were developed for the average and peak flow conditions. Hydraulic bottlenecks, which limit the hydraulic throughput capacity of the existing facilities, and flow distribution problems were identified and evaluated. The hydraulic throughput capacity of each unit process was determined. The results of the hydraulic modelling performed are summarized in Technical Memorandum 4 – Hydraulic Throughput Capacity of Existing Facilities.

Evaluation of Potential Improvements. Based upon stress testing and hydraulic modeling results, major bottlenecks that limit plant capacity were identified and potential solutions were developed to increase peak instantaneous capacity. Budgetary cost estimates were developed for each potential solution. The results of this analysis are summarized in Technical Memorandum 5 – Budgetary Cost Estimates for Potential Plant Improvements.

1.2 Report Organization

The project notebook consists of a final report and a series of attachments. The main body of the report contains a summary of the results from the stress testing, plant data analysis, and the evaluation of process improvements and upgrade options. The detailed results from the historical data review, short-term testing (stress tests, dye tests, and flow meter calibration), online monitoring, and hydraulic throughput capacity assessment are included in the project notebook as attachments. Tables describing the design criteria, scope of work, estimated capital costs for the potential process modifications and capital upgrades, and the current National Pollution Control Discharge Elimination System (NPDES) discharge permit for the site are also included as attachments.

Effluent Pumps	5	Q = 70 mgd at 11 head, VSD 3 units

2.1.1 Preliminary Treatment

The SEWPCP receives wastewater from the Lower Delaware low-level interceptor through an 11-foot-diameter gravity sewer. Mechanically-cleaned bar racks provide coarse screening before the raw sewage pump station. The pump station wet well is separated into two hydraulically-isolated chambers, each of which is serviced by three raw sewage pumps with a rated capacity of 70 mgd each. The pump station operation is controlled manually based on the level in the wet well. Under high flow conditions the pumps are susceptible to

CONTROL PLANT
CITY OF PHILADELPHIA WATER DEPARTMENT

vortexing, resulting in a sudden deterioration in the measured pump output (flow). Pump capacity is restored by temporarily shutting down the pump and allowing the wet well levels to rise. The maximum flow measured at the raw sewage pump station is approximately 286 mgd with both wet wells in service and 200 mgd with only one wet well in service.

The pump risers discharge into a common channel that leads to six mechanically-cleaned bar screens. The bar screens are located in the influent channel to the grit chambers with one bar screen per grit chamber. The grit chambers consist of six 10 by 140 feet channels with chain and flight collection mechanisms and screw conveyors to remove the grit. Under normal flow conditions, two out of six grit tanks are in service. The accumulated grit is pumped from the grit tanks, washed, and hauled offsite for disposal. The wastewater from the grit tanks flows into a common channel that leads to two flocculation tanks. The flocculation tanks are two-pass aerated tanks, which provide a total flow path length of 450 feet. The flocculation tanks discharge into a common primary influent channel.

Under high flow conditions, the grit chambers flood into the lower basement area through the grit conveyor wall notch. The hydraulic restriction is associated with the primary clarifier launders and the piping between the primary tanks and aeration basins. This issue is discussed in greater detail in Section 3.2.

2.1.2 Primary Treatment

The SEWPCP has four 250 by 125 feet rectangular primary clarifiers with a side wall depth of 12 feet. Each tank has seven chain and flight mechanisms that move the sludge to the influent end of the basin. The flow from the flocculation tanks enters the common influent channel between Primary Clarifiers 2 and 3. Each clarifier has 14 inlet weirs from the common influent channel. The primary sludge is pumped from two tanks every other day. The primary sludge is pumped to the sludge holding tank and then is pumped directly to the SWWPCP for treatment. There are no recycle streams returning to the SEWPCP headworks associated with this process. The primary effluent discharges into a common effluent channel that leads to two flow splitter boxes that control the flow distribution to the aeration basins.

The SEWPCP receives a significant quantity of ferric sludge from the Queen's Lane Water Treatment Plant. The water treatment plant sludge has very good settling characteristics and therefore enhances the performance of the primary treatment system.

However, in 1998, Queen's Lane Water Treatment Plant changed the coagulation procedures used at the facility. The chemical characteristics of the water treatment plant sludge changed, increasing the impact of the Queen's Lane sludge on the treatment processes at the SEWPCP.

The Queen's Lane sludge has exhibited the ability to remove phosphate from the wastewater stream, resulting in periodic incidences of severe nutrient deficiency in the secondary treatment process. Periods of nutrient deficiency encourage the growth of filamentous microorganisms in the activated sludge system, causing bulking sludge and premature failure of the secondary clarifiers.

2.1.3 Secondary Treatment

The SEWPCP has eight 4-pass aeration basins. The basins were originally designed as UNOX pure oxygen. They are currently operating with air. Under current loading conditions, six of the eight aeration basins are in service. Each basin is 52.5 by 210 feet, with a side wall depth of 14.3 feet. The aeration basin consists of four cells operating in series; the primary effluent follows a serpentine flow pattern through the basin, and the RAS is pumped to the upstream end of Cell A. There are no structures to allow step-feed in the basin. The water surface level (WSL) in the basin is controlled by the basin effluent weir structure.

Each cell has a single-paddle, submerged aerator/mixer located in the center of the tank. The SEWPCP operates the first cell as an anoxic selector in the summer months to improve the settling characteristics of the mixed liquor by turning off the first aerator/mixer. During high flow conditions, operations staff also turn off the aerators/mixers in the first and fourth cells to reduce the energy demand. This retains more solids in the aeration basin through settling, which reduces the solids loading on the secondary clarifiers.

The east and west secondary treatment processes are operated as separate systems. The mixed liquor from the east aeration basins flows to the east secondary clarifiers, and the RAS from the east secondary clarifiers is pumped to the east aeration basins. The RAS is flow-paced at approximately 30 percent of the flow through the plant. The mixed liquor from each set of aeration basins flows through a common mixed liquor channel to a set of six secondary clarifiers.

There are twelve 68 by 214 feet rectangular secondary clarifiers with a sidewall depth of 11 feet. Each clarifier has four chain and flight mechanisms that transport the sludge to a central hopper located at approximately the mid-length of the clarifier. The waste activated sludge (WAS) is pumped from the RAS system 24 hours per day. The target WAS flow rate is established based on a target solids retention time of 1.5 days and current mixed liquor concentration in the aeration basins.

2.1.4 Effluent Pumping and Disinfection

The secondary effluent flow from the east and west secondary treatment processes flows through a common conduit to the effluent pump station wet well and chlorine contact chamber. Under dry weather flow conditions, the secondary effluent flows by gravity through the outfall to the Delaware River. The outfall conduit provides contact time for disinfection.

The SEWPCP has five effluent pumps, each with a rated capacity of 70 mgd. The effluent pumps are operated based on the WSL in the effluent pump station wet well and, under wet weather flow and/or high tide conditions, will operate automatically. Three 24-hour composite samples are collected at the end of the facility outfall.

2.2 Regulatory Requirements

The SEWPCP NPDES permit limits include effluent BOD_5 and TSS concentrations; mass discharges; and percent removal for daily, weekly (calendar), and monthly averages. Table

2.2 summarizes the NPDES permit criteria for the facility in effect during testing. Compliance is based on the flow measured by the raw sewage flow meters located in the influent pump station and two 24-hour composite samples collected daily at the facility outfall.

PWD has negotiated a new NPDES permit for this facility effective August 1st, 2000. The modifications to the NPDES permit are summarized below.

As part of PWD's long-term combined sewer overflow (CSO) control program, PWD will be reducing the frequency and volume of untreated sewage discharges through the CSOs; in order to account for the increased loading due to the combined sewage flows that exceed the treatment plant's rated hydraulic capacity, the following methods may be used for calculating and reporting mass loadings and effluent concentrations on the monthly discharge monitoring reports:

- If a calendar month includes one or more days where flows exceed 168 mgd, a value of 85 percent may be used for those days for the purpose of calculating average monthly TSS percent removal. The actual TSS percent removal associated with those days shall be reported on the appropriate space provided on the DMR.
- If a calendar month includes one or more days where flow exceed 168 mgd, a value of 86 percent may be used for those days for the purpose of calculating average monthly BOD_5 percent removal. The actual BOD_5 percent removal associated with those days shall be reported on the appropriate space provided on the DMR.
- When daily flows exceed 168 mgd, the TSS and BOD_5 mass loadings for those days may be omitted from the average monthly and average weekly mass loading calculations, in accordance with the requirements of the Delaware River Basin Commission for Zone 3 of the Delaware Estuary. The actual TSS and BOD_5 loadings associated with those days shall be reported on the appropriate space provided on the DMR.

The BOD_5 in the raw wastewater shall be reduced by at least 86 percent as a monthly average. The percent removal shall be calculated from daily 24-hour composite samples of the influent and effluent. The BOD_5 percent removal requirement may be relaxed to 85 percent when the influent BOD_5 concentration is less than 75 mg/L on a monthly average basis, as long as the $CBOD_{20}$ allocation, equivalent mass BOD_5 limitation, and effluent BOD_5 concentration of 15 mg/L are not exceeded on a monthly average basis. At all other times, the 86 percent removal equipment would apply.

A copy of the new NPDES permit is located in the project notebook.

TABLE 2.2
SOUTHEAST WPCP – NPDES PERMIT REQUIREMENTS

Parameter	Units	Monthly Average	Weekly Average	Maximum Day	Peak Instantaneous

Flow	mgd	112		168	224

2.3 Current Loading And Performance Achieved

2.3.1 Unit Process Loading

Table 2.3 presents a summary of the current unit process loading over a three-year period from July 1995 to July 1998. The average and maximum daily flows were 106 mgd and 212 mgd, respectively. The maximum instantaneous flow was 286 mgd.

On September 16, 1999, during Hurricane Floyd, the maximum instantaneous flow was 274 mgd. The flow remained above 200 mgd for over 14 hours. During that period, the maximum WSL in the raw sewage wet well was 19.5 feet. During the five years from July 1995 to present, SEWPCP has not exceeded the CSO action level established for the facility.

The average raw sewage TSS and BOD_5 concentrations were 143 mg/L and 87 mg/L, respectively. The average organic loadings to the treatment plant, calculated based on the raw sewage TSS and BOD_5 concentration and the average flow for each day, were 126,281 lbs/day and 75,834 lbs/day, respectively.

[3] Based on all units in service
[4] Based on six aeration basins in service

2.3.2 Primary Treatment Performance

The average and peak surface overflow rates (SOR) for the primary clarifiers were approximately 850 gpd/ft^2 and 2,286 gpd/ft^2, respectively. Typical overflow rates for rectangular clarifiers are between 1,000 gpd/ft^2 and 3,000 gpd/ft^2. The primary clarifiers at the SEWPCP are operating slightly below their expected capacity based on typical SORs.

The removal efficiencies achieved in the primary clarifiers are very good. This is due to the low hydraulic loading rate and the relatively high proportion of ferric solids from Queen's Lane Water Treatment Plant. The average TSS and BOD$_5$ removal efficiencies in the primary clarifiers were 73 percent and 49 percent, respectively.

2.3.3 Secondary Treatment Performance

The average primary effluent TSS and BOD$_5$ concentrations were 34 mg/L and 43 mg/L, respectively. The average and 95th percentile total BOD$_5$ loadings to the secondary treatment system, calculated based on the primary effluent BOD$_5$ concentration and the average flow for each day, were 37,293 lbs/day and 61,629 lbs/day, respectively.

The aeration basins are currently operating with a solids residence time (SRT) of 0.7 days. The food to microorganisms (F:M) ratio in the aeration basins averaged 0.5 day^{-1}. The F:M ratio generally peaked in March each year, mainly due to an increase in food (BOD$_5$ loading) during the early spring periods. The average sludge volume index (SVI) between

July 1995 and December 1998 was 144 mL/g. The SVI was more than 200 mL/g approximately 5 percent of the time, indicating that the facility experiences occasional bulking incidents.

During January through March of 1999, the SEWPCP experienced a major sludge bulking incident. A microscopic examination of the mixed liquor indicated severe nutrient (phosphorus) deficiency in the biomass. Phosphoric acid was added to the return sludge, and the SVI dropped to levels typical for the facility.

The average and peak SORs for the secondary clarifiers were approximately 800 gpd/ft^2 and 1,640 gpd/ft^2, respectively. Typical SORs for rectangular Gould-type clarifiers are between 800 gpd/ft^2 and 1,500 gpd/ft^2. The secondary clarifiers at the SEWPCP are operating at their expected maximum hydraulic capacity based on typical SORs.

The average and peak solids loading rates (SLRs) for the secondary clarifiers were approximately 9 lbs/day/ft^2 and 20 lbs/ft^2 per day based on RAS flows of 30 percent. Typical peak SLRs for rectangular Gould-type clarifiers are between 20 lbs/day/ft^2 and 40 lbs/ft^2 per day. The secondary clarifiers at the SEWPCP are operating below the expected maximum hydraulic capacity based on typical SLRs.

The secondary clarifiers at the SEWPCP achieve a very good quality final effluent. The daily TSS and BOD$_5$ concentrations were consistently below the NPDES criteria of 60 mg/L. The average effluent TSS and BOD concentrations were 5.7 and 7.5 mg/L, respectively.

SECTION 3

CURRENT CAPACITY

3. Maximum Instantaneous Capacity

3.1 Maximum Treatment Capacity

The current maximum instantaneous treatment capacity of the unit processes at the SEWPCP was estimated using a combination of manufacturers information, standard engineering design loading and performance criteria, operations staff observations of previous performance, and field testing of specific unit processes.

The field testing conducted at the SEWPCP included the following:

Online Monitoring Data

- Secondary Clarifier 12
- Plant flow, RAS flow, mixed liquor TSS, sludge blanket level, and effluent TSS from March 1 to June 30, 1999

Primary Clarifier Stress Tests

- Primary Clarifier 4

Secondary Clarifier Stress Tests

- Secondary Clarifier 1 – gradual increase in hydraulic loading
- Secondary Clarifier 1 – sudden increase in hydraulic loading (spike loading)

Secondary Clarifier Dye Tests

- Secondary Clarifier 11

Table 3.1 summarizes the estimated treatment capacity for each unit. The basis of the estimated capacity is discussed below. The detailed field test results are presented in Technical Memorandum 2 – Short-Term Test Results and Technical Memorandum 3 – Long-Term Online Monitoring Results.

3.1.2 Preliminary Treatment

The estimated treatment capacity of the preliminary treatment system is 200 mgd. This is based on operators' observations for the maximum pumping capacity of the raw sewage pump station with one side of the wet well out of service because of partial blockage or failure of the coarse bar screens. The bar screen can be put back into service quickly. However the potential of permanently damaging the screen and pumps increases at flow rates greater than 240 mgd. With both sides of the raw sewage pump station wet well in service, the maximum capacity of the raw sewage pump station is 286 mgd. Maintaining the maximum flow rate requires manual control of the pumps, with four of the six pumps in operation at one time. The pumps are rotated into service as the pump output is reduced due to vortexing/cavitation. The capacity is limited by the wet well configuration.

TABLE 3.1
SOUTHEAST WWTP TREATMENT CAPACITY ASSESSMENT

Unit Process	Estimated Capacity (mgd)	Criteria
Pumping and Screening	286 240[1] – 1 coarse screen partialy blocked 200[2] – 1 wet well out of service	Observed maximum flow Observed maximum flow Observed maximum flow
Grit Removal	350[3] – 1 channel out of service	
Primary Treatment	225 mgd[4] – existing condition (hydraulic limitations) 260 mgd[4] – new launders 330 mgd[4] – improved sludge pumping	2,400 gpd/ft² – test results 2,800 gpd/ft² – SW test results 3,500 gpd/ft² – potential
Aeration Basins	N/A No change in organic loading pattern	
Secondary Clarifiers	200 mgd[4] – existing (sludge bulking incidence) 330 mgd[4] – current mixed liquor concentration	Long-term monitoring results Based on allowable SOR of 1,800 gpd/ft²
	236 mgd[4] – mixed liquor concentration 2,000 mg/L	Based on allowable SLR of 30 lbs/day
Effluent Pump Station	280 mgd[5] (1 pump out of service)	70 mgd per pump
Disinfection	395 mgd – volume of plant outfall	HRT - 15 minutes

[1] Based on one screen partially blocked
[2] Based on one screen (1/2 of the wet well) out of service
[3] Based on removal of 60 mesh (0.25mm) particles
[4] Based on one clarifier out of service
[5] Based on 1 pump out of service rated capacity of pumps 70 mgd

The estimated treatment capacity of the bar screens and grit removal tanks is 350 mgd. This is based on five of the six channels in service, with an allowable average velocity in the grit channel of 1 ft/sec. The theoretical removal efficiency of the grit removal system is 90 percent of particles greater than 60 mesh (25 mm) under peak flow conditions.

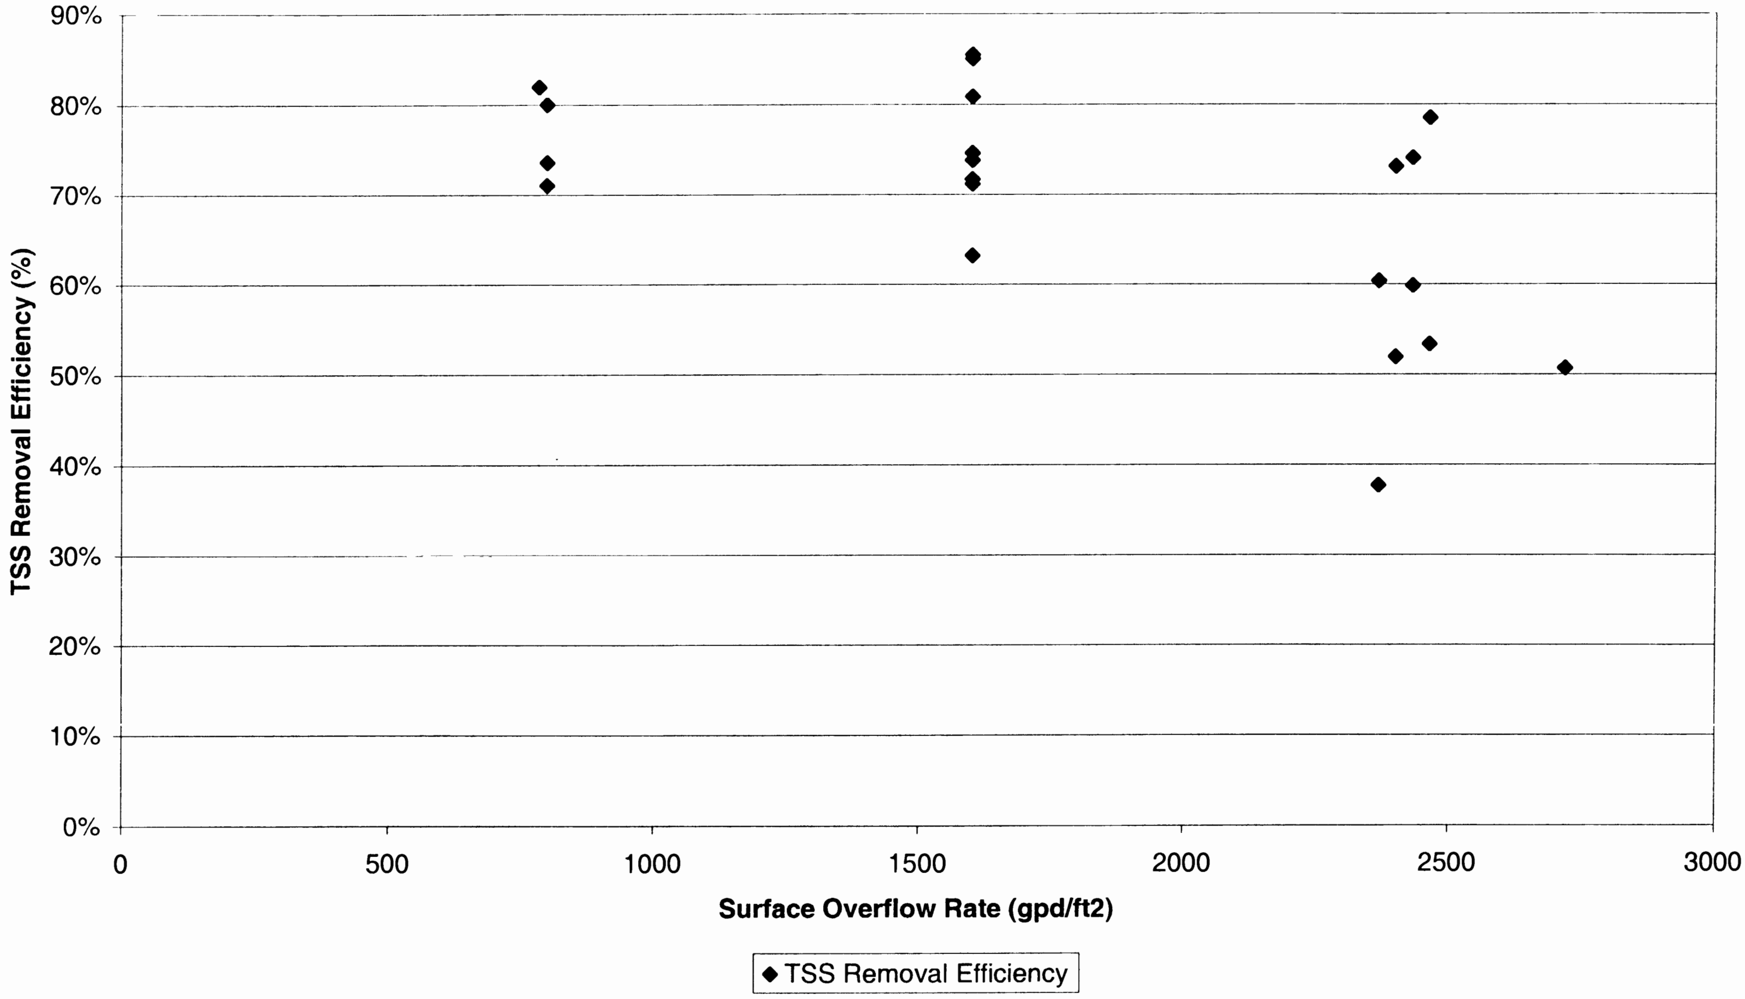
3.1.3 Primary Treatment

Six primary stress tests were conducted at the three wastewater treatment plants owned and operated by the PWD. Table 3.2 summarizes the physical characteristics of the clarifiers at each site and the stress tests performed. The primary clarifiers at all three plants are hydraulically similar. Differences in behaviour are the result of differences in influent characteristics and minor differences in influent and effluent structures.

One stress test was performed on the primary clarifiers at the SEWPCP. Figure 3.1 presents the measured TSS removal efficiency as a function of SOR observed during the test. The test procedures and detailed results are described in Technical Memorandum 2.

The performance of the primary clarifier at SEWPCP deteriorated at a SOR of 2,400 gpd/ft². Clarifier deterioration was due to hydraulic throughput failure of the launders, resulting in unbalanced flow distribution over the length of the effluent weir. At 75 mgd, the center half of the launder was submerged. The velocity at the outside ends of the weirs increased, resulting in increased upward velocities in these locations. Throughout the test, the clarifier

Figure 3-1
SEWPCP Primary Clarifier Stress Test
TSS Removal Efficiency versus Surface Overflow Rate (SOR)



01/02/2002
9:52 AM

SE Figures for final report.xls

launders had a free discharge into the clarifier collection channel (the WSL in the collection channel was not impacting the hydraulic throughput capacity of the launders). The estimated treatment capacity of the primary clarifiers is 225 mgd with three clarifiers in service. The capacity-limiting factor was the hydraulic throughput capacity of the clarifier launders. The primary clarifiers at the SEWPCP are virtually identical to the primary clarifiers at the SWWPCP, except for the configuration of the effluent launders. If the effluent launders on the SEWPCP primary clarfiers were replaced, the expected performance of these clarifiers would be similar to the measured performance of the SWWPCP primary clarifiers (allowable SOR of 2,800 gpd/ft^2). The estimated capacity of the primary clarifiers would increase to 260 mgd with three clarifiers in service or 350 mgd with all four clarifiers is service.

Target SOR (range) gpd/ft^2	1,000-2,400	1,000-3,500	1,000-3,000	750-2,800

The capacity of the primary clarifiers at the SEWPCP could be further increased by improving the sludge removal procedures for the primary clarifiers. This modification would require removing the primary sludge from the clarifiers more frequently. Allowable surface overflow rates of up to 3,500 gpd/ft^2 were observed at the SWWPCP for the test conducted on Primary Clarifier 4. The test was conducted without BRC solids and with no sludge blanket in the clarifier.

Based on an allowable SOR of 3,500 gpd/ft^2, the theoretical maximum treatment capacity of the existing primary clarifiers is 330 mgd with three clarifiers in service or 440 mgd with all four clarifiers in service.

3.1.4 Secondary Treatment

Six secondary clarifier stress tests were conducted at the three wastewater treatment plants owned and operated by the PWD. Table 3.3 summarizes the physical characteristics of the clarifiers at each site and the secondary clarifier stress tests performed. The secondary clarifiers at all three plants are very similar and performed similarly. Differences in performance were largely the result of differences in mixed liquor settling characteristics and solids loading during the tests.

Dye tests	1	0	3	1

Two stress tests and one dye test were performed on the SEWPCP secondary clarifiers. The test procedures and results are described in Technical Memorandum 2; the main findings are summarized below.

Two stress tests were conducted on Secondary Clarifier 11 at the SEWPCP. Figures 3-2a and 3-2b present the flow and effluent TSS concentration as a function of time for each test. Figure 3-3 presents the effluent TSS concentration as a function of SOR for both tests. The first test was conducted by increasing the hydraulic loading on the clarifier gradually, in incremental steps. The second test was conducted by increasing the hydraulic loading suddenly from normal dry weather flow to peak flow within approximately five minutes. In both tests, the effluent TSS concentration remained well below 60 mg/L. The maximum SOR achieved during the tests was 2,100 gpd/ft^2.

Dye tests are used to evaluate the hydraulic efficiency of the secondary clarifiers. A clarifier dye test was performed on Secondary Clarifier 1. The test results indicated that there is relatively even flow distribution throughout the clarifier body, with only small areas of the tank not utilized for clarification. The slight short-circuiting observed is considered normal for a clarifier of this design.

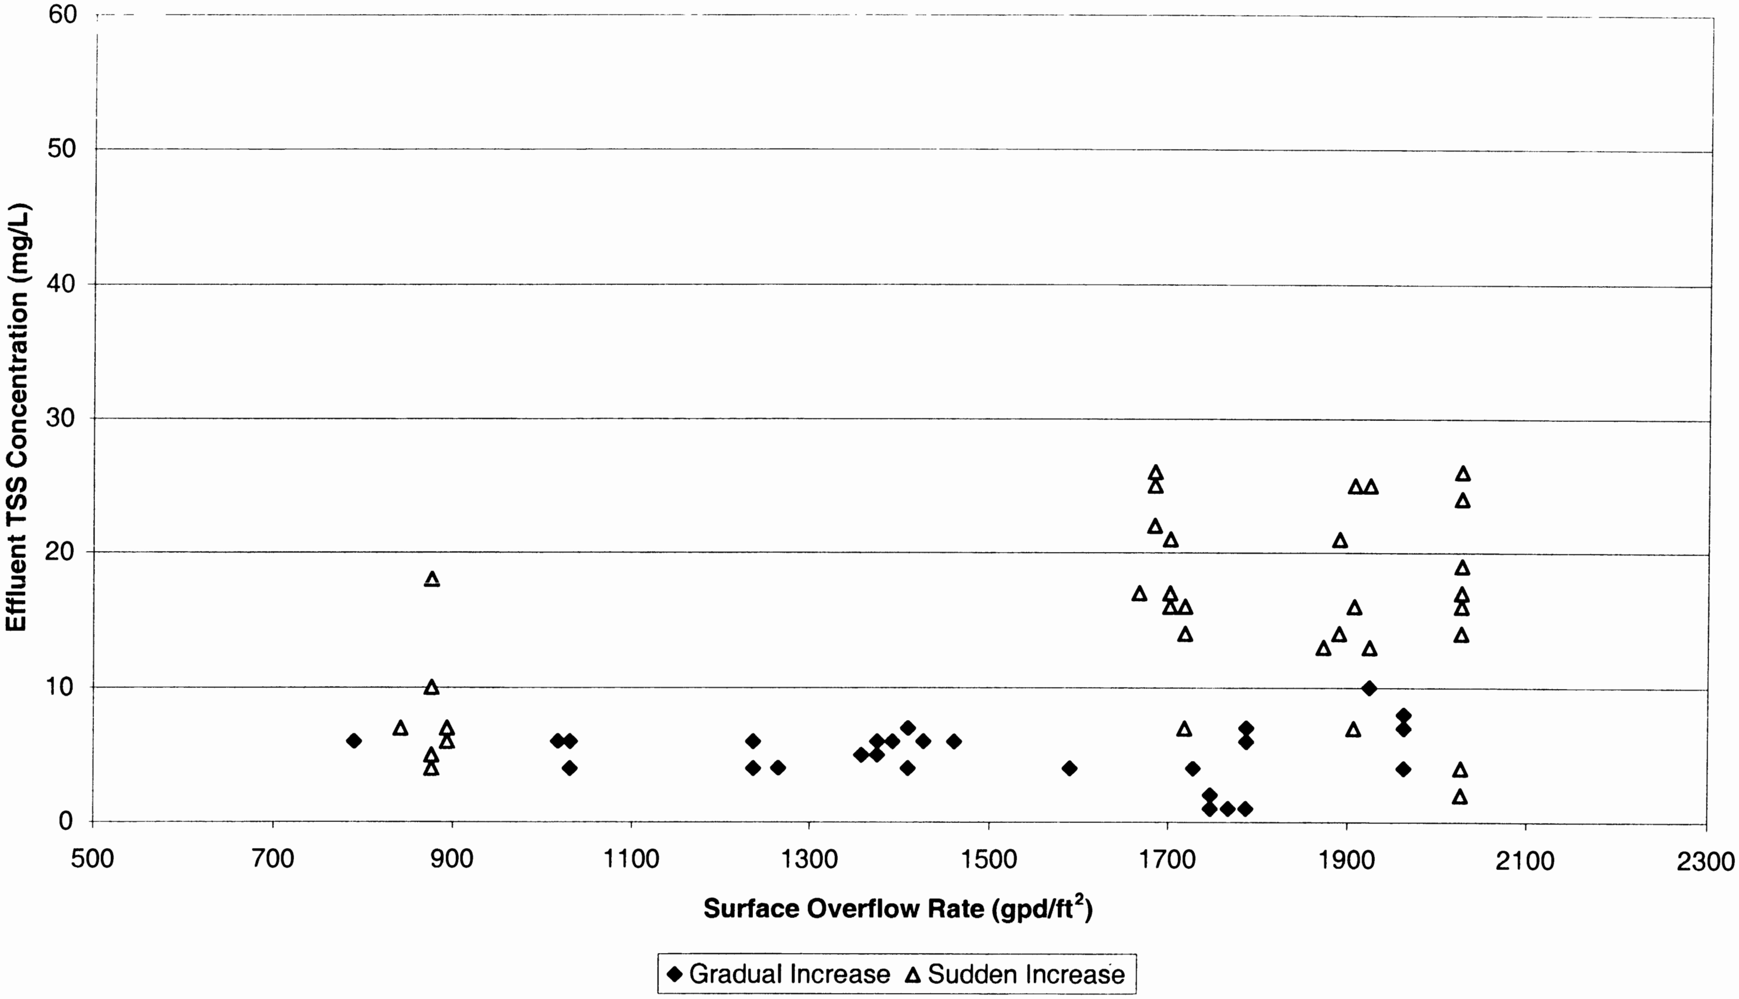
SE Figures for final report.xls

Figure 3-3
SEWPCP Secondary Clarifier Stress Test
Effluent TSS Concentration versus Surface Overflow Rate (SOR)



The performance of Secondary Clarifier 2 was monitored over a four-month period using online instrumentation to quantify the dynamic performance of the clarifiers to naturally-occurring storm events. The online instrumentation recorded total plant flow, RAS flow, mixed liquor TSS concentration, sludge blanket levels, and effluent TSS concentration. The online monitoring recorded the response of Secondary Clarifier 2 to seven storm events. Table 3.4 summarizes results of the online monitoring program; more detailed results are presented in Technical Memorandum 3.

The secondary clarifier TSS concentration exceeded 60 mg/L for short periods of time during the first three storms. The effluent TSS concentration rose significantly at plant flow rates between 120 to 220 mgd. The maximum SOR based on total plant flow and number of clarifiers in service during the storm events ranged from 1,250 to 1,300 gpd/ft^2. This is significantly lower than the maximum allowable SOR observed during the secondary clarifier stress test.

TABLE 3.4
RESULTS OF THE ONLINE MONITORING PROGRAM

Date	SVI ml/g	MLSS mg/L	TSS >60 mg/L		Peak Achieved	
			Q mgd	SOR gpd/ft^2	Q mgd	SOR gpd/ft^2
March 14	217	1,357	220	1,260	220	1,260
March 21	383	1,340	116	660	227	1,300
April 9	214	967	190	1,088	218	1,250
April 11	186	1,203	~	~	220	1,230
April 23	190	1,077	~	~	214	1,230
May 19	155	683	~	~	230	1,580
May 24	141	1,067	~	~	226	1,290

The secondary clarifier effluent TSS concentration did not exceed 60 mg/L for the remaining four storms, even though the maximum flow rate was similar to the first three storms. The main reason for the difference in performance between the first month of the online monitoring period and the remaining three months was the settling characteristics of the mixed liquor.

During February and March 1999, the SEWPCP experienced a severe sludge bulking incident. Samples of the mixed liquor were sent to Dr. David Jenkins at the University of California for microbial species identification. The results indicated that the overabundance of filamentous organisms that were causing the bulking incidence were associated with nutrient deficiency in the activated sludge system.

A sampling program was initiated to track the ortho-phosphate concentration at various points in the collection system and WPCP to identify the cause of the deficiency, and a temporary chemical feed system was installed to add phosphoric acid upstream of the aeration basin. It was determined that the ferric sludge from Queen's Lane Water Treatment Plant was absorbing the ortho-phosphate in the raw sewage before it arrived at the SEWPCP. The ortho-phosphate in the plant influent was less than the detection limit for most of the samples collected. The settling characteristics of the activated sludge improved after the nutrient deficiency was corrected.

The estimated capacity of the secondary clarifiers is 330 mgd with one clarifier out of service. This is based on the observed performance of the secondary clarifiers during the stress tests and on allowable SOR of 1,800 gpd.ft^2. Under bulking sludge conditions, the estimated capacity is less than 200 mgd. The secondary clarifiers at the three facilities are very similar, and therefore the results from stress testing at the other facilities can be used to predict the performance of the secondary clarifiers at the SEWPCP. The secondary clarifier stress test at the NEWPCP indicated that the clarifiers were susceptible to solids flux failure at solids loading rates of approximately 30 lbs/day. The solids flux failure was due to inefficiencies in the solids removal systems. Based on the stress test results from NEWPCP, the estimated capacity of the secondary clarifiers will be reduced if the mixed liquor concentration is increased.

At a mixed liquor concentration of 2,000 mg/L, the capacity of the secondary clarifiers would be reduced to 236 mgd. Modifications to the solids removal systems will be required to maintain current treatment capacity if higher mixed liquor concentrations are required in the future. Higher mixed liquor concentrations would be required if there were a significant change in the raw sewage quality due to changes in the industrial contributions or reduction in the ferric sludge.

3.1.5 Disinfection and Effluent Pump Station

The estimated capacity of the SEWPCP effluent pump station is 280 mgd. This is based on the rated capacity of the existing pumps with one pump out of service. The rated capacity of the disinfection is 395 mgd. This is based on 15 minute HRT in the existing outfall under peak flow conditions.

3.2 Hydraulic Throughput Capacity

The hydraulic throughput capacity of the unit processes at the SEWPCP was estimated using WinHYDRO, a computer model that facilitates complex analysis of plant hydraulics.

Hydraulic and energy gradelines from the headworks to the plant outfall were developed for a number of flow rates. The hydraulic throughput capacity of each unit process was developed based on the assumption that the downstream hydraulic bottlenecks had been resolved. Table 3.5 summarizes the estimated hydraulic throughput capacity for each unit process. The detailed hydraulic modeling results are presented in Technical Memorandum 4 – Hydraulic Throughput Capacity of Existing Facilities.

TABLE 3.5
SOUTHEAST WWTP CURRENT HYDRAULIC THROUGHPUT CAPACITY

Unit Process	Estimated Capacity (mgd)	Basis of Capacity Estimate
Outfall	450	• Flow path – Delaware River to the effluent pump station • Hydraulic control section – mean high tide 97.75 feet • Two outfall channels in service • Hydraulic exceedance – pump station discharge weir
Secondary effluent channel	Version A – 250 Version B >330	• Flow path – effluent PS wet well to secondary clarifier overflow weir • Hydraulic control section – wet well water surface level Version A – wet well level at maximum WSL 100.75 feet Version B – wet well level at WSL 97 feet • Ten secondary clarifiers in service • Hydraulic exceedance – clarifier overflow weir elevation
Mixed liquor channel	Version B > 330	• Flow path – effluent PS wet well to aeration basin overflow weir • Hydraulic control section – secondary clarifier weir The secondary clarifier weir has a free discharge • Hydraulic exceedance – aeration basin overflow weir
Aeration basin and primary flow split box	Capacity 1 – 235 Capacity 2 – 250 Capacity 3 – 330	• Flow path – aeration basin overflow weir to the primary clarifier overflow weir • Hydraulic control section – aeration basin overflow weir • 50/50 flow split between east and west side, six aeration basins in service • Hydraulic exceedance 1 – flow split weir elevation Hydraulic exceedance 2 – primary clarifier overflow weir Hydraulic exceedance 3 – top of concrete
Preliminary treatment	>330	• Flow path – primary clarifier overflow weir to the common influent channel downstream of the raw sewage pump station • Hydraulic control section – primary clarifier overflow weir • Four primary clarifiers and five grit channels and bar screens in service • Hydraulic exceedance – raw sewage pump station discharge weir

The hydraulic throughput capacity of the SEWPCP is greater than 330 mgd, except for the following locations:

- **Primary Clarifier Launders** - The primary clarifier launder capacity is exceeded at less than 75 mgd per clarifier. The launder becomes flooded and the water surface in the clarifier increases and backs up into the flocculation basins and grit tanks. This hydraulic limitation is the result of the small collection channel into which the launders discharge prior to discharging into the main primary effluent channels.

- **Aeration Basin Overflow Weir** - Under high flow conditions, the WSL in the aeration basin increases and submerges the primary effluent flow split weirs. The primary effluent flow split weirs become submerged at approximately 235 mgd. The primary clarifier effluent weirs become submerged at approximately 250 mgd. The WSL in the flocculation tanks and grit chambers is impacted by the increase in the WSL in the primary clarifiers. The hydraulic limitation is the aeration basin outfall weirs. The weir discharge is restricted to keep oxygen in the enclosed aeration tanks.

3.3 Capacity Limiting Factors

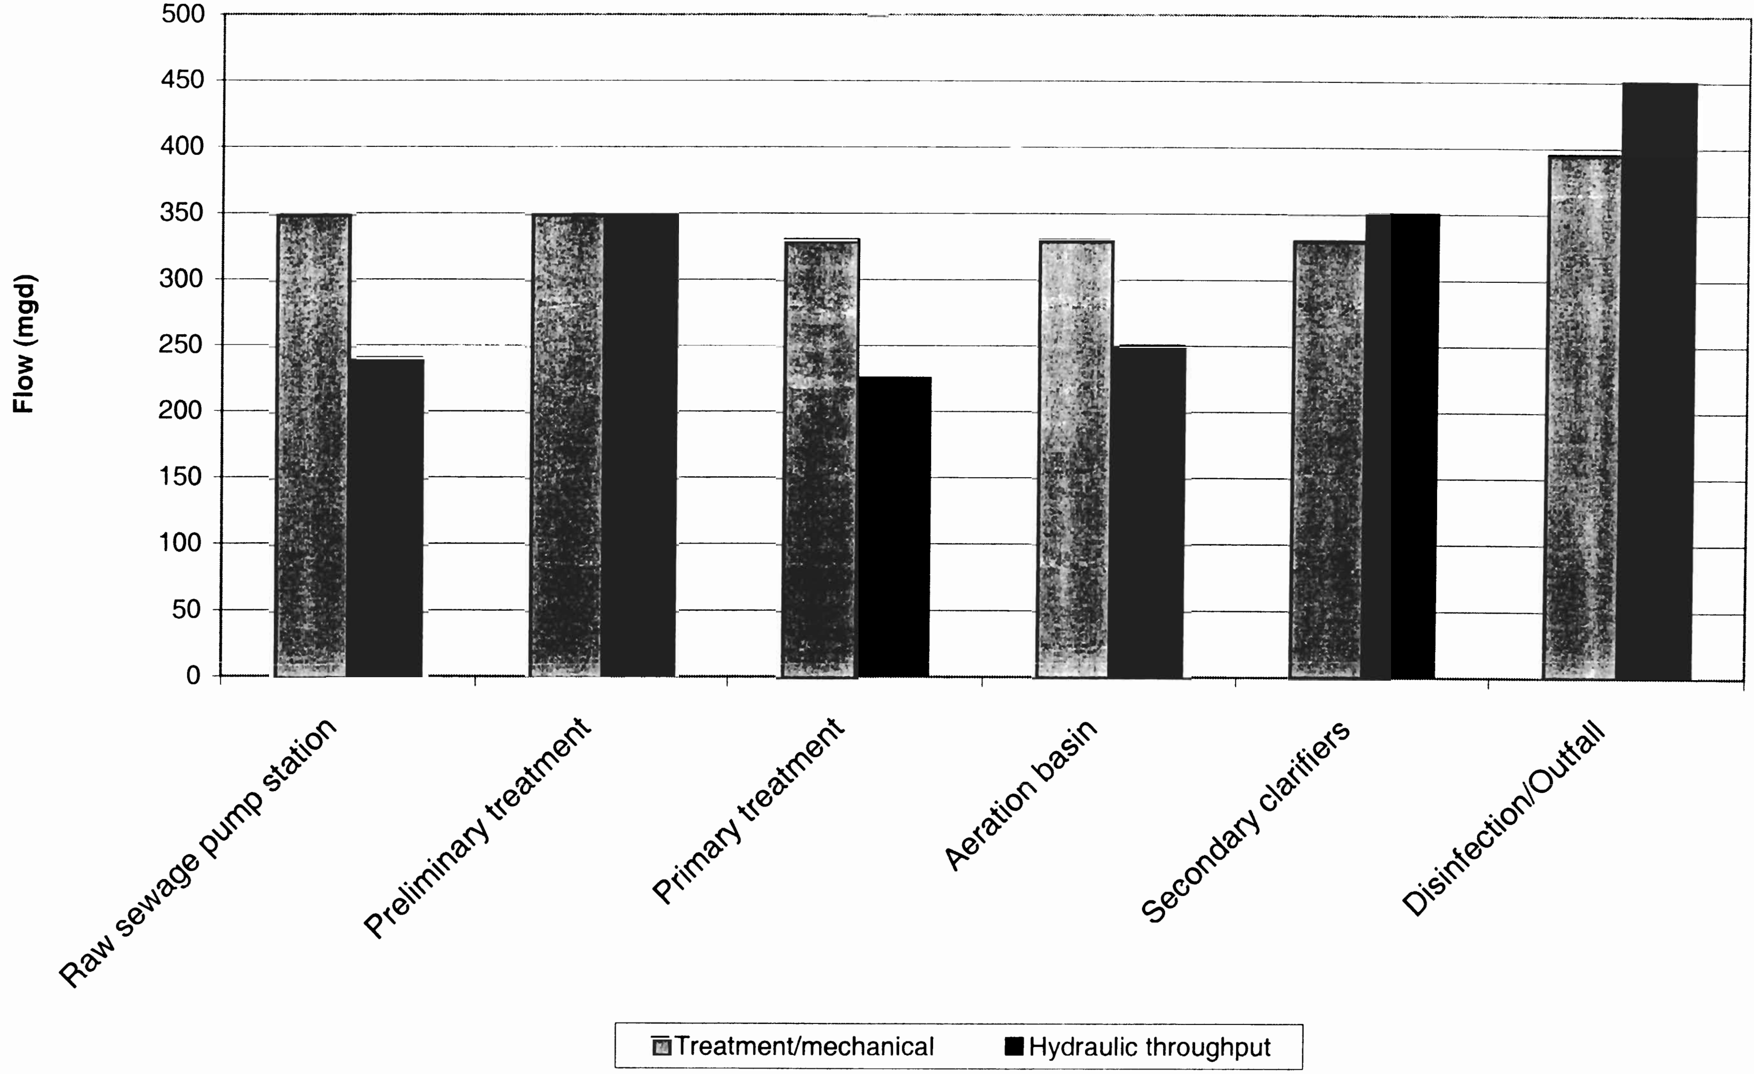
Figure 3-4 presents a summary of the estimated current peak instantaneous capacity on a unit process basis for the SEWPCP. The major capacity bottlenecks for the facility follow:

- **Raw Sewage Pump Station** - Estimated capacity of 200 mgd with one bar rack out of service. The bar rack can be put back into service quickly. However, the potential of permanently damaging the screens and pumps increases. The maximum capacity of the raw sewage pump station with both sides of the wet well in service is 286 mgd. Modifications to the pump station wet well and inlet structure are required to resolve this bottleneck.

- **Primary Clarifier Launders** - Estimated hydraulic throughput capacity of the primary clarifier launders is 225 mgd with three clarifiers in service. Replacing the clarifier launders would increase the primary treatment capacity to 260 mgd. Improved primary sludge pumping would increase the capacity to 300 mgd.

- **Aeration Basin Influent** - Estimated hydraulic throughput capacity of the aeration basin and primary effluent channels is 235 mgd before submerging the aeration basin influent weir. The facility will continue to operate but there will be deterioration in process control under these circumstances. The estimated hydraulic throughput capacity of the aeration basin and primary effluent channels is 250 mgd before flooding occur of the primary clarifier effluent weir. Secondary effluent pumping or aeration basin by-pass (extreme step feed) is required to resolve this bottleneck.

Figure 3-4
Southeast WPCP - Estimated Current Capacity



SECTION 4

CURRENT SUSTAINABLE TREATMENT CAPACITY

4. Current Sustainable Treatment Capacity

4.1 Sustainable Treatment

The estimated treatment capacities summarized in section 3 of this report utilize maximum instantaneous limits currently in PWD's NPDES permits as the goal for the effluent quality. Since the maximum instantaneous and maximum daily limits are the same values, a process operation whose final effluent quality will meet the instantaneous maximum limits will also meet the daily maximum limits. However, the current NPDES permits, based on expected performance for plants that intake substantial quantities of stormwater, include maximum weekly and monthly limits that are significantly more stringent than the daily/ instantaneous limits. Furthermore, strict compliance with maximum monthly concentration limits will not guarantee monthly compliance with other quality limits in the permit, such as average monthly and weekly loading limits and percent removal requirements.

An important but difficult question remains regarding how long a facility (or process) can sustain high flows that allow effluent quality to meet all the permit effluent quality requirements.

The performance of the secondary clarifiers determines the final effluent quality from the SEWPCP. The data collected during the field-testing was used to predict final effluent quality as a function of flow rate. The predicted final effluent TSS and BOD_5 concentration for a given flow rate was used to determine the maximum flow that could be maintained for an infinite period of time with effluent quality meeting the monthly and weekly loading and percent removal requirements in the NPDES permit.

Secondary clarifier capacity is defined by either the clarification capacity, which is a function of SOR, or the solids flux capacity, which is a function of solids loading rate (SLR). Clarifier performance as a function of both SOR and SLR was collected during the testing for a range of operating conditions. Data from the six secondary clarifier stress test was used to quantify the secondary clarifier performance as a function of hydraulic loading and to identify the maximum allowable solids loading rate for the clarifiers.

The historical data was used to determine the yield and mixed liquor concentrations required as a function of primary effluent quality. The data from the primary clarifier stress tests was used to determine the expected primary effluent quality as a function of flow rate. The mixer liquor required for the expected primary effluent quality determines the solids loading rate for the secondary clarifier.

4.2 Analysis Methodology

4.2.1 Predicting Secondary Effluent Quality as a Function of the SOR

In the stress tests of the secondary clarifiers, the TSS and BOD_5 concentrations in the secondary effluent were measured as a function of the surface overflow rate applied to the clarifiers. A linear regression was performed on the field testing data to establish the relationship between SOR and TSS and BOD_5 concentrations in the effluent. The intercept and slope values obtained for the regression were statistically analyzed to find the 95% confidence level associated with these two coefficients. Using the upper 95% confidence level interval provides a conservative description of the relationship between the SOR and effluent quality. The model is used to predict TSS or BOD_5 for a given SOR; the value generated using the linear regression will be lower than the actual value observed 95 out of 100 times.

The estimated effluent concentrations and discharge loads (which are equal to the effluent flow rate multiplied by the effluent concentration) can then be compared to permit levels to determine the sustainable treatment capacity of the facility on a SOR basis.

4.2.2 Effect of the SLR on Secondary Clarifier Performance

Failure of the secondary clarifiers may occur due either to clarification or thickening. An increase in the hydraulic loading to the primary clarifiers will result in an increase in organic loading to the aeration basin due to an increase in the amount of organic material entering the plant and deterioration in the primary clarifier performance. An increase in the organic loading to the aeration tanks results in an increase in the mixed liquor concentrations and therefore an increase in he solids loading for a given flow. Therefore the analysis done in terms of the SOR must be complemented with an analysis of the effect of influent flow rate versus SLR.

Stress tests were performed on the primary clarifiers, and removal efficiencies as a function of the surface overflow rate in the primary clarifiers were documented. The data was used to predict the quality of the primary effluent as a function of the influent flow rate. This analysis, combined with analysis of historical data on solids production, was used to estimate the SLR as a function of flow, taking into account both the performance of the primary clarifiers and the increase in the organic loading associated with augmented flows.

The stress tests on the secondary clarifiers indicated that the maximum SLR that could be maintained before thickening failure occurs is 35 lb/(ft^2.day). The flow at which these solids loading rates are achieved is the maximum sustained flow that can be maintained in the plant before thickening failure occurs.

4.3 Analysis Results

4.3.1 Predicting Maximum Flows as a Function of the SOR

Figure 4.1 is a plot of the TSS in the secondary effluent and the SOR applied in the secondary clarifier from the six secondary clarifier stress tests conducted at the facilities owned and operated by PWD. The data from all six secondary clarifier stress tests were used in the preparation of this plot. Figure 4.2 presents the same analysis was done for the BOD_5 concentration in the secondary effluent.

Figure 4-1
Secondary Clarifier Stress Test - Effluent TSS Concentration as a Function of SOR

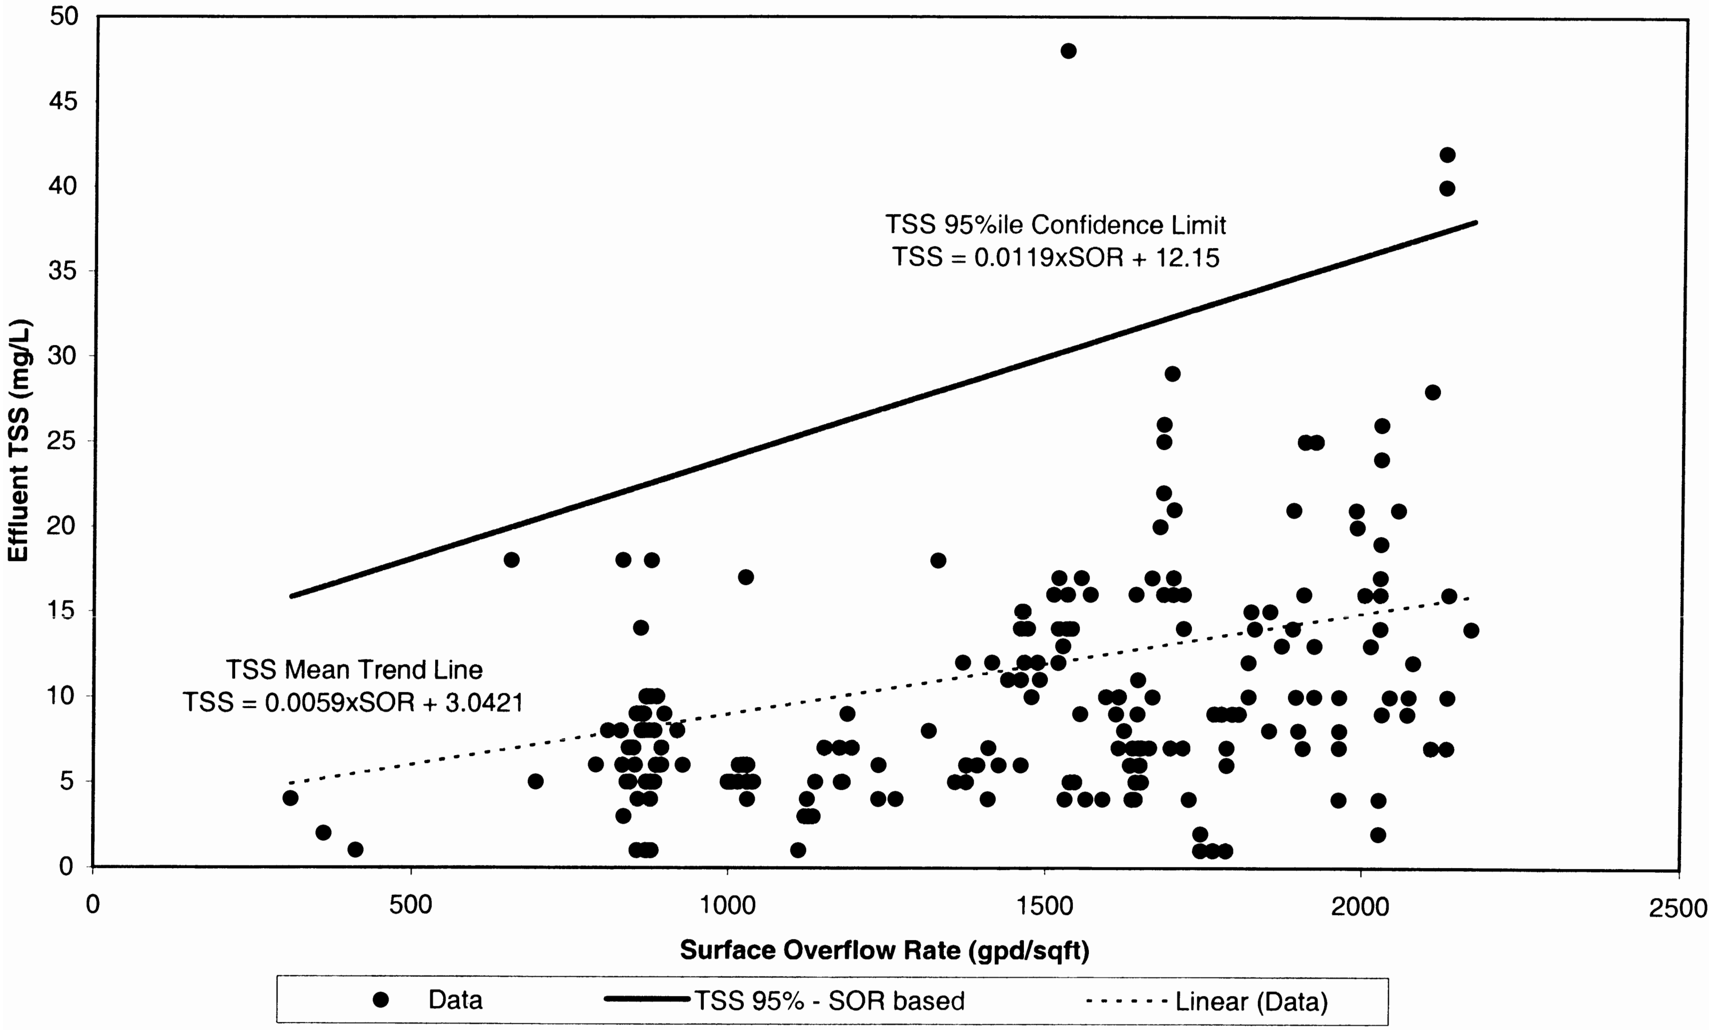


Figure 4-2
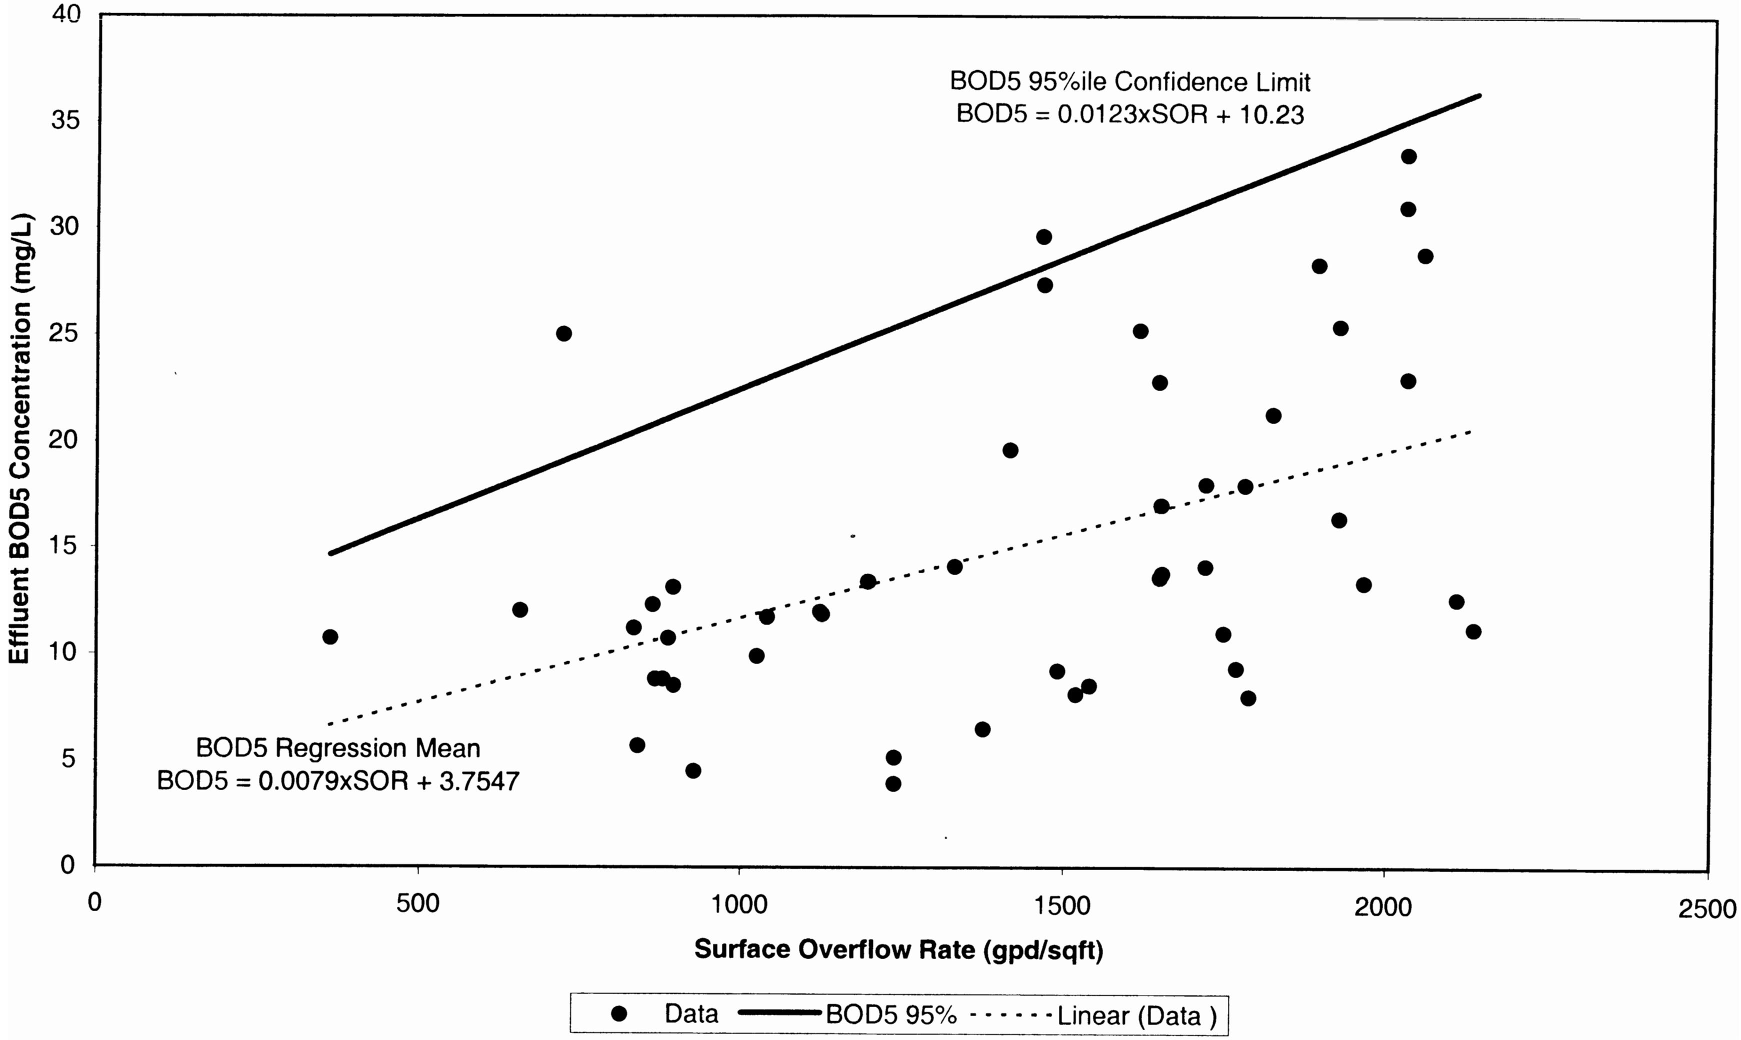
Secondary Clarifier Stress Test - Effluent BOD5 Concentration as a Function of SOR



The amount of TSS and BOD$_5$ discharged results from the product of the flow rate and the concentrations predicted by the 95% confidence level regressions. The discharge values were then compared to the NPDES Permit values for the SEWPCP. The results of this analysis are presented in Table 4.1.

TABLE 4.1 SOUTHEAST WPCP – NPDES PERMIT REQUIREMENTS AND RESULTS OF THE SUSTAINABLE FLOW ANALYSIS

Parameter	Units	NPDES Limit	Maximum Sustainable Flow based on SOR		Maximum Sustainable Flow based on SLR
			TSS Limit	BOD$_5$ Limit	
Maximum Day Limits	mgd	168			190
Maximum Week Limits	mgd		195	165	
BOD$_5$ Concentration	mg/L	45			
BOD5 Mass Loading	lbs/day	29,475			
TSS Concentration	mg/L	45			
TSS Mass Loading	lbs/day	42,035			
Maximum Monthly Limits	mgd	112	150	125	
BOD$_5$ Concentration	mg/L	30			
BOD$_5$ Mass Loading	lbs/day	19,650			
BOD $_5$ Percent Removal	%	86			
TSS Concentration	mg/L	30			
TSS Mass Loading	lbs/day	28,025			
TSS Percent Removal	%	85			

The maximum sustainable flows at which the SEWPCP can meet the weekly NPDES TSS and BOD$_5$ effluent mass loading requirements are 195 and 165 mgd, respectively. The BOD$_5$ weekly mass loading is the limiting criteria because the allowable effluent BOD$_5$ mass loading is significantly lower. The maximum daily flow in the NPDES permit is 168 mgd. This is very similar to the predicted maximum sustainable flow at which the facility can meet the weekly mass loading limits.

The maximum sustainable flows at which the SEWPCP can meet the monthly NPDES TSS and BOD$_5$ effluent mass loading requirements are 150 and 125 mgd, respectively. The maximum month sustainable capacity is slightly higher than the average design capacity of the facility.

4.3.2 Predicting Maximum Flows as a Function of SLR

The stress tests of the secondary clarifiers indicated that the maximum solids loading rate that could be sustained by the secondary clarifiers was 35 lb/(ft^2.day). The solids loading rate is a function of the MLSS concentration in the aeration basin and the influent and RAS flow rates. The MLSS concentration is dependent on the loading to the aeration basins, which in turn is dependent on the performance of the primary clarifiers as a function of the flow. The objective is to develop an overall correlation between the flow coming into the plant and the resulting solids loading rate into the secondary clarifiers.

The primary clarifier stress test results were used to determine the TSS percent removal in the primary clarifiers as a function of influent flow rate. A regression analysis of all stress test results performed in the primary clarifiers (except the test performed at the Southeast Plant where the clarifier failed prematurely due to the hydraulic limitations of the launders) was performed, and the lower 95% confidence levels associated with the regression parameters were calculated. Figure 4.3 presents the results of this analysis.

The yield for the SEWPCP was estimated based on the historical tonnage of waste activated sludge pumped to the SWWPCP and the TSS and BOD_5 concentrations in the primary effluent. The SEWPCP is operated at an SRT of 1.9 days, the RAS flow rate is about 30% of the influent flow rate, and the raw wastewater has an average TSS concentration of 142 mg/L. For the determination of the SLR limiting flow, it was assumed that all of the primary and secondary clarifiers are online, but that only six out of the eight aeration basins are in use. This corresponds to current operating practice at the site.

The SLR becomes 35 lb (ft^2.day) at the SEWPCP when the sustained flow is equal to 190 mgd. At flow rates greater than 190 mgd, thickening failure will occur unless measures are taken to reduce the solids loading rate to the secondary clarifiers. Preventative measures that are currently implemented at the SEWPCP include reducing the mixing in the aeration basin to allow solids to settle in Cells 1 and 4 and using the two aeration basins that are out of service as RAS storage for the duration of the storm.

Alternatively, step feed could be implemented at the SEWPCP by constructing an "in basin" primary effluent conduit along the length of the basin. The conduit would operate as a submerged diffusor and would require structural modifications to existing tanks. Improving the primary clarifier performance by providing "out of clarifier" primary sludge thickening or enhanced primary clarifier performance through chemical addition would also reduce the solids loading to the secondary clarifiers. However, these alternatives would require capital expenditure for additional facilities. Improving the solids removal efficiency of the clarifiers would effectively increase the allowable solids loading rate to the clarifier. This would require modifications to the existing RAS system.

4.4 Control of High Flow Duration

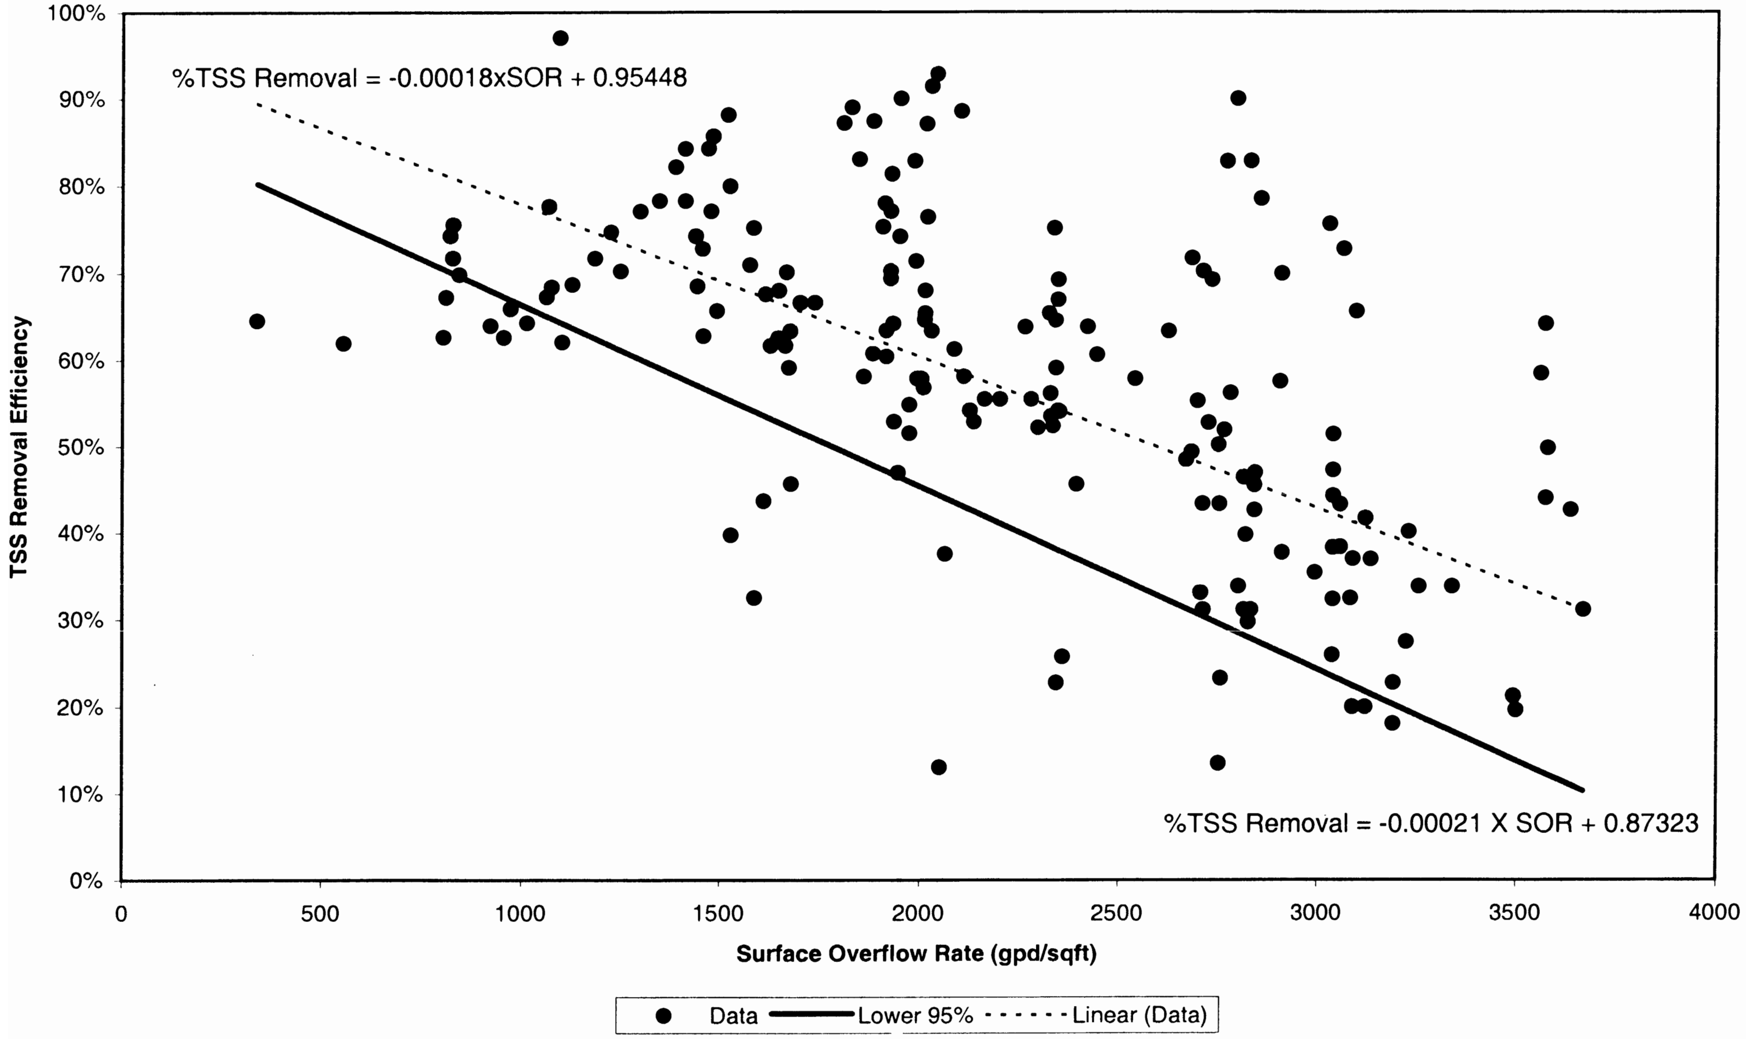
Discussions with PWD managers directing PWD 's CSO program indicated that current CSO inline storage and draw-down plans expect that stored combined sewerage would be released to the plant over a 12-hour period following a storm event. This is a volume of combined sewerage that PWD's plants have not received in the past. Furthermore, there is flexibility in the draw-down strategy since the primary objective of the effort would be to return the storing sewer back to its original condition prior to the next storm event. It was clear that this is only a current plan and it would change should PWD be required in the future to provide additional combined sewerage storage to meet receiving water quality objectives.

From the wastewater treatment plant perspective, a number of factors can influence the ability of a plant to achieve weekly or monthly limits whenever the plant is being stressed by storm-induced, high influent flows. The number and distribution of rain events during the week/month, together with plant effluent quality during non-rain event periods, rank high on the list of influences. PWD's revised permit language provides effluent quality relief, but only when the daily plant flow exceeds the permitted maximum daily flows currently stated in the permits. No such relief occurs for flows below the maximum daily flow limits.

Since the impact of stored combined sewerage on the SEWPCP performance is an unchartered experience, it is recommended that the duration of storage be no greater than a 24-hour period for each storm event. Should the CSO program's strategy for stored combined sewerage change beyond this 24-hour period, the issue of plant compliance for all monthly and weekly effluent quality requirements should be reviewed.

Figure 4-3

Primary Clarifier Stress Test – Percent TSS Removal Efficiency as a Function of SOR



SECTION 5

POTENTIAL UPGRADES

5. Potential Upgrades

A list of potential improvements was developed to increase the capacity or improve the performance of the SEWPCP; the potential improvements are based on the results of stress tests on unit processes, long-term monitoring of the plant, and hydraulic modelling

Each upgrade option has been prioritized based upon the following criteria:

- **Priority A – Existing Facilities Optimization.** Improvements that are easily implemented, low cost, high benefit, and will have an immediate positive impact upon normal operations. These are options that can be included in short-term capital budgets.
- **Priority B – Proactive Improvements.** Improvements that are moderate in cost and will have a positive impact on plant capacity. This category also includes improvements that are necessary to maintain existing capacity for increased mixed liquor suspended solids in the aeration tanks. These are options that should be included in a long-term improvement plan.
- **Priority C - Capacity De-bottlenecking.** Improvements that have large costs associated with them and will greatly increase capacity above the current permitted peak flow. These options should be considered in an overall long-term, wet-weather flow control program and in the long-term improvement plan if significantly more treatment capacity is required at the facility.

The list of potential upgrades, budgetary cost estimates, and their associated prioritization is summarized below. The detailed descriptions of each upgrade are presented in Technical Memorandum 5 - Budgetary Cost Estimates for Potential Plant Improvements.

The cost estimates are based on preliminary costs and are for use as "budgetary" values only. The cost estimates are Class "C" cost estimates (order-of-magnitude costs) as defined by the American Association of Cost Engineers. The level of accuracy of the Class "C" cost estimates is +50 percent to –30 percent of the actual cost of construction. These costs can be used for decisionmaking to select options for more detailed analysis that are most feasible from both a design and cost perspective.

Table 5.1 includes the final estimated cost for each improvement. Table 5.2 presents a summary of the overall cost for improvements at the SEWPCP, which are broken down into alternatives that are dependant upon one another for an increase in capacity at the plant.

TABLE 5.1
POTENTIAL UPGRADE OPTIONS AT SOUTHEAST WPCP

Option No.	Description	Priority Classification	Estimated Conceptual Cost
1	Provide permanent facilities for phosphorous addition if influent phosphorous deficiency remains	A	$200,000
2	Resolve capacity limitation in existing pump station by adding a new bar rack	C	$8-10M, if feasible
3	New influent pump station (Includes adding new bar rack)	C	$24,140,000
4	Replace existing primary clarifier effluent launders with new launders running parallel to flow to increase hydraulic capacity	C	$1,265,000
5	Provide separate primary sludge thickening	C	$3,645,000
6	Provide an additional effluent pump at the effluent pumping station	C	$319,000
7	Provide primary effluent bypass to secondary clarifiers	C	$644,000
8	Resolve hydraulic limitation between primary clarifiers and aeration basin	C	$3,600,000

TABLE 5.2
SUMMARY OF BUDGETARY COSTS FOR POTENTIAL IMPROVEMENTS AT SOUTHEAST WPCP

Improvement Alternatives	Total Costs for Improvements (Million $)	Cumulative Costs for Improvements (Million $)	Peak Treatment Capacity (MGD)			
			Plant	Preliminary	Primary	Secondary
All process improvements (Option 1)	0.2	0.2	240	240	240	240
Increase in raw pumping capacity (Option 2/3)	24.14	24.34	240	330	240	240
Increase primary capacity, bypass aeration basins (Options 4, 5, 6, 7)	5.87	30.21	330	330	330	240
Increase primary and secondary treatment capacity (Options 4, 6, 8)	5.18	33.81	330	330	330	330

Process Improvements. The capacity of the SEWPCP is determined by the solids settling characteristics of the mixed liquor TSS. As discussed in Section 3.1.4, the solids received from Queen's Lane WTP cause a nutrient imbalance in the aeration basin, and phosphorus addition is required to correct this imbalance. Permanent facilities for phosphorus addition address the nutrient deficiency and are currently in use at the plant.

Increase in Raw Pumping Capacity. The capacity of the raw sewage pumping station limits the capacity of the SEWPCP. The objective of Improvement Alternative 2 is to increase the raw sewage pumping capacity. This is required before any other alternatives can be considered for increasing plant flow. The current raw water pumping station is limited to a flow of 200 mgd with one bar rack out of service because of hydraulic limitations in the raw water pump station wet well area.

The facility can operate up to a maximum capacity of 240 mgd with one bar rack partially obstructed. However, there is a greater potential for causing permanent damage to the bar rack or raw sewage pumps operating in this fashion. In the past ten years, a bar rack has been taken out of service for maintenance only once. In the past five years, the hydraulic throughput capacity has never been less than required as a result of maintenance activities. If more CSO flow is brought to the facility, the frequency of the hydraulic throughput being limited by a bar rack out of service will increase.

The hydraulic limitation of the raw sewage pump station is a result of the configuration of the inlet structures. The estimated capital cost of providing a new influent pump station is $24,140,000. A detailed hydraulic evaluation of the pump station inlet structure may identify a more cost-effective method of increasing the hydraulic throughput capacity. Potential retrofits include installing an additional bar rack, additional or larger inlet conduit and/or sluice gates, and modifications to the pump suction channels. However, due to the depth of the pump suction, any modification that requires changes to the inlet structure footprint will be expensive. A new influent pump station may be the preferred alternative.

Increase Primary Treatment Capacity with Aeration Bypass. The estimated primary treatment capacity is 225 mgd with three primary tanks in service. The capacity is limited by the hydraulic capacity of the effluent launders. Replacing the effluent launders will increase the primary treatment capacity to 260 mgd with three tanks in service. The estimated capital cost to replace the clarifier launders is $1,265,000.

The potential primary treatment capacity of the SEWPCP is 330 mgd. Increased primary sludge pumping would be required to achieve the additional primary treatment capacity. The estimated cost of providing a gravity sludge thickening facility at the SEWPCP is $3,645,000.

A bypass between the primary clarifier effluent channel and the mixed liquor channel/secondary clarifier influent will be required to circumvent the hydraulic bottleneck between the primary clarifiers and the aeration basins. One aproach would be to construct the primary effluent channel to the mixed liquor channel. The estimated cost for this potential upgrade is $644,000. The primary effluent would be added to the upstream end of the mixed liquor channel and pass through the secondary clarifiers before discharge. The estimated peak hydraulic capacity of the secondary clarifiers is 330 mgd at current mixed liquor concentrations. The primary effluent will increase the hydraulic loading on the secondary clarifiers without increasing the solids loading. Therefore, the secondary clarifiers have sufficient hydraulic capacity to treat the additional load.

The advantage of this approach is that the primary effluent will receive some additional treatment due to contact with the mixed liquor and the "sweeping" action of the activated sludge in the secondary clarifiers. The final effluent will be of higher quality than the blended effluent from the secondary clarifier and bypass stream combined after the secondary clarifier. However, the contact time between the activated sludge and primary effluent bypass will be very small and therefore BOD_5 removal from the primary effluent will be minimal. A relaxation in the permit requirements on days when aeration tank bypassing occurs is recommended. Additionally, to get the flow out of the plant, a new effluent pump would need to be added at a cost of $319,000.

Increase Primary and Secondary Treatment Capacity. The objective of this plan is to increase the secondary treatment capacity by eliminating the hydraulic bottlenecks at the influent end of the aeration basins. Offline sludge thickening would not be required because the primary effluent would receive full secondary treatment and no bypass arrangement of the aeration basins would be used. The estimated capital cost to provide intermittent pumping between the primary clarifiers and the aeration basin is $3,600,000. Additionally, a new effluent pump would need to be added to increase the capacity of the effluent pumping station from 280 mgd to 350 mgd. The capital cost would be $319,000 for the new pump. The hydraulic residence time of the outfall is greater than 15 minutes at this flowrate, therefore no additional chlorine contact time would be required.

INTRODUCTION

1. Introduction

1.1 Project Objectives and Methodology

As part of its obligations under the Federal Clean Water Act and the Pennsylvania Clean Streams Law, the City of Philadelphia Water Department (PWD) has initiated a program with an objective to minimize the impact of Combined Sewer Overflows (CSO) on local receiving waters. One of the proposed strategies for reducing the CSO volume is to maximize flow to be treated by the water pollution control plants (WPCP) during periods of wet weather. To implement this strategy effectively, the PWD needs to have a clear understanding of the factors that affect how much flow each of the three WPCPs can effectively treat. With this knowledge, the PWD will be able to identify and prioritize plant upgrades and other system modifications that will allow it to meet the CSO minimization objectives in the most environmentally-sound and cost-effective manner.

PWD contracted CH2M HILL to conduct stress testing at the three wastewater treatment plants that are owned and operated by the City. The objective of the stress testing was to determine the reliable maximum capacity of these facilities and identify cost-effective methods of increasing the ability of the existing facilities to treat peak hydraulic flows associated with wet weather conditions. The major tasks performed during the project are briefly described below.

Historical Data and Operations Review. The objective of the historical data and operations review was to evaluate the physical condition, current loading, and treatment efficiency provided by the existing unit processes. A tour of the plant was conducted, and the process equipment and facilities were examined. Operating records, design information, and engineering drawings were studied to develop a strong understanding of the operations and constraints. Technical Memorandum 1 – Historical Data Review was produced to summarize the results of the site visit and historical data analysis.

Short-Term Stress Testing. CH2M HILL performed a series of capacity and diagnostic tests to determine the loading versus performance characteristics of specific unit processes at each facility. The short-term stress testing focused on determining the response of the primary and secondary clarifiers to increased hydraulic loading under different operating conditions. The short-term stress testing at the Southwest WPCP (SWWPCP) included primary clarifier stress tests, secondary clarifier stress tests, secondary clarifier dye tests, and flow meter calibration. The results of each test are summarized in a test description report in Technical Memorandum 2 – Short-Term Test Results.

Long-Term Stress Test (Online Monitoring). Online monitoring equipment was installed to quantify the dynamic load/response characteristics of the secondary treatment system to naturally-occurring storm events. The equipment was also used to monitor the effect increased flows had on the solids inventory in the system and secondary effluent quality. Online monitoring included total plant flow, return activated sludge (RAS) flow, mixed liquor suspended solids (MLSS) concentration, sludge blanket levels, and secondary effluent total suspended solids (TSS) concentration. The equipment was in place from March 1 to June 30, 1999 and recorded data on a 10-minute interval. The long-term monitoring period was extended to include the fall and winter period from October 1, 1999 to January 31, 2000. The results of the long-term stress test are summarized in Technical Memorandum 3 – Long-Term Online Monitoring Results. The detailed online monitoring data and instrument calibration records are provided under separate cover.

Hydraulic Throughput Capacity Assessment. WinHYDRO, a computer model that facilitates complex analysis of plant hydraulics, was used to evaluate the hydraulic throughput capacity of the SWWPCP. Hydraulic and energy grade lines from the headworks to the plant outfall were developed for the average and peak flow conditions. Hydraulic bottlenecks, which limit the hydraulic throughput capacity of the existing facilities, and flow distribution problems were identified and evaluated. The hydraulic throughput capacity of each unit process was determined. The results of the hydraulic modelling performed are summarized in Technical Memorandum 4 – Hydraulic Throughput Capacity of Existing Facilities.

Evaluation if Potential Improvements. Based upon stress testing and hydraulic modeling results, major bottlenecks that limit plant capacity were identified and potential solutions were developed to increase peak instantaneous capacity. Budgetary cost estimates were developed for each potential solution. The results of this analysis are summarized in Technical Memorandum 5 – Budgetary Cost Estimates for Potential Plant Improvements.

1.2 Report Organization

The project notebook consists of a final report and a series of attachments. The main body of the report contains a summary of the results from the stress testing, plant data analysis, and the evaluation of process improvements and upgrade options. The detailed results from the historical data review, short-term testing (stress tests, dye tests and flow meter calibration), online monitoring, and hydraulic throughput capacity assessment are included in the project notebook as attachments. Tables describing the design criteria, scope of work, and estimated capital costs for the potential process modifications and capital upgrades, and the current National Pollution Discharge Elimination System (NPDES) discharge permit for the site are also included as attachments.

2.1.1 Preliminary Treatment

The SWWPCP receives wastewater from a triple-barrel, high-level gravity sewer; a low-level gravity sewer; and the DELCORA forcemain. The triple-barrel, high-level sewer provides approximately 68 percent of the flow to the facility. Three venturi flumes, one for each line in service, measure the flow. The DELCORA forcemain provides approximately 23 percent of the flow to the facility and is measured by a separate venturi flume. Flow from the Biosolids Recycling Center (BRC) is combined with the low-level gravity sewer discharges upstream of the low-level pump wet well. The plant drain system, which includes the recycle flow from the sludge thickening processes onsite, also flows to the low-level pump wet well. The BRC and plant drain flows are measured separately and provide a significant solid and organic loading to the facility. The flow from the low-level pump is measured by a Parshall flume and represents less than 10 percent of the flow to the facility.

The low-level flow discharges on the east side of the common raw sewage channel. Inadequate mixing of the combined raw sewage flow is a concern because the low-level sewer flow travels preferentially to the east side of the SWWPCP facility. The inadequate mixing results in higher organic loadings to the east primary clarifiers (Clarifiers 1 and 5) and the east secondary treatment system.

The SWWPCP has six mechanically-cleaned bar screens. Five of the six screens have 1-inch bar openings, while the sixth screen has 5/8-inch openings. In general, the bar screens operate satisfactorily. However, the 5/8-inch screen experiences grit accumulation upstream of the screen. The screenings are collected and are hauled offsite for disposal. The SWWPCP is able to pass the current peak flow with five of the six screens in service.

The SWWPCP has four rectangular detritor grit removal tanks. Under dry weather flow conditions, two of the four grit tanks are in service. The standby grit tanks are brought into service under high flow conditions. The grit is removed from the detritors and is pumped to the hydrogritters. The washed grit is then removed from the site for disposal. The recycle stream from the hydrogritters discharges into the flocculation basin. A significant volume of grit passes through the existing grit removal system and is deposited in the flocculation tanks downstream. The flocculation tanks must be drained so that the accumulated grit can be removed on a periodic basis. The grit removal process requires one tank to be out of service for approximately two weeks. The hydraulic throughput capacity of the flocculation basins is very limited during this cleaning process.

There are two flocculation tanks at the SWWPCP. Under high flow conditions, the water surface level (WSL) in the flocculation tanks is very close to the top of the wall. Splashing and periodic, short-term overtopping of the walls can occur under high flow conditions when either one primary clarifier and/or one flocculation tank is out of service. The hydraulic restriction is associated with the primary clarifier collection channel and the piping between the primary tanks and aeration basins. This issue is discussed in greater detail in Section 3.2.

2.1.2 Primary Treatment

The SWWPCP has five 250 by 125 feet rectangular primary clarifiers with a side wall depth of 12 feet. Each tank has seven chain and flight mechanisms that move the sludge to the influent end of the basin. The flow from the flocculation tanks enters the common influent channel between Primary Clarifiers 2 and 3. The flow is unequally distributed between tanks, with the east clarifiers receiving approximately 20 percent more flow. The sludge blanket level in Primary Tank 5 is higher than the sludge blanket levels in the other clarifiers because of the higher solids loading associated with the BRC flows. The primary sludge is pumped sequentially from each tank once per day. The primary sludge is pumped to the mixing chamber where it is combined with the thickened waste activated sludge (WAS) and the sludge pumped from the Southeast WPCP (SEWPCP).

Primary effluent discharges into a common effluent channel. Two flow splitter boxes control the flow distribution to the aeration basins. The 20 percent flow imbalance between the east and west primary clarifiers is also seen in the flow distribution to secondary treatment.

The SWWPCP collects a 24-hour composite primary effluent sample from the east and west flow splitter boxes. The primary effluent TSS and five-day biochemical oxygen demand (BOD_5) concentrations are approximately 10 percent higher in the east flow splitter box. Therefore, the loading to the east secondary system is higher due to both a hydraulic imbalance as well as an organic loading imbalance.

2.1.3 Secondary Treatment

The SWWPCP has ten 4-pass UNOX pure oxygen aeration basins. Under current loading conditions, eight of the ten aeration basins are in service. Each basin is 160 by 40 feet with a side wall depth of 17 feet. The aeration basins consist of four cells operating in series. The primary effluent follows a serpentine flow pattern through the basin, and the return activated sludge (RAS) is pumped to the upstream end of Cell A. There are no structures to allow step-feed in the basin.

Each cell has a single, two-paddle submerged aerator/mixer located in the center of the tank. The SWWPCP operates the first cell as an anoxic selector by turning off the first aerator/mixer in the summer months to combat Nocardia and thereby improve the settling characteristics of the mixed liquor. During the winter months, the SWWPCP turns off the aerator mixer in the second cell as part of its ongoing energy management efforts. The first mixer is placed back in service when the second mixer is turned off.

The east and west secondary treatment processes are operated as separate systems. The mixed liquor from the east aeration basins flows to the east secondary clarifiers, and the RAS from the east secondary clarifiers is pumped to the east aeration basins. The mixed liquor suspended solids concentration is approximately 2,270 mg/L and 1,940 mg/L for the east and west secondary systems, respectively. The difference in mixed liquor concentration is due to the difference in loading. The RAS is flow-paced at approximately 32 percent of the flow through the plant.

The mixed liquor from each set of four aeration basins flows through a common mixed liquor channel to a set of ten secondary clarifiers. The caulking on some of the clarifier launders is missing, resulting in a large volume of flow in the launders that is not controlled by the clarifier weir elevation. This results in a flow imbalance between clarifiers that is difficult to predict or control.

Each set of secondary clarifiers consists of ten 76 by 260 foot rectangular clarifiers with a sidewall depth of 11 feet. Each clarifier has eight chain and flight mechanisms that transport the sludge to a central hopper located at approximately the mid-length of the clarifier. The RAS flow rate is measured separately for each clarifier. The maximum RAS per clarifier is limited to 6.2 mgd.

2.1.4 Disinfection

Secondary effluent from the east and west secondary treatment processes flows through the secondary effluent channel to the effluent pump station wet well. The conduit is separated for approximately 200 feet before it is combined upstream of the common wet well. Under dry weather flow conditions, the secondary effluent flows by gravity through a triple-barrel outfall to the Delaware River. The outfall conduit provides contact time for disinfection.

The SWWPCP has five effluent pumps, four of which are in service. Three of the effluent pumps are equipped with variable speed drives, two pumps are single speed only. The effluent pumps are operated based on the WSL in the effluent pump station wet well. Under wet weather flow and/or high tide conditions, the pumps are controlled automatically based on wet well level, but they must be placed into service manually.

2.1.5 Solids Handling

The waste activated and primary sludge generated at the SEWPCP is treated at the SWWPCP. The WAS from the SEWPCP and SWWPCP is pumped to the sludge thickeners. The SWWPCP has eight 18 by 70 feet dissolved air floatation (DAF) sludge thickeners. All attempts are made to keep the eight tanks in service, because additional sludge thickening capacity is often required. The thickened WAS sludge is pumped to the sludge-mixing chamber where it is combined with the primary sludge. The underflow from the DAF sludge thickeners flows to the plant drain and therefore to the wet well of the low-level sewage pump station. However, when the sludge volume index (SVI) of the WAS is high, the DAF units are not able to separate the WAS, and the underflow from the DAF units has a very high solids concentration. The sludge thickening process can become limiting, depending on the quality and quantity of sludge pumped from the SEWPCP, BRC centrate loadings, and/or if one or more units is out of service.

The SWWPCP has 12 anaerobic digesters with an average hydraulic residence time (HRT) of 18 days. The combined primary and waste activated sludge is pumped to the anaerobic digesters sequentially, with each digester receiving solids for nine minutes on each sequence. The digested solids are transported to the BRC for composting and beneficial reuse. The recycle streams from the BRC facility are returned to the SWWPCP headworks for treatment.

2.2 Regulatory Requirements

The SWWPCP NPDES permit limits include effluent BOD_5 and TSS concentrations; mass loading discharges; and percent removal for daily, weekly averages and monthly averages. Table 2.2 summarizes the NPDES permit criteria for the facility in effect during testing. Compliance is based on the flow measured by the four venturi meters and one Parshall flume located upstream of the preliminary treatment and 24-hour composite samples collected daily at the influent and outfall station.

TABLE 2.2
SOUTHWEST WPCP – NPDES PERMIT REQUIREMENTS

Parameter	Units	Monthly Average	Weekly Average	Maximum Day	Peak Instantaneous
BOD_5					
Concentration	mg/L	30	45		60
Mass loading	lbs./day	21,650	32,475	--	
Percent removal	%	89.25			
TSS					
Concentration	mg/L	30	45	--	60
Mass loading	lbs./day	50,040	75,060		
Percent removal	%	85			
Flow	mgd	200		300	400

PWD has negotiated a new NPDES permit for the facility effective July 2000. The modifications to the NPDES permit are summarized below.

As part of PWD's long-term combined sewer overflow (CSO) program, PWD will be reducing the frequency and volume of untreated sewage discharges through the CSOs. In order to account for the increased loading due to the combined sewage flows that exceed the treatment plant's rated hydraulic capacity, the following methods may be used for calculating and reporting mass loadings and effluent concentrations on the monthly discharge monitoring report.

- If a calendar month includes one or more days where flows exceed 300 mgd, a value of 85 percent may be used for those days for the purpose of calculating average monthly TSS percent removal. The actual TSS percent removal associated with those days shall be reported on the appropriate space provided on the DMR.
- If a calendar month includes one or more days where flows exceed 300 mgd, a value of 89.25 percent may be used for those days for the purpose of calculating average monthly BOD_5 percent removal. The actual BOD_5 percent removal associated with those days shall be reported on the appropriate space provided on the DMR.
- When daily flows exceed 300 mgd, the TSS and BOD_5 mass loadings for those days may be omitted from the average monthly and average weekly mass loading calculations. The actual TSS and BOD_5 loadings associated with those days shall be reported on the appropriate space provided on the DMR.

PWD has requested that $cBOD_5$ data be used to establish compliance with permit requirements. Analysis of the data collected over the previous permit cycle indicated that there is relatively little variation in the influent ratios of $cBOD_5/BOD_5$. Therefore, calculating the theoretical influent $cBOD_5$ loadings based on historic BOD_5 data can be used to develop recommended $cBOD_5$ limits for this facility.

The new NPDES $cBOD_5$ permit requirements for SW WPCP are:

	Concentration (mg/L)	Mass Loading (lbs/day)	Percent Removal (%)
Average monthly	25	19,800	89.25
Average weekly	40	29,700	
Instantaneous maximum	50		

The $cBOD_5$ in the raw wastewater shall be reduced by at least 89.25 percent as a monthly average. The percent removal shall be calculated from daily 24-hour composite samples of the influent and effluent. The $cBOD_5$ percent removal requirement will be relaxed to 86 percent when the influent $cBOD_5$ concentration is less than 103 mg/L on a monthly average basis as long as the $cBOD_{20}$ allocation, equivalent mass BOD_5 limitation, and an effluent $cBOD_5$ concentration of 14 mg/L are not exceeded on a monthly basis.

A copy of the new NPDES permit is located in the Project Notebook.

2.3 Current Loading and Performance Achieved

2.3.1 Unit Process Loading

Table 2.3 presents a summary of the current unit process loading over a three-year period from July 1995 to July 1998. The average and maximum daily flows were 176 mgd and 384 mgd, respectively. The maximum instantaneous flow was 439 mgd. On September 16, 1999, during Hurricane Floyd, the maximum instantaneous flow at the plant reached 486 mgd.

The average raw sewage TSS and BOD_5 concentrations were 154 mg/L and 108 mg/L, respectively. The average organic loadings to the treatment plant, calculated based on the raw sewage TSS and BOD_5 concentration and the average flow for each day, were 224,434 lbs/day and 156,642 lbs/day, respectively. Approximately 30 percent of the TSS loading to the SWWPCP is from the BRC recycle streams.

2.3.2 Primary Treatment Performance

The average and peak SORs for the primary clarifiers were approximately 1,126 gpd/ft^2 and 2,810 gpd/ft^2, respectively. Typical overflow rates for rectangular clarifiers are between 1,000 gpd/ft^2 and 3,000 gpd/ft^2. The primary clarifiers at the SWWPCP are operating at close to the expected maximum capacity based on typical SORs.

The removal efficiencies are lower than expected based on current hydraulic loading. The expected TSS and BOD_5 removal efficiencies are 60 and 35 percent, respectively. The average TSS removal efficiencies in the primary clarifiers were 47 and 43 percent for the east and west sides of the plant, respectively.

Based on solids removal efficiency, the east clarifiers performed slightly better than the west clarifiers. This is due to the higher solids concentration in the primary influent on the east side of the plant. Based on primary effluent solids concentration, the west primaries performed significantly better than the east primaries. The average TSS concentrations in the primary effluent were 125 mg/L and 95 mg/L for the east and west, respectively. The BOD_5

removal efficiencies in the primary clarifiers were 28 and 38 percent for east and west primary clarifiers, respectively. The BOD_5 removal efficiencies were closer to the expected values.

2.3.3 Secondary Treatment Performance

The average primary effluent TSS and BOD_5 concentrations were 110 mg/L and 75 mg/L, respectively. The average and 95th percentile total BOD_5 loading to the secondary treatment system, calculated based on the primary effluent BOD_5 concentration, and the average flow for each day were 104,720 lbs/day and 153,0455 lbs/day, respectively.

TABLE 2.3
SOUTHWEST WPCP – SUMMARY OF CURRENT UNIT PROCESS LOADINGS (JULY 1995 – JULY 1998)

Unit Process	Units	Current Loadings		Typical Values	Notes
		Average	Maximum		
Loading

Notes:
1. Maximum hydraulic loading based on instantaneous flow
2. Maximum loading based on 95th percentile
3. Based on two units in service for average day flow and four units in service for maximum flow
4. Based on all units in service
5. Based on eight aeration basins in service

The Southwest WPCP has three sources that provide flow to the plant. The high level interceptor can deliver up to 540 mgd to the plant. The DELCORA interceptor can deliver up to 110 mgd. The low level gravity sewer delivered capacity is limited to the pumping capacity at the headworks, which is 96 mgd with all three pumps running.

The estimated treatment capacity of the preliminary treatment system is 475 mgd. This is based on two of the three low level pumps in service (64 mgd) and the remainder of flow provided by the interceptors. Treatment capacity is based upon acceptable bar screen face velocities and one bar screen out of service. Under peak flow conditions, the face velocity on the bar screens will vary between 0.2 to 0.4 ft/sec.

The design of the SWWPCP allows the east and west secondary treatment processes to be operated as different systems. The organic loading to the east secondary treatment system is approximately 20 percent higher. The average mixed liquor concentrations in the east and west secondary treatment systems were 2,265 mg/L and 1,947 mg/L, respectively. The east and west aeration basins are currently operating with a solids residence time (SRT) of 2.0 days. The food to microorganisms (F:M) ratio in the aeration basins averaged 0.4 day^{-1}.

The average SVIs were 111 mL/g and 94 mL/g for the east and west systems, respectively, indicating a well-settled sludge. Typically, SVI values for a well-settled activated sludge are between 100 mL/g and 150 mL/g. During the summer months, the SWWPCP experiences occasional episodes of Norcardia infestations. Plant operations is able to control the filamentous growth by creating an anoxic selector in the first cell of the aeration basin by turning off the first aerator/mixer.

The average and peak SORs for the secondary clarifiers were approximately 445 gpd/ft^2 and 1,110 gpd/ft^2, respectively. Typical SORs for rectangular Gould-type clarifiers are between 800 gpd/ft^2 to 1,500 gpd/ft^2. The secondary clarifiers at the SWWPCP are operating well below their expected maximum hydraulic capacity based on typical SORs.

The average and peak solids loading rates (SLRs) for the secondary clarifiers were approximately 12 and 19 lbs/day/ft^2 on the east clarifiers and 10 and 15 lbs/day/ft^2 on the west clarifiers. Typical peak SLRs for rectangular Gould-type clarifiers are between 20 and 40 lbs/day/ft^2. The secondary clarifiers at the SWWPCP are operating at lower than typical SLRs.

The secondary clarifiers at the SWWPCP achieve a very good quality final effluent. The daily TSS and BOD_5 concentrations were consistently below the NPDES criteria of 60 mg/L. The average effluent TSS and BOD_5 concentrations were 6.4 and 9.1 mg/L, respectively.

SECTION 3

CURRENT CAPACITY

3. Maximum Instantaneous Capacity

3.1 Maximum Treatment Capacity

The current maximum instantaneous treatment capacity of the unit processes at the SWWPCP was estimated using a combination of manufacturers information, standard engineering design loading and performance criteria, operations staff observations of previous performance, and field testing of specific unit processes.

The field testing conducted at the SWWPCP included the following:

Online Monitoring Data

- Secondary Clarifier 2
- Plant flow, RAS flow, mixed liquor TSS, sludge blanket level, and effluent TSS from March 1 to June 30 1999, and from October 1, 1999, to January 31, 2000

Primary Clarifier Stress Tests

- Primary Clarifier 5 with BRC solids
- Primary Clarifier 4 without BRC solids

Secondary Clarifier Stress Tests

- Secondary Clarifier 20

Flow Distribution Dye Tests

- East and west mixed liquor channel
- Primary clarifiers

Table 3.1 summarizes the estimated treatment capacity for each unit. The basis of the estimated capacity is discussed below. The detailed field test results are presented in Technical Memorandum 2 – Short-Term Test Results and Technical Memorandum 3 – Long-Term Online Monitoring Results

3.1.2 Preliminary Treatment

The estimated treatment capacity of the preliminary treatment system is 475 mgd. This is based on the rated capacity of 32 mgd of the existing pumps with two of the three pumps in service, plus an estimated capacity of 475 mgd for the high-level interceptor.

For peak flow conditions, the face velocity for the bar screens will vary from 0.2 to 0.4 ft/s. The face velocity is determined by the water surface level through the bar screen channel.

The theoretical treatment capacity of the grit removal tanks is 625 mgd. This is based on three of the four grit detritors in service, with an allowable SOR of 58,000 gpd/ft^2. The theoretical removal efficiency of the grit removal system is 90 percent of particles greater than 60 mesh (25 mm) under peak flow conditions.

TABLE 3.1
SOUTHWEST WPCP TREATMENT CAPACITY ASSESSMENT

Unit Process	Estimated Capacity (mgd)	Criteria
Preliminary Treatment	540 mgd – screening and raw sewage pumping capacity	
	Low level interceptor[1] – 64 mgd	Rated capacity of pumps
	High level interceptor – 475 mgd	Observed maximum flow
Grit Removal	625 mgd – grit removal [2]	SOR – 58,000 gpd/ft^2
Primary Treatment	250 mgd[3] – with BRC solids	Based on allowable SOR – 2,000 gpd/ft^2
	350 mgd[3] – with BRC solids	Based on allowable SOR – 2,800 gpd/ft^2
	440 mgd[3] – without BRC solids	Based on allowable SOR – 3,500 gpd/ft^2
Aeration Basins	N/A no change to organic loading patterns.	
Secondary Clarifiers	675 mgd [3] – existing	Based on allowable SOR – 1,800 gpd/ft^2
	550 mgd [3] – mixed liquor concentration 2,000 mg/L	Based on allowable SLR – 30 lbs/day/ft^2
	350 mgd [3] – mixed liquor concentration 3,000 mg/L	Based on allowable SLR – 30 lbs/day/ft^2
ES station	460 mgd [4] (1 pump out of service)	115 mgd rated capacity
Chlorination	830 mgd – volume of plant outfall	HRT – 15 minutes

[1] Based on design capacity of 32 mgd for each pump, with one pump out of service
[2] Based on unit out of service
[3] Based on one clarifier out of service
[4] Based on one pump out of service

3.1.3 Primary Treatment

Six primary stress tests were conducted at the three wastewater treatment plants owned and operated by the PWD. Table 3.2 summarizes the physical characteristics of the clarifiers at each site and the stress tests performed. The primary clarifiers at all three plants are hydraulically similar. Differences in behaviour are the result of differences in influent characteristics and minor differences in influent and effluent structures.

TABLE 3.2

Target SOR (range) gpd/ft^2	1,000-2,400	1,000-3,500	1,000-3,000	750-2,800

Two stress tests were performed on the primary clarifiers at the SW WPCP. Figure 3-1 presents the measured TSS removal efficiency as a function of SOR and Figure 3-2 presents the measured effluent TSS concentration as a function of SOR. The test procedures and detailed results are described in Technical Memorandum 2; the main findings are summarized below.

Primary Clarifier 5 – With BRC Recycle. The stress test on the SWWPCP Primary Clarifier 5 indicated that the clarifier performance deteriorated at a SOR of 2,800 gpd/ft^2 with a removal efficiency less than 60 percent. However, the primary effluent TSS concentration was consistently greater than 80 mg/L at SOR greater than 2,300 gpd/ft^2. The apparently high solids removal efficiency was associated with the high solids concentration in the primary influent. The sludge blanket in the clarifier was greater than four feet and rose steadily through the test. The solids in the primary effluent were black.

Primary Clarifier 4 – Without BRC Recycle Stream. The stress test on the SWWPCP Primary Clarifier 4 indicated that the clarifier performance deteriorated at a SOR of 3,100 gpd/ft^2 with a TSS removal efficiency of less than 60 percent. The sludge blanket in the clarifier remained relatively constant through the test, rising slightly at the effluent end of the clarifier at the end of the test period. The primary effluent TSS concentration remained below 80 mg/L throughout the test.

Figure 3-1
SWWPCP Primary Clarifier Stress Test
TSS Removal Efficiency as a Function of Hydraulic Loading

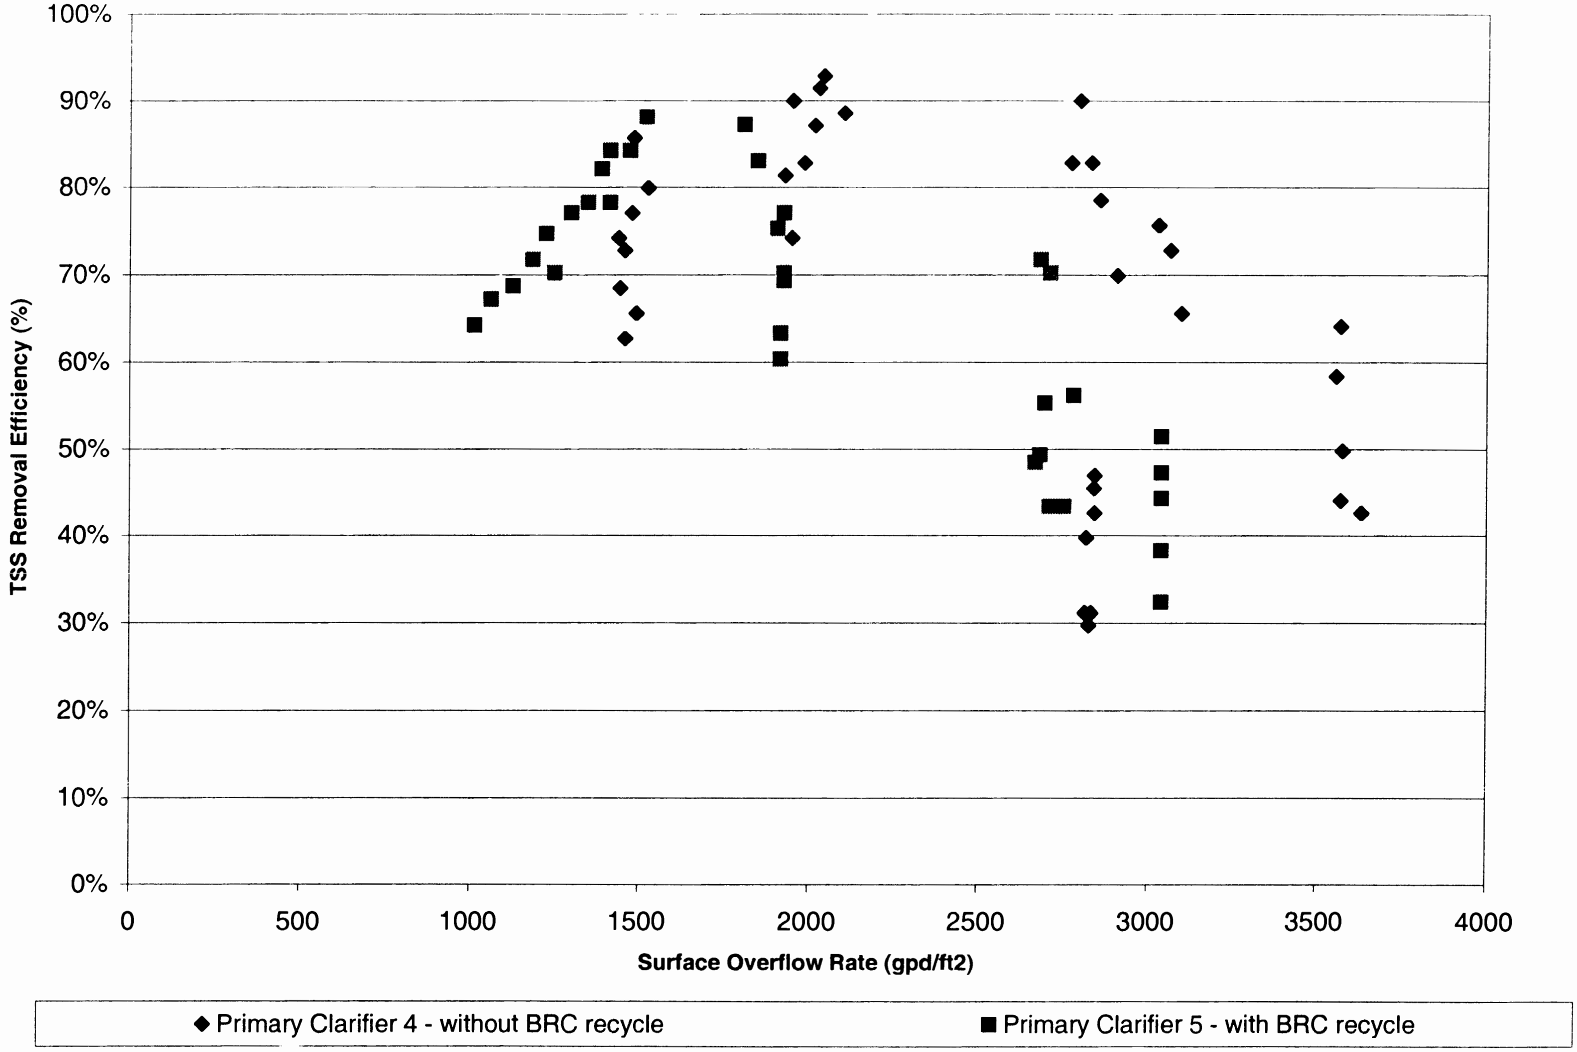

Figure 3-2
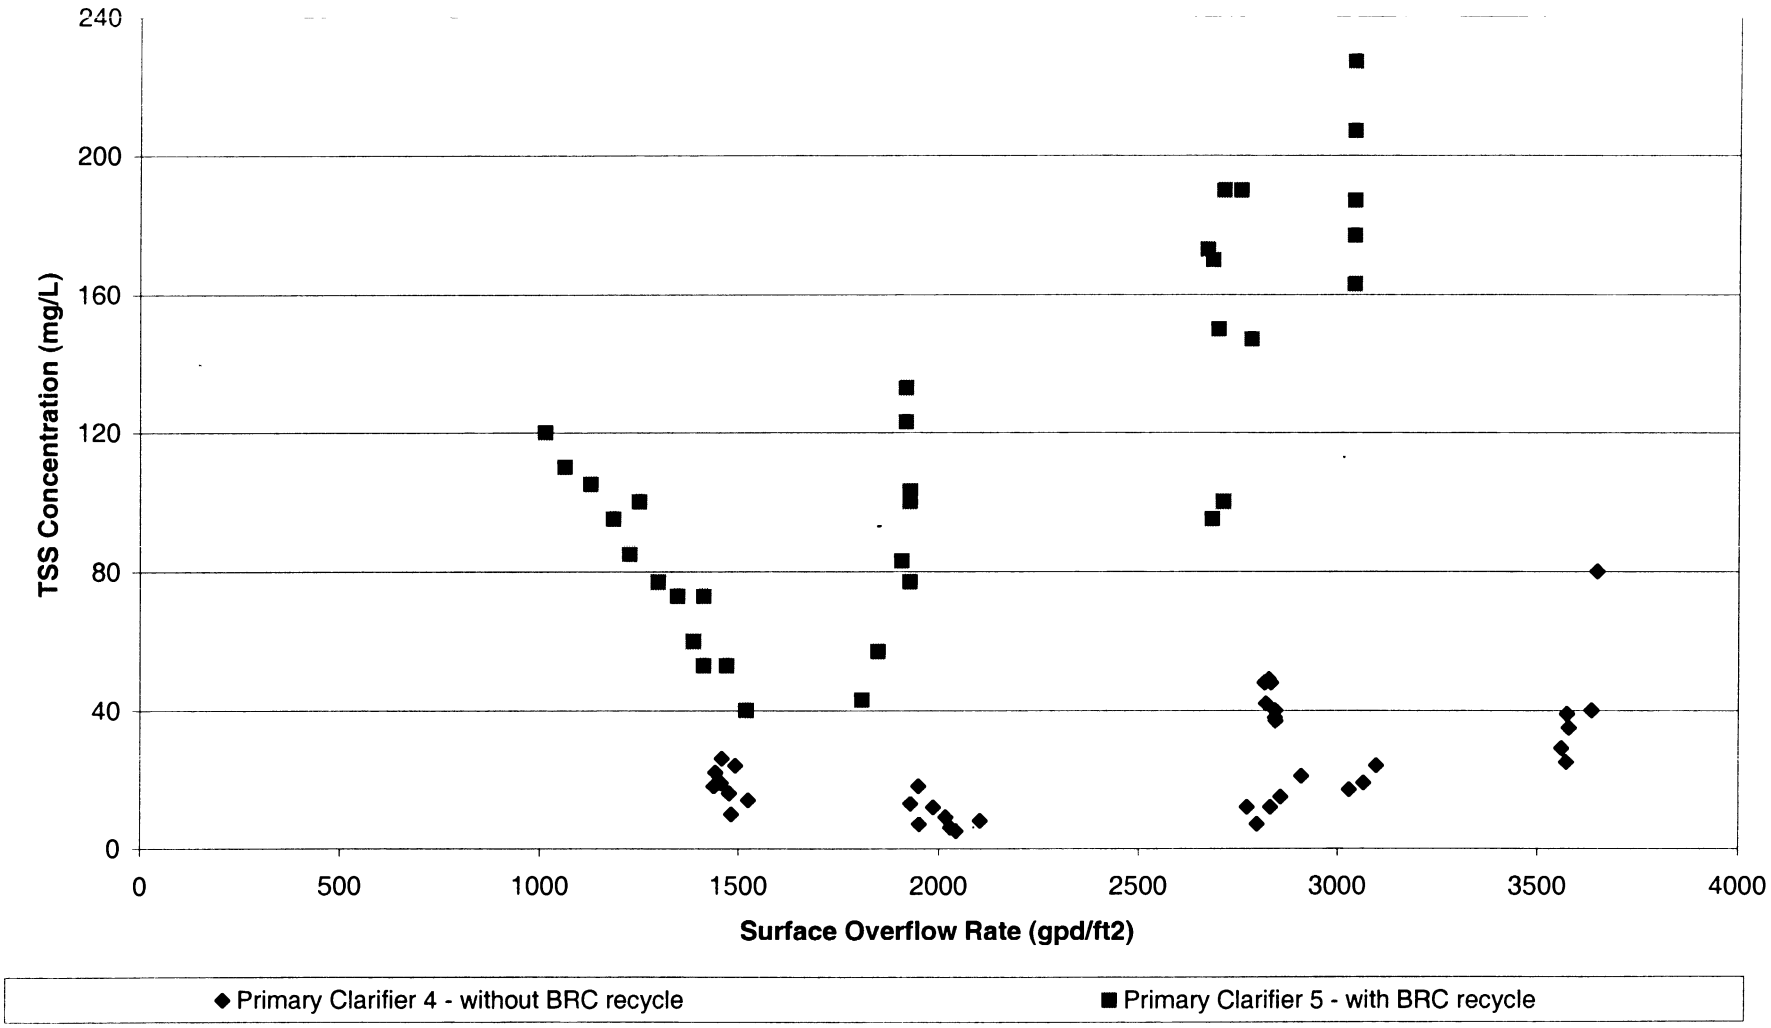
SWWPCP Primary Clarifier Stress Test
TSS Concentration as a Function of Hydraulic Loading



The estimated treatment capacity of the SWWPCP primary clarifiers is between 250 and 350 mgd with four clarifiers in service. This is based on the results of the Primary Clarifier 5 stress test. The clarifier performance deteriorated at an SOR of 2,000 and 2,800 gpd/ft^2, respectively. The BRC recycle stream has a negative impact on the primary clarifier performance. The BRC solids impact the east primary clarifiers, but have a less significant impact on the west primary clarifiers. Under high flow conditions, the TSS removal efficiency of Primary Clarifier 5 is poor at overflow rates greater than 2,000 gpd/ft^2. More significantly, the primary effluent TSS concentration is more than four times higher for Primary Clarifier 5. This results in a significant increase in organic loading to the east secondary treatment system.

The estimated treatment capacity of the primary clarifiers without BRC loading is 440 mgd with four clarifiers in service. This is based on the results of the Primary Clarifier 4 stress test performed at the SWWPCP. The clarifier performance deteriorated at an SOR of 3,500 gpd/ft^2, and the primary effluent TSS concentration remained below 80 mg/L throughout the test.

3.1.4 Secondary Treatment

Six secondary clarifier stress tests were conducted at the three wastewater treatment plants owned and operated by the PWD. Table 3.3 summarizes the physical characteristics of the clarifiers at each site and the secondary clarifier stress tests performed. The secondary clarifiers at all three plants are very similar and performed similarly. Differences in performance were largely the result of differences in mixed liquor settling characteristics and solids loading during the tests.

Target SOR (range) gpd/ft^2	860-2,000	600-2,100		1,000-2,100
Dye tests	1	0	3	1

One stress test was performed on the SWWPCP secondary clarifiers. The test procedures and results are described in Technical Memorandum 2; the main findings are summarized below.

The stress test was conducted on Secondary Clarifier 20. Figure 3-3 presents the flow and effluent TSS concentration as a function of time for the test. Figure 3-4 presents the effluent TSS concentration as a function of SOR. The test was conducted by increasing the hydraulic loading on the clarifier in incremental steps. The effluent TSS concentration remained below 60 mg/L. The maximum SOR achieved during the tests was 2,100 gpd/ft^2. The blanket in the clarifier began to rise at an SOR of 2,100 gpd/ft^2.

Dye dilution was used to measure the flow in the mixed liquor channel for the east and west secondary treatment system. The testing indicated that the east side received approximately 20 percent more primary effluent flow.

The operators' experience indicates that the secondary clarifiers will fail at a total plant flow rate of less than indicated by the stress test results and that the east clarifiers are more susceptible to failure. The mixed liquor concentration is approximately 17 percent higher in the east secondary treatment system and the hydraulic loading is approximately 20 percent greater. The combination of increased flow and increased mixed liquor concentration results in an increase of 35 to 40 percent in the solids loading to the east clarifiers. The operators use the two empty aeration tanks to store RAS, thereby reducing the solids loading on the clarifiers during high flow conditions.

The caulking on the secondary clarifier effluent launders is in poor condition. A large volume of flow was observed coming up through the launder joints and connections after rather than over the clarifier effluent weirs. This results in an uneven flow distribution between clarifiers that is difficult to control or predict. Replacing the caulking in the clarifiers affected will improve the flow distribution between clarifiers and prevent premature failure.

The performance of the secondary clarifier was monitored over two 4-month periods using online instrumentation to quantify the dynamic performance of the clarifiers to naturally-occurring storm events. The online instrumentation recorded total plant flow, RAS flow, mixed liquor TSS concentration, sludge blanket levels, and effluent TSS concentration. The online monitoring recorded the response of the secondary clarifier to 15 storm events. Table 3.4 summarizes results of the online monitoring program; more detailed results are presented in Technical Memorandum 3.

TABLE 3.4
RESULTS OF THE ONLINE MONITORING PROGRAM

Date	SVI ml/g	MLSS mg/L	Online TSS Concentration		24 h Average Effluent TSS	Peak Achieved	
			Average mg/L	Peak mg/L	(mg/L)	Q mgd	SOR gpd/ft^2
March 6	NA	1,240	NA	NA	2.5	334	845
March 14	131	1,750	NA	NA	3.6	382	967
March 21	98.5	1,340	NA	NA	16.8	425	1,075

December 10	105	1,240	34.9	59	22	344	870
December 13	100	1,300	17.2	34	23	414	1,048
December 20	78	1,540	14.2	22	11.2	337	853
Jan 10, 2000	138	1,380	14.1	19	11.3	354	896

The secondary clarifier TSS concentration did not exceed 60 mg/L during the online monitoring period. During the storm events of December 6, December 10, and December 13, 1999, the online effluent TSS monitor indicated that the effluent TSS concentration reached peaks of 40, 59 and 34 mg/L, respectively. During the storm event of December 10, 1999, the effluent TSS concentration increased dramatically under relatively low hydraulic loading conditions. The plant flow data indicates that, during the storm, the return activated sludge pump was operating erratically. The inconsistent pumping during the storm likely resulted in elevated effluent TSS concentration in the final effluent.

Figure 3-3
SWWPCP Secondary Clarifier Stress Test
Effluent TSS Concentration Versus Time

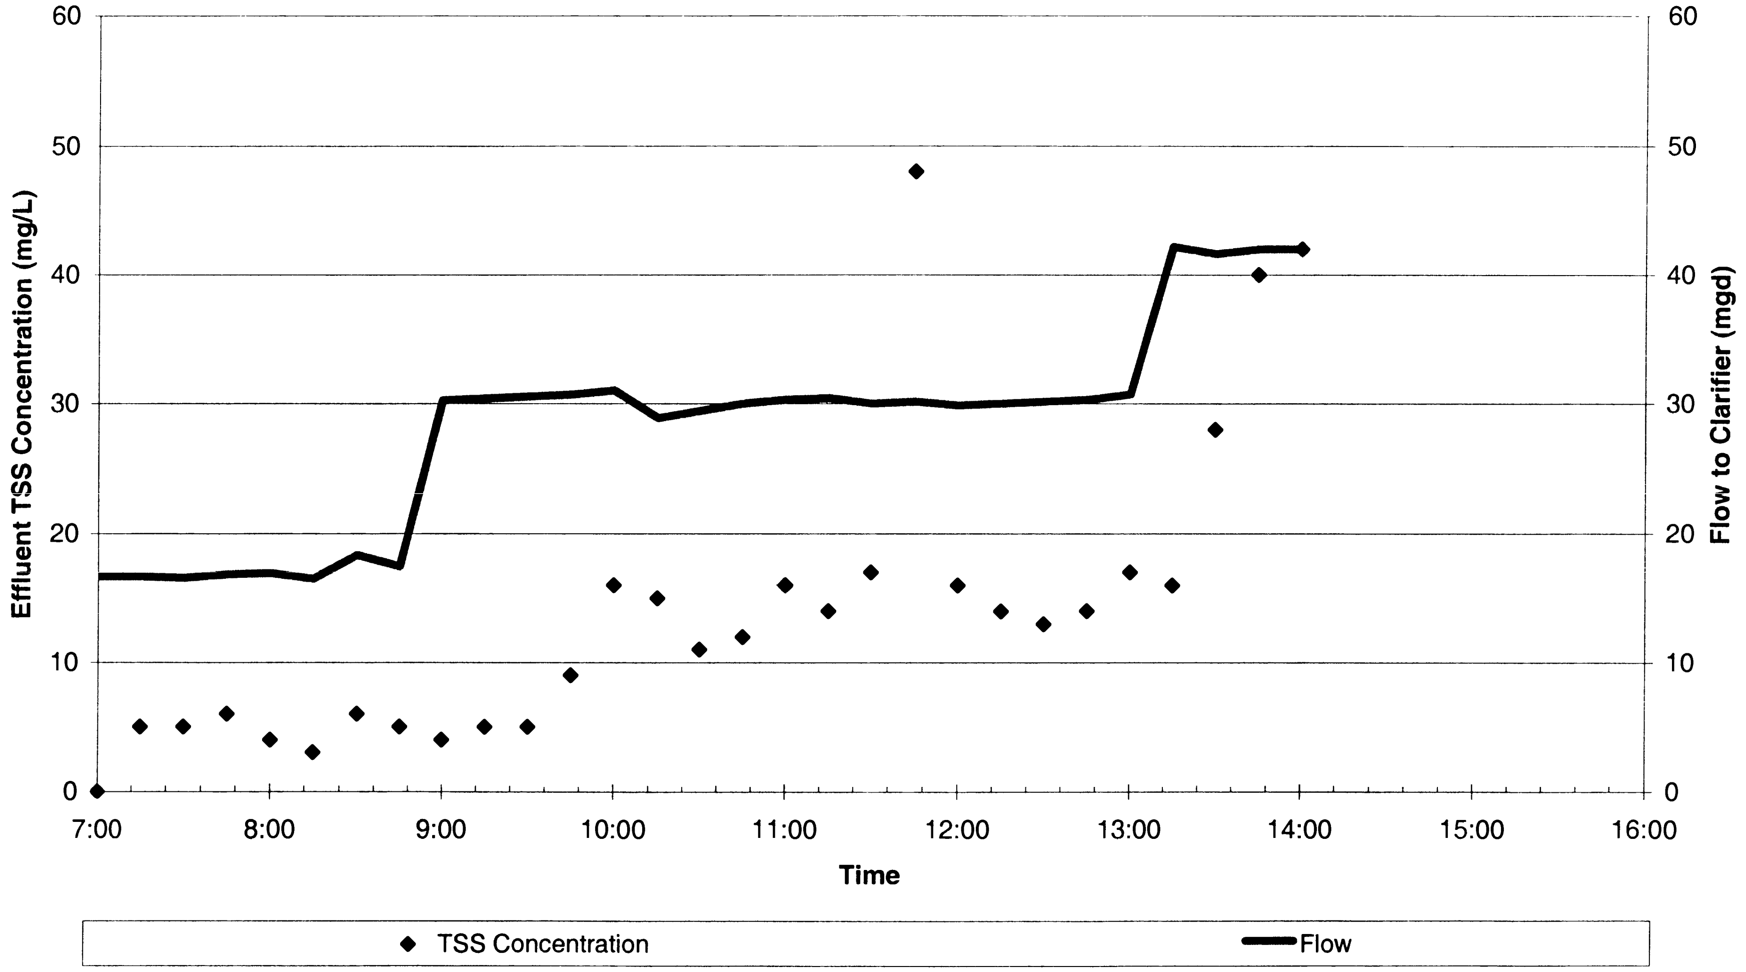

Figure 3-4
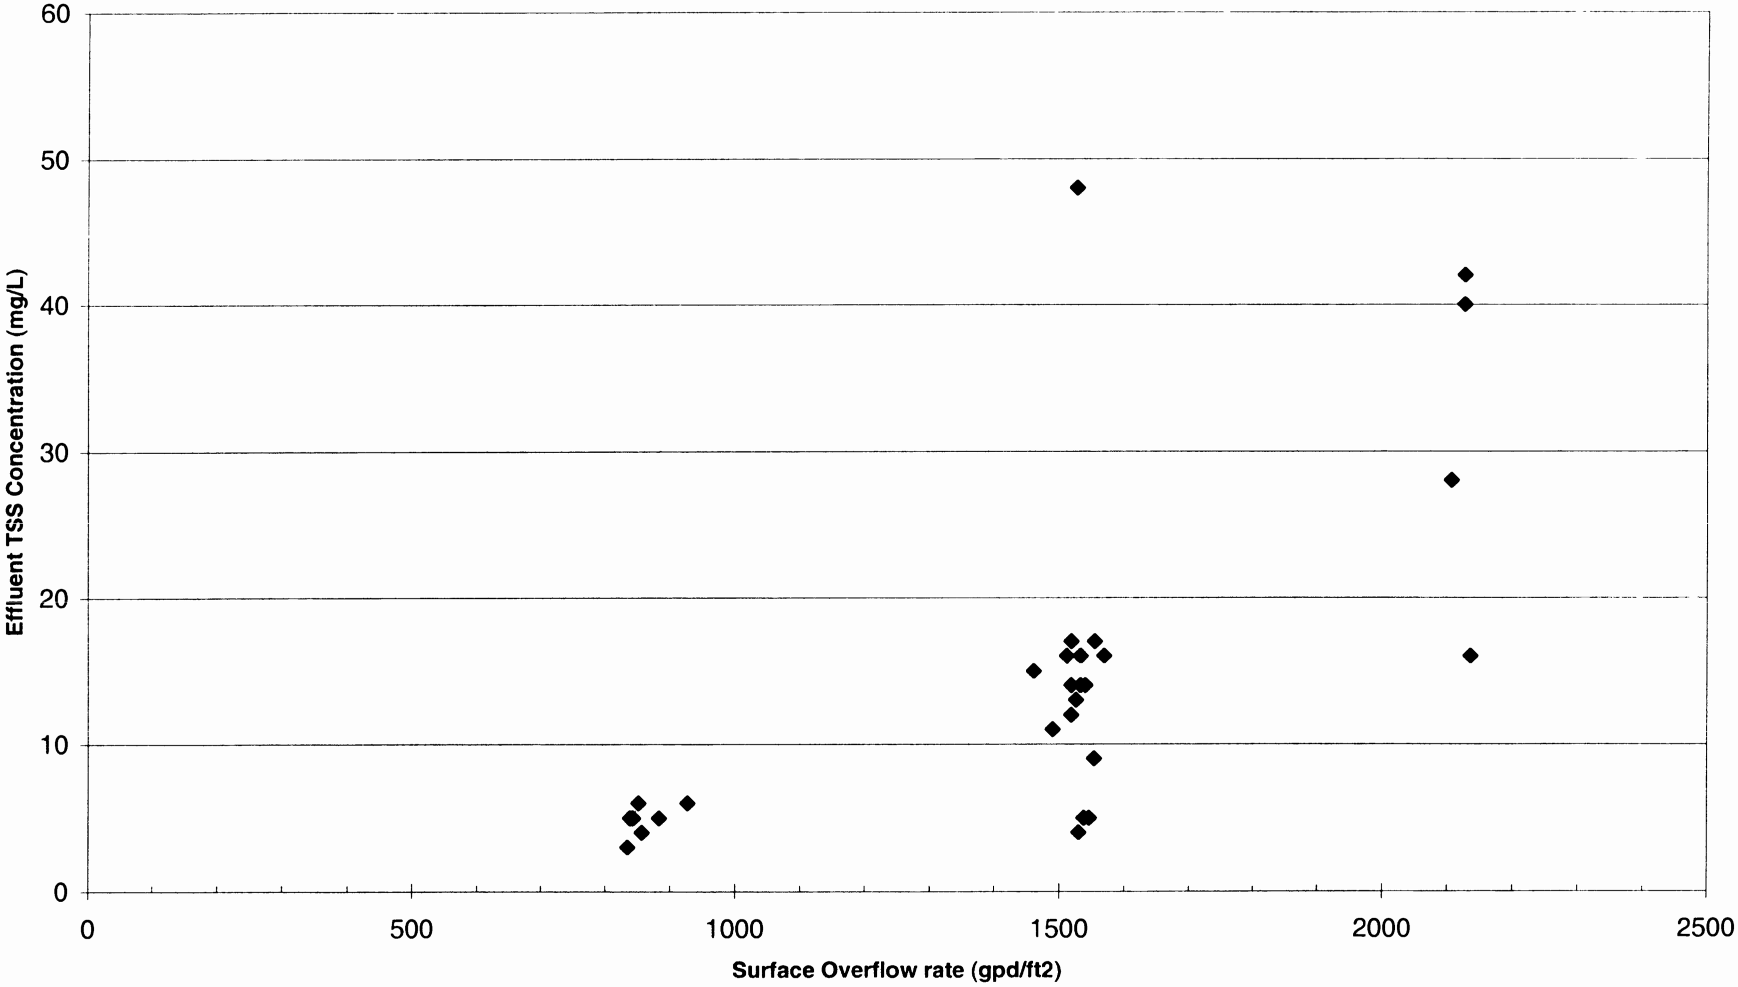
SWWPCP - Secondary Clarifier Stress Test
Effluent TSS Concentration as a Function of Hydraulic Loading



3.1.5 Disinfection and Effluent Pump Station

The estimated capacity of the SWWPCP effluent pump station is 460 mgd. This is based on the rated capacity of the existing pumps with one pump out of service. The rated capacity of the disinfection is 830 mgd. This is based on 15-minute HRT in the existing outfall under peak flow conditions.

3.2 Hydraulic Throughput Capacity

The hydraulic throughput capacity of the unit processes at the SWWPCP were estimated using WinHYDRO, a computer model that facilitates complex analysis of plant hydraulics. Hydraulic and energy gradelines from the headworks to the plant outfall were developed for a number of flow rates. The hydraulic throughput capacity of each unit process was developed based on the assumption that the downstream hydraulic bottlenecks had been resolved. Table 3.2 summarizes the estimated hydraulic throughput capacity for each unit process. The detailed hydraulic modelling results are presented in Technical Memorandum 4 – Hydraulic Throughput Capacity of Existing Facilities.

TABLE 3.2
SOUTHWEST WWTP CURRENT HYDRAULIC THROUGHPUT CAPACITY

Unit Process	Estimated Capacity (mgd)	Basis of capacity estimate
Outfall	>800 mgd	• Flow path – from the Delaware River to the effluent pump station • Hydraulic control section – mean high tide of 97.75 feet • Two outfall channels in service • Hydraulic exceedance – pump station discharge weir elevation
Secondary effluent channel	Version A – 410 Version B – >800	• Flow path – effluent PS wet well to the secondary clarifier weir • Hydraulic control section – PS wet well water surface level Version A – wet well level at maximum WSL - 99 ft feet Version B – wet well level at WSL – 96 feet • Twenty secondary clarifiers in service • Hydraulic exceedance – secondary clarifier overflow weir elevation
Mixed liquor channel	790	• Flow path – secondary clarifier effluent weir to the aeration basin overflow weir • Hydraulic control section – secondary clarifier weir • The secondary clarifier weir has a free discharge Hydraulic exceedance – aeration basin overflow weir elevation
Aeration basin and primary flow split box	Capacity 1 - 340 Capacity 2 - 410 Capacity 3 > 500	• Flow path – aeration basin overflow weir to the primary clarifier overflow weir • Hydraulic control section – aeration basin overflow weir • 50/50 flow split between east and west side, eight aeration basins in service • Hydraulic exceedance [1] – primary effluent flow split weir elevation Hydraulic exceedance [2] – primary clarifier overflow weir elevation Hydraulic exceedance [3] – top of concrete

TABLE 3.2
SOUTHWEST WWTP CURRENT HYDRAULIC THROUGHPUT CAPACITY

Unit Process	Estimated Capacity (mgd)	Basis of capacity estimate
Preliminary treatment	520 – Parshall flume 680 – top of concrete	• Flow path – primary clarifier overflow weir to influent channel downstream of the Parshall flume • Hydraulic control section – primary clarifier overflow weir • Five primary clarifiers, two flocculation tanks, four detritors, and five bar screens in service • Hydraulic exceedance – Parshall flume flooded Hydraulic exceedance – top of concrete at bar screens

The hydraulic throughput capacity of the SWWPCP is greater than 600 mgd, except for the following locations:

- **Aeration Basin Overflow Weir** - Under high flow conditions, the water surface level in the aeration basin increases and submerges the primary effluent flow split weirs. The primary effluent flow split weirs become submerged at approximately 340 mgd with eight aeration basins in service. The primary clarifier effluent weirs become submerged at approximately 410 mgd. The water surface level in the flocculation tanks and grit chambers are impacted by the increase in water surface level in the primary clarifiers. The hydraulic limitation is the aeration basin outfall weirs. The weir discharge is restricted to keep oxygen in the enclosed aeration tanks.

- **Parshall Flume** - At flow rates greater than 520 mgd, the water surface level downstream of the parshall flume will impact the flow measurement.

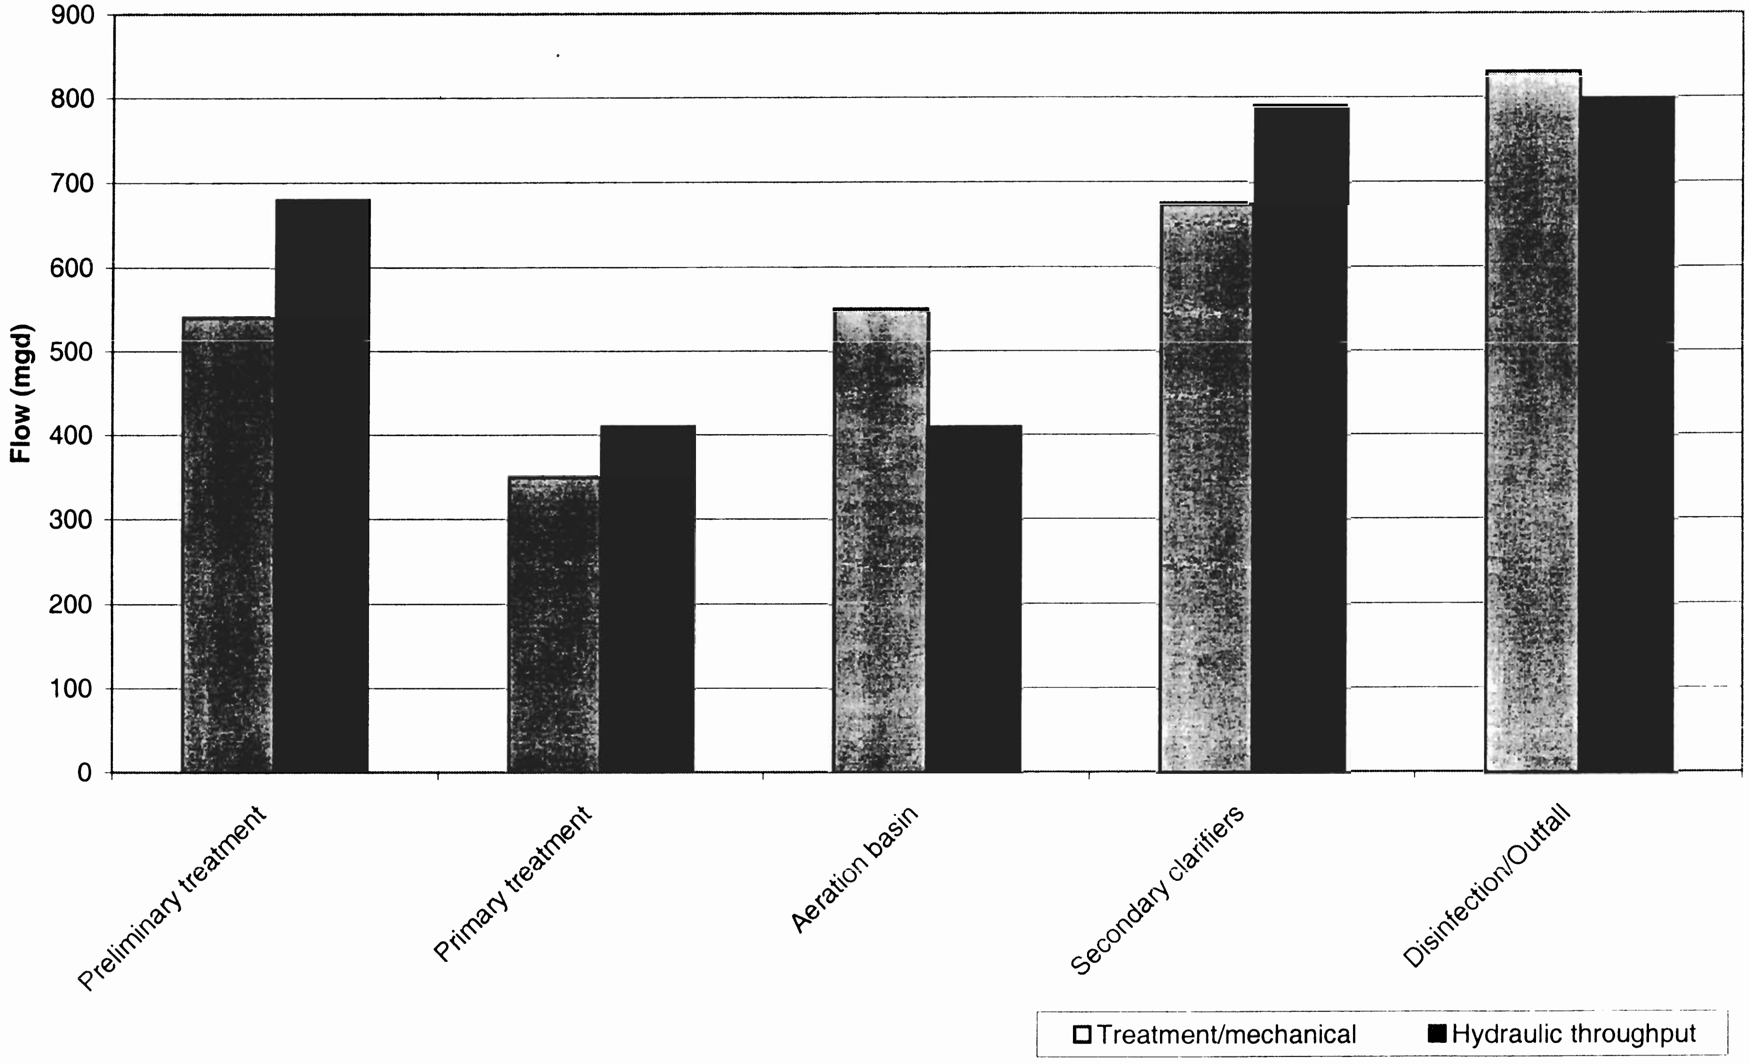
3.3 Capacity Limiting Factors

Figure 3-5 presents a summary of the estimated current capacity on a unit process basis for the SWWPCP. The major capacity bottlenecks for the facility follow:

- **Aeration Basin** - The hydraulic throughput capacity of the aeration basins is limited to 340 mgd with eight basins in service. At flow rates greater than 340 mgd, the weirs in the flow distribution box become flooded, resulting in loss of control over the flow distribution between aeration basins. The facility will continue to operate, but there will be a deterioration in process control under these circumstances. At flow rates greater than 410 mgd, the primary clarifier weirs are impacted. Loss of control of the flow distribution will not result in an immediate failure of the treatment system. However, there will be a negative impact on treatment efficiency if the flows remain greater than 340 mgd over an extended period of time. Secondary effluent pumping or aeration basin bypass (extreme step feed) is required to resolve this bottleneck.

- **Primary Treatment** - The estimated treatment capacity of the primary clarifiers is 350 mgd based on an allowable SOR of 2,800 gpd/ft^2 and four clarifiers in service. The capacity of the primary clarifiers could be increased to 440 mgd if the recycle stream from the BRC facilities is not treated at the SWWPCP.

Figure 3-5
Southwest WPCP - Estimated Current Capacity



SECTION 4

CURRENT SUSTAINABLE TREATMENT CAPACITY

4. Current Sustainable Treatment Capacity

4.1 Sustainable Treatment

The estimated treatment capacities summarized in Section 3 of this report utilize maximum instantaneous limits currently in PWD's NPDES permits as the goal for the effluent quality. Since the maximum instantaneous and maximum daily limits are the same values, a process operation whose final effluent quality will meet the instantaneous maximum limits will also meet the daily maximum limits. However, the current NPDES permits, based on expected performance for plants that intake substantial quantities of stormwater, include maximum weekly and monthly limits that are significantly more stringent than the daily/ instantaneous limits. Furthermore, strict compliance with maximum monthly concentration limits will not guarantee monthly compliance with other quality limits in the permit, such as average monthly and weekly loading limits and percent removal requirements.

An important but difficult question remains regarding how long a facility (or process) can sustain high flows that allow effluent quality to meet all the permit effluent quality requirements.

The performance of the secondary clarifiers determines the final effluent quality from the SWWPCP. The data collected during the field-testing was used to predict final effluent quality as a function of flow rate. The predicted final effluent TSS and BOD_5 concentration for a given flow rate was used to determine the maximum flow that could be maintained for an infinite period of time with effluent quality meeting the monthly and weekly loading and percent removal requirements in the NPDES permit.

Secondary clarifier capacity is defined by either the clarification capacity, which is a function of SOR or the solids flux capacity which is a function of solids loading rate (SLR). Clarifier performance as a function of both SOR and SLR was collected during the testing for a range of operating conditions. Data from the six secondary clarifier stress tests was used to quantify the secondary clarifier performance as a function of hydraulic loading and to identify the maximum allowable solids loading rate for the clarifiers.

The historical data was used to determine the yield and mixed liquor concentrations required as a function of primary effluent quality. The data from the primary clarifier stress tests was used to determine the expected primary effluent quality as a function of flow rate. The mixer liquor required for the expected primary effluent quality determines the solids loading rate for the secondary clarifier.

4.2 Analysis Methodology

4.2.1 Predicting Secondary Effluent Quality as a Function of the SOR

In the stress tests of the secondary clarifiers, the TSS and BOD_5 concentrations in the secondary effluent were measured as a function of the surface overflow rate applied to the clarifiers. A linear regression was performed on the field testing data to establish the relationship between SOR and TSS and BOD_5 concentrations in the effluent. The intercept and slope values obtained for the regression were statistically analyzed to find the 95% confidence level associated with these two coefficients. Using the upper 95% confidence level interval provides a conservative description of the relationship between the SOR and effluent quality. The model is used to predict TSS or BOD_5 for a given SOR; the value generated using the linear regression will be lower than the actual value observed 95 out of 100 times.

The estimated effluent concentrations and discharge loads (which are equal to the effluent flow rate multiplied by the effluent concentration) can then be compared to permit levels to determine the sustainable treatment capacity of the facility on a SOR basis.

4.2.2 Effect of the SLR on Secondary Clarifier Performance

Failure of the secondary clarifiers may occur either due to clarification or thickening. An increase in the hydraulic loading to the primary clarifiers will result in an increase in organic loading to the aeration basin due to an increase in the amount of organic material entering the plant and deterioration in the primary clarifier performance. An increase in the organic loading to the aeration tanks results in an increase in the mixed liquor concentrations and therefore an increase in he solids loading for a given flow. Therefore, the analysis done in terms of the SOR must be complemented with an analysis of the effect of influent flow rate versus SLR.

Stress tests were performed on the primary clarifiers, and removal efficiencies as a function of the surface overflow rate in the primary clarifiers were documented. The data was used to predict the quality of the primary effluent as a function of the influent flow rate. This analysis, combined with analysis of historical data on solids production, was used to estimate the SLR as a function of flow, taking into account both the performance of the primary clarifiers and the increase in the organic loading associated with augmented flows.

The stress tests on the secondary clarifiers indicated that the maximum SLR that could be maintained before thickening failure occurs is 35 lb/(ft^2.day). The flow at which these solids loading rates are achieved is the maximum sustained flow that can be maintained in the plant before thickening failure occurs.

4.3 Analysis Results

4.3.1 Predicting Maximum Flows as a Function of the SOR

Figure 4.1 is a plot of the TSS in the secondary effluent and the SOR applied in the secondary clarifier from the six secondary clarifier stress tests conducted at the facilities owned and operated by PWD. The data from all six secondary clarifier stress tests was used in the preparation of this plot. Figure 4.2 presents the same analysis was done for the BOD_5 concentration in the secondary effluent.

The amount of TSS and BOD_5 discharged results from the product of the flow rate and the concentrations predicted by the 95% confidence level regressions. The discharge values were compared to the NPDES Permit values for the SWWPCP. The results of this analysis are presented in Table 4.1.

Table 4.1 Southwest WPCP – NPDES Permit Requirements and Results of the Sustainable Flow Analysis[1]

Parameter	Units	NPDES Limit	Maximum Sustainable Flow based on SOR		Maximum Sustainable Flow based on SLR
			TSS Limit	BOD$_5$ Limit	
Maximum Day Limits	Mgd	400			320
Maximum Week Limits	Mgd		380	225	
BOD$_5$ Concentration	mg/L	45			
BOD$_5$ Mass Loading	lbs/day	32,475			
TSS Concentration	mg/L	45			
TSS Mass Loading	lbs/day	75,060			
Maximum Monthly Limits	Mgd	200	288	175	
BOD$_5$ Concentration	mg/L	30			
BOD$_5$ Mass Loading	lbs/day	21,650			
BOD$_5$ Percent Removal	%	89.25			
TSS Concentration	mg/L	30			
TSS Mass Loading	lbs/day	50,040			
TSS Percent Removal	%	85			

1 – BOD$_5$ limits based on old permit, plant now monitors cBOD$_5$ for compliance.

The maximum sustainable flows at which the model predicts the SWWPCP can meet the weekly NPDES TSS and BOD$_5$ effluent mass loading requirements are 380 and 225 mgd, respectively. The BOD$_5$ weekly mass loading is the limiting criteria because the allowable effluent BOD$_5$ mass loading is significantly lower than the weekly concentration limit. The maximum weekly flow in the NPDES permit is 300 mgd. The model predicts that the facility will not be able to meet the BOD$_5$ weekly mass loading at a sustained flow of 300 mgd.

The maximum sustainable flows at which the model predicts the SWWPCP can meet the monthly NPDES TSS and BOD$_5$ effluent mass loading requirements are 288 and 175 mgd, respectively. The maximum month sustainable capacity for BOD$_5$ is lower than the average design capacity of the facility. This corresponds reasonably well to the historical performance of the facility. The SWWPCP is currently operating at 88 percent of its rated capacity. A 30-day running average of the effluent BOD$_5$ data was within 95 percent of its monthly average BOD$_5$ mass loading requirements on two occasions over the three-year period from July 1995 to July 1998.

The sustainable capacity values for weekly and monthly flows based on BOD$_5$ limits as estimated by the model are low due to several factors that influence the model in relation to the SW WPCP. First, an analysis for the SWWPCP plant operations versus the other two plants indicates that the SW plant normally runs its secondary clarifiers at lower surface overflow rates (SORs). Observing the trend in data in Figure 4.2 for lower SOR values, it is apparent that the model is conservative in SORs below 1000 gpd/sf, which is where under high flow conditions the SW WPCP will operate. Additionally, the model predicted sustainable flow at the plant is developed assuming two secondary clarifiers out of service.

The most significant influence on the SWWPCP ability to sustain high flows is the difference in the operation of the plant during these events as compared to what is done at the other PWD treatment plants. Operational changes that cannot be reflected in the model results, such as the ability to store solids in tanks that are off-line, significantly increases the ability of the plant to sustain adequate treatment during high flow events. SWWPCP has been able to treat over 300 mgd of flow for a sustained period of time (almost a week) during unusual storm events without any significant deterioration of the effluent quality.

Figure 4-1
Secondary Clarifier Stress Test - Effluent TSS Concentration as a Function of SOR

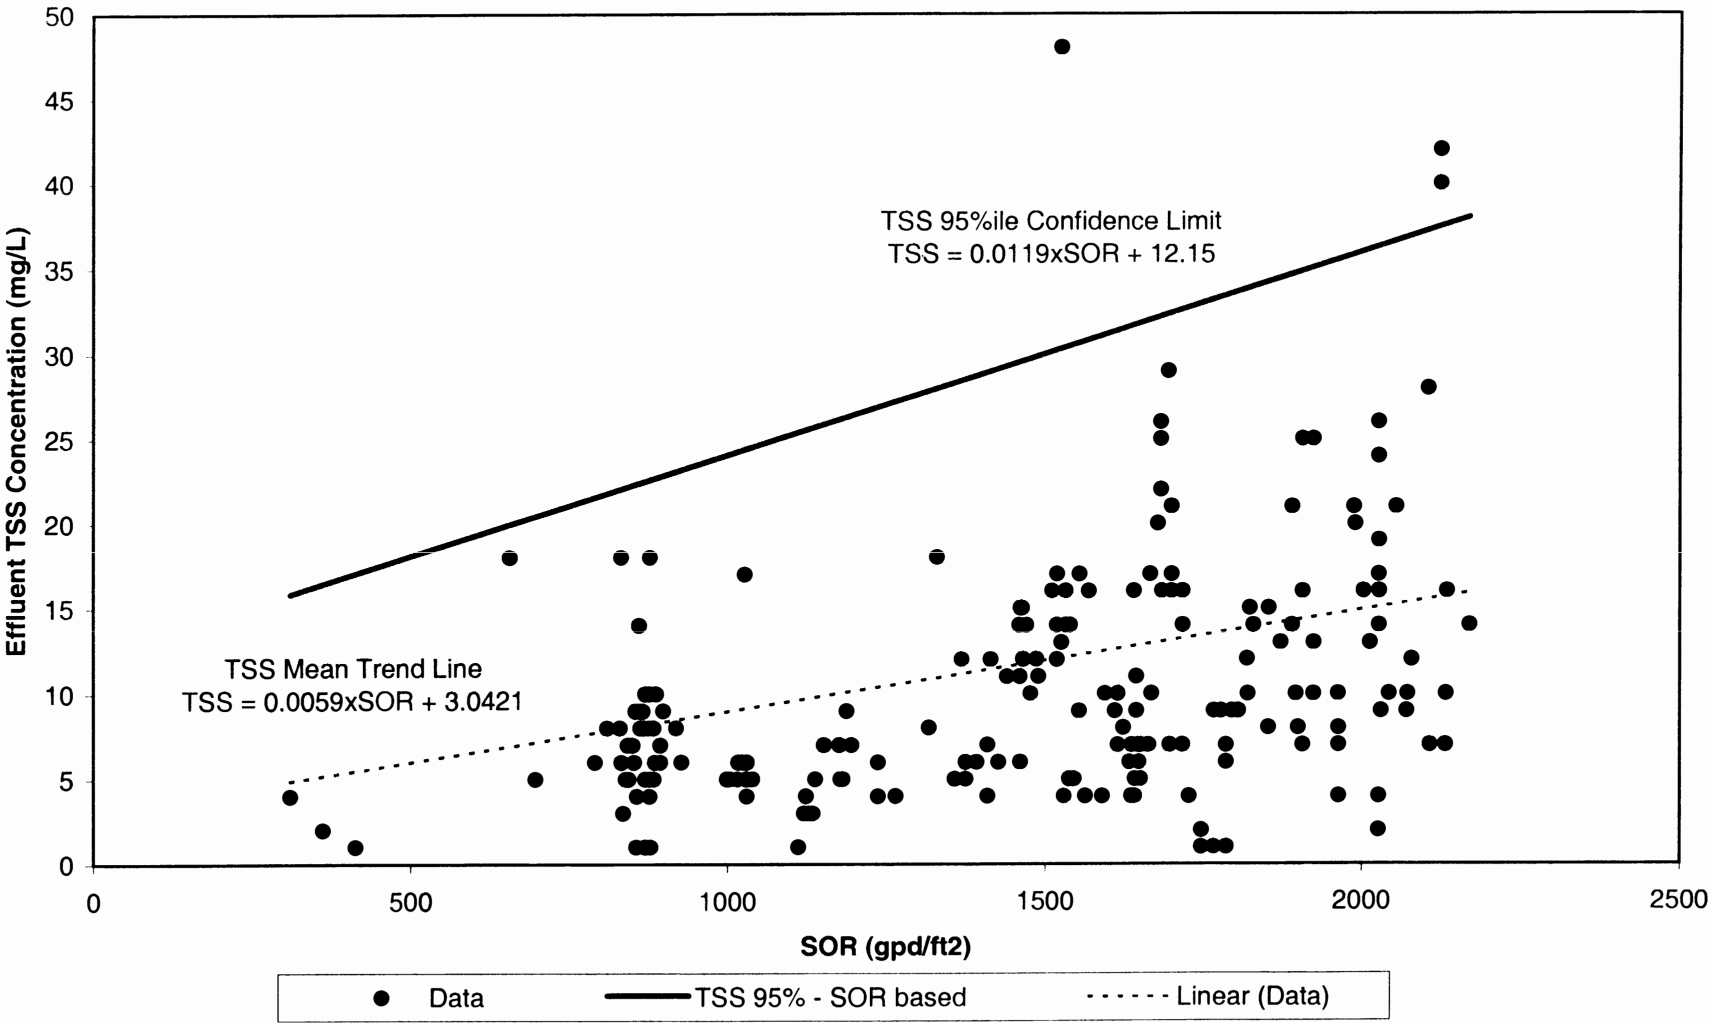


Figure 4-2
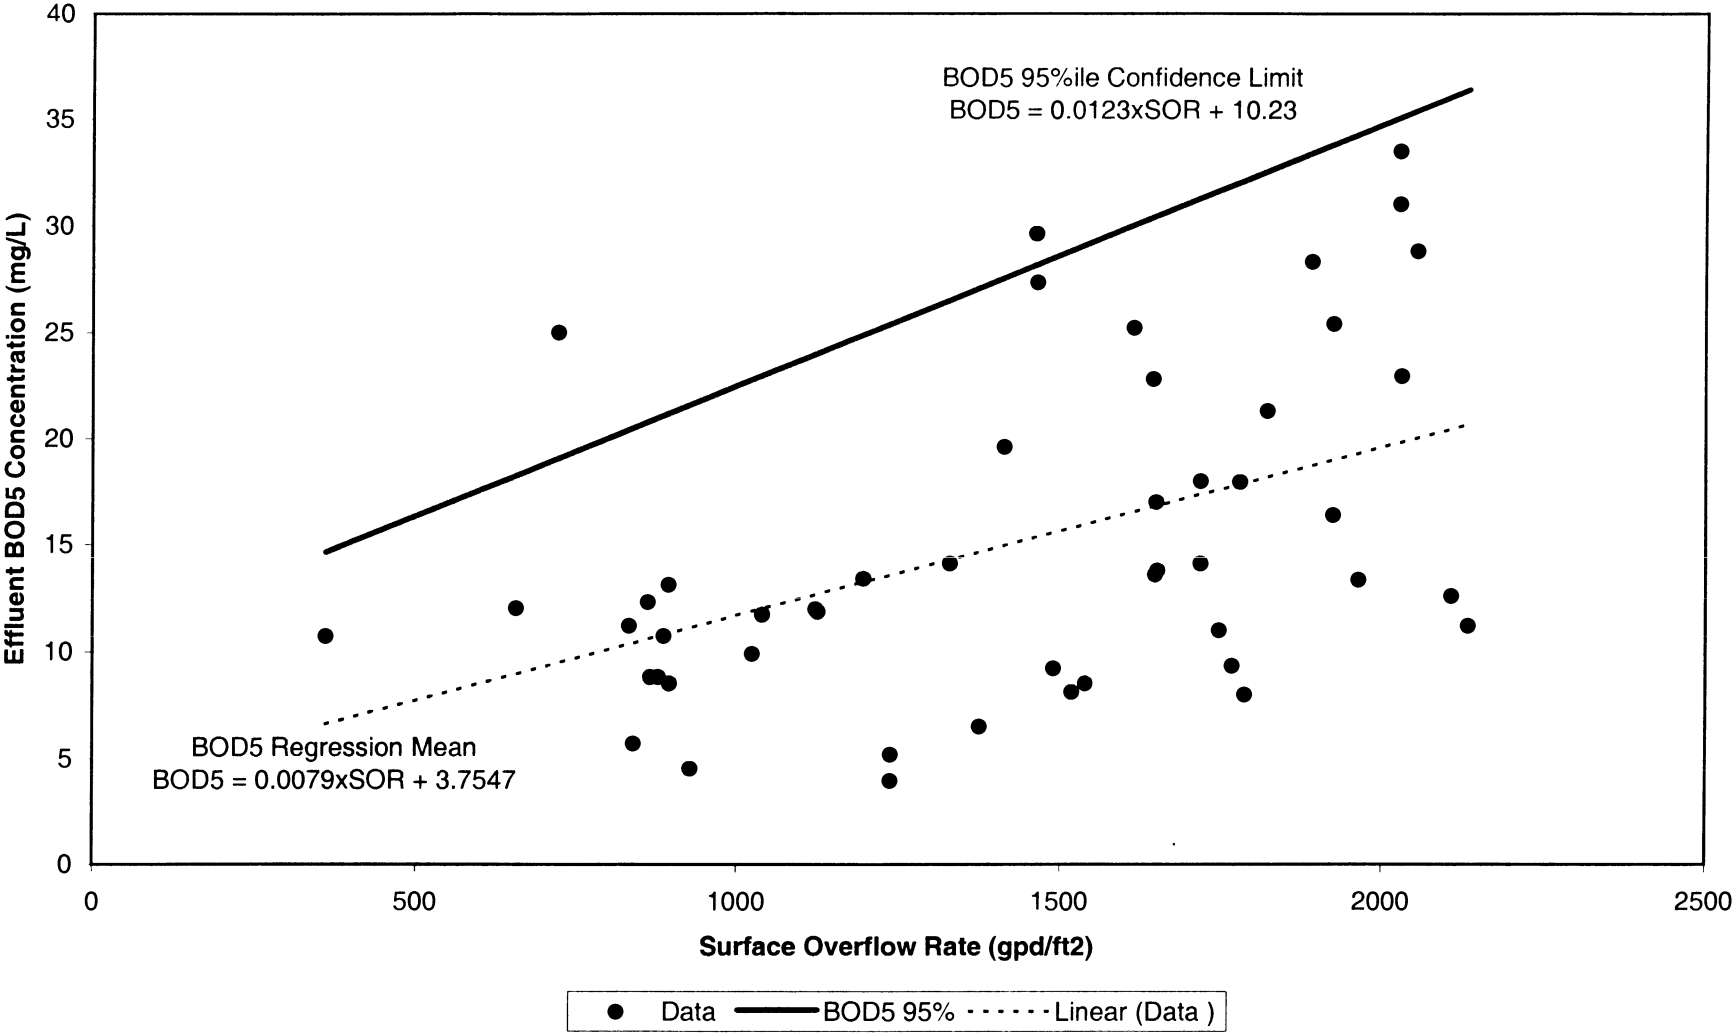
Secondary Clarifier Stress Test - Effluent BOD5 Concentration as a Function of SOR



4.3.2 Predicting Maximum Flows as a Function of SLR

The stress tests of the secondary clarifiers indicated that the maximum solids loading rate that could be sustained by the secondary clarifiers was 35 lb/(ft^2.day). The solids loading rate is a function of the MLSS concentration in the aeration basin and the influent and RAS flow rates. The MLSS concentration is dependent on the loading to the aeration basins, which in turn is dependent on the performance of the primary clarifiers as a function of the flow. The objective is to develop an overall correlation between the flow coming into the plant and the resulting solids loading rate into the secondary clarifiers.

The primary clarifier stress test results were used to determine the TSS percent removal in the primary clarifiers as a function of influent flow rate. A regression analysis of all stress test results performed in the primary clarifiers (except the test performed at the Southeast Plant where the clarifier failed prematurely due to the hydraulic limitations of the launders) was performed, and the lower 95% confidence levels associated with the regression parameters were calculated. Figure 4.3 presents the results of this analysis.

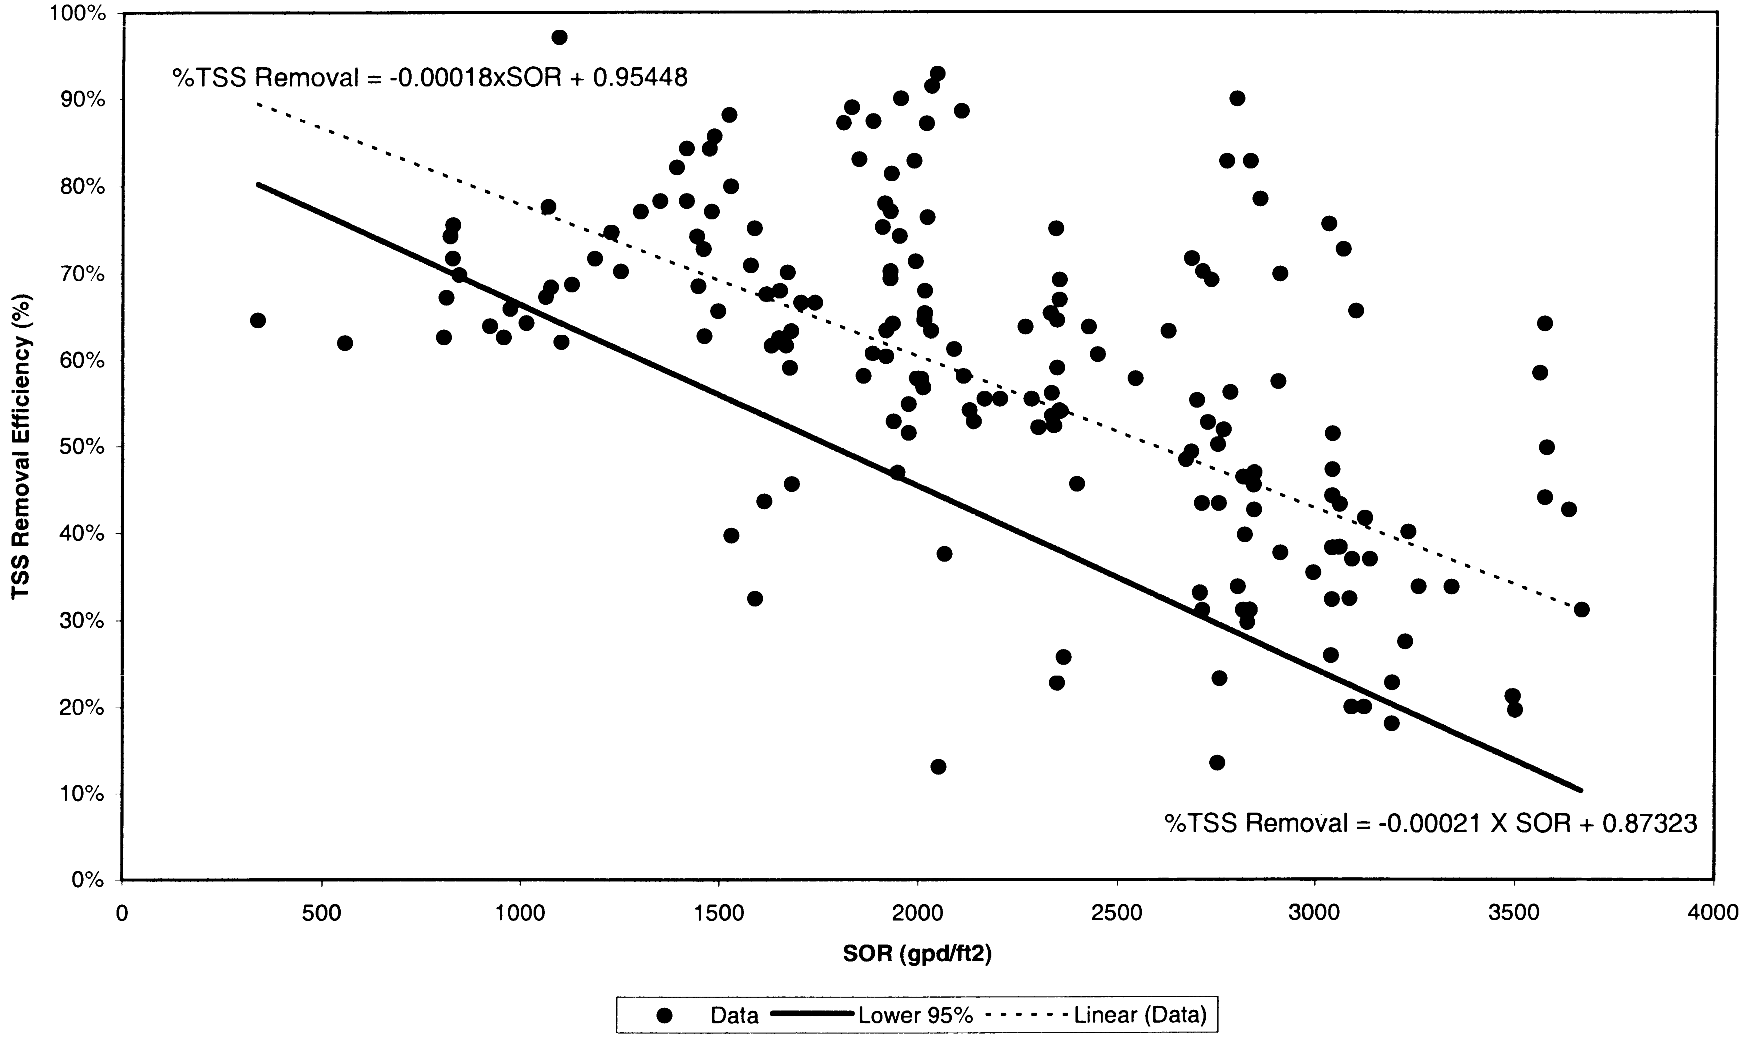
The yield for the SWWPCP was estimated based on the historical data of waste activated produced and the TSS and BOD_5 concentrations in the primary effluent. The SWWPCP is operated at an SRT of 1.9 days, the RAS flow rate is about 35 percent of the influent flow rate, and the raw wastewater has an average TSS concentration of 154 mg/L. For the determination of the SLR limiting flow, it was assumed that all of the primary and secondary clarifiers are in service, but that only eight of the ten aeration basins are in use. This corresponds to current operating practice at the site.

The SLR becomes 35 lb (ft^2.day) at the SWWPCP when the sustained flow is equal to 320 mgd. At flow rates greater than 320 mgd, thickening failure will occur unless measures are taken to reduce the solids loading rate to the secondary clarifiers. Preventative measures that are currently implemented at the SWWPCP include reducing the mixing in the aeration basin to allow solids to settle in Cells 3 and 4 and using the two aeration basins that are out of service as RAS storage for the duration of the storm.

Alternatively, step feed could be implemented at the SWWPCP by constructing an "in basin" primary effluent conduit along the length of the basin. The conduit would operate as a submerged diffusor and would require structural modifications to existing tanks. Improving the primary clarifier performance by providing pretreatment of the BRC centrate would significnatly improve the primary clarifier performance. Providing "out of clarifier" primary sludge thickening or enhanced primary clarifier performance through chemical addition would also reduce the solids loading to the secondary clarifiers. These alternatives would require capital expenditure for additional facilities.

Improving the solids removal efficiency of the secondary clarifiers would effectively increase the allowable solids loading rate to the clarifier. This would require modifications to the existing RAS system.

Figure 4-3
Primary Clarifier Stress Test – Percent TSS Removal Efficiency as a Function of SOR



4.4 Control of High Flow Duration

Discussions with PWD managers directing PWD's CSO program indicated that current CSO inline storage and draw-down plans expect that stored combined sewerage would be released to the plant over a 12-hour period following a storm event. This is a volume of combined sewerage that PWD's plants have not received in the past. Furthermore, there is flexibility in the draw-down strategy since the primary objective of the effort would be to return the storing sewer back to its original condition prior to the next storm event. It was clear that this is only a current plan and it would change should PWD be required in the future to provide additional combined sewerage storage to meet receiving water quality objectives.

From the wastewater treatment plants' perspective, a number of factors can influence the ability of a plant to achieve weekly or monthly limits when the plant is being stressed by storm-induced, high influent flows. The number and distribution of rain events during the week/month, together with plant effluent quality during non-rain event periods, rank high on the list of influences. PWD's revised permit language provides effluent quality relief, but only when the daily plant flow exceeds the permitted maximum daily flows currently stated in the permits. No such relief occurs for flows below the maximum daily flow limits.

Since the impact of stored combined sewerage on the SWWPCP performance is an unchartered experience, it is recommended that the duration of storage be no greater than a 24-hour period for each storm event. Should the CSO program's strategy for stored combined sewerage change beyond this 24-hour period, the issue of plant compliance for all monthly and weekly effluent quality requirements should be reviewed.

SECTION 5

POTENTIAL UPGRADES

5. Potential Upgrades

A list of potential upgrades was developed to increase the capacity or improve the performance of the SWWPCP. The potential improvements are based on the results of stress tests on unit process, long-term monitoring of the plant, and hydraulic modelling.

Each upgrade option has been prioritized based upon the following criteria:

- **Priority A – Existing Facilities Optimization.** Improvements that are easily implemented, low cost, high benefit, and will have an immediate positive impact upon normal operations. These are options that can be included in short-term capital budgets.
- **Priority B – Proactive Improvements.** Improvements that are moderate in cost and will have a positive impact on plant capacity. These are options that should be included in a long-term improvement plan.
- **Priority C – Improvements to Increase the Solids Handling Capacity of the Secondary Clarifier.** The stress tests identified that the solids handling capacity of the secondary clarifiers is very limited. This category includes improvements that are necessary to increase the secondary clarifier capacity with current mixed liquor concentration and/or to maintain existing capacity if increased mixed liquor suspended solids are required in the future.
- **Priority D - Capacity De-bottlenecking.** Improvements that have large costs associated with them and will greatly increase capacity above the current permitted peak flow. These options should be considered in an overall long-term, wet-weather, flow-control program and in the long-term improvement plan if significantly more treatment capacity is required at the facility.

The list of potential upgrades, budgetary cost estimate, and their associated prioritization is summarized below. Detailed descriptions of each upgrade are presented in Technical Memorandum 5 – Budgetary Cost Estimates for Potential Plant Improvements.

The cost estimates shown here are based on preliminary costs and are for use as "budgetary" values only. The cost estimates are Class "C" cost estimates (order-of-magnitude costs) as defined by the American Association of Cost Engineers. The level of accuracy of the Class "C" cost estimates is +50 percent to –30 percent of the actual cost of construction. These costs can be used for decisionmaking to select those options for more detailed analysis that are most feasible from both a design and cost perspective.

Table 5.1 includes the final estimated cost for each improvement. Table 5.2 presents a summary of the overall cost for improvements at the SWWPCP, which are broken down into alternatives that are dependant upon one another for an increase in capacity at the plant.

TABLE 5.1
POTENTIAL UPGRADE OPTIONS AT SOUTHWEST WPCP

Option No.	Description	Priority Classification	Estimated Conceptual Cost
1	Replace caulking on secondary clarifier launders to improve flow distribution [1]	A	$1,640,000
2	Provide preliminary treatment for the BRC centrate that is recycled to the plant	B/C	$8,585,000
3	Modify existing RAS system in the secondary clarifiers	C	$4,256,000
4	Provide primary effluent bypass to secondary clarifiers	D	$902,000
5	Provide separate facilities for primary sludge thickening	D	$9,892,000
6	Resolve hydraulic limitations between primary clarifiers and aeration basin	D	$5,429,000
7	Provide an additional effluent pump at the effluent pumping station	D	$806,000

[1] Complete or in progress.

TABLE 5.2
SUMMARY OF BUDGETARY COSTS FOR POTENTIAL IMPROVEMENTS AT SOUTHWEST WPCP

Plan	Total Costs for Improvements (Million $)	Cumulative Costs for Improvements (Million $)	Peak Treatment Capacity (mgd)			
			Facility	Preliminary	Primary	Secondary
Process improvements (Option 1)	1.64	1.64	340[1]	540	350	340
Increase primary treatment capacity w/ aeration bypassing (Options 2, 4, 5)	19.4	21.0	440	540	440	340[2]
Increase secondary treatment capacity (Options 2, 3, 6, 7)	19.1	31.5	540	540	540[3]	540

1. Existing facility is able to treat peak instantaneous flows of 440 mgd for a short period of time
2. Capacity of secondary is limited by hydraulic restriction into the aeration basin, however bypass will allow plant to increase overall capacity.
3. Deterioration of primary clarifier performance is offset by maintaining aeration basins in service

Process Improvements. The performance of the secondary clarifiers at the SWWPCP is negatively affected by an uneven flow distribution between individual clarifiers due to deterioration of the grouting in the effluent launders. The objective of this plan is to improve the performance of the SWWPCP under high flow conditions by improving the flow distribution. These improvements will not increase the peak hydraulic capacity of the facility beyond its current capabilities.

Increase Primary Treatment Capacity with Aeration Bypassing. The primary treatment capacity is limited at the SWWPCP. A significant portion of capacity is being used to treat the BRC recycle stream. Poor primary clarifier performance under current loading conditions requires a higher mixed liquor concentration, which has a negative impact on the secondary clarifier capacity. The objective of Options 2, 4, and 5 is to increase the peak capacity of the primary treatment to 440 mgd and to improve primary clarifier performance under all flow conditions.

The work would include providing pretreatment of the BRC recycle stream at the BRC facility, increased sludge removal from the primary tanks, and a bypass conduit from the primary effluent channel to the mixed liquor channel.

The estimated cost of providing pretreatment of the BRC recycle stream is $8,585,000. This includes chemical addition, coagulation, flocculation, and sedimentation facilities. However, based on recent jar testing work performed by PWD, the cost of chemical addition may be reduced if the recycle stream can be treated immediately.

A bypass between the primary clarifier effluent channel and the plant outfall will be required to circumvent the hydraulic bottleneck between the pimary clarifiers and the aeration basins. One approach would be to construct the primary effluent channel to the mixed liquor channel. The estimated cost for this potential upgrade is $902,000. The primary effluent would be added to the upstream end of the mixed liquor channel and pass through the secondary clarifiers before discharge. The estimated peak hydraulic capacity of the secondary clarifiers is 695 mgd at current mixed liquor concentrations. The primary effluent will increase the hydraulic loading on the secondary clarifiers without increasing the solids loading. Therefore, the secondary clarifiers have sufficient hydraulic capacity to treat the additional load.

The advantage of this approach is that the primary effluent will receive some additional treatment due to contact with the mixed liquor and the "sweeping" action of the activated sludge in the secondary clarifiers. The final effluent will be of higher quality than the blended effluent from the secondary clarifier and the bypass stream combined after the secondary clarifier. However, the contact time between the activated sludge and primary effluent bypass will be very small, and therefore BOD_5 removal from the primary effluent will be minimal. A relaxation in the permit requirements on days when aeration tank bypassing occurs is recommended. An alternative approach would be to bypass both the aeration basin and the secondary clarifiers. The primary effluent would flow directly to the secondary effluent channel. This approach would not provide the benefit of additional treatment as the primary effluent passes through the aerated mixed liquor channel and secondary clarifiers.

The potential primary treatment capacity of the SWWPCP is 540 mgd with five clarifiers in service. Increased primary sludge pumping may be required to achieve the additional primary treatment capacity. The estimated cost of providing a gravity sludge thickening facility at the SWWPCP is $9,892,000.

Increase Secondary Treatment Capacity. The objective of the remaining improvements is to increase the secondary treatment capacity to 540 mgd by eliminating the hydraulic bottlenecks at the influent end of the aeration basins. Offline sludge thickening would not be required because the primary effluent would receive full secondary treatment and no bypass arrangement of the aeration basins would be used. The estimated capital cost to provide intermittent pumping between the primary clarifiers and the aeration basin is $5,429,000. The capacity of the effluent pump station will also need to be increased. The estimated capital cost of providing an additional effluent pump is $806,000. In addition, to achieve this full plant capacity of 540 mgd, BRC pretreatment (Option 2) and modifications to the existing RAS system (Option 3) would have to be implemented.

Executive Summary

Background and Project Summary

As part of the series of memoranda prepared for the Philadelphia Water Department's (PWD) Combined Sewer Overflow (CSO) Long Term Control Plan (LTCP) update, this report presents the conceptual design and cost analyses for four wet weather treatment alternatives for the Northeast Water Pollution Control Plant (NE WPCP). The wet weather treatment technologies for the NE WPCP evaluated in this report are as follows:

1. Vortex Swirl Concentrators
2. Conventional Clarifiers
3. Chemically Enhanced Primary Treatment (CEPT) with Conventional Clarifiers
4. Ballasted Flocculation (includes fine screening)

Conceptual treatment trains were developed for each treatment technology at various wet weather flows ranging from 69 million gallons per day (mgd) to 1100 mgd and cost curves for capital, operations and maintenance (O&M), and lifecycle costs were generated for each treatment train alternative.

Currently, the NE WPCP has a flow capacity of 435 mgd. With several process and hydraulic modifications, as identified in the 2001 Stress Testing Report and the NE WPCP Flow Study, the capacity of the existing plant can potentially reach 650 mgd (CH2M HILL, 2001; CH2M HILL, 2008a, d). This work includes the construction of a 250-mgd secondary bypass from the existing primary sedimentation tanks to the chlorine contact chamber. In sizing the wet weather treatment trains, it was assumed that these upgrades, costing $98.1M, will have been completed, increasing the plant's capacity to a minimum of 650 mgd (Section 2). Any wet weather flow in excess of 650 mgd would be diverted to the new wet weather facility.

To expand the flow capacity of NE WPCP beyond 650 mgd for the treatment of wet weather flows, a separate wet weather treatment train will be required. Wet weather flows in excess of 650 mgd will be diverted to one of the new treatment trains, listed above, eventually blending with effluent from both the secondary system and the bypass from the existing plant. Conceptual designs and cost estimates were performed for each treatment train at various design flows.

Flow Scenarios

Conceptual designs and cost estimates were developed at several design flows for each wet weather treatment train under evaluation (Exhibit ES-1). These flows were selected based on the ability to meet permit requirements, the land area available onsite, and the maximum expected flow from the upgraded collection system, as described in Section 4. The Vortex/Swirl and Conventional Clarification trains were both flow-limited by permit requirements.

EXHIBIT ES-1
Design Flows Evaluated for each Wet Weather Treatment Train

Treatment Train	Design Flows Evaluated (mgd)
#1) Vortex/Swirl Concentrators	69, 183
#2) Conventional Clarifiers	160, 376
#3) CEPT w/ Conventional Clarifiers	150, 300, 1000
#4) Ballasted Flocculation	150, 500, 1100

Comparison of Treatment Alternatives

Effluent Water Quality

While each flow scenario for each treatment train evaluated is sized to produce blended effluent concentrations compliant with permit limits, the resulting water quality differs widely between different scenarios. The TSS and BOD concentrations of the blended effluent for each treatment train and flow scenario is presented under Section 9 in Exhibits 9-1 and 9-2, respectively. In general, ballasted flocculation achieves the lowest TSS and BOD concentrations after treatment and can operate an unlimited number of times during the month while allowing the NE WPCP to continue to meet permit limits.

Capital and O&M Costs

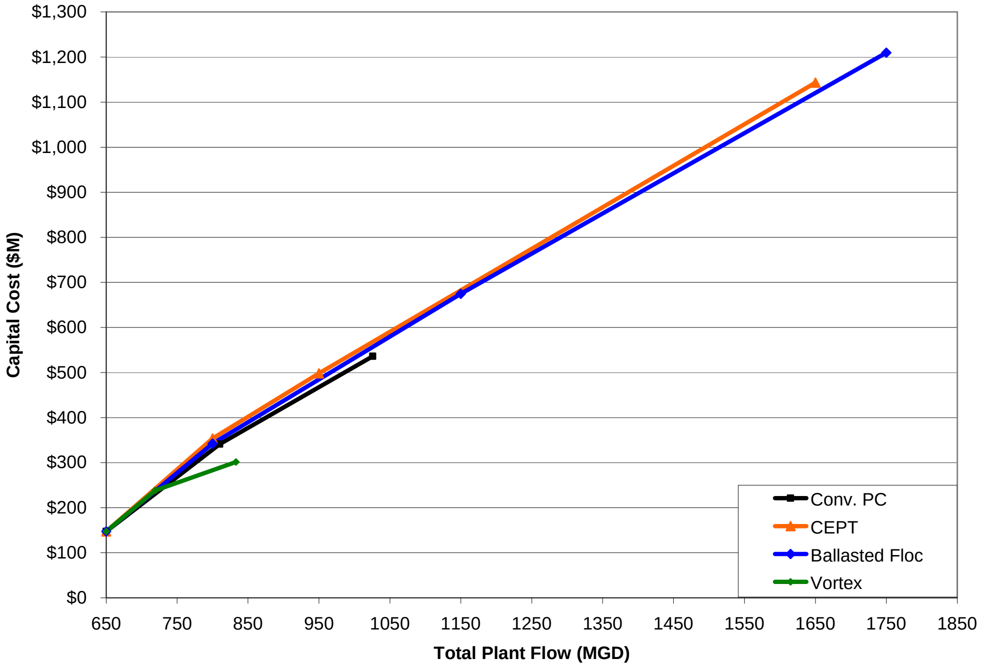
As shown in Exhibit ES-2, the capital costs for Trains #2 - #4 track each other very closely, with CEPT being slightly more expensive. Train #1, the vortex/swirl, appears least expensive and most cost effective as flows increase (Exhibit ES-3). Train #3, CEPT, appears slightly less cost-effective than Train #4, Ballasted Flocculation, due to greater cost for piles due to its larger footprint.

The comparison of O&M costs for each treatment train is shown in Exhibit ES-4. As expected, the O&M costs for vortex swirls and conventional clarifiers, which do not require chemical settling aids, are the lowest. Ballasted Flocculation has the highest O&M costs due to the use of chemicals and the complexity of its system.

Taking construction, non-construction, and O&M costs into consideration, Exhibit ES-5 shows the present value of the total cost of each wet weather treatment train. This graph suggests that there is negligible cost difference between Train #3, CEPT, and Train #4, Ballasted Flocculation at this plant. As expected, Trains #1 and #2 are least expensive due to its low chemical usage and minimal O&M costs.

EXHIBIT ES-2

Comparison of Capital Costs for All Treatment Trains



Note: Capital cost presented includes cost of improvements recommended in the Stress Testing Report ($147 M). Total plant flow includes flow from both the conventional plant and the wet weather treatment facility.

EXHIBIT ES-3

Comparison of Capital Cost Effectiveness for all Treatment Trains

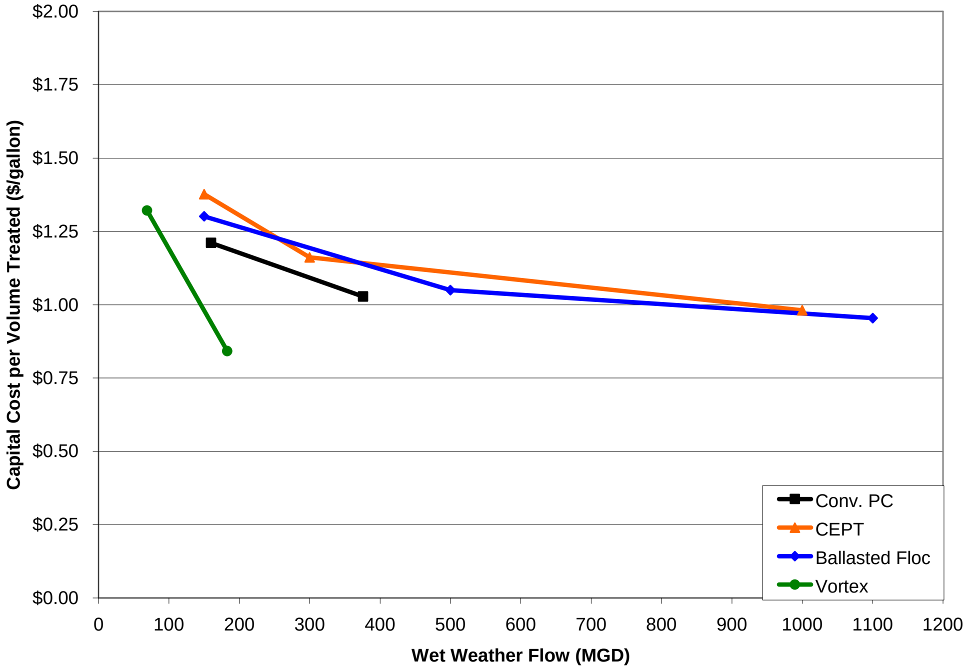


EXHIBIT ES-4
Comparison of Operations and Maintenance Costs for all Treatment Trains

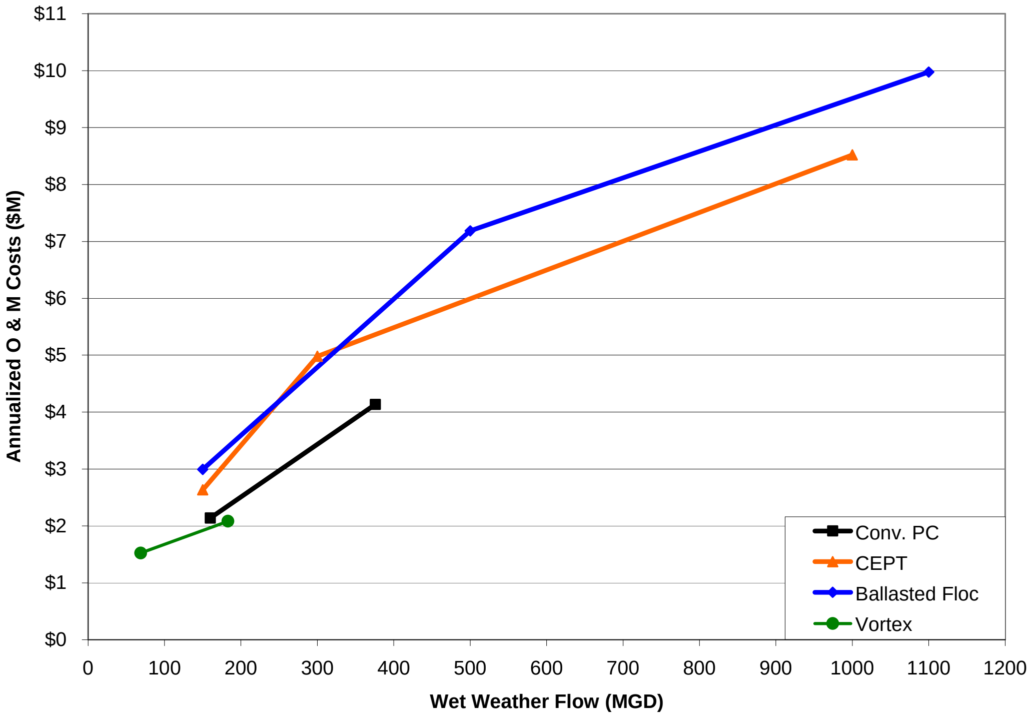

EXHIBIT ES-5
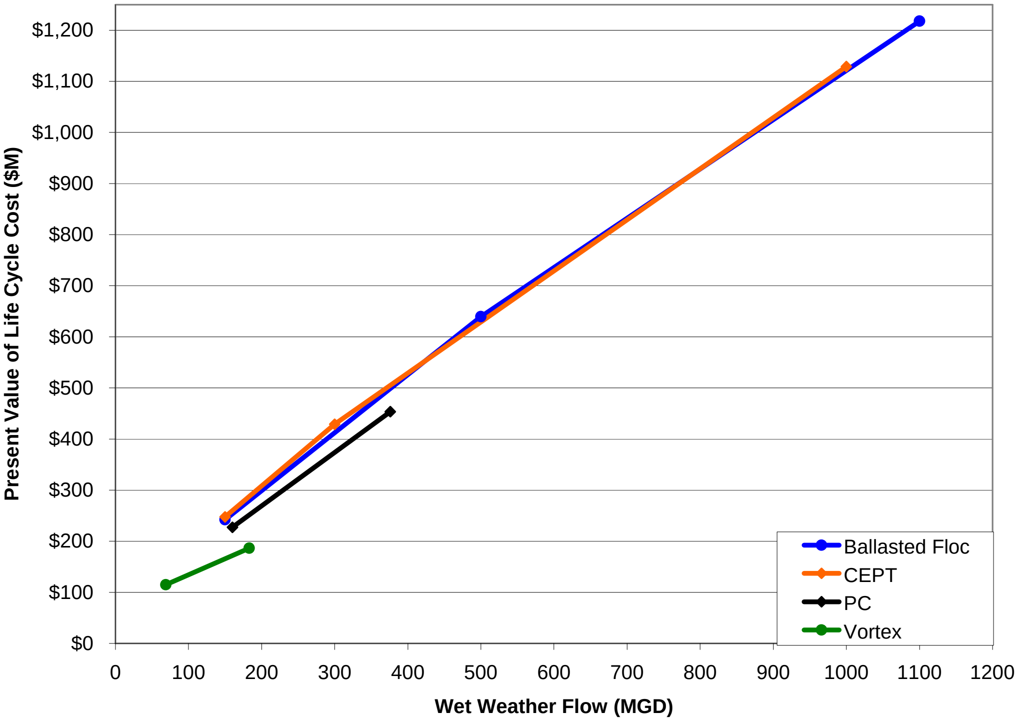
Comparison of Life-Cycle Costs for all Treatment Trains



Overall Comparison

Aside from capital, O&M, and lifecycle costs, there are numerous other criteria by which the treatment trains should be evaluated, including system reliability, community impacts, the ability to handle large variations in flow, land requirements, constructability, requirements for maintenance and operator attention, and sustainability. The main advantages and disadvantages for Treatment Trains #1 - #4, as evaluated in this report, are described in Exhibit ES-6.

EXHIBIT ES-6
Summary of Pros and Cons for Each Wet Weather Treatment Train

Treatment Train	Pros	Cons
Train #1: Vortex/Swirl Concentrators	• Simple operation • Low maintenance requirements – no moving parts	• Only cost competitive at high loading rates and low removal efficiencies. • Maximum design flow may decrease if the assumed number of operating days is greater than 7.
Train #2: Conventional Clarifiers	• Simple operation • Same technology as existing plant – operators familiar with equipment	• Space limited • Maximum design flow may decrease if the assumed number of operating days is greater than 7.
Train #3: CEPT	• Lower chlorine dose possible due to high TSS removal efficiencies • May be operated as Conventional Clarifiers if chemicals found to be unnecessary	• Operators unfamiliar with technology • Space limited • Uses two additional chemical systems for coagulation and flocculation • Maximum design flow may decrease if the assumed number of operating days is greater than 9.
Train #4: Ballasted Flocculation	• Can treat up to 1500 mgd with available land on site • Highest removal efficiencies • Unlimited number of operating days per month • Lower chlorine dose possible due to high TSS removal efficiencies	• Operators unfamiliar with technology • Most labor intensive and complex system • Uses two additional chemical systems for coagulation and flocculation

The costs for wet weather treatment at the NE WPCP should be analyzed with the costs of other wet weather treatment alternatives, such as improvements in the collection system, to determine which treatment train alternatives and flow regimes should be evaluated further. Treatment trains that are selected for further evaluation should undergo more detailed design and costing methods, water quality sampling, and bench and pilot scale testing, so that removal efficiencies, land requirements, capital costs, and O&M costs can be further refined.

1.0 Introduction

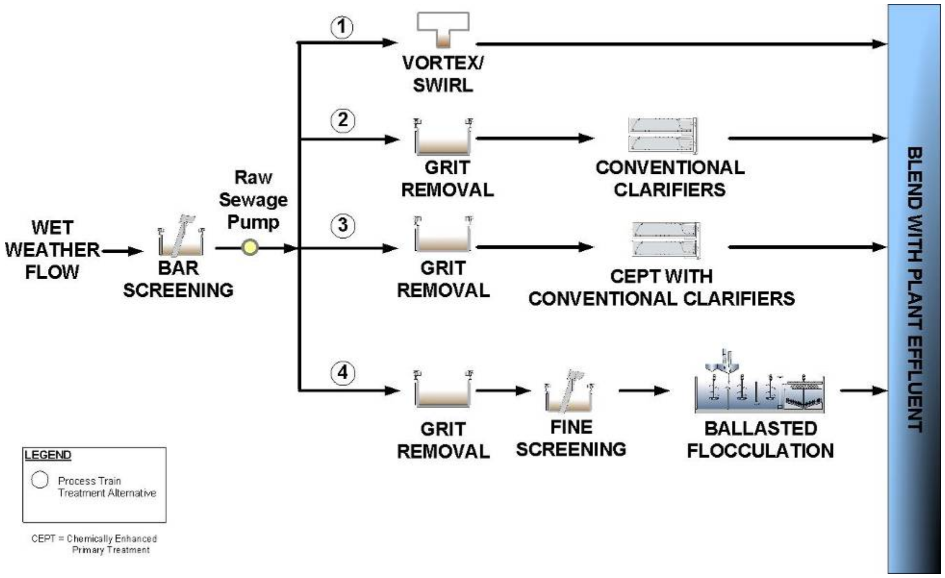
As part of the series of memoranda prepared for the Philadelphia Water Department's (PWD) Combined Sewer Overflow (CSO) Long Term Control Plan (LTCP) update, this report presents the conceptual design and cost analyses for four wet weather treatment alternatives for the Northeast Water Pollution Control Plant (NE WPCP). These treatment alternatives were short listed from previous evaluations by the LTCP team (PWD, CDM, and CH2M HILL) based on information from: water quality data analysis and review of available land for NE WPCP; survey of various potential wet weather treatment technologies; and site visits to three existing wet weather treatment facilities in Ohio (CH2M HILL, 2007b; CH2M HILL, 2008b). A treatment train utilizing CEPT with Plate Settlers was evaluated for the Southeast WPCP, but was subsequently eliminated due to its extremely high cost (CH2M HILL, 2008c).

The wet weather treatment technologies for the NE WPCP evaluated in this report are as follows:

1. Vortex Swirl Concentrators
2. Conventional Clarifiers
3. Chemically Enhanced Primary Treatment (CEPT) with Conventional Clarifiers
4. Ballasted Flocculation (includes fine screening)

Conceptual treatment trains were developed for each treatment technology at various wet weather flows ranging from 69 million gallons per day (mgd) to 1100 mgd (Exhibit 1-1). Cost curves for both capital and operations and maintenance (O&M) costs were generated for each treatment train alternative. This report presents the conceptual design parameters, site layouts, cost estimates, and potential issues of each treatment train alternative.

EXHIBIT 1-1
Schematic View of Treatment Trains Evaluated



2.0 Improvements to Existing Plant

In order to increase the flow capacity of the NE WPCP for wet weather conditions, the potential of maximizing flow through the existing plant must first be evaluated. From 2004 to 2007, the NE WPCP treated an average daily flow of 185 mgd with an instantaneous peak flow of 417 mgd (CH2M HILL, 2008b). Historically, plant operation has demonstrated that the secondary system can treat 435 mgd without experiencing catastrophic failure in the secondary clarifiers.

Since 2001, PWD has been actively planning to evaluate and implement options to increase the capacity of the NE WPCP to treat wet-weather flows. The 2007 Flow Study for the plant presented various options for hydraulic and process improvements that would increase plant capacity from 435 mgd to 535 mgd by incorporating a 100-mgd secondary bypass during wet weather events (CH2M HILL, 2007a). Subsequent studies indicated that it is possible to pass 650 mgd through the existing primary treatment system using a 215-mgd secondary bypass without exceeding permit limits (CH2M HILL, 2008d). A conceptual design project is currently underway for a pretreatment facility to treat an additional 250 mgd of flow (CH2M HILL, 2008e).

The improvements necessary to achieve a plant capacity of 650-mgd are presented in Exhibit 2-1. The majority of these improvements were identified in the 2001 Stress Testing Report and are based on results of stress tests on unit processes, long-term monitoring of the plant, hydraulic modeling, and input from NE WPCP plant staff (CH2M HILL, 2001). These improvements were also evaluated in further detail in the NE WPCP Flow Study (CH2M HILL, 2007a).

In sizing the wet weather treatment trains, it was assumed that the upgrades presented in Exhibit 2-1 will have been completed, increasing the plant's capacity to a minimum of 650 mgd. Thus, the baseline cost that is used in the wet weather treatment train cost estimates is $147.3 million (Exhibit 2-1). This is reflected in the cost curves for each treatment train, presented in latter sections of the report.

EXHIBIT 2-1
Cost Summary of Potential Improvements for Existing NE WPCP

	Improvement Description	**Cost**[(1)]
1	Frankford grit chamber bypass replacement to reduce hydraulic restriction	$3,057,279
2	Rehabilitation of Frankford high level second barrel	$11,421,413
3	New conduits between preliminary treatment building and the Set-1 primary sedimentation tanks	$2,500,000 (2)
4	Construction of new diversion chamber, conduit and new pretreatment system (screening, grit removal) upstream of Set 2 Primaries	$70,050,000 (3)
5	Installation of new influent baffles in Set-2 primary sedimentation tanks	$384,332
6	Removal of double-deck effluent channel in Set-2 final sedimentation tanks	$590,954
7	Construction of 215-mgd bypass conduit from Set-1 primary sedimentation tanks to the existing chlorine contact chamber	$26,347,571 (4)
8	Construction of four new gravity thickeners for thickening of primary sludge (tentative location north of existing digesters- NE-1.8 on Figure 3-4)	$32,895,246 (5)
	TOTAL	**$147,246,795**

(1) Assume escalation factor of 19.8% - based on 9/1/2009 start date and 2-year construction duration.

(2) Based on PWD design cost estimates.

(3) See Northeast WPCP Pretreatment Facility Conceptual Design Report (CH2M HILL, 2008e)

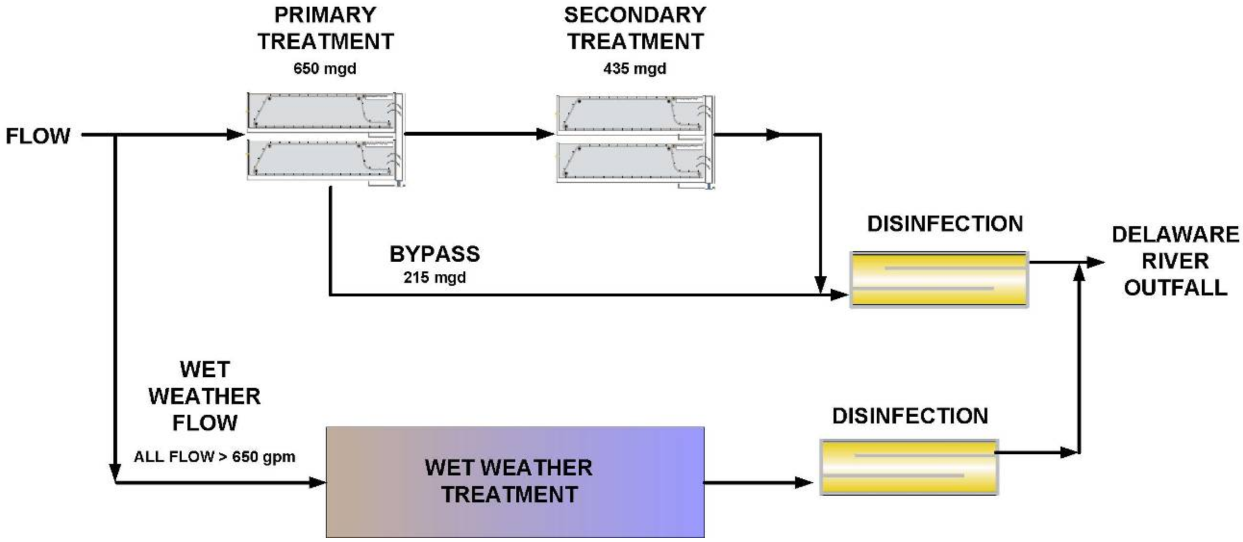
(4) Costs for these line-items were approximated by scaling the costs found in the Flow Study report for upgrades to 535 mgd only. More definitive costs for upgrades to 650 mgd can be substituted once they become available.

(5) See Flow Study Update memo (CH2M HILL, 2008d). New thickeners for the existing primaries will be located in the area of the abandoned digesters. This cost does not include remediation/demolition of the abandoned digesters.

3.0 Wet Weather Treatment Alternatives: Evaluation Methodology

To expand the flow capacity of NE WPCP beyond 650 mgd for the treatment of wet weather flows, a separate wet weather treatment train will be required. Wet weather flows in excess of 650 mgd will be diverted to this new treatment train, eventually blending with both secondary effluent and the secondary bypass effluent (Exhibit 3-1).

EXHIBIT 3-1
Anticipated Wet Weather Flow Pattern in NE WPCP



As depicted in Exhibit 1-1, the four wet weather treatment trains under evaluation for the new wet weather treatment facility are:

1. Vortex Swirl Concentrators
2. Conventional Clarifiers
3. Chemically Enhanced Primary Treatment (CEPT) with Conventional Clarifiers
4. Ballasted Flocculation (includes fine screening)

Conceptual designs and cost estimates were performed for each treatment train at different design flows. This section describes the development of the various design flows and the key assumptions for design and cost estimating.

3.1 Design Flows

The design flows that were selected for evaluation for each treatment train in the new wet weather facility are shown in Exhibit 3-2 and are described below in further detail.

EXHIBIT 3-2
Design Flows Evaluated for each Wet Weather Treatment Train

Treatment Train	Design Flows Evaluated (mgd)
#1) Vortex/Swirl Concentrators	69, 183
#2) Conventional Clarifiers	160, 376
#3) CEPT w/ Conventional Clarifiers	150*, 300, 1000
#4) Ballasted Flocculation	150*, 500, 1100

*The 150 MGD flow point for Trains #3 and #4 was selected arbitrarily to widen the range of the cost curves.

3.1.1 Design Flows by Permit Limits

The maximum allowable flow through each wet weather treatment train is a function of its removal efficiency, the achievable effluent concentration after blending, and the plant's continued ability to meet NPDES permit limits for weekly and monthly TSS and BOD concentrations. The data analysis performed for NE WPCP determined that the monthly TSS limit was the most stringent, and were thus used to determine the maximum allowable flow through each train, as shown in Exhibit 3-3 (CH2M HILL, 2008d).

EXHIBIT 3-3
Maximum Allowable Flow of Wet Weather Treatment Trains to Meet NPDES Permit Requirements

Treatment Train	TSS Removal Efficiency(1) (%)	Achievable Effluent TSS Concentration of Wet Weather Train(2) (mg/l)	Maximum Allowable Flow Through Wet Weather Train Assuming 215-mgd Secondary Bypass(3) (mgd)	Maximum Allowable Flow Through Wet Weather Train Assuming No Bypass (3) (mgd)
#1) Vortex/Swirl Concentrators	30%	221	69	183
#2) Conventional Clarifiers	55%	142	161	376
#3) CEPT w/ Conventional Clarifiers	80%	63	Unlimited*	Unlimited*
#4) Fine Screening -> Ballasted Floc	91%	30	Unlimited*	Unlimited*

*The flow for Train #3 is unlimited assuming the wet weather treatment train operates for no more than seven days per month, an estimate provided by CDM (CH2M HILL, 2008). Since the effluent water quality for Train #4 exceeds permit requirements, it is truly unlimited in flow and frequency of operation. See Section 9.1.

(1) TSS removal efficiencies are based on industry standards. Specific references are provided in TM-SE2 (CH2M HILL, 2008a).

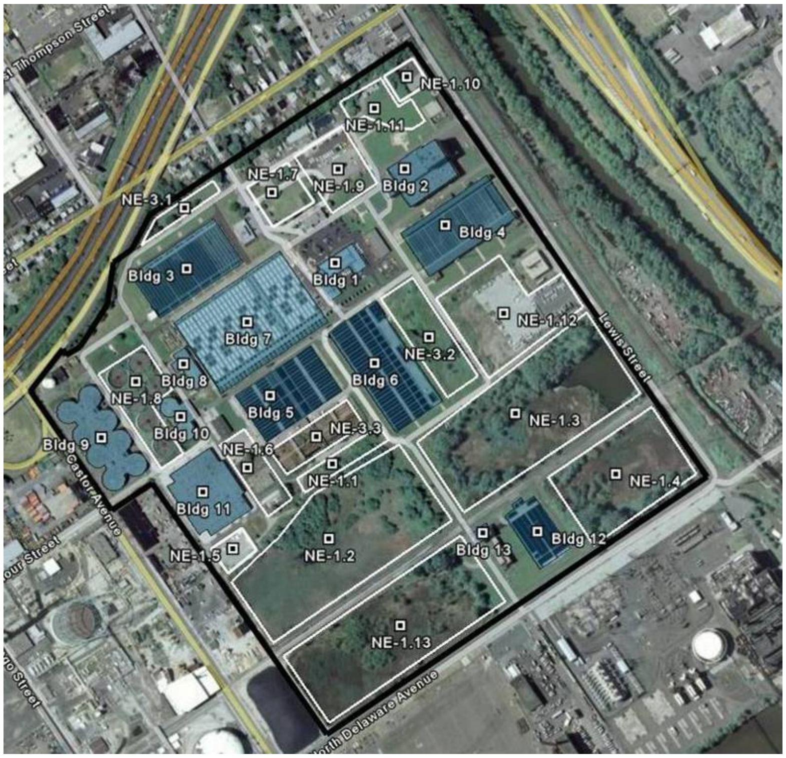
(2) Achievable effluent concentrations based on 95th percentile influent wet weather TSS concentration (316 mg/L)

(3) Maximum flow determined by NPDES Monthly TSS Limit. The allowable daily blended effluent TSS concentration during wet weather was calculated to be 99 mg/L (CH2M HILL, 2008b).

Both the vortex/swirl and conventional clarification trains are limited by permit requirements for this plant. The permitted flows are largely affected by the 215-mgd bypass, which undergoes only primary treatment, reducing the effluent quality of the conventional plant. Since the bypass has not been constructed yet, Exhibit 3-3 also includes the maximum allowable flow assuming no bypass. The permitted flows under both scenarios are used as design points for the vortex/swirl and conventional clarification trains in this report.

The trains with chemical addition obtain higher removal efficiencies and are considered unlimited by permit requirements. For CEPT, the flows are only unlimited if the wet weather treatment facility operates for no more than seven days per month. For the Ballasted Flocculation train, whose effluent quality exceeds that of permit requirements, both the flow and frequency of operation is unlimited (See Section 9.1). The design flow points for these "unlimited" trains were primarily based on the available land area on the existing plant site, as discussed below.

EXHIBIT 3-4
Available Land Areas Within NE WPCP Site



3.1.2 Design Flows by Available Land - Fleet Auction Lot: 300 MGD, 500 MGD

During discussions of land utilization at the existing site, it was agreed that the existing Fleet auction lot north of the lagoons would be the optimal location for the new wet weather facility (NE -1.12 in Exhibit 3-4). It was found that a 300-mgd CEPT facility, or a 500-mgd ballasted flocculation facility, could fit on this existing lot. This assumes that, if needed, the existing cogeneration building at the corner of the lot could be demolished to increase the land area available.

3.1.3 Design Flows by Available Land - Fleet Auction Lot and Sludge Lagoon: 1000 MGD

To expand beyond 300 and 500 mgd flow capacities, it was decided that only one section of the sludge lagoons would be utilized (NE-1.3 in Exhibit 3-4). This serves to minimize disturbance of the sludge lagoons, which would require remediation if used for construction. A small section in the NE-1.4 sludge lagoon was also set aside for the new chlorine contact chamber for the wet weather treatment train. The combination of the fleet auction lot and the NE-1.3 sludge lagoon provide sufficient area for a 1000-mgd CEPT facility or a 1500-mgd ballasted flocculation facility. Since 1500 mgd exceeds the expected collection system capacity, it is not evaluated as a design point (see following section).

3.1.4 Design Flows by Collection System Capacity Assumptions: 1100 MGD

According to CDM's assumptions on the capacity of the upgraded collection system, the collection system capacity for the NE WPCP could reach 1,740 mgd after transmission improvements, which is equivalent to three times the existing collection system capacity (Myers, 2007a). Assuming the existing plant will be able to handle 650 mgd, the maximum flow to the new wet weather facility would be 1090 mgd. The maximum design flow point used for the ballasted flocculation was thus 1100 mgd.

3.2 Key Design Assumptions

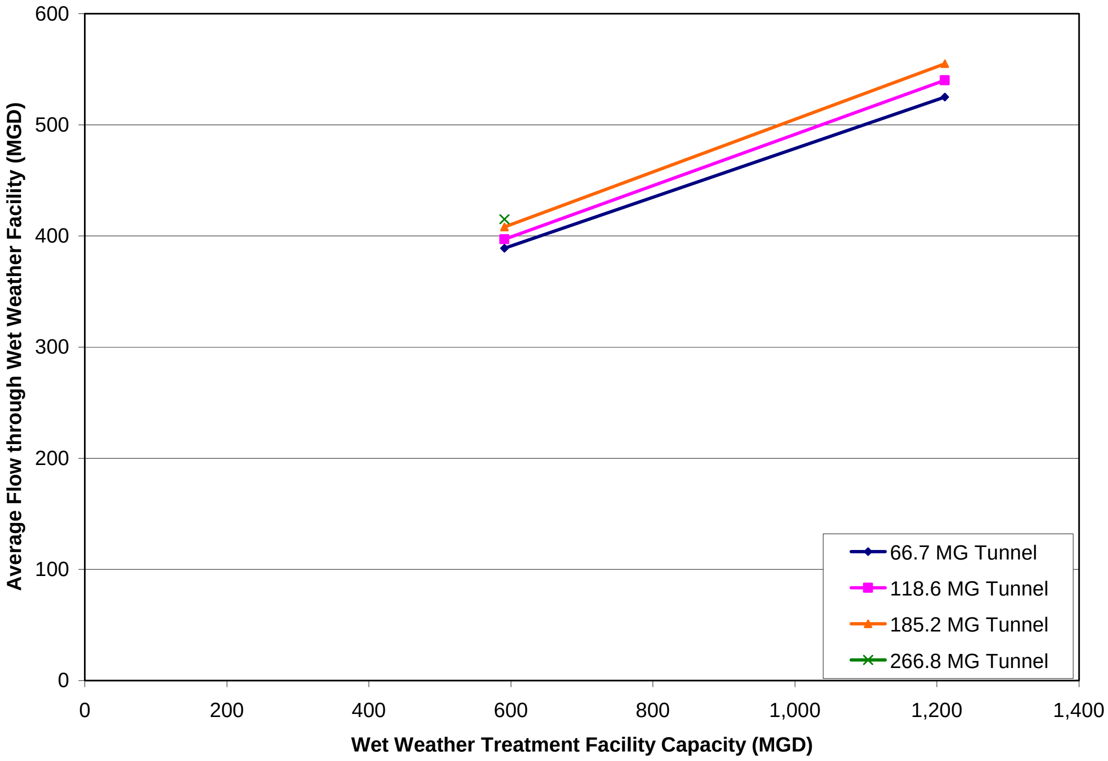
3.2.1 Average Design Flow

In the previous section, the design flow capacities were identified for each treatment train based on permit limits, available land area, and collection system capacity. These flows are the peak flows that the wet weather facilities are designed to treat under each scenario.

The average flow that the wet weather facility will receive, however, depends on conditions in the collection system. Preliminary model simulations have been performed for the Northeast Drainage district (NEDD) under several deep tunnel and plant expansion scenarios (CDM, 2008). Simulation results suggest that the average flow delivered to the wet weather facility increases as the capacity of the facility increases, and is not highly sensitive to the volume of storage in the collection system (Exhibit 3-5).

Model runs for a 591-mgd and a 1,211-mgd wet weather facility generated an average flow of 415-mgd and 555-mgd, respectively, assuming the largest storage tunnel scenario. Based on these model results, the maximum average design flow assumed for the new wet weather treatment trains evaluated in this report is 555-mgd. For the Ballasted Flocculation 500-mgd scenario, an average flow of 415-mgd was assumed. For trains with peak capacities less than 415 mgd, the average flow is assumed to be equivalent to the peak flow of the facility (Exhibit 3-6).

EXHIBIT 3-5
Average Annual Wet Weather Treatment Rates Under Various Deep Tunnel and Plant Expansion Scenarios



*This plots the average wet weather treatment rates using data from the high flow scenario hydrologic model (CDM, 2008).

EXHIBIT 3-6
Average Design Flows

Maximum Design Flow (mgd)	Average Design Flow (mgd)
69	69
150	150
160	160
183	183
300	300
376	376
500	415(1)
1000, 1100	555(2)

(1) Model runs with a 591-mgd facility generated an average flow of 415-mgd.

(2) Model runs with a 1,211-mgd facility generated an average flow of 555-mgd.

3.2.2 Process

The process design described herein is based on conceptual design parameters and will require refinement as the planning and design efforts progress. For the purposes of developing capital costs, sizing of most facilities was based on maximum design flows. The average design flow, as described above, was used for sizing chemical storage facilities, storage for screenings and grit, and sludge handling facilities.

Preliminary Treatment

Each wet weather train evaluated in this report was sized to treat influent flow in excess of the plant's flow capacity of 650 mgd. For each case, the head of the new wet weather facility is located in the existing Fleet auction lot, southeast of the Set-1 primaries. A new influent conduit running south along Lewis Street will divert excess wet weather flow to the new preliminary treatment building (PTB) of the wet weather treatment facility. The new PTB will contain an influent wet well at a similar elevation to the existing low level wet well, bar screens, influent pumps, and screenings and grit handling systems. The influent pumps were designed to increase the hydraulic grade line so that the wet weather flow can discharge to the river outfall by gravity from the wet weather treatment facilities. The screenings and grit handling systems include screenings washers and compactors, as well as grit concentrators and classifiers. This system will handle screenings from both the bar screens and the fine screens when required.

From the PTB, the wet weather flow will continue on to further treatment through processes dependent on each treatment train. These are described in further detail in Sections 4 through 7.

Disinfection

The final process of all treatment trains is chlorination and dechlorination. The wet weather flow will be dosed with sodium hypochlorite at the head of the new chlorine contact chamber. The chlorine contact chamber is sized to provide a 20-minute detention time at peak flow, with the exception of the 1,000 mgd and 1,100 mgd flow scenarios. In these scenarios, the chamber is sized for a 10-minute detention time at peak flow, and it is assumed that the chlorine dosage will be increased correspondingly to provide adequate disinfection. Sodium bisulfite is then used for dechlorination at the end of the chlorine contact chamber.

Chemical Feed

For Treatment Trains #3 and #4, which provide chemically-enhanced clarification, a coagulant and flocculant are added as settling aids. For Train #3, CEPT, these chemicals are added to a rapid mixer and flocculation basin upstream of the sedimentation tank. In the ballasted flocculation train (#4), the settling aids are added to mixing zones that are part of the ballasted flocculation unit.

Ferric chloride was selected as the coagulant for all trains since it is currently used at PWD's water treatment plants. However, if there are concerns with the iron affecting the digestion process downstream, aluminum sulfate (alum) can be used as a substitute.

Polymer is used as the flocculant and is stored in liquid form to allow immediate startup of the wet weather system.

Ten-day storage at average flow was assumed for all chemicals.

Sludge Handling

Primary sludge from all treatment trains is pumped to new gravity thickeners, where the solids concentration is expected to increase to a minimum of 3 percent. The thickeners are sized to handle the average wet weather flow (as presented in Exhibit 3-6) with a 95 percentile influent solids concentration (316 mg/L) for a continuous period of 24 hours.

The thickened sludge will be pumped to the plant's anaerobic digesters for further treatment. The sludge will be screened through StrainPress® sludge cleaners to remove inert solids before entering the digesters. PWD is currently conducting a study of the existing digesters and expects that proposed improvements will generate capacity equivalent to two extra digesters. Capital costs for each treatment train include the cost of new digesters that may be required beyond this improved capacity. The digesters were sized to provide 20-day storage for solids, assuming average flow, a 95 percentile influent solids concentration (316 mg/L), an average wet weather event duration of five hours, and five events in 20 days.

Along with the four new thickeners for the existing plant, these new digesters will be located in the area of the abandoned digesters (Figure 3-4, NE-1.8). The cost of demolishing the abandoned digesters and removing the sludge contained is not included in the capital cost estimates. The design parameters that were assumed for all the treatment train processes are summarized in Exhibit 3-7. The process flows are described in further detail in each of the treatment train sections.

EXHIBIT 3-7
Key Process Design Assumptions for Wet Weather Treatment Trains(1)

Preliminary Treatment			
Bar Screens	Opening Size	15	mm (0.59 in)
	Screenings Production(2)	3.5	cf/mg
Influent Pumps	Type	Vertical End-Suction	
	Total Dynamic Head (TDH)	45	ft (match existing wet well elevations)
Fine Screens	Opening Size	6	mm (0.24 in)
	Screenings Production(2)	2.5	cf/mg
	Screenings Compaction Factor	2	
Grit Removal	Type	Vortex Grit Unit	
	Grit Production(2)	4	cf/mg
Screenings and Grit	Number of Days Storage	1	Day
Primary Clarifiers	Type	Rectangular Basin	
	Sludge Collection Mechanism	Chain-and-flight	
Flocculation Tank	Detention Time (at max flow)	10	Min
	Number of Stages	3	
Wet Weather Treatment Technology	**Surface Overflow Rate (gpd/sf)**		

EXHIBIT 3-7
Key Process Design Assumptions for Wet Weather Treatment Trains(1)

Vortex/Swirl	36,000 (25 gpm/sf)		
Conventional Clarifiers	2,400 (3)		
CEPT	3,000		
Ballasted Flocculation	84,600 (60 gpm/sf)		
Chlorine Contact			
Chlorine Contact Chamber	Detention Time	10 -20	Min
Chemical Feed			
Chemical	**Purpose**	**Concentration**	**Storage (at avg flow)**
Ferric Chloride	Coagulation	60 mg/L	10 days
Liquid Polymer	Flocculation	2 mg/L	10 days
Sodium Hypochlorite	Chlorination	5 mg/L	10 days
Sodium Bisulfite	De-chlorination	1.5 mg/L(4)	10 days
Primary Sludge Generation(5)			
Train	**% TSS Removal**	**% Solids in Sludge**	
#1: Vortex/Swirl	30%	0.07%(6)	
#2: Conventional Clarifiers	55%	0.5%	
#3: CEPT	80%	0.5%	
#4: Ballasted Floc	90%	0.3%	
Sludge Thickening			
Gravity Thickeners	Max Hydraulic Loading Rate (limiting factor for Trains #1 and #4)	900	gal/sf/day
	Max Solids Loading Rate (limiting factor for Trains #2, #3)	30.7	lb/sf/day
	% Solids of Thickened Sludge	3	% minimum
StrainPress® Sludge Screens	Sludge Throughput	200 – 400	gpm
Digesters			
Anaerobic Digesters	Detention Time	20	days
	Diameter	115	ft
	Side Water Depth	25	ft
	Volatile Solids Destruction	50	%

(1) Unless otherwise noted, all design parameters are based on standard textbook values.

(2) Estimated from 2004-2005 grit and screenings disposal records from the SE WPCP. It is assumed that

EXHIBIT 3-7
Key Process Design Assumptions for Wet Weather Treatment Trains(1)

the difference in grit and screenings quantities between the plants are negligible.

(3) Based on stress testing results on existing primary clarifiers

(4) Assumes 1 mg/L residual chlorine concentration at the end of the chlorine contact chamber

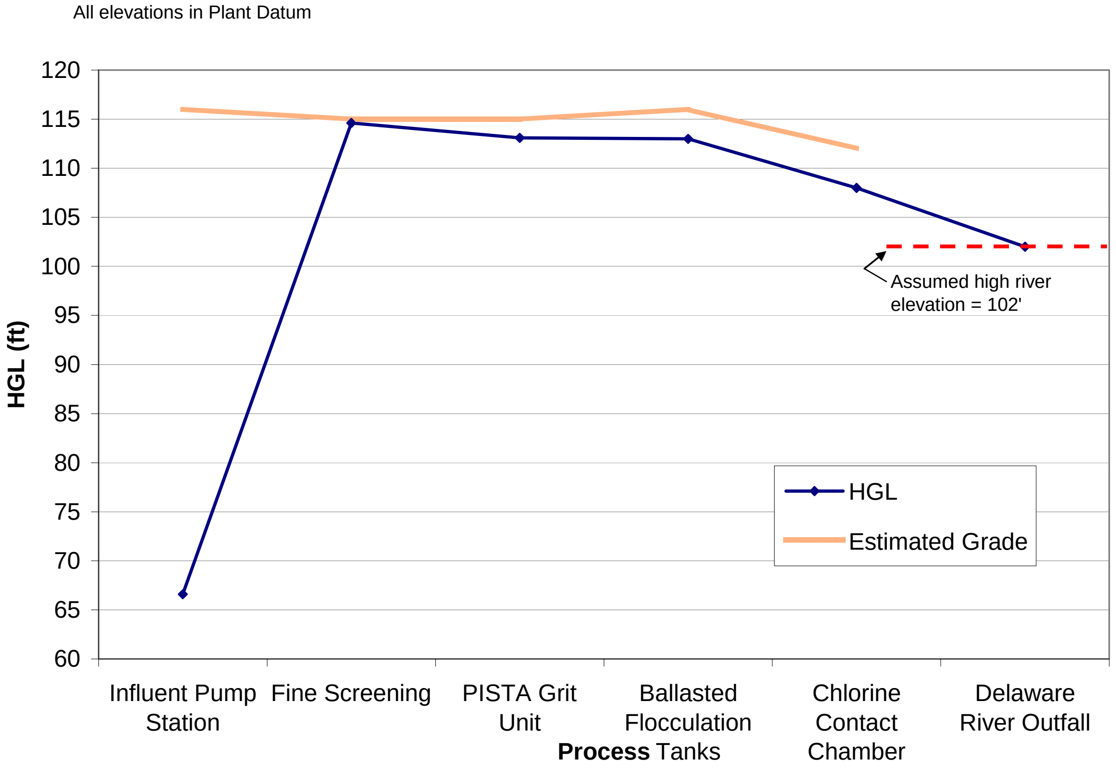
(5) Assumes 95 percentile influent TSS concentration of 316 mg/L, and volatile solids percentage of 70%

(6) Based on a 10% underflow from the vortex/swirl concentrator

3.2.3 Hydraulics

To eliminate the need for an effluent pump station, the elevations of the new wet weather treatment trains were set to allow gravity flow to the Delaware River outfall. A preliminary hydraulic profile for the ballasted flocculation train at 1100 mgd is shown in Exhibit 3-8 as an example of a maximum head loss scenario.

EXHIBIT 3-8
Preliminary Hydraulic Gradeline for the Ballasted Flocculation Treatment Train at 1100 MGD



As an initial condition, the high river elevation was assumed to be 102 feet. This is similar to the assumption made for the Delaware River in the Southeast WPCP memo (CH2M HILL, 2008c).

The water surface level of the chlorine contact chamber was assumed to be 2 feet higher than the top of the existing chlorine contact chamber (108 feet). The contact chamber was elevated from the existing chamber to avoid flooding of the chamber and the final sedimentation tank weirs, which the current plant occasionally experiences during high river level conditions. The estimated head-loss through the new outfall conduit is 3.2 ft (using Manning’s Equation).

The elevation of the chlorine contact chamber sets the elevations of the upstream unit processes. As shown in Exhibit 3-8, the water surface elevations are slightly beneath the existing grade elevation. The hydraulic grade-line of the wet weather facility is higher than the existing plant due to its location on the east side, which is higher in elevation than the rest of the site. Capital cost estimates assume complete burial of all tanks.

3.2.4 Existing Site

In developing conceptual layouts of the wet weather treatment trains, several assumptions were made about the existing site:

- The cogeneration building in the Fleet auction lot (NE-1.12 of Exhibit 3-4) can be demolished to increase the land area available for the wet weather facility.
- The existing outfall pier (approximately 600-ft long) needs to be expanded to support the new outfall conduit. Pier expansion is included in the capital cost estimates.

3.2.5 Site Conditions

The site and soil conditions in the Fleet auction lot and the sludge lagoons were assumed to be similar to the rest of the NE WPCP. Two main assumptions were made based on existing plant drawings:

- Piles will be needed for foundations of all structures. A pile density and depth of 0.069 piles/sf and 30 feet were used for all water-bearing structures on site. A pile density and depth of 0.089 piles/sf and 50 feet were used for the outfall conduit to the Delaware River. T A pile density and depth of 0.0043 piles/sf and 30 feet were used for all other structures. These numbers were based on existing pile plans for the Northeast WPCP.
- Dewatering will be required for some buried structures. According to plant drawings, the groundwater elevation ranges from approximately 5-ft to 20-ft below grade at the NE WPCP.

3.3 Cost Estimating Assumptions

CH2M HILL’s costing model was used to develop conceptual level estimates of both capital and life-cycle costs for each of the treatment trains and flows. This tool was supplemented by budgetary quotes from vendors for all major pieces of equipment. These estimates are defined as Class 4 estimates by the Association for the Advancement of Cost Engineers (AACE) and have an expected level of accuracy of +50 to -30 percent.

3.3.1 Capital Costs

Construction Costs

Construction costs were developed using the costing model for each building or unit process of a treatment train, and were based on estimated materials, labor, equipment, and installation costs. Contractor markups applied to the construction subtotal costs are presented in Exhibit 3-9. The percentages used are industry standards and are in agreement with CDM’s assumptions. The escalation factors applied are based on a construction start-date of September 1, 2009, and the estimated construction duration of each scenario (Exhibit 3-10). This start-date was chosen since PWD's LTCP Update must be submitted by this date. A location adjustment factor of 15.2 percent was applied to the escalated construction cost, which is in agreement with the ENR 20-city Construction Cost Index (CCI).

Lastly, a market adjustment factor of 15 percent was applied to account for: busy contractors; contractors selectively bidding jobs; contractors selectively choosing which Owners they want to do jobs for; premium wages to keep skilled workers and management staff; availability of crafts/trades; immigration impacts and uncertainty; abnormal fuel impacts and uncertainty; and abnormal material impacts of the last two years.

EXHIBIT 3-9
Contractor Markups Assumed in Capital Cost Estimates

Contractor Markups	%	Applied to:
Overhead (OH)	10%	Subtotal of Construction Cost
Profit (P)	5%	Subtotal of Construction Cost + OH
Mobilization, Bonds, and Insurance (MOB)	5%	Subtotal of Construction Cost + OH&P
Contingency	25%	Subtotal of Construction Cost + OH&P + MOB

EXHIBIT 3-10
Escalation Factors for Various Construction Scenarios

Flow Capacity of Wet Weather Treatment Train (mgd)	Estimated Construction Duration (months)(1)	Escalation Factor(2)
69	24	19.8%
150, 160	26	20.5%
183	27	21.2%
300	30	21.8%
376	32	22.5%
500	36	23.9%
1000, 1100	48	28.2%

(1) Escalation factors are based on mid-point of construction with a construction start-date of 9/1/2009.

(2) Construction durations were estimated based on facilities of similar size, and need to be refined through each stage of design.

Non-Construction Costs

A factor of 30 percent was applied to the total construction costs to estimate non-construction costs related to the project. The breakdown of these factors is shown in Exhibit 3-11.

EXHIBIT 3-11
Non-Construction Cost Factors

Non-Construction Expenditure	Factor*

EXHIBIT 3-11
Non-Construction Cost Factors

Non-Construction Expenditure	Factor*
Permitting	2%
Engineering	10%
Services During Construction	10%
Commissioning and Startup	3%
Legal/Administration	5%

*Each factor was applied to the total construction cost of the project, including all markups and escalation.

Land Remediation

Under certain high-flow scenarios, the new chlorine contact chamber will be located next to the existing chamber, in an abandoned sludge lagoon. This capped sludge lagoon will need remediation before construction can begin. For the higher flows of 1000 and 1100 mgd, an additional 11.4 acres of abandoned sludge lagoons must also be utilized to provide enough space for the new facility.

The estimated cost of remediation is $1.14 M per acre, as estimated by PWD. This assumes a relatively low hazard level of the material being removed.

3.3.2 O&M and Life Cycle Cost Analysis

Life cycle and O&M costs of each treatment train at each flow were also estimated using CH2M HILL's costing model and were based on financial and operational assumptions as listed in Exhibit 3-12. The O&M costs cover labor, power for equipment and buildings, chemicals, sludge and trash disposal, and repair, maintenance and replacement of structures and equipment. O&M costs are mainly based on average flows through the plant, as described in Section 3.2.1 and shown in Exhibit 3-6.

The additional labor required for each treatment train is dependent on the flow capacity of the train, as shown in Exhibit 3-13. It was assumed that new maintenance workers and operators would be hired for the new wet weather facility, working full time throughout the year. For some flow scenarios, it was assumed that a portion of the labor requirements during wet weather events could be met by increasing the number of shifts for existing operators, who would work overtime at a rate of 1.5 times their normal wage. It was assumed that the operators on overtime would work one 8-hour shift per wet weather event.

A detailed break down of the O&M costs and the energy requirements for each train are presented in Attachment NE-2.1. It should be noted that all O&M costs presented for the treatment trains are annualized O&M costs that include escalation over the 30-year period.

Life cycle costs were calculated using the total capital cost, including construction and non-construction costs, and O&M costs. The present value of the life cycle costs are presented in the cost summary section of each train.

EXHIBIT 3-12
Assumed Factors for Life Cycle Cost Estimates

Factor	Value	
Financial		
Annual Discount Rate	4.875	%
Life-Cycle Calculation Period	30	Years
Inflation Rate	4	%(1)
Operation		
Days of operation of wet weather treatment train	51	days(2)
Duration of wet weather event	5	Hours(2)
Labor		
Hourly wage for plant operator	$50.44	including fringe benefits
Hourly wage for plant operator on overtime	$75.65	including fringe benefits
Hourly wage for maintenance worker	$52.35	including fringe benefits
Fringe benefits and overhead multiplier	2.7	applied on top of raw hourly rate
Number of working hours for full time operators at wet weather facility	2,080	hours per year per operator
Number of working hours for operators on overtime at wet weather facility	408	hours per year per operator (8 hours per event)
Number of working hours for maintenance workers at wet weather facility	2,080	hours per year per worker
Power for Buildings		
Building Electrical Cost Assumed	$0.10	$/kwh
Building Electrical Requirements	2	watts/sf of building area
Building Heating Requirements	1.2	BTU/hr/surface area of building
Natural gas cost assumed	$14	per MBTU
Power for Equipment(3)	$0.10	$/kwh
Chemicals(4)		
Ferric Chloride	$310	$/dry ton
Liquid Polymer	$3983	$/dry ton
Sodium Hypochlorite	$1450	$/dry ton
Sodium Bisulfite	$1000	$/dry ton
Repair, Maintenance, and Replacement		
	Percentage assumed for annual O&M cost	
Finishes	2%	of finishes cost during construction

EXHIBIT 3-12
Assumed Factors for Life Cycle Cost Estimates

Factor	Value	
Equipment	1%	of capital cost of equipment
Instrumentation and Controls	5%	of capital cost of I&C
Mechanical	0.1%	of capital cost of mechanical work (incl. valves)
Electrical	1%	of capital cost of electrical equipment
Disposal		
Grit and Screenings Disposal and Hauling Costs	$100	per cubic yard
Final Sludge Disposal Costs(5)	$75	per wet ton
Other		
Other O&M Costs (including vehicles, lab tests, office equipment and other miscellaneous costs)	$10,000	per additional full-time operator and maintenance worker
Contingency		
Contingency applied to O&M costs	20	%

(1) Based on CCI Index

(2) The maximum average annual number of wet weather events with flows higher than 650 MGD is 51 under scenarios modeled by CDM. Similarly, the maximum average annual wet weather duration is 219 hours (CDM, 2008). The duration of each event is then assumed to be 5 hours.

(3) Equipment power costs estimated by PWD.

(4) Based on existing costs at the plant (McKeon, 2008)

(5) Final sludge mass assumes 30% dewatered cake.

EXHIBIT 3-13
Additional Labor Requirements for each Flow Scenario

Treatment Train Flow Capacity	Number of Additional Full-Time Operators(1)	Number of Existing Operators on Overtime(2)	Number of Additional Maintenance Workers(1)
69, 150, 160, 183	1	1	2
300, 376, 500	2	0	4
1000, 1100	2	1	4

(1) Full-time operators and maintenance workers are new hires who work 2080 hours per year. Maintenance workers include different trades required for the facility (e.g. electricians, instrument technicians, mechanics, etc.) (2) Existing operators on overtime work 8 hours per wet weather event, or 408 hours per year.

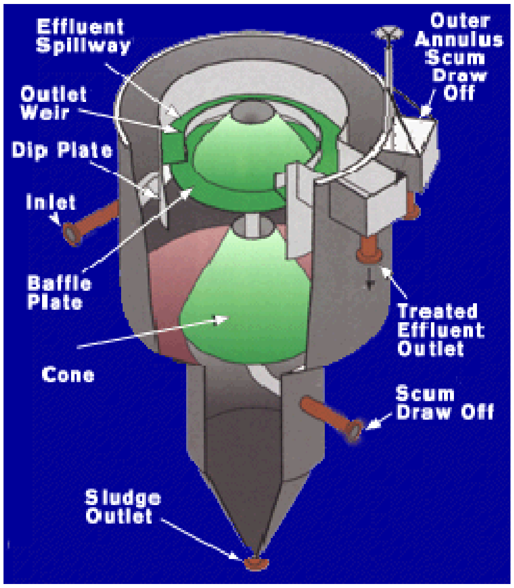
4.0 Treatment Train #1- Vortex/Swirl Concentrators

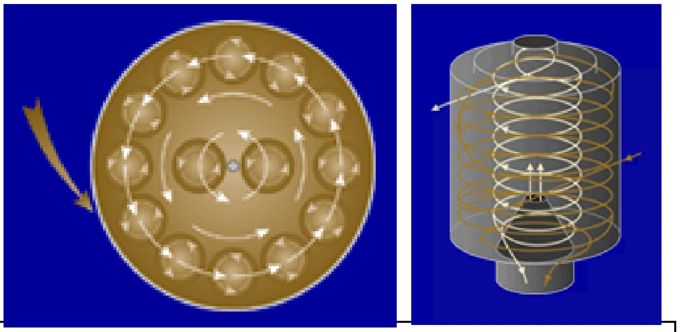
4.1 Process Flow Diagram

The first treatment train under evaluation utilizes the vortex separation technology as its main treatment process. After passing through bar screens and influent pumping at the PTB, the wet weather flow will enter the primary vortex/swirl concentrators. Vortex/swirl concentrators are flow-through structures with no moving parts. The wet weather flow enters the cylindrical structure tangentially, producing a swirling motion that concentrates the solids in the center (Exhibit 4-1). An underflow drain in the center of the unit continually draws the solid materials out of the flow.

The treated effluent flows out of the top of the vessel, continuing on to the chlorine contact chamber. The solids underflow, typically 10 percent of the influent, undergoes grit removal through a vortex grit unit before settling and thickening in gravity thickeners. The conceptual process flow diagram for this treatment train is shown in Exhibit 4-2.

EXHIBIT 4-1
Diagrammatic Cutaway of Vortex/Swirl Device (Storm King®, H.I.L. Technologies)





Flow Pattern Plan and Profile Views (H.I.L. Technologies)
The flow in vortex/swirl devices initially follows a path around the perimeter of the unit and is then directed into an inner swirl pattern with a lower velocity than the outer swirl. Solids separation is achieved by both centrifugal force and gravity because of the long flow path and inertial separation due to the circular flow pattern. The concentrated underflow passes through an outlet in the bottom of the vessel while the treated effluent flows out of the top of the vessel.

4.2 Conceptual Design and Site Layouts

A conceptual design and site layout was developed for a flow of 69 mgd, the maximum allowable flow to meet permit requirements assuming the 215-mgd secondary bypass, and for 183 mgd, the maximum allowable flow assuming no bypass. The main design parameters are shown in Exhibit 4-2 and the conceptual site layouts and footprints are shown in Exhibits 4-3. Since the entire facility can fit on the existing Fleet auction lot, no land acquisition or remediation will be required.

4.3 Operational and Technology-Specific Issues

The effectiveness of vortex/swirl concentrators greatly depends on the hydraulic loading rate on the unit and the characteristics of the solids entering the unit. The optimal loading rate must be determined through pilot or operational testing. In order to operate the vortex/swirl at its optimal operating rate or “sweet spot”, the vortex/swirl units can be brought online one by one as the influent flow increases. Alternatively, an equalization basin can be constructed to maintain a specific flow-rate into the units. An equalization basin was not included in the cost estimates, but conservative hydraulic loading rates were assumed for facility sizing.

4.3.1 Startup and Shutdown

The pretreatment processes (bar screens, influent pumps, and grit removal) can be brought online quickly at the start of a wet weather event. Vortex/ swirl concentrators would be empty at the start of a wet weather event. At small flows, the wet weather flow will exit through the underflow. As flows increase, the vessel will fill due to the increased hydraulic load and begin discharging treated effluent to the outfall.

During shutdown, the vortex/swirl and grit units will be emptied by pumping from the underflow sections to the main plant’s influent wet well. The influent wet well in the new PTB would also be pumped down to the plant’s existing wet well using dewatering pumps (Exhibit 4-2).

For long term shutdown, the chlorine contact chamber could be pumped down, with the flow recycled to the head of the main plant.

4.3.2 Interaction with Main Plant

The waste streams generated by the screenings washer/compactor and the grit classifiers are sent to the gravity thickeners of the wet weather treatment train and will not affect the main plant.

The overflow from the gravity thickeners is conveyed to the head of the entire plant. The estimated overflow range from wet weather thickeners is 6 to 18 mgd. To minimize the effect of this volume, the overflow is recycled back to the head of the entire plant so that it can be distributed across all units in operation.

4.3.3 Impact on plant operations

Since the vortex/swirl unit has no moving parts, it is expected to have little operations and maintenance requirements. However, operators’ attention may be necessary to monitor the hydraulic loading rates into the vortex/swirls to ensure that the "sweet spot" is maintained. The treatment train also includes grit pumps, concentrators, and classifiers, as well as sludge pumps and other equipment, all of which require maintenance. In addition, the new chemical building will include storage of sodium hypochlorite and bisulfite, which are fed to the new chorine contact chamber. Storage of hypochlorite will need to be monitored, since it degrades over time. In addition, the hypochlorite feed-lines should be flushed or degassed periodically.

4.4 Cost Analyses

The estimated capital, O&M, and lifecycle costs are shown in Exhibit 4-4. Total capital costs and the capital costs per volume treated for all scenarios are shown in Exhibits 4-5 and 4-6. The estimated O&M costs by category are also presented in Exhibits 4-7. A more detailed breakdown of these costs is presented in Attachment NE-2.1.

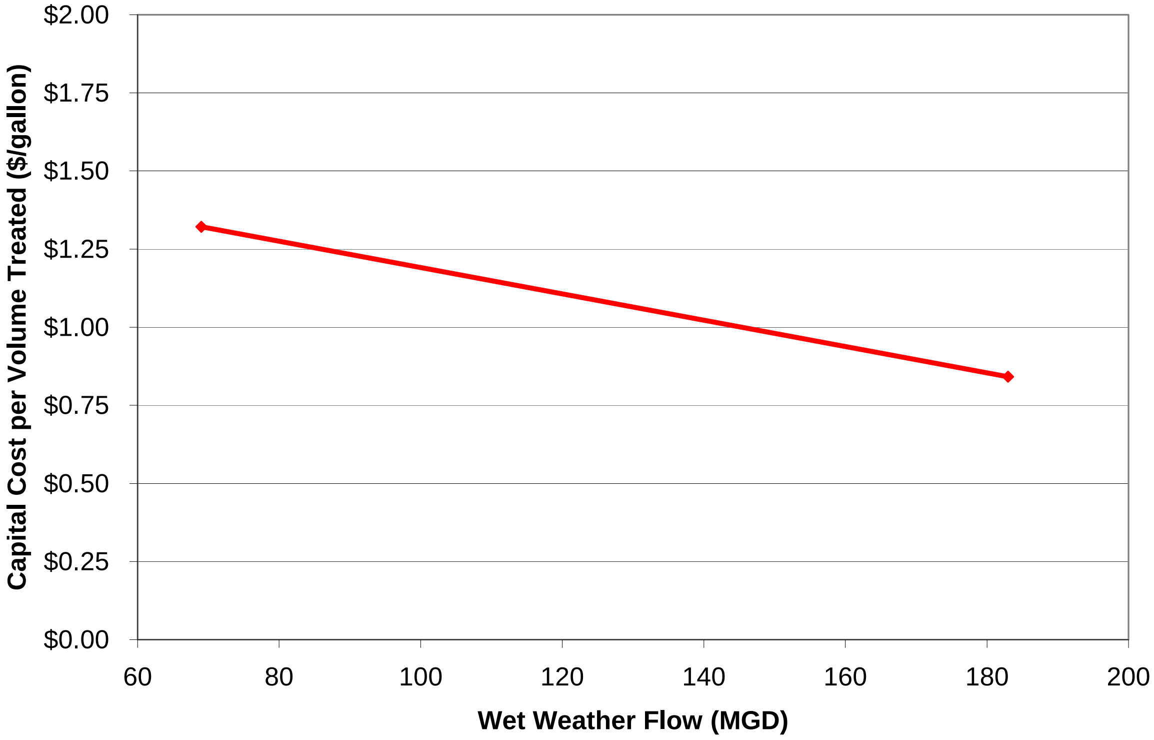

EXHIBIT 4-7
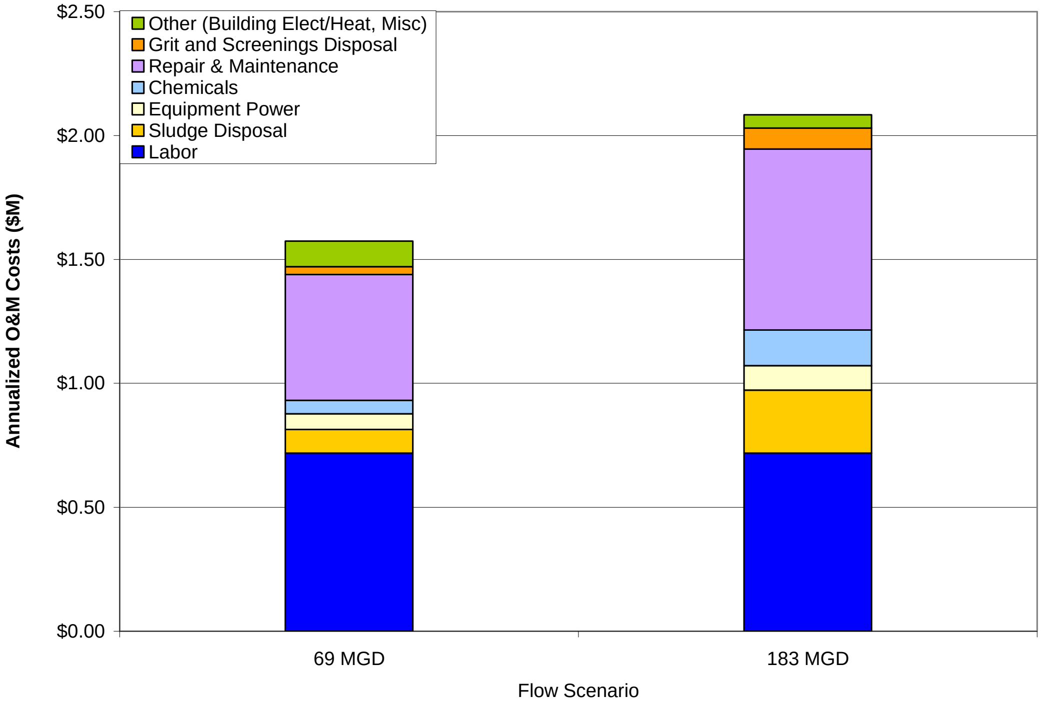
Operations and Maintenance by Category for Treatment Train #1: Vortex/Swirl



5.0 Treatment Train #2 - Conventional Clarifiers

5.1 Process Flow Diagram

Through treatment train #2, the wet weather flow undergoes essentially the same level of primary treatment as the flow through the existing NE WPCP. After preliminary treatment through the bar screens and grit removal, the wet weather flow passes through conventional primary clarifiers at a maximum loading rate of 2400 gpd/sf. This is the overflow rate achievable by the plant's existing primary clarifiers, as shown through stress testing (CH2M HILL, 2001). Primary sludge is collected by chain and flights in the clarifier tanks and is pumped to the gravity thickeners for thickening. The process flow diagram for this treatment train is shown in Exhibit 5-1.

5.2 Conceptual Design and Site Layouts

Conceptual designs were developed for a flow of 160 mgd, the maximum allowable flow to meet permit requirements assuming a 215-mgd secondary bypass, and 376 mgd, the allowable flow assuming no bypass. Key design parameters at these flows are shown in Exhibit 5-1 and conceptual layouts are shown in Exhibit 5-2. No remediation will be required for the 160-mgd flow scenario since the entire facility can fit on the existing Fleet auction lot. For the 376 mgd flow scenario, remediation will be required to site the new chlorine contact chamber.

5.3 Operational and Technology-Specific Issues

5.3.1 Startup and Shutdown

When the wet weather facility is initially put into service, it will take 2-3 hours before the conventional clarifiers begin to discharge treated wet weather flow. This is equivalent to the time needed to displace the existing wastewater in the tanks, or to fill the tanks if they are empty.

For shut down, the tank may be filled with treated effluent, or pumped down to the existing plant if freezing becomes an issue.

5.3.2 Interaction with Main Plant

Since the existing plant uses primary clarifiers, the new primary clarifiers for wet weather treatment can provide redundancy on primary treatment for the entire plant. If connected to the influent to the existing aeration basins, the new clarifiers could be used for treatment of dry weather flows.

The waste streams generated by the screenings washer/compactor and the grit classifiers are sent to the primary clarifiers of the wet weather treatment train and will not affect the main plant. As with the other treatment trains, the overflow from the gravity thickeners will be conveyed to the head of the entire plant. The estimated overflow range from wet weather

thickeners only is 4 to 11 mgd. To minimize the effect of this volume, the overflow is recycled back to the head of the entire plant so that it can be distributed across all units in operation.

5.3.3 Impact on Plant Operations

The operations and maintenance requirements for this treatment train should be similar to those needed for corresponding processes at the existing plant.

5.4 Cost Analyses

The estimated capital, O&M, and lifecycle costs are shown in Exhibit 5-3. Total capital costs and the capital costs per volume treated are also shown in Exhibits 5-4 and 5-5. Estimated O&M costs by category are presented in Exhibit 5-6. A more detailed breakdown of these costs is presented in Attachment NE-2.1.

6.0 Treatment Train #3 - Chemically Enhanced Primary Treatment (CEPT)

6.1 Process Flow Diagram

Chemically enhanced primary treatment (CEPT) improves the removal efficiency of TSS and BOD through the addition of coagulants and flocculants to primary clarifiers. With chemical enhancement, the surface overflow rate of the primary clarifier is expected to increase from 2400 gpd/sf to 3000 gpd/sf, and the removal efficiency from 55 percent to 80 percent. As shown in the process flow diagram in Exhibit 6-1, the flow path is similar to Treatment Train #2. The only difference is the addition of rapid mixers and flocculation basins upstream of the primary clarifiers, along with their associated chemical feed and storage systems.

6.2 Conceptual Design and Site Layouts

Conceptual designs were developed for three different flow scenarios for this train: 150, 300 and 1000 mgd. Key design parameters at these flows are shown in Exhibit 6-1. As shown in Exhibit 6-2, there is adequate space on the Fleet auction lot to treat up to 300 mgd of wet weather flow. Utilizing the adjacent sludge lagoon area allows an increased flow capacity to 1000 mgd. This sludge lagoon, as well as the lagoon area for the new chlorine contact chamber, will need remediation.

6.3 Operational and Technology-Specific Issues

6.3.1 Startup and Shutdown

When the wet weather facility is initially put into service, it will take 2-3 hours before the clarifiers begin to discharge treated wet weather flow. This is equivalent to the time needed to displace the existing wastewater in the tanks, or to fill the tanks if they are empty.

For shut down, the tanks may be filled with treated effluent, or drained down to the existing plant if freezing becomes an issue.

The other processes in the system are physical or physical/chemical treatment systems that are easily and quickly brought online and will achieve normal levels of treatment efficiency quickly.

6.3.2 Interaction with Main Plant

As described in the previous treatment trains, the overflow from the thickeners, ranging from 7 to 48 mgd depending on the flow scenario, is recycled back to the head of the plant for distribution across the main plant and the wet weather treatment train.

6.3.3 Impact on Plant Operations

CEPT requires the addition of chemicals, ferric chloride and polymer, that are not currently used at the NE WPCP. Storage of these new chemicals will need to be monitored to ensure that they are not degraded over time, especially during long periods of shutdown. The system effluent may need to be recycled to the head of the existing plant until the unit process is stabilized.

6.4 Cost Analyses

The estimated capital, O&M, and lifecycle costs for each flow scenario are shown in Exhibit 6-3. Total capital costs and the capital costs per volume treated are also shown in Exhibits 6-4 and 6-5. Estimated O&M costs by category are shown in Exhibit 6-6. A breakpoint in the O&M costs can be seen after a flow of 300-mgd. This is because O&M costs such as for chemical and sludge disposal are dependent on the average flow of the plant, not the peak. For example, while the 1000-mgd facility can treat a peak of 1000-mgd, the average flow through the facility is only 555 mgd, so the O&M (Section 3.2.1). Thus, facilities with peak flows greater than the average wet weather flow will experience a relatively smaller increase in O&M costs.

A more detailed breakdown of these costs is presented in Attachment NE-2.1.

7.0 Treatment Train #4 - Ballasted Flocculation

The final treatment train uses ballasted flocculation to achieve removal efficiencies beyond that of CEPT. Ballasted flocculation, often referred to as "high rate treatment," creates extremely dense flocs with high settling velocities that can be removed efficiently even at very high surface overflow rates. Two proprietary systems that use ballasted flocculation are the DensaDeg and Actiflo systems. The DensaDeg system uses chemical sludge produced within it (recirculated from the clarifier underflow to the system influent) as a ballasting agent. The Actiflo system uses microsand as the ballasting agent. Both systems can achieve TSS removals in the range of 85 to 95 percent.

Actiflo requires separate gravity thickeners to process the sludge it generates, while Densadeg recirculates its sludge within its own process and therefore produces a thicker sludge not requiring thickening. The overall cost differential is not significant in most cases, however, since Densadeg has a lower overflow rate (40 gpm/sf compared with 60 gpm/sf) and larger footprint (CH2M HILL, 2007b). Since the overall cost of the Actiflo and DensaDeg systems have been found to be similar, only one system was chosen for evaluation for this treatment train. The Actiflo system was selected in order to show the possibility of adding gravity thickeners to the plant layout. Pilot testing should be performed to determine the system best suited for the plant, while providing other benefits such as:

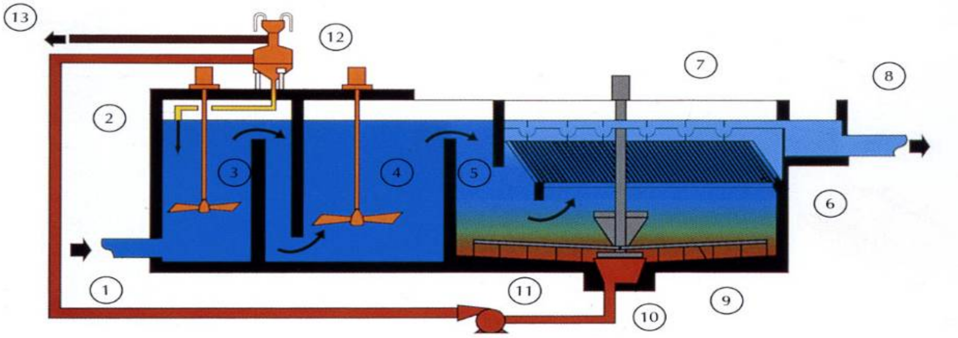
- Identification of influent wastewater constituents that may affect performance of either technology
- Determining suitable chemical dosages for the ballasted flocculation system
- Providing effluent quality information that can be used for design of downstream disinfection processes
- Assessing treatment performance at typical design overflow rates
- Providing better understanding of system operation through pilot testing.

7.1 Process Flow Diagram

In the ballasted flocculation treatment train, wet weather flow passes through bar screening, influent pumps, grit removal, and fine screening before entering the ballasted flocculation system (Exhibit 7-2). A schematic of the Actiflo system is shown in Exhibit 7-1.

Using the numbers in the Exhibit, the wastewater enters at point (1) along with the coagulant (ferric chloride) to the flash mixing zone (3) where microsand is also added (2). Addition of the coagulant enhances flocculation by destabilizing suspended solids in the wastewater. Compartment (4) is a gentle mixing zone where polymer is added to promote formation of strong flocs around the microsand. The flocculated solids flow to compartment (5), the clarification zone. Most of the solids settle at the bottom of this compartment, but this zone also has lamella settling modules (6) to enhance removal of suspended solids that may be present in the wastewater. The solids accumulated at the bottom of the clarification compartment (10) are recycled to a hydrocyclone (12), where the sludge is separated from the microsand. The microsand is recycled back to the flash mixing zone (3), and the sludge leaves the system by stream (13).

EXHIBIT 7-1
Schematic of the ACTIFLO High-Rate Primary Clarifier (scanned from vendor's brochure)



As shown in Exhibit 7-2, the sludge from the ballasted flocculation process is pumped to gravity thickeners to be thickened from 0.3 percent solids to 3-4 percent solids.

7.2 Conceptual Design and Site Layouts

Conceptual designs using the ballasted flocculation system were developed for flow capacities of 150, 500 and 1,100 mgd. The key design parameters are presented in Exhibit 7-2. As seen in the conceptual layouts in Exhibit 7-3, the Fleet auction lot provides adequate space for treating up to 500 mgd. With the adjacent sludge lagoon area, the flow capacity can reach 1500 mgd. However, since the upgraded collection system is not likely to convey more than 1100 mgd, the maximum design point for this train is 1100 mgd. Due to its extremely high surface overflow rate of 60 gpm/sf, ballasted flocculation has minimal space requirements compared to the other alternatives.

7.3 Operational and Technology-Specific Issues

7.3.1 Startup and Shutdown

Ballasted flocculation systems stabilize quickly, with Actiflo taking less than 20 minutes and DensaDeg less than 45 minutes to start producing good quality effluent based on demonstration testing. Infilco Degremont indicated that the DensaDeg process will produce design effluent immediately if left filled with chlorinated plant effluent. However, based on piloting studies, a connection should be provided for discharging wet weather effluent to the head of the existing plant during startup or until ballasted flocculation system performance stabilizes. To facilitate startup, the ballasted flocculation system should also be underloaded initially.

Shutdown can occur at the operator's convenience. Typically, equipment will simply need to be switched off. The hydrocyclones should be pumped down before being turned off. The tanks themselves can either be filled with treated effluent, or drained down. To prevent freezing during cold weather, any system that is not totally enclosed should have a constant flow of water, or be drained down. The cost estimate does not include a building for the ballasted flocculation units since they are able to be effectively operated in an outdoor environment, and the inclusion of a building would add unnecessary capital costs to this alternative.

The advantage of leaving the basins filled with water is that the startup time is substantially reduced and the basins reach their design effluent quality much more quickly. This reduces the volume of partially treated water that must be returned to the existing treatment plant. Running a small flow through the tanks also helps in maintaining equipment, such as the tank mixers. Actiflo's manufacturer recommends leaving the sand in the tanks only if the tanks are filled with effluent. With sand readily available in the tanks, treatment can begin sooner. If the system were fully drained, the sand within the Actiflo system would require removal and disposal to prevent freezing. Upon startup, sand would have to be reintroduced into the treatment flow using the bulk sand feed system. Infilco Degremont indicates that solids should be removed from the DensaDeg system within six hours to prevent septicity. The DensaDeg system can then be left filled with chlorinated plant effluent.

7.3.2 Interaction with Main Plant

During startup, effluent from the ballasted flocculation system will be discharged to the head of the main plant until system performance stabilizes.

Similar to the other treatment trains, recycle flows from the screenings washer/compactor and grit classifier will be conveyed to the ballasted flocculation system with the wet weather treatment train. The overflow streams from the gravity thickeners, however, must be sent to the head of the main plant for distribution across both the wet weather treatment train and the existing plant. Since this treatment train has the highest removal efficiency, it generates the highest sludge and overflow volumes. In addition, the solids content of the sludge is thinner compared to primary clarifier sludge as a result of the cyclones used to separate the ballast from the sludge. The estimated overflow volume is 49 to 108 mgd, depending on the flow capacity of the treatment train.

7.3.3 Impact on plant operations

To simplify routine operation, Actiflo and Densadeg typically have automated routine startup and shutdown sequences with PLC programming and adjustable timers (service interval, tank fill, equipment run, shutdown, and tank drain). However, operator attention will be necessary to monitor or optimize performance, and to confirm successful facility startup. The operators will have the following responsibilities:

- Start the process train
- Monitor coagulant and polymer dose and perform jar tests to optimize chemical dosing.
- Manage the loading of screenings and grit dumpsters.
- Observe equipment operation and contact maintenance if equipment malfunctions.

7.3.4 Other Issues

Foaming – Foaming may occur due to the addition of coagulants and polymer settling aids, and should be investigated in pilot studies. For example, during startup of the Actiflo unit at Lawrence WWTP in Lawrence, Kansas, the observed foaming resulted from the reaction of ferric chloride with biodegradable surfactants in the incoming wastewater. Foaming can be controlled using silica-based defoamers such as Tramfloc 110, Chemco DF, and Neo Solutions NS-8454 at low dosages.

Floc Carryover and Microsand Loss – Floc carryover is an issue for the DensaDeg system that should be investigated through pilot tests. As flows approach the design SOR, sludge densities may decrease, sending large flocs of sludge out in the effluent. These large flocs not only affect effluent quality in terms of TSS and BOD levels, but may also decrease effectiveness of the disinfection process downstream.

Regarding the Actiflo system, a certain degree of microsand loss is expected from normal operation of the system. The manufacturer indicates that about 8 pounds of microsand are lost for each million gallons of wastewater treated. The sand must be replaced for optimal operation of the system. According to information gathered during the team's site visit to the Cincinnati Metropolitan Sewer District, the SSO 700 Facility loses 350 lbs of sand per 15 mg wet weather event. In the conceptual design of this treatment train, adequate storage space was provided in the chemical buildings for 10 day storage of sand. Additionally, the microsand needs to be maintained in the system in case rapid startup is required, and the sand must be prevented from freezing during the winter so that the unit can start up quickly if needed during the cold season. The DensaDeg unit is totally drained when the system is shut down, and no chemical sludge is maintained in the system when it is not in use.

Sludge Concentration - One important difference between Actiflo and Densadeg is the sludge concentration that they produce. Sludge from the DensaDeg system can be four to five times more concentrated than sludge from the Actiflo system. Since the two systems are expected to produce the same mass of sludge, because they operate with similar coagulant dosages, it is expected that the volume of sludge produced in the ACTIFLO system will be four to five times greater than that in the DensaDeg unit. Gravity thickeners have been included in the conceptual design for the Actiflo treatment train to thicken the sludge to 3-4 percent solids. These thickeners may not be necessary if the Densadeg system is chosen.

7.4 Cost Analyses

The estimated capital, O&M, and lifecycle costs for each flow scenario are shown in Exhibit 7-4. Total capital costs and the capital costs per volume treated are also shown in Exhibits 7-5 and 7-6. Estimated O&M costs by category are presented in Exhibit 7-7. As described in the CEPT section, the breakpoint in the O&M costs at 500-mgd is due to the dependence on average flow, rather than peak flow, of the chemical and sludge disposal costs.

A more detailed breakdown of these costs is presented in Attachment NE-2.1.

EXHIBIT 7-4
Cost Summary for Ballasted Flocculation: Treatment Train #4

	Wet Weather Flow (mgd)		
Cost	**150**	**500**	**1100**
Capital Cost ($M)	$195	$527	$1,062
Annual Operations and Maintenance Cost ($M)	$3.0	$7.2	$10.0
Present Value of the Cost ($M)	$242	$639	$1,218

EXHIBIT 7-5
Capital Costs for Treatment Train #4: Ballasted Flocculation
Includes cost to upgrade plant capacity to 650 MGD

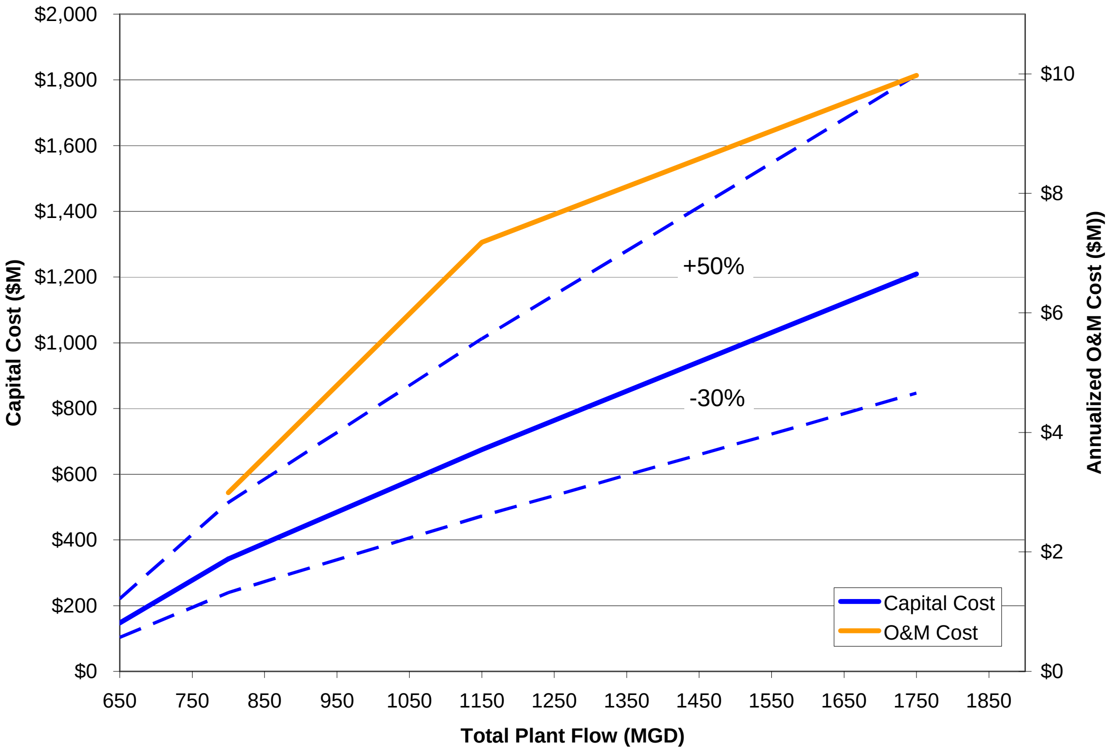

EXHIBIT 7-6
Capital Costs per Gallon Treated for Treatment Train #4: Ballasted Flocculation

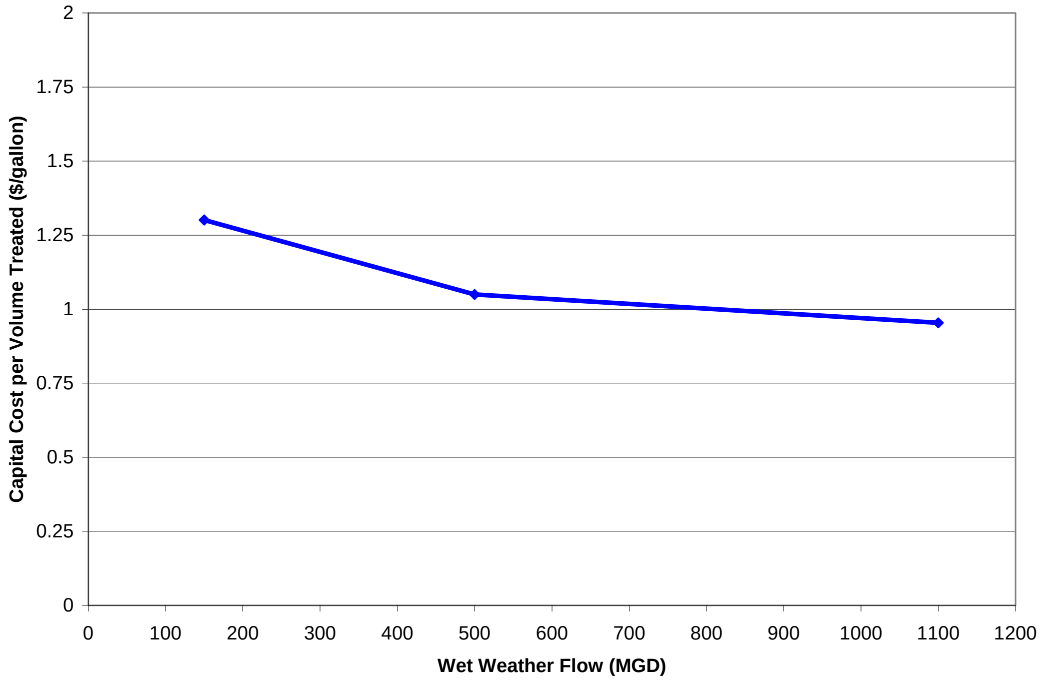

EXHIBIT 7-7
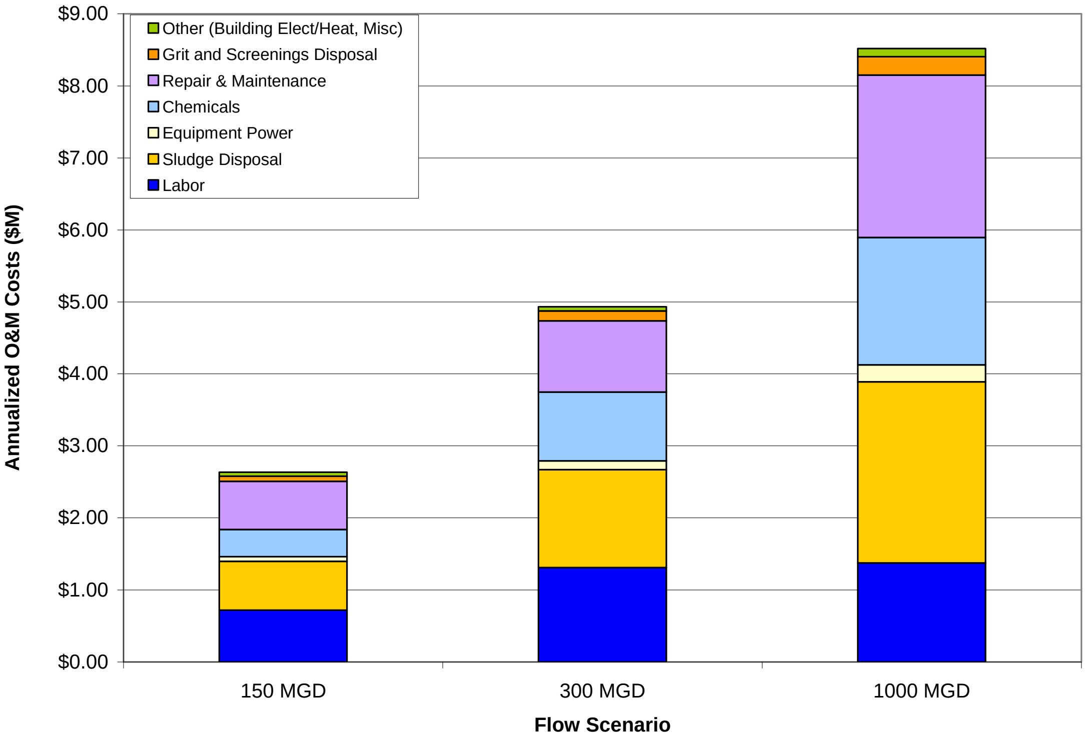
Operations and Maintenance Costs by Category for Treatment Train #4: Ballasted Flocculation



8.0 Alternatives for Optimizing Capital Costs

8.1 Ballasted Flocculation

As mentioned in Section 7, the costs presented for Treatment Train #4, Ballasted Flocculation, are based on the Actiflo system, which is similiar in cost to Densadeg, the other proprietary high rate treatment technology. If the ballasted flocculation treatment train is selected, a cost estimate for the Densadeg system should be developed to examine the cost differential. The main contributions to the cost differential will include:

- **Reduction in number of thickeners** - Densadeg maintains a 3-4 percent sludge thickness for its ballast, compared to the 0.3 percent sludge thickness in the Actiflo system.
- **Increase in footprint** – Densadeg has a 40 gpm/sf loading rate, compared to Actiflo's 60 gpm/sf loading rate.
- **Elimination of fine screening** – Actiflo requires fine screening to protect the hydrocyclones in the system, which separate sand from sludge. Since Densadeg uses sludge only as its ballast, it does not require fine screening upstream.

Implications to operations and maintenance should also be examined between the two systems. For example, Actiflo requires sand as the ballasting agent, which requires storage and maintenance.

8.2 Refined Design Assumptions via Influent Sampling

Influent sampling at the plant during wet weather events will shed light on the wastewater characteristics of the wet weather flow, as well as the flow regime during events. More concrete numbers for influent TSS, BOD, and flow can be used to refine process design parameters, which may lead to a reduction in the size and cost of the treatment trains.

9.0 Comparison of Treatment Alternatives

9.1 Effluent Water Quality

While each flow scenario for each treatment train evaluated above is capable of producing blended effluent concentrations that meet permit limits, the resulting water quality differs widely between different scenarios. The TSS and BOD concentrations of the blended effluent for each treatment train and flow scenario is presented in Exhibit 9-1 and 9-2, respectively.

EXHIBIT 9-1
Blended Effluent TSS Concentrations

		Blended Effluent TSS Concentration (mg/L)								
		Wet Weather Treatment Train Flow (mgd)								
Treatment Train	**Wet Weather Treatment Train Effluent Conc. (mg/L)**	***69***	***150***	***160***	***183****	***300***	***376****	***500***	***1000***	***1100***
#1) Vortex/Swirl Concentrators	221	83			87					
#2) Conventional Clarifiers	142			83			82			
#3) CEPT w/ Conventional Clarifiers	63		67			66			65	
#4) Ballasted Flocculation	30		61					51		44

Notes: Based on the 95th percentile wet weather TSS concentration of 68 mg/L and a maximum of 650 MGD through the existing plant. Allowable daily blended effluent TSS concentration on wet weather days is 99 mg/L to meet monthly TSS permit limits.

*As discussed in Section 3.1, the Vortex-183 mgd and CEPT-376 mgd flow scenarios are only allowable assuming no secondary bypass at the plant. Thus, these concentrations assume a 95th percentile wet weather TSS concentration of 31 mg/L and a maximum of 435 MGD through the existing plant.

EXHIBIT 9-2
Blended Effluent cBOD Concentrations

		Blended Effluent cBOD Concentration (mg/L)								
		Wet Weather Treatment Train Flow (mgd)								
Treatment Train	**Wet Weather Treatment Train Effluent Conc. (mg/L)**	***69***	***150***	***160***	***183****	***300***	***376****	***500***	***1000***	***1100***
#1) Vortex/Swirl Concentrators	117	37			49					
#2) Conventional Clarifiers	91			41			53			
#3) CEPT w/ Conventional Clarifiers	66		36			41			51	
#4) Ballasted Flocculation	55		34					40		45

Notes: Based on the 95th percentile wet weather cBOD concentration of 29 mg/L and a maximum of 650 MGD through the existing plant.

*As discussed in Section 3.1, the Vortex-183 mgd and CEPT-376 mgd flow scenarios are only allowable assuming no secondary bypass at the plant. Thus, these concentrations assume a 95th percentile wet weather cBOD concentration of 20 mg/L and a maximum of 435 MGD through the existing plant.

As described in Section 3.1, Trains #1 and #2, Vortex/Swirl and Conventional Clarification, are limited in flow by permit conditions. Trains #3 and #4, CEPT and Ballasted Flocculation, are considered unlimited in flow if the number of wet weather days is less than 7 days per month. To illustrate the risk of exceeding permit limits at each flow scenario, Exhibit 9-3 presents the maximum number of days that the wet weather treatment train can operate at its maximum capacity without exceeding monthly TSS permit limits. The ballasted flocculation train is unlimited in frequency of operation since its effluent quality (30 mg/L TSS) surpasses permit limits without blending. The CEPT train can operate more frequently at higher flows since its effluent quality (63 mg/L TSS) is slightly better than the quality from the conventional secondary treatment plant (68 mg/L TSS)

A frequency plot of the estimated number of wet weather events per month is shown in Exhibit 9-4 (Myers, 2008b). As shown, wet weather events have occurred at a historical maximum of 15 per month. It should be noted that the wet weather event referred to in this plot occurs whenever rainfall exceeds 0.1 inch, and does not necessarily correspond to operation of the new wet weather treatment train. If the flow does not exceed the capacity of the conventional plant, the wet weather treatment train will not come online. Thus, the new wet weather treatment train is expected to operate less than 15 times per month.

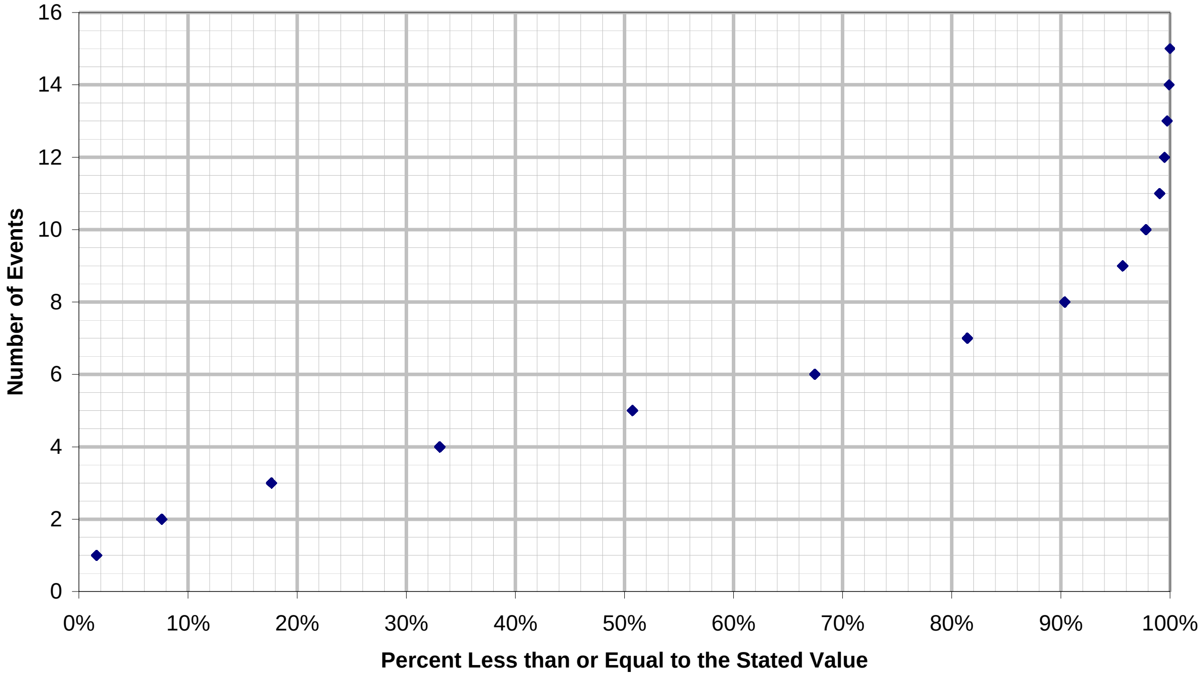
It should be noted that a continuous simulation-based approach would give a more accurate estimate of risk, and more detailed analyses should be performed during the facility planning and design phases.

EXHIBIT 9-3
Allowable Number of Operating Days of Wet Weather Treatment Train

	Maximum Allowable Number of Operating Days per Month(1)								
	Wet Weather Treatment Train Flow (mgd)								
Treatment Train	***69***	***150***	***160***	***183****	***300***	***376****	***500***	***1000***	***1100***
#1) Vortex/Swirl Concentrators	7			7					
#2) Conventional Clarifiers			7			7			
#3) CEPT w/ Conventional Clarifiers		7			8			9	
#4) Ballasted Flocculation	UNLIMITED								

Notes:
(1) Allowable number of operating days without exceeding permit limits for monthly TSS concentrations. Assumes entire plant operates at maximum capacity during every wet weather event.

EXHIBIT 9-4
Cumulative Frequency Plot of the Number of Wet Weather Events per Month



Notes: Based on Philadelphia International Airport NOAA Rain Gauge Hourly Data from1902-2000. Minimum Interevent Time = 4 hrs, Minimum Storm = 0.1 Inches (provided by CDM)

9.2 Capital, O&M and Life-Cycle Costs

As shown in Exhibit 9-5, the capital costs for Trains #2 - #4 track each other very closely, with CEPT being slightly more expensive. Train #1, the vortex/swirl, appears least expensive and most cost effective as flows increase (Exhibit 9-6). Train #3, CEPT, appears slightly less cost-effective than Train #4, Ballasted Flocculation, due to greater cost for piles for its larger footprint.

The comparison of O&M costs for each treatment train is shown in Exhibit 9-7. As expected, the O&M costs for vortex swirls and conventional clarifiers, which do not require chemical settling aids, are the lowest. Ballasted Flocculation has the highest O&M costs due to the use of chemicals and the complexity of its system.

Taking construction, non-construction, and O&M costs into consideration, Exhibit 9-8 shows the present value of the total cost of each wet weather treatment train. This graph suggests that there is negligible cost difference between Train #3, CEPT, and Train #4, Ballasted Flocculation at this plant. As expected, Trains #1 and #2 are least expensive due to its low chemical usage and minimal O&M costs.

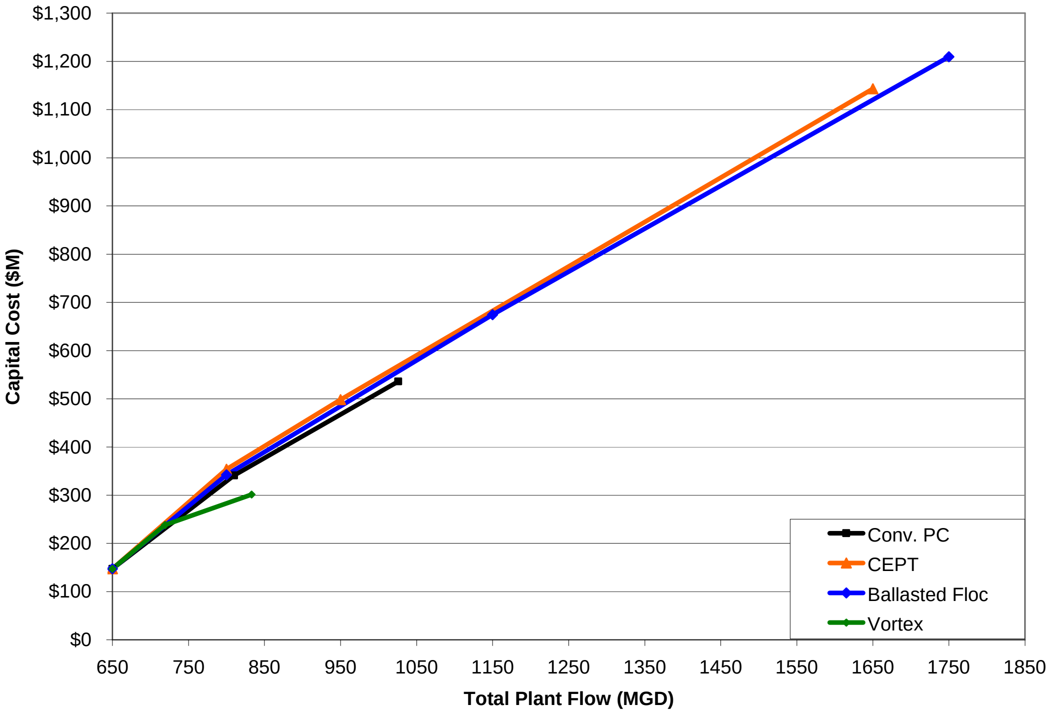

EXHIBIT 9-6
Comparison of Cost Effectiveness for all Treatment Trains

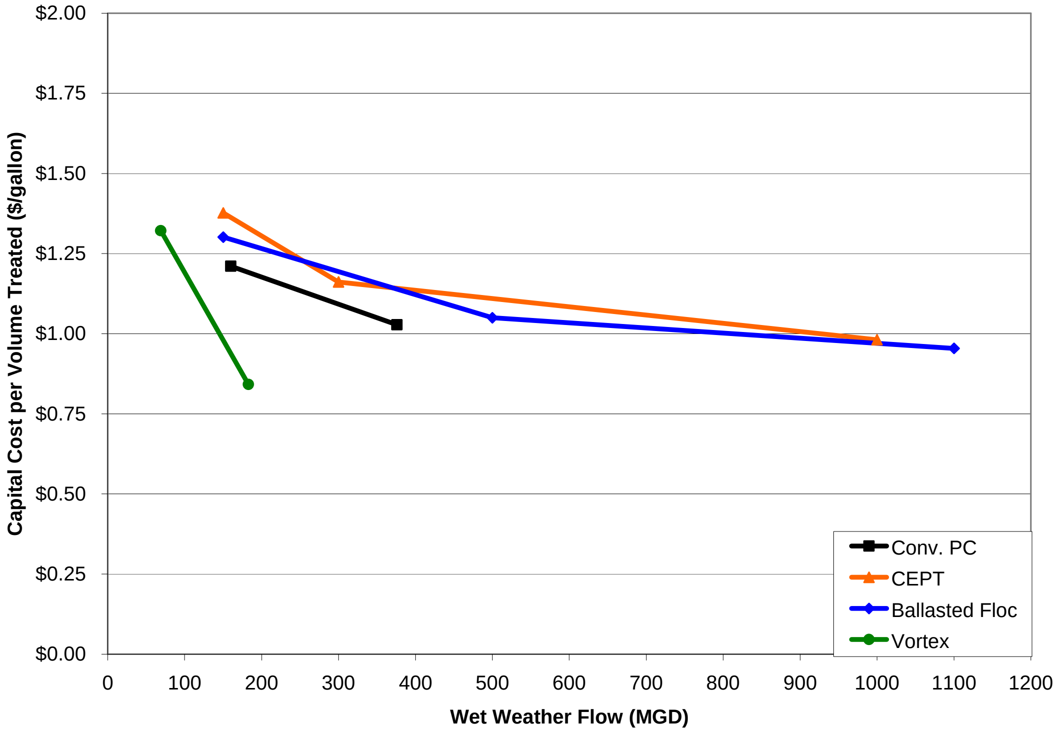

EXHIBIT 9-7
Comparison of Operations and Maintenance Costs for all Treatment Trains

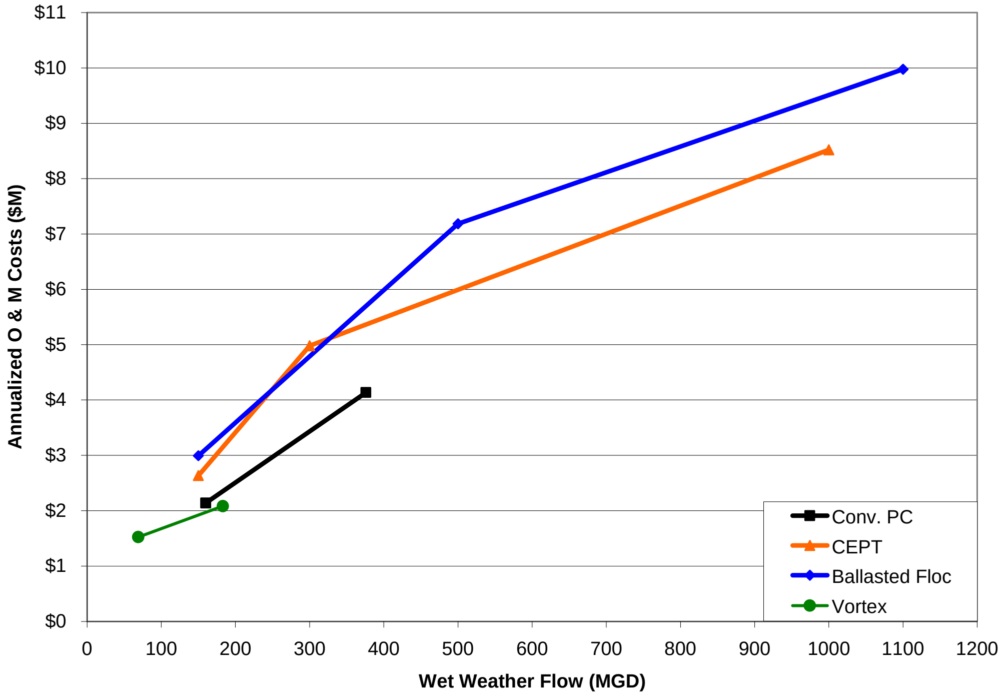

EXHIBIT 9-8
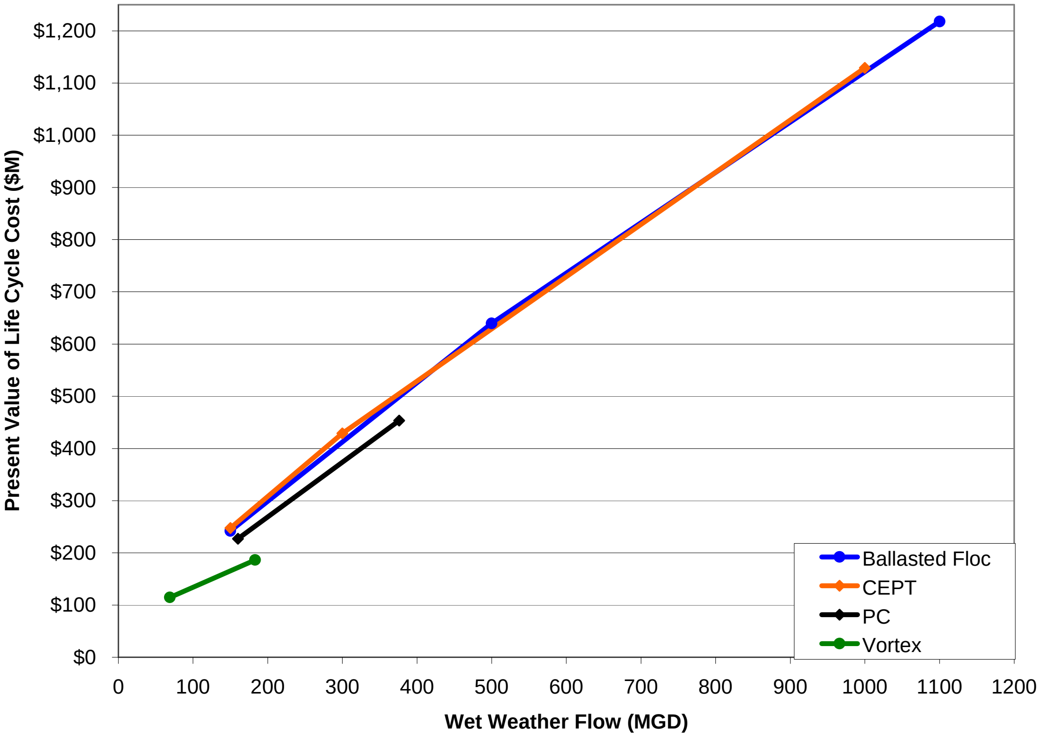
Comparison of Life-Cycle Costs for all Treatment Trains



9.3 Overall Comparison

Aside from capital, O&M, and lifecycle costs, there are numerous other criteria by which the treatment trains should be evaluated, including:

- Reliability of the system
- Community and environmental impacts or perception
- Ability to handle large variations in flow
- Land requirements
- Constructability
- Requirements for maintenance and operator attention
- Sustainability

These evaluation criteria were discussed in Workshop No. 2B, and are presented in TM-SE2 for various wet weather treatment technologies (CH2M HILL, 2008a). Several key advantages and disadvantages of Treatment Trains #1 - #4, as evaluated in this report, are described in Exhibit 9-9.

EXHIBIT 9-9
Summary of Pros and Cons for Each Wet Weather Treatment Train

Treatment Train	Pros	Cons
Train #1: Vortex/Swirl Concentrators	• Simple operation • Low maintenance requirements – no moving parts	• Only cost competitive at high loading rates and low removal efficiencies. • Maximum design flow may decrease if the assumed number of operating days is greater than 7.
Train #2: Conventional Clarifiers	• Simple operation • Same technology as existing plant –operators familiar with equipment	• Space limited • Maximum design flow may decrease if the assumed number of operating days is greater than 7.
Train #3: CEPT	• Lower chlorine dose possible due to high TSS removal efficiencies • May be operated as Conventional Clarifiers if chemicals found to be unnecessary	• Operators unfamiliar with technology • Space limited • Uses two additional chemical systems for coagulation and flocculation • Maximum design flow may decrease if the assumed number of operating days is greater than 9.
Train #4: Ballasted Flocculation	• Can treat up to 1500 mgd with available land on site • Highest removal efficiencies • Unlimited number of operating days per month • Lower chlorine dose possible due to high TSS removal efficiencies	• Operators unfamiliar with technology • Most labor intensive and complex system • Uses two additional chemical systems for coagulation and flocculation

The costs for wet weather treatment at the NE WPCP should be analyzed with the costs of other wet weather treatment alternatives, such as improvements in the collection system, to determine which treatment train alternatives and flow regimes should be evaluated further. Treatment trains that are selected for further evaluation should undergo more detailed design and costing methods, water quality sampling, and bench and pilot scale testing, so that removal efficiencies, land requirements, capital costs, and O&M costs can be further refined.

Executive Summary

Background and Project Summary

As part of the series of memoranda prepared for the Philadelphia Water Department's (PWD) Combined Sewer Overflow (CSO) Long Term Control Plan (LTCP) update, this report presents the conceptual design and cost analyses for five wet weather treatment alternatives for the Southeast Water Pollution Control Plant (SE WPCP). The wet weather treatment technologies for the SE WPCP evaluated in this report are as follows:

1. Vortex Swirl Concentrators (at low and high loading rates)
2. Conventional Clarifiers
3. Chemically Enhanced Primary Treatment (CEPT) with Conventional Clarifiers
4. CEPT with Plate Settlers (includes fine screening)
5. Ballasted Flocculation (includes fine screening)

Conceptual treatment trains were developed for each treatment technology at various wet weather flows ranging from 80 million gallons per day (mgd) to 1200 mgd and cost curves for capital, operations and maintenance (O&M), and lifecycle costs were generated for each treatment train alternative.

In order to increase the flow capacity of the SE WPCP for wet weather conditions, the potential of maximizing flow through the existing plant was evaluated. According to stress testing results, the SE WPCP currently has a firm capacity of 240 mgd (CH2M HILL, 2001). With several process and hydraulic modifications, the SE WPCP's firm capacity can potentially reach 330 mgd. The necessary improvements to achieve this flow were identified in the Stress Testing Report and are based on results of stress tests on unit processes, long-term monitoring of the plant, hydraulic modeling, and input from SE WPCP plant staff.

In sizing the wet weather treatment trains, it was assumed that the upgrades proposed in the Stress Testing Report and discussed in this report will have been completed, increasing the plant's capacity to a minimum of 330 mgd. Thus, the baseline cost that is used in the wet weather treatment train cost estimates is $48.1, which is reflected in the cost curves for each treatment train.

To expand the flow capacity of SE WPCP beyond 330 mgd for the treatment of wet weather flows, a separate wet weather treatment train will be required. Wet weather flows in excess of 330 mgd will be diverted to one of the new treatment trains, listed above, eventually blending with effluent from the existing plant. Conceptual designs and cost estimates were performed for each treatment train at various design flows.

Design Flows

The maximum allowable flow through each wet weather treatment train is a function of its removal efficiency, the achievable effluent concentration after blending, and the plant's continued ability to meet NPDES permit limits for weekly and monthly TSS and BOD concentrations. With the exception of the vortex/swirl train at high loading rates, the flows through the candidate wet weather treatment trains were unlimited by permit requirements, assuming that the wet weather treatment facility operates for no more than seven days per month. Other design flow points were selected based on the existing collection system capacity, the existing outfall conduit capacity, and limits of available land on site and are indicated in the Exhibit ES-1.

EXHIBIT ES-1
Design Flows Evaluated for each Wet Weather Treatment Train

Treatment Train	Design Flows Evaluated (mgd)
#1) Vortex/Swirl Concentrators	
High Loading Rate:	80, 200, 380
Low Loading Rate:	80, 200, 900
#2) Conventional Clarifiers	80, 200, 540, 900
#3) CEPT w/ Conventional Clarifiers	80, 200, 470, 900
#4) CEPT w/ Plate Settlers	80, 200, 900
#5) Ballasted Flocculation	80, 200, 900, 1200

Comparison of Treatment Alternatives

Effluent Water Quality

While each flow scenario for each treatment train evaluated is sized to produce blended effluent concentrations compliant with permit limits, the resulting water quality differs widely between different scenarios. The TSS and BOD concentrations of the blended effluent for each treatment train and flow scenario is presented under Section 10 in Exhibits 10-1 and 10-2, respectively. In general, ballasted flocculation achieves the lowest TSS and BOD concentrations after treatment and can operate an unlimited number of times during the month and continue to meet permit limits.

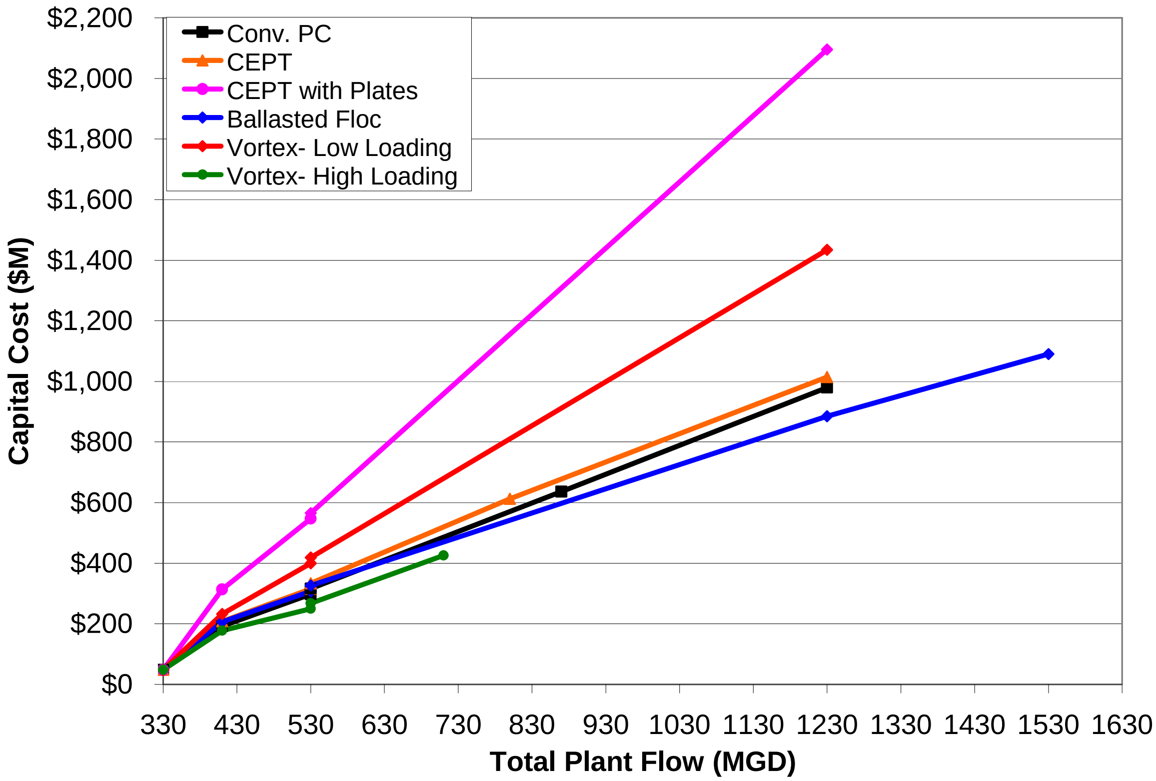
Capital and O&M Costs

The capital cost estimates for the five treatment trains are shown in Exhibit ES-2. Train #4, CEPT with Plates, is the most expensive, followed by Train #1, vortex/swirl at low loading rates. Trains #2, 3, and 5 appear to have similar costs throughout the entire flow range, with Train 5 being slightly less costly. Translated into a capital cost per volume treated, all trains appear to become more cost effective as flow capacity increases (Exhibit ES-3).

The comparison of O&M costs for each treatment train is shown in Exhibit ES-4. As expected, the O&M costs are lowest for vortex swirls at high loading and conventional clarifiers, which do not require chemical settling aids. Vortex swirls at low loading rates has the highest O&M costs for repair and maintenance of the large number of vortex units and gravity thickeners required.

Taking construction, non-construction, and O&M costs into consideration, Exhibit ES-5 shows the present value of the total cost of each wet weather treatment train. Train #4, CEPT with Plates, remains most costly since it requires the highest capital and O&M costs. Train #1, vortex/swirl concentrators, appears to be least costly from the life-cycle cost perspective, especially at lower flows. This is due to its low chemical usage and minimal operations and maintenance needs.

EXHIBIT ES-2
Comparison of Capital Costs for All Treatment Trains



Note: Capital cost presented includes cost of improvements recommended in the Stress Testing Report ($48.1M). Total plant flow includes flow from both the conventional plant and the wet weather treatment facility.

EXHIBIT ES-3
Comparison of Capital Cost Effectiveness for all Treatment Trains

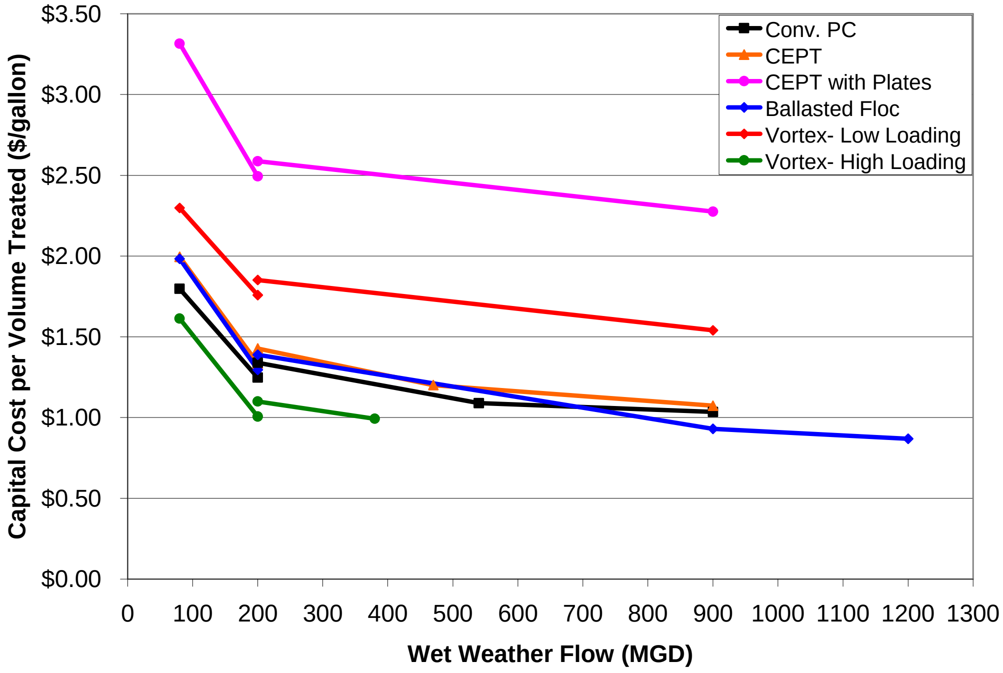


EXHIBIT ES-4
Comparison of Operations and Maintenance Costs for all Treatment Trains

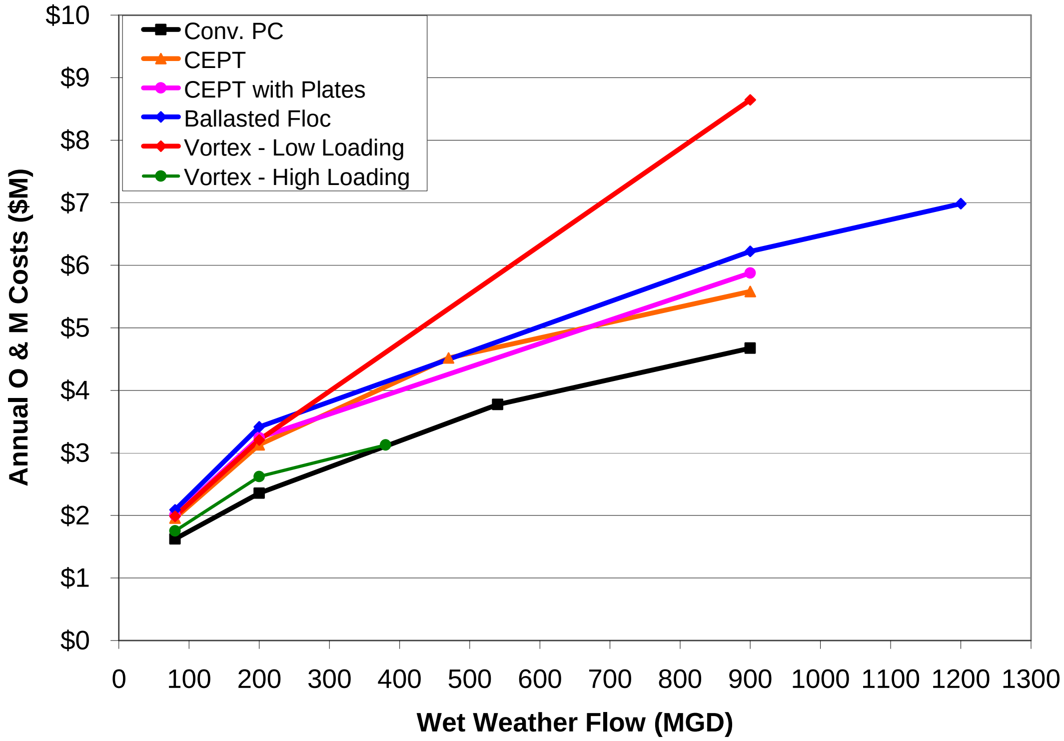

EXHIBIT ES-5

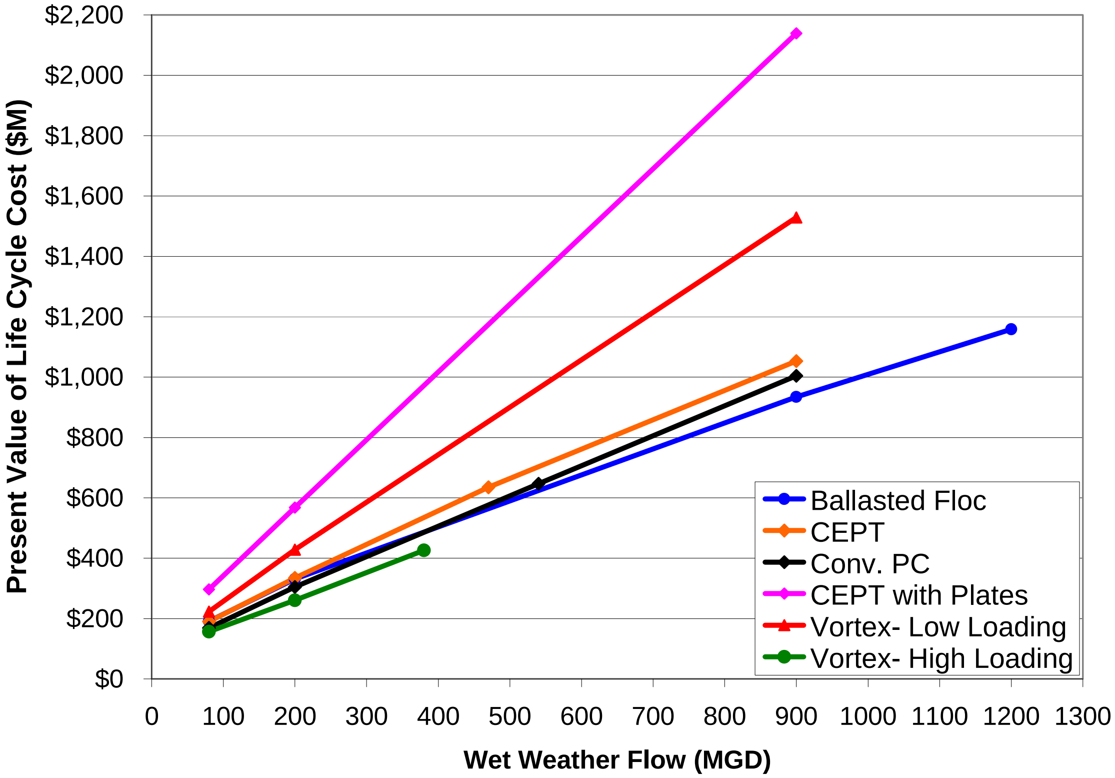
Comparison of Life-Cycle Costs for all Treatment Trains



Overall Comparison

Aside from capital, O&M, and lifecycle costs, there are numerous other criteria by which the treatment trains should be evaluated, including:

- Reliability of the system
- Community and environmental impacts or perception
- Ability to handle large variations in flow
- Land requirements
- Constructability
- Requirements for maintenance and operator attention
- Sustainability

These evaluation criteria were discussed in Workshop No. 2B, and are presented in TM-SE2 for various wet weather treatment technologies (CH2M HILL, 2008). The main advantages and disadvantages for Treatment Trains #1 - #5, as evaluated in this report, are described in Exhibit ES-6.

EXHIBIT ES-6
Summary of Pros and Cons for Each Wet Weather Treatment Train

Treatment Train	Pros	Cons
Train #1: Vortex/Swirl Concentrators	• Simple operation • Low maintenance requirements – no moving parts	• Only cost competitive at high loading rates and low removal efficiencies. • Maximum design flow may decrease if the assumed number of operating days is greater than 7.
Train #2: Conventional Clarifiers	• Simple operation • Same technology as existing plant –operators familiar with equipment	• Space limited • May exceed instantaneous blended effluent BOD concentration at high flows • Maximum design flow may decrease if the assumed number of operating days is greater than 7.
Train #3: CEPT	• Lower chlorine dose possible due to high TSS removal efficiencies	• Operators unfamiliar with technology • Space limited • Uses chemicals • Can treat less flow on existing site than conventional clarifiers • Operators unfamiliar with technology
Train #4: CEPT with Plates	• Can treat 900 mgd with available land on site • Lower chlorine dose possible due to high TSS removal efficiencies • Unlimited number of operating days per month	• High capital and O&M costs • Operators unfamiliar with technology • Labor intensive to clean plates • Uses chemicals
Train #5: Ballasted Flocculation	• Can treat up to 1200 mgd with available land on site • Highest removal efficiencies • Unlimited number of operating days per month • Lower chlorine dose possible due to high TSS removal efficiencies	• Operators unfamiliar with technology • Second most labor intensive • Uses chemicals

The costs for wet weather treatment at the SE WPCP should be analyzed with the costs of other wet weather treatment alternatives, such as improvements in the collection system, to determine which treatment train alternatives and flow regimes should be evaluated further. Treatment trains that are selected for further evaluation should undergo more detailed design and costing methods, water quality sampling, and bench and pilot scale testing, so that removal efficiencies, land requirements, capital costs, and O&M costs can be further refined.

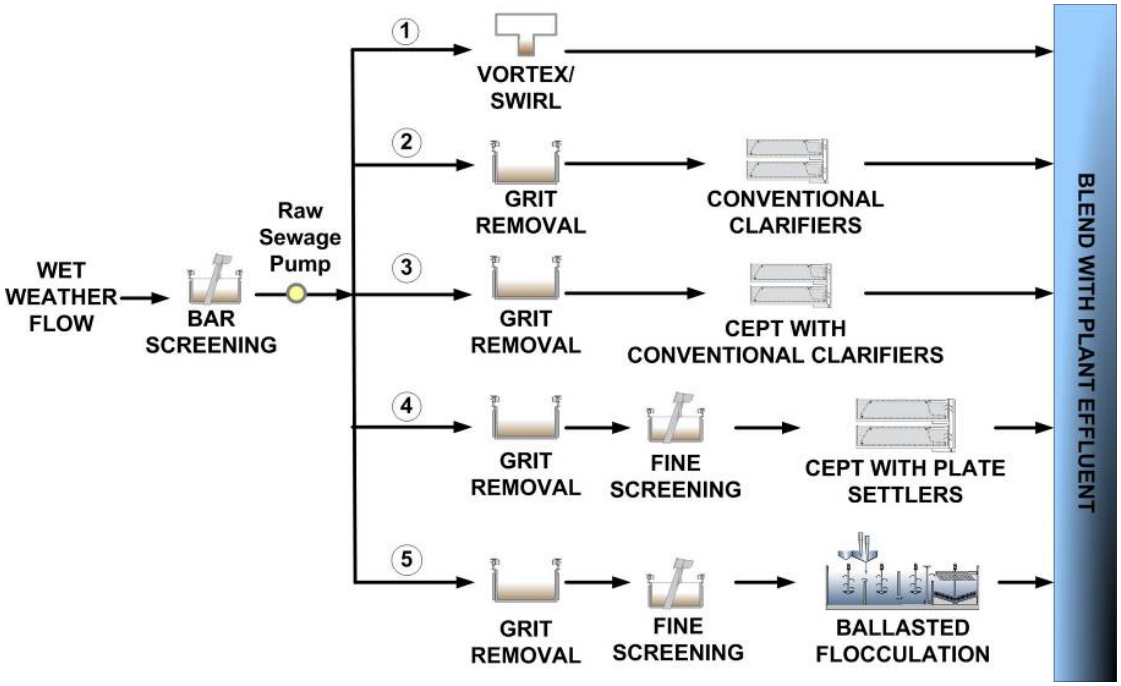
1.0 Introduction

As part of the series of memoranda prepared for the Philadelphia Water Department's (PWD) Combined Sewer Overflow (CSO) Long Term Control Plan (LTCP) update, this report presents the conceptual design and cost analyses for five wet weather treatment alternatives for the Southeast Water Pollution Control Plant (SE WPCP). These treatment alternatives were short listed from previous evaluations by the LTCP team (PWD, CDM, and CH2M HILL) based on information from: water quality data analysis and review of available land for SE WPCP; survey of various potential wet weather treatment technologies; and site visits to three existing wet weather treatment facilities in Ohio (CH2M HILL, 2007a; CH2M HILL, 2008). The wet weather treatment technologies for the SE WPCP evaluated in this report are as follows:

1. Vortex Swirl Concentrators (at low and high loading rates)
2. Conventional Clarifiers
3. Chemically Enhanced Primary Treatment (CEPT) with Conventional Clarifiers
4. CEPT with Plate Settlers (includes fine screening)
5. Ballasted Flocculation (includes fine screening)

Conceptual treatment trains were developed for each treatment technology at various wet weather flows ranging from 80 million gallons per day (mgd) to 900 mgd (Exhibit 1-1). Cost curves for both capital and operations and maintenance (O&M) costs were generated for each treatment train alternative. This report presents the conceptual design parameters, site layouts, cost estimates, and potential issues of each treatment train alternative.

EXHIBIT 1-1
Schematic View of Treatment Trains Evaluated



2.0 Improvements to Existing Plant

In order to increase the flow capacity of the SE WPCP for wet weather conditions, the potential of maximizing flow through the existing plant was evaluated. According to stress testing results, the SE WPCP currently has a firm capacity of 240 mgd (CH2M HILL, 2001). Firm capacity is defined as the treatment capacity when the largest unit process is out of service. With several process and hydraulic modifications, the SE WPCP's firm capacity can potentially reach 330 mgd (Exhibit 2-1). The necessary improvements to achieve this flow were identified in the Stress Testing Report and are based on results of stress tests on unit processes, long-term monitoring of the plant, hydraulic modeling, and input from SE WPCP plant staff.

In sizing the wet weather treatment trains, it was assumed that the upgrades proposed in the Stress Testing Report and identified in Exhibit 2-1 will have been completed, increasing the plant's capacity to a minimum of 330 mgd. Thus, the baseline cost that is used in the wet weather treatment train cost estimates is $48.1 million (Exhibit 2-1). This is reflected in the cost curves for each treatment train, presented in latter sections of the report.

EXHIBIT 2-1
Cost Summary of Potential Improvements for Existing SEWPCP

	Improvement Description	**Cost(1)**
1	Provide facilities for phosphorous addition to wastewater	Completed
2, 3	Resolve capacity limitations associated with having one coarse bar rack out of service and hydraulic bottleneck at existing influent pump station	$23,780,982
4	Replace existing primary clarifier effluent launders with new launders running parallel to flow to increase hydraulic capacity	$2,591,292
5	Provide two gravity thickeners to perform offline sludge thickening and improve performance of the primary clarifiers	$13,499,572
6	Provide an additional 71-MGD effluent pump at the effluent pumping station	$783,037
8	Resolve hydraulic limitation between primary clarifiers and the aeration basins by adding pumps to pass greater flow and increase available head.	$7,441,414
	TOTAL	**$48,096,297**

(1) See Section 3.3 for markups applied. Assume escalation factor of 19.8% - based on 9/1/2009 start date and 2-year construction duration.

Since Improvements # 2, 3, and 5 involve the addition of new structures on site, these improvements were examined more closely to see how they would interface with the new wet weather treatment trains.

2.1 Improvements #2 and #3

The current configuration of the influent wet wells limits the plant flow to 200 mgd when one coarse screen is out of service. To provide redundancy, Improvements #2 and 3 include the addition of two new bar screens and influent pumps with a capacity of 130 mgd. Due to the configuration and space limitations of the existing influent pump station, a new pump station will be needed for this new equipment. Since any new wet weather treatment facility will also require influent screening and pumping, a single building can be constructed to house all the new equipment. This new preliminary treatment building (PTB) will include the two new bar screens and influent pumps for the existing plant, as well as the additional units needed for the wet weather treatment train alternatives. A new conduit will be constructed from the new PTB to the head of the existing grit channels, carrying up to 130 mgd to the existing plant for treatment during either dry or wet weather conditions. The cost shown in Exhibit 2-1 for this improvement includes only the cost for a new PTB with the two bar screens and influent pumps for the existing plant. The additional cost of equipment for wet weather flows is included in the cost estimates for the separate wet weather treatment trains. The footprint of the entire PTB for dry and wet weather flows is shown in the conceptual layouts for each wet weather treatment train.

2.2 Improvement #5

To increase the capacity of the existing primary clarifiers, Improvement #5 provides for the addition of offline sludge thickening. Currently, primary sludge is thickened in the clarifiers. The thickened sludge is pumped from the clarifiers to sludge storage tanks, which store the sludge until it is pumped to the Southwest WPCP for further treatment. The addition of separate gravity thickeners on site will eliminate the need to carry a sludge blanket in the primary clarifiers. This will eliminate scour of the solids from the sludge blanket during high surface overflow rates, allowing the clarifiers to maintain removal efficiencies during peak flows.

The cost estimate for this improvement, shown in Exhibit 2-1, is based on the addition of two gravity thickeners, which would thicken the dilute sludge before it is pumped to the existing sludge storage tanks. The sizing of these gravity thickeners is based on a 55 percent removal efficiency in the existing clarifiers, a 0.5 percent solids concentration, and a solids loading rate of 30.7 lb/sf/day for the thickeners. These assumptions are consistent with those for the wet weather treatment trains (see Section 3.2). Cost estimates also include thickened sludge pumps and Strainpress sludge cleaners for pumping to the digesters. Since the majority of the proposed wet weather treatment trains require gravity thickening also, all gravity thickeners for both the existing plant and the wet weather treatment facility will be located in the same area on site.

3.0 Wet Weather Treatment Alternatives: Evaluation Methodology

To expand the flow capacity of SE WPCP beyond 330 mgd for the treatment of wet weather flows, a separate wet weather treatment train will be required. Wet weather flows in excess of 330 mgd will be diverted to this new treatment train, eventually blending with effluent from the existing plant. As depicted in Exhibit 1-1, the five wet weather treatment trains under evaluation are:

1. Vortex Swirl Concentrators (at low and high loading rates)
2. Conventional Clarifiers
3. Chemically Enhanced Primary Treatment (CEPT) with Conventional Clarifiers
4. CEPT with Plate Settlers (includes fine screening)
5. Ballasted Flocculation (includes fine screening)

Conceptual designs and cost estimates were performed for each treatment train at different design flows. This section describes the development of the various design flows and the key assumptions for design and cost estimating.

3.1 Design Flows

The maximum allowable flow through each wet weather treatment train is a function of its removal efficiency, the achievable effluent concentration after blending, and the plant's continued ability to meet NPDES permit limits for weekly and monthly TSS and BOD concentrations. The data analysis performed for SE WPCP determined that the monthly TSS limit was the most stringent, and were thus used to determine the maximum allowable flow through each train, as shown in Exhibit 3-1 (CH2M HILL, 2008).

EXHIBIT 3-1
Maximum Allowable Flow of Wet Weather Treatment Trains to Meet NPDES Permit Requirements

Treatment Train	TSS Removal Efficiency[1] (%)	Achievable Effluent TSS Concentration of Wet Weather Train[2] (mg/l)	Maximum Allowable Flow Through Wet Weather Train[3] (mgd)
#1) Vortex/Swirl Concentrators			
High Loading Rate:	30%	154	378
Low Loading Rate:	65%[4]	77	Unlimited*
#2) Conventional Clarifiers	55%	99	Unlimited*
#3) CEPT w/ Conventional Clarifiers	80%	44	Unlimited*
#4) Fine Screening -> CEPT w/ Plate Settlers	81%	42	Unlimited*
#5) Fine Screening -> Ballasted Floc	91%	21	Unlimited*

*These flows are unlimited assuming the wet weather treatment train operates for no more than seven days per month, an estimate provided by CDM (CH2M HILL, 2008).

(1) TSS removal efficiencies are based on industry standards. Specific references are provided in TM-SE2 (CH2M HILL, 2008).

(2) Achievable effluent concentrations based on 95th percentile influent wet weather TSS concentration (220 mg/L)

(3) Maximum flow determined by NPDES Monthly TSS Limit. The allowable daily blended effluent TSS concentration during wet weather was calculated to be 99 mg/L (CH2M HILL, 2008).

(4) Based on results of Wet Weather Demonstration Project in Columbus, Georgia (WERF, 2003)

With the exception of the vortex/swirl train at high loading rates, the flows through the candidate wet weather treatment trains were unlimited by permit requirements, assuming that the wet weather treatment facility operates for no more than seven days per month. For these "unlimited" trains, the maximum design flow was based on CDM's assumptions on the capacity of the upgraded collection system. Other design flow points were selected based on the existing collection system capacity, the existing outfall conduit capacity, and limits of available land on site. The design flows that were selected for evaluation for each treatment train are shown in Exhibit 3-2 and are described below in further detail.

EXHIBIT 3-2
Design Flows Evaluated for each Wet Weather Treatment Train

Treatment Train	Design Flows Evaluated (mgd)
#1) Vortex/Swirl Concentrators	
High Loading Rate:	80, 200, 380
Low Loading Rate:	80, 200, 900
#2) Conventional Clarifiers	80, 200, 540, 900
#3) CEPT w/ Conventional Clarifiers	80, 200, 470, 900
#4) CEPT w/ Plate Settlers	80, 200, 900
#5) Ballasted Flocculation	80, 200, 900, 1200

3.1.1 Minimum Design Flow: 80 MGD

The 80 mgd flow point reflects the capacity of the wet weather treatment train required to bring the treatment capacity of SE WPCP to the same level as the existing collection system capacity. In a technical memorandum provided by CDM, it was noted that the existing collection system can deliver 410 mgd to the SE WPCP assuming all process and hydraulic limitations in the plant are removed (Myers, 2007). With the assumption that 330 mgd can be treated by upgrading the existing plant, the new wet weather treatment train will need a minimum capacity of 80 mgd.

3.1.2 Maximum Design Flow: 380 or 900 MGD

The 900 mgd flow point is based on the maximum flow expected to be delivered to SE WPCP after improvements have been made to the collection system. In a technical memorandum provided by CDM, it was noted that collection system improvements could allow a flow of up to 1,230 mgd to the SE WPCP (Myers, 2007). Again, assuming a flow capacity of 330 mgd for the upgraded existing plant, the new wet weather treatment train will need to treat a maximum of 900 mgd. This excludes Train #1, Vortex /Swirl, which is capped at 380 mgd by permit limits.

3.1.3 200 MGD Design Flow

The 200 mgd flow point is the maximum flow that the new wet weather treatment train can discharge through the plant’s existing outfall conduits. The estimated capacity of the existing 7 feet by 9 feet twin outfall conduits is 530 mgd. This hydraulic capacity assumes gravity flow from the new chlorine contact chamber (CCC) of the wet weather treatment train (water surface level of 109.88 feet) to the Delaware River (assume maximum river level of 102 feet; see Section 3.2.3 on hydraulics). Under these assumptions, the 330 mgd from the main plant will be pumped from the existing effluent pump station to the head of the new CCC, blending with up to 200 mgd of the wet weather flow before chlorination. This will ensure that adequate chlorination contact time is maintained. (Currently, flow from the existing plant achieves chlorination contact through the outfall conduits alone. At 330 mgd, the contact time is 20 minutes.)

Wet weather flow in excess of 200 mgd (or 530 mgd for total plant flow) will require the construction of a new double barrel outfall conduit from the plant to the Delaware River. In this case, flow from the main plant will not be affected and will only blend with the wet weather flow at the river outfall.

3.1.4 Design Flows by Available Land

For Trains #2 and #3, Conventional Clarifiers and CEPT, design flows may be limited by the available land within the property boundaries of the SE WPCP. With the footprint of the wet weather treatment facility limited to the existing site, the maximum flow capacities of Trains #2 and #3 are 540 mgd and 470 mgd, respectively. Flow capacities exceeding these values will require acquisition of neighboring properties.

For Train #4, CEPT with Plates, a 900 mgd facility will require all the available land on site. Train #5, Ballasted Flocculation, occupies the smallest footprint and will be able to treat flows of up to 1200 mgd using the available land on site.

3.2 Key Design Assumptions

3.2.1 Average Design Flow

In the previous section, the design flow capacities were identified for each treatment train based on permit limits, available land area, and collection system capacity. These flows are the peak flows that the wet weather facilities are designed to treat under each scenario.

The average flow that the wet weather facility will receive, however, depends on conditions in the collection system. Preliminary model simulations have been performed for the Southeast Drainage district (SEDD) under several deep tunnel and plant expansion scenarios (CDM, 2008). Simulation results suggest that the average flow delivered to the wet weather facility increases as the capacity of the facility increases, and is not highly sensitive to the volume of storage in the collection system (Exhibit 3-3).

Model runs for a 490-mgd and a 900-mgd wet weather facility generated an average flow of 204-mgd and 229-mgd, respectively, assuming the largest storage tunnel scenario. Based on these model results, the maximum average design flow assumed for the new wet weather treatment trains evaluated in this report is 229-mgd. The average flows assumed for each of the treatment train scenarios is presented in Exhibit 3-4.

Maximum Design Flow (mgd)	Average Design Flow (mgd)
80	80
200	200
380, 470, 540	204 (1)
900, 1200	229 (2)

(1) Model runs with a 490-mgd facility generated an average flow of 204-mgd.

(2) Model runs with a 900-mgd facility generated an average flow of 229-mgd.

3.2.2 Process

The process design described herein is based on conceptual design parameters and will require refinement as the planning and design efforts progress. For the purposes of developing capital costs, sizing of most facilities was based on maximum design flows. The average design flow was used for sizing the chlorine contact chamber, chemical storage facilities, screenings and grit storage, and sludge handling facilities.

Preliminary Treatment

Each wet weather train evaluated in this report was sized to treat influent flow in excess of the plant's flow capacity of 330 mgd. For each case, the main treatment train is located on the strip of vacant land to the east of the existing structures. A new influent conduit will divert excess wet weather flow to the new preliminary treatment building (PTB) of the wet weather treatment facility, to be located at the northeast corner of the plant. The new PTB will contain an influent wet well at a similar elevation to the existing wet well, bar screens, influent pumps, and screenings and grit handling systems. The influent pumps were designed to increase the hydraulic grade line so that the wet weather flow can discharge to the river outfall by gravity from the wet weather treatment facilities. The screenings and grit handling systems include screenings washers and compactors, as well as grit concentrators and classifiers. This system will handle screenings from both the bar screens and the fine screens when required.

From the PTB, the wet weather flow will continue on to further treatment through processes dependent on each treatment train. These are described in further detail in Sections 4 through 8.

Disinfection

The final process of all treatment trains is chlorination and dechlorination. The wet weather flow will be dosed with sodium hypochlorite at the head of the new chlorine contact chamber, which provides a minimum of 20 minutes detention time at average flow. At higher flows, it is assumed that the chlorine dosage will be increased correspondingly to provide adequate disinfection. Sodium bisulfite is then used for dechlorination at the end of the chlorine contact chamber.

For wet weather design flows of less than 200 mgd, the new CCC and the existing outfall conduits will be shared by the wet weather flow and the flow from the main plant. Under these scenarios, the CCC is sized for both the average design flow of the wet weather treatment facility and the maximum flow of 330 mgd from the plant.

Chemical Feed

For Treatment Trains #3, #4 and #5, which provide chemically-enhanced clarification, a coagulant and flocculant are added as settling aids. For Trains #3 and #4 that use CEPT, these chemicals are added to a rapid mixer and flocculation basin upstream of the sedimentation tank. In the ballasted flocculation train (#5), the settling aids are added to mixing zones that are part of the ballasted flocculation unit.

Ferric chloride was selected as the coagulant for all trains since it is currently used at PWD's water treatment plants. However, if there are concerns with the iron affecting the digestion process downstream, aluminum sulfate (alum) can be used as a substitute.

Polymer is used as the flocculant, and is stored in both liquid and dry form. Since preparation of dry polymer usually takes approximately 2 hours, a liquid polymer system is provided to allow immediate startup of the wet weather treatment system. With the exception of liquid polymer, a 10-day storage at average flow was assumed for all chemicals. The option of using liquid polymer only is discussed in Section 9.1.

Sludge Handling

Primary sludge from all treatment trains is pumped to gravity thickeners, where the solids concentration is expected to increase to a minimum of 3 percent. The thickeners are sized to handle the average wet weather flow (as presented in Exhibit 3-4) with a 95 percentile influent solids concentration (220 mg/L) for a continuous period of 24 hours.

The thickened sludge will be pumped to the plant's existing sludge storage tanks, from which it will be pumped to anaerobic digesters at the Southwest (SW) WPCP. The sludge will be screened through StrainPress® sludge cleaners to remove inert solids before entering the digesters. Since the maximum inlet pressure of the sludge cleaners is 14 psi, they will be located at the SW WPCP at the tail end of the sludge pump discharge.

Capital costs for each treatment train include the cost of extra digesters that may be required at the SW WPCP, assuming a maximum of seven wet weather days in one month. The digesters were sized to provide 20-day storage for solids, assuming average flow (as presented in Exhibit 3-4), a 95 percentile influent solids concentration (220 mg/L), an average wet weather event duration of seven hours, and five events in 20 days. The cost of an additional sludge pump and 8" force main to the SW WPCP ($7.7 M, including markups) was also added as a line-item to the overall cost of each scenario.

The design parameters that were assumed for all the treatment train processes are summarized in Exhibit 3-5. The process flows are described in further detail in each of the treatment train sections.

EXHIBIT 3-5
Key Process Design Assumptions for Wet Weather Treatment Trains(1)

Preliminary Treatment

Bar Screens	Opening Size	15	mm (0.59 in)
	Screenings Production(2)	3.5	cf/mg
Influent Pumps	Type	Vertical End-Suction	
	Total Dynamic Head (TDH)	45	ft (match existing wet well elevations)
Fine Screens	Opening Size	6	mm (0.24 in)
	Screenings Production(2)	2.5	cf/mg
	Screenings Compaction Factor	2	
Grit Removal	Type	Vortex Grit Unit	
	Grit Production(2)	4	cf/mg
Screenings and Grit	Number of Days Storage	1	day
Primary Clarifiers	Type	Rectangular Basin	
	Sludge Collection Mechanism	Chain-and-flight	
Flocculation Tank	Detention Time (at max flow)	10	min
	Number of Stages	3	

Wet Weather Treatment Technology	Surface Overflow Rate (gpd/sf)
Vortex/Swirl	High: 36,000 (25 gpm/sf)
	Low: 7,200 (5 gpm/sf)
Conventional Clarifiers	2,400 (3)
CEPT	3,000
CEPT with Plates	7,000
Ballasted Flocculation	84,600 (60 gpm/sf)

Chlorine Contact

Chlorine Contact Chamber	Detention Time (at avg flow)	20	min

Chemical Feed

Chemical	Purpose	Concentration	Storage (at avg flow)
Ferric Chloride	Coagulation	60 mg/L	10 days
Liquid Polymer	Flocculation	2 mg/L	20 hours(4)
Dry Polymer	Flocculation	2 mg/L	10 days
Sodium Hypochlorite	Chlorination	5 mg/L	10 days
Sodium Bisulfite	De-chlorination	1.5 mg/L(5)	10 days

EXHIBIT 3-5
Key Process Design Assumptions for Wet Weather Treatment Trains(1)

Primary Sludge Generation(6)

Train	**% TSS Removal**	**% Solids in Sludge**
#1: Vortex/Swirl	High Loading Rate: 30%	0.07%(7)
	Low Loading Rate: 65%	0.14% (7)
#2: Conventional Clarifiers	55%	0.5%
#3: CEPT	80%	0.5%
#4: CEPT with Plates	80%	0.5%
#5: Ballasted Floc	90%	0.3%

Sludge Thickening

Gravity Thickeners	Max Hydraulic Loading Rate (limiting factor for Trains #1 and #5)	900	gal/sf/day
	Max Solids Loading Rate (limiting factor for Trains #2, #3, and #4))	30.7	lb/sf/day
	% Solids of Thickened Sludge	3	% minimum
StrainPress® Sludge Screens	Sludge Throughput	200 – 400	gpm

Digesters (SW WPCP)

Anaerobic Digesters	Detention Time	20	days
	Diameter	115	ft
	Side Water Depth	25	ft
	Volatile Solids Destruction	50	%

(1) Unless otherwise noted, all design parameters are based on standard textbook values.

(2) Estimated from 2004-2005 grit and screenings disposal records from the SE WPCP.

(3) Based on stress testing results on existing primary clarifiers

(4) Liquid polymer required for startup only

(5) Assumes 1 mg/L residual chlorine concentration at the end of the chlorine contact chamber

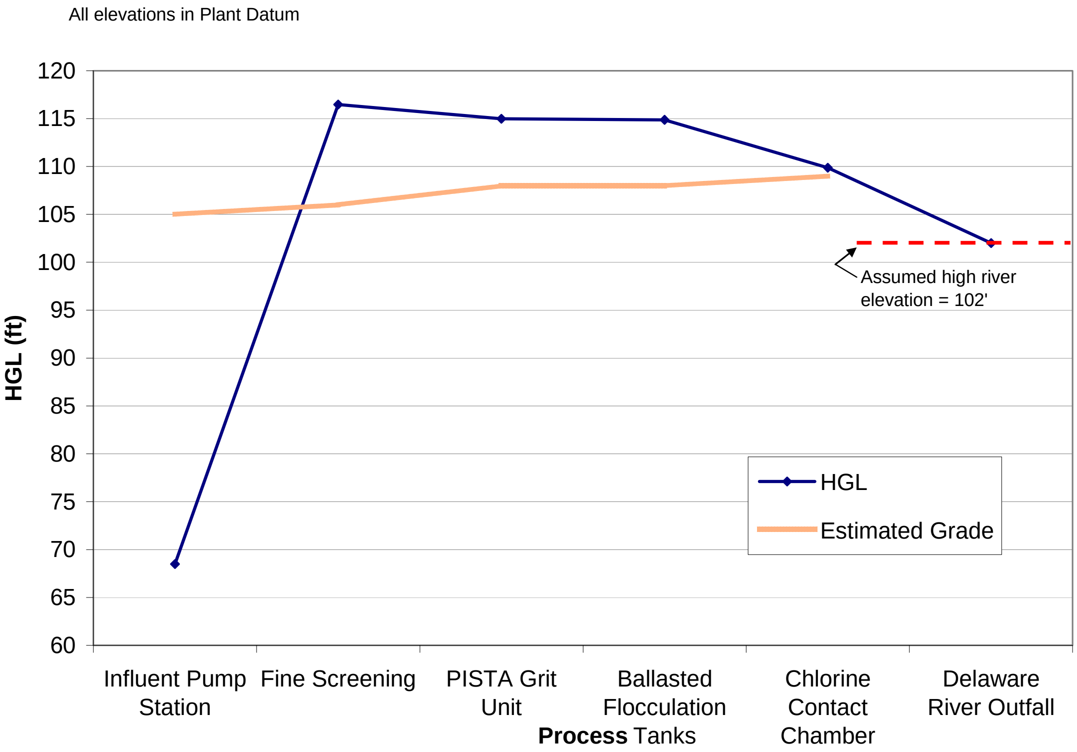
(6) Assumes 95 percentile influent TSS concentration of 220 mg/L, and volatile solids percentage of 70%

(7) Based on a 10% underflow from the vortex/swirl concentrator

3.2.3 Hydraulics

To eliminate the need for a new effluent pump station, the elevations of the new wet weather treatment trains were set to allow gravity flow to the Delaware River outfall. A preliminary hydraulic profile for the ballasted flocculation train at 900 mgd is shown in Exhibit 3-6 as an example of a maximum head loss scenario.

EXHIBIT 3-6
Preliminary Hydraulic Gradeline for the Ballasted Flocculation Treatment Train at 900 MGD



As an initial condition, the high river elevation was assumed to be 102 feet. The mean high tide level shown in SE WPCP plant drawings of the outlet structure is 97.75 feet. According to historic data, the peak river level in 2005 was 101.49 feet. Head loss through the outfall conduits at 900 mgd was estimated to be 7.88 feet using Manning's equation (assume new twin outfall conduits, 13.5 feet by 10 feet each; K factor of 3 for minor losses). As shown in the hydraulic profile, this sets the water surface level of the new chlorine contact chamber at 109.88 feet. This is only 0.7 feet lower than the high discharge level of the existing effluent pumps at the plant (110.58 feet), so is assumed to be a reasonable elevation.

The elevation of the chlorine contact chamber sets the elevations of the upstream unit processes. As shown in Exhibit 3-6, the tank walls may rise above grade by several feet. To be conservative, however, the capital cost estimates assume complete burial of all tanks.

3.2.4 Existing Site

In developing conceptual layouts of the wet weather treatment trains, it was assumed that the parking lot to the east of the existing Equipment Building (northeast corner of the plant) can be reduced in size if necessary to accommodate the new Preliminary Treatment Building.

3.2.5 Site Conditions

The site and soil conditions on the vacant land surrounding the plant were assumed to be similar to the SE WPCP. Two main assumptions were made based on existing plant drawings:

- Piles will be needed for foundations of all structures. A pile density and depth of 0.056 piles/sf and 30 feet were used for all structures on site. A pile density and depth of 0.062 piles/sf and 50 feet were used for the outfall conduits going out to the Delaware River. These numbers were based on existing pile plans for the SE WPCP.
- Dewatering will be required for all buried structures. According to plant drawings, the groundwater elevation is approximately 5-ft below grade at the SE WPCP.

3.3 Cost Estimating Assumptions

CH2M HILL's costing model was used to develop conceptual level estimates of both capital and life-cycle costs for each of the treatment trains and flows. This tool was supplemented by budgetary quotes from vendors for all major pieces of equipment. These estimates are defined as Class 4 estimates by the Association for the Advancement of Cost Engineers (AACE) and have an expected level of accuracy of +50 to -30 percent.

3.3.1 Capital Costs

Construction Costs

Construction costs were developed using the costing model for each building or unit process of a treatment train, and were based on estimated materials, labor, equipment, and installation costs. Contractor markups applied to the construction subtotal costs are presented in Exhibit 3-7. The percentages used are industry standards and are in agreement with CDM's assumptions. The escalation factors applied are based on a construction start-date of September 1, 2009, and the estimated construction duration of each scenario (Exhibit 3-8). This start-date was chosen since PWD's LTCP Update must be submitted by this date. A location adjustment factor of 15.2 percent was applied to the escalated construction cost, which is in agreement with the ENR 20-city Construction Cost Index (CCI).

Lastly, a market adjustment factor of 15 percent was applied to account for: busy contractors; contractors selectively bidding jobs; contractors selectively choosing which Owners they want to do jobs for; premium wages to keep skilled workers and management staff; availability of crafts/trades; immigration impacts and uncertainty; abnormal fuel impacts and uncertainty; abnormal material impacts of the last two years; and Katrina impacts.

EXHIBIT 3-7
Contractor Markups Assumed in Capital Cost Estimates

Contractor Markups	%	Applied to:
Overhead (OH)	10%	Subtotal of Construction Cost
Profit (P)	5%	Subtotal of Construction Cost + OH
Mobilization, Bonds, and Insurance (MOB)	5%	Subtotal of Construction Cost + OH&P
Contingency	25%	Subtotal of Construction Cost + OH&P + MOB

EXHIBIT 3-8
Escalation Factors for Various Construction Scenarios

Flow Capacity of Wet Weather Treatment Train (mgd)	**Estimated Construction Duration (months)**(1)	**Escalation Factor**(2)
80	24	19.8%
200	27	21.2%
380	30	21.8%
470	36	23.9%
540	36	23.9%
900	48	28.2%

(1) Escalation factors are based on mid-point of construction with a construction start-date of 9/1/2009.

(2) Construction durations were estimated based on facilities of similar size, and need to be refined through each stage of design.

Non-Construction Costs

A factor of 30 percent was applied to the total construction costs to estimate non-construction costs related to the project. The breakdown of these factors is shown in Exhibit 3-9.

EXHIBIT 3-9
Non-Construction Cost Factors

Non-Construction Expenditure	**Factor***
Permitting	2%
Engineering	10%
Services During Construction	10%
Commissioning and Startup	3%
Legal/Administration	5%

*Each factor was applied to the total construction cost of the project, including all markups and escalation.

Land Acquisition

For Trains #2 and 3, Conventional Clarifiers and CEPT, neighboring properties must be purchased in order to reach flow capacities beyond 540 mgd and 470 mgd, respectively. The cost of this land was estimated to be $784,000 per acre, based on cost information found in the Philadelphia parcelBase, relating to the 2007 purchase of a block directly east of the plant (Parcel block 88-4-3514-60).

For both cases, the estimated parcel of land that would need to be acquired is 11 acres (See Exhibits 5-2 and 6-2). The estimated cost of acquiring this block of land is $9.23M in 2009 dollars, which includes a 7 percent markup for permitting, legal and administration fees.

3.3.2 O&M and Life Cycle Cost Analysis

Life cycle and O&M costs of each treatment train at each flow were also estimated using CH2M HILL's costing model and were based on financial and operational assumptions as listed in Exhibit 3-10. The O&M costs cover labor, power for equipment and buildings, chemicals, and repair, maintenance and replacement of structures and equipment. O&M costs are based on average flows through the plant, as described in Section 3.2.1 and shown in Exhibit 3-4.

The additional labor required for each treatment train is dependent on the flow capacity of the train, as shown in Exhibit 3-11. It was assumed that new maintenance workers and operators would be hired for the new wet weather facility, working full time throughout the year. For some flow scenarios, it was assumed that a portion of the labor requirements during wet weather events could be met by increasing the number of shifts for existing operators, who would work overtime at a rate of 1.5 times their normal wage. It was assumed that the operators on overtime would work one 8-hour shift per wet weather event.

A detailed break down of the O&M costs and the energy requirements for each train are presented in Attachment SE-3.1. It should be noted that all O&M costs presented for the treatment trains are annualized O&M costs that include escalation over the 30-year period.

Life cycle costs were calculated using the total capital cost, including construction and non-construction costs, and O&M costs. The present value of the life cycle costs are presented in the cost summary section of each train.

EXHIBIT 3-10
Assumed Factors for Life Cycle Cost Estimates

Factor	Value	
Financial		
Annual Discount Rate	4.875	%
Life-Cycle Calculation Period	30	Years
Inflation Rate	4	%(1)
Operation		
Days of operation of wet weather treatment train	35	days(2)
Duration of wet weather event	7	Hours
Labor		
Hourly wage for plant operator	$50.44	including fringe benefits
Hourly wage for plant operator on overtime	$75.65	including fringe benefits

Electrical	1%	of capital cost of electrical equipment
Disposal		
Grit and Screenings Disposal and Hauling Costs	$100	per cubic yard
Final Sludge Disposal Costs$^{(6)}$	$75	per wet ton
Other		
Other O&M Costs (including vehicles, lab tests, office equipment and other miscellaneous costs)	$10,000	per additional full-time operator and maintenance worker
Contingency		

EXHIBIT 3-10
Assumed Factors for Life Cycle Cost Estimates

Factor	Value	
Contingency applied to O&M costs	20	%

(1) Based on CCI Index

(2) The maximum average annual number of wet weather events with flows higher than 330 MGD is 35 under scenarios modeled by CDM. Similarly, the maximum average annual wet weather duration is 222 hours (CDM, 2008). The duration of each event is then assumed to be 7 hours.

(3) Equipment power estimated by PWD.

(4) Based on existing costs at the plant (McKeon, 2008)

(5) For Train #4, CEPT with Plates, the equipment cost does not include that of the stainless steel plates.

(6) Final sludge mass assumes 30% dewatered cake.

EXHIBIT 3-11
Additional Labor Requirements for each Flow Scenario

Treatment Train Flow Capacity	Number of Additional Full-Time Operators(1)	Number of Existing Operators on Overtime(2)	Number of Additional Maintenance Workers(1)
80, 200, 380	1	1	2
470, 540	2	0	4
900, 1200	2	1	4

(1) Full-time operators and maintenance workers are new hires who work 2080 hours per year. Maintenance workers include different trades required for the facility (e.g. electricians, instrument technicians, mechanics, etc..)

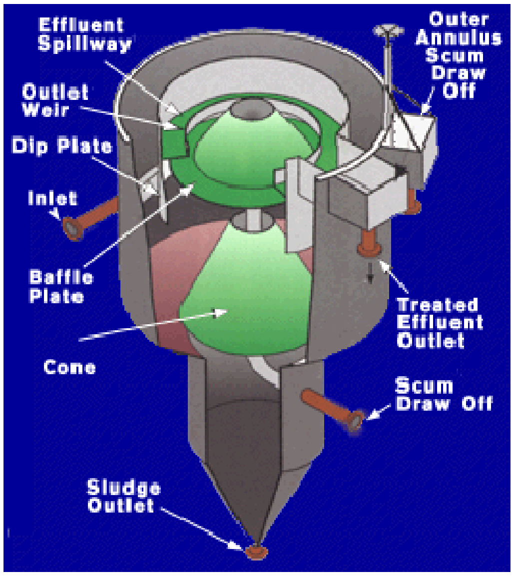
(2) Existing operators on overtime work 8 hours per wet weather event, or 280 hours per year.

4.0 Treatment Train #1- Vortex/Swirl Concentrators

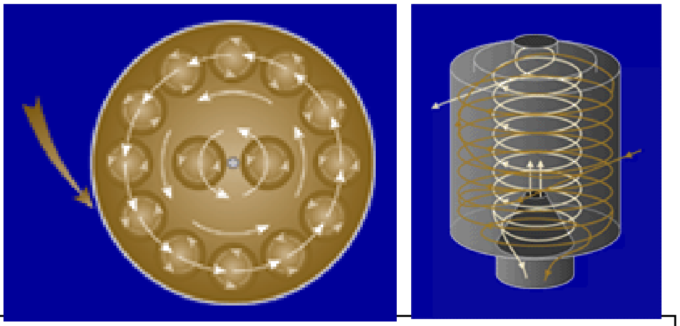
4.1 Process Flow Diagram

The first treatment train under evaluation utilizes the vortex separation technology as its main treatment process. After passing through bar screens and influent pumping at the PTB, the wet weather flow will enter the primary vortex/swirl concentrators. Vortex/swirl concentrators are flow-through structures with no moving parts. The wet weather flow enters the cylindrical structure tangentially, producing a swirling motion that concentrates the solids in the center (Exhibit 4-1). An underflow drain in the center of the unit continually draws the solid materials out of the flow.

EXHIBIT 4-1
Diagrammatic Cutaway of Vortex/Swirl Device (Storm King®, H.I.L. Technologies)



The treated effluent flows out of the top of the vessel, continuing on to the chlorine contact chamber. The solids underflow, typically 10 percent of the influent, undergoes grit removal through a vortex grit unit before settling and thickening in gravity thickeners. The conceptual process flow diagram for this treatment train is shown in Exhibit 4-2.



Flow Pattern Plan and Profile Views (H.I.L. Technologies)
The flow in vortex/swirl devices initially follows a path around the perimeter of the unit and is then directed into an inner swirl pattern with a lower velocity than the outer swirl. Solids separation is achieved by both centrifugal force and gravity because of the long flow path and inertial separation due to the circular flow pattern. The concentrated underflow passes through an outlet in the bottom of the vessel while the treated effluent flows out of the top of the vessel.

4.2 Conceptual Design and Site Layouts

Two different loading rates were assumed for this treatment train, as presented in Exhibit 4-4.

EXHIBIT 4-4
Design Assumptions for Treatment Train #1: Vortex/Swirl Concentrators

Loading Rate (gpm/sf)	Removal Efficiency (%)	Flows Evaluated (mgd)
25	30	80, 200, 380
5	65	80, 200, 900

As with clarification units, the performance of the vortex swirl concentrators varies widely depending on the loading rate. In typical installations where vortex swirls are used to treat combined sewer overflows in the collection system, the units are designed for a loading rate of approximately 25 gpm/sf. At this loading rate, manufacturers estimate that a TSS removal rate of 30 percent can be achieved.

According to a study performed in Columbus, Georgia, the vortex performs similarly to a primary clarifier at loading rates of 5 gpm/sf or less (7,200 gpd/sf). The study showed that removal efficiencies of up to 70 percent were achieved at a 5 gpm/sf loading rate (WERF, 2003). To be conservative, a 65 percent removal efficiency was assumed in this report. Actual performance of the units will need to be verified in pilot studies.

The main design parameters for each flow scenario of this treatment train are shown in Exhibit 4-2. The conceptual site layouts for the minimum and maximum flow scenarios are shown in Exhibits 4-3.

4.3 Operational and Technology-Specific Issues

The effectiveness of vortex/swirl concentrators greatly depends on the hydraulic loading rate on the unit and the characteristics of the solids entering the unit. The optimal loading rate must be determined through pilot or operational testing. In order to operate the vortex/swirl at its optimal operating rate or “sweet spot”, the vortex/swirl units can be brought online one by one as the influent flow increases. Alternatively, an equalization basin can be constructed to maintain a specific flow-rate into the units. An equalization basin was not included in the cost estimates, but conservative hydraulic loading rates were assumed for facility sizing.

4.3.1 Startup and Shutdown

The pretreatment processes (bar screens, influent pumps, and grit removal) can be brought online quickly at the start of a wet weather event. Vortex/ swirl concentrators would be empty at the start of a wet weather event. At small flows, the wet weather flow will exit through the underflow. As flows increase, the vessel will fill due to the increased hydraulic load and begin discharging treated effluent to the outfall.

During shutdown, the vortex/swirl and grit units will be emptied by pumping from the underflow sections to the main plant's influent wet well. The influent wet well in the new PTB would also be pumped down to the plant's existing wet well using dewatering pumps (Exhibit 4-2).

For long term shutdown, the chlorine contact chamber could be pumped down, with the flow recycled to the head of the main plant.

4.3.2 Interaction with Main Plant

The waste streams generated by the screenings washer/compactor and the grit classifiers are sent to the gravity thickeners of the wet weather treatment train and will not affect the main plant. However, there are two streams from the gravity thickeners that will interact with the main plant.

Thickened sludge from the gravity thickeners is pumped to the existing sludge storage tanks at a rate of 0.2 to 4.3 mgd, depending on the flow capacity of the treatment train. This does not include the two gravity thickeners needed for the existing plant. Since the thickened sludge can be pumped at any time, the thickeners themselves can serve as storage tanks for the sludge before it is pumped to the existing storage tanks.

The overflow from the gravity thickeners is conveyed to the head of the entire plant. The estimated overflow range from wet weather thickeners only is 8 to 86 mgd, depending on the treatment train capacity. To minimize the effect of this volume, the overflow is recycled back to the head of the entire plant so that it can be distributed across all units in operation.

4.3.3 Impact on plant operations

Since the vortex/swirl unit has no moving parts, it is expected to have little operations and maintenance requirements. However, operators' attention may be necessary to monitor the hydraulic loading rates into the vortex/swirls to ensure that the "sweet spot" is maintained. The treatment train also includes grit pumps, concentrators, and classifiers, as well as sludge pumps and other equipment, all of which require maintenance. In addition, the new chemical building will include storage of sodium hypochlorite and bisulfite, which are fed to the new chorine contact chamber. Storage of hypochlorite will need to be monitored, since it degrades over time. In addition, the hypochlorite feed-lines should be flushed or degassed periodically.

4.4 Cost Analyses

The estimated capital, O&M, and lifecycle costs for each flow scenario at low and high loading rates are shown in Exhibit 4-5 and 4-6, respectively. Total capital costs and the capital costs per volume treated for all scenarios are shown in Exhibits 4-7 and 4-8. The estimated O&M costs by category are also presented in Exhibits 4-9 and 4-10. A more detailed breakdown of these costs is presented in Attachment SE-3.1. As expected, the cost of this technology at low loading rates is significantly greater than the cost for high loading rates due to the greater number of units required for operation at lower loading rates.

EXHIBIT 4-5
Cost Summary for Vortex/Swirl Treatment Train #1 with Low Loading Rates

5.0 Treatment Train #2 - Conventional Clarifiers

5.1 Process Flow Diagram

Through treatment train #2, the wet weather flow undergoes essentially the same level of primary treatment as the flow through the existing SE WPCP. After preliminary treatment through the bar screens and grit removal, the wet weather flow passes through conventional primary clarifiers at a maximum loading rate of 2400 gpd/sf. This is the overflow rate achievable by the plant's existing primary clarifiers, as shown through stress testing (CH2M HILL, 2001). Primary sludge is collected by chain and flights in the clarifier tanks and is pumped to the gravity thickeners for thickening. The process flow diagram for this treatment train is shown in Exhibit 5-1.

5.2 Conceptual Design and Site Layouts

Conceptual designs were developed at four different flow scenarios for this train: 80, 200, 540, and 900 mgd. Key design parameters at these flows are shown in Exhibit 5-1. The conceptual layouts for the 80, 540, and 900 mgd scenarios are shown in Exhibit 5-2. At a flow of 900 mgd, 11 acres of land will need to be acquired to the east of the plant. The 540 mgd scenario can fit on the existing site.

5.3 Operational and Technology-Specific Issues

5.3.1 Startup and Shutdown

The startup time required for conventional clarifiers will be 2-3 hours, the duration needed to displace the wastewater in the existing tank. For shut down, the tank may be filled with treated effluent, or pumped down to the existing plant if freezing becomes an issue.

5.3.2 Interaction with Main Plant

Since the existing plant uses primary clarifiers, the new primary clarifiers for wet weather treatment can provide redundancy on primary treatment for the entire plant. If connected to the influent of the existing aeration basins, the new clarifiers could be used for treatment of dry weather flows.

The waste streams generated by the screenings washer/compactor and the grit classifiers are sent to the primary clarifiers of the wet weather treatment train and will not affect the main plant. As with the other treatment trains, there are two streams from the gravity thickeners that will interact with the main plant.

Thickened sludge from the gravity thickeners is pumped to the existing sludge storage tanks at an estimated rate of 0.3 to 3.6 mgd, depending on the flow capacity of the treatment train. This does not include the two gravity thickeners needed for the existing plant. Since

the thickened sludge can be pumped at any time, the thickeners themselves can serve as storage tanks for the sludge before it is pumped to the existing storage tanks.

The overflow from the gravity thickeners is conveyed to the head of the entire plant. The estimated overflow range from wet weather thickeners only is 2 to 18 mgd, depending on the treatment train capacity. To minimize the effect of this volume, the overflow is recycled back to the head of the entire plant so that it can be distributed across all units in operation.

5.3.3 Impact on Plant Operations

The operations and maintenance requirements for this treatment train should be similar to those needed for corresponding processes at the existing plant.

5.4 Cost Analyses

The estimated capital, O&M, and lifecycle costs for each flow scenario are shown in Exhibit 5-3. Total capital costs and the capital costs per volume treated are also shown in Exhibits 5-4 and 5-5. Estimated O&M costs by category are presented in Exhibit 5-6. A more detailed breakdown of these costs is presented in Attachment SE-3.1.

6.0 Treatment Train #3 - Chemically Enhanced Primary Treatment (CEPT)

6.1 Process Flow Diagram

Chemically enhanced primary treatment (CEPT) improves the removal efficiency of TSS and BOD through the addition of coagulants and flocculants to primary clarifiers. With chemical enhancement, the surface overflow rate of the primary clarifier is expected to increase from 2400 gpd/sf to 3000 gpd/sf, and the removal efficiency from 55 percent to 80 percent. As shown in the process flow diagram in Exhibit 6-1, the flow path is similar to Treatment Train #2. The only difference is the addition of rapid mixers and flocculation basins upstream of the primary clarifiers, along with their associated chemical feed and storage systems.

6.2 Conceptual Design and Site Layouts

Conceptual designs were developed at four different flow scenarios for this train: 80, 200, 470, and 900 mgd. Key design parameters at these flows are shown in Exhibit 6-1. As with Treatment Train #2, the 900 mgd flow scenario requires acquisition of neighboring property. As shown in Exhibit 6-2, there is adequate space on the existing site to treat up to 470 mgd of wet weather flow. Compared to Treatment Train #2, the CEPT primary clarifiers have a smaller footprint due to its slightly higher surface overflow rate, but the number of gravity thickeners required increases due to the higher removal efficiency of CEPT.

6.3 Operational and Technology-Specific Issues

6.3.1 Startup and Shutdown

The startup time of the CEPT treatment train is approximately 2 to 3 hours, which is the time it takes to either fill up an empty clarifier tank, or to displace existing wastewater in a tank. As with the conventional primary clarifiers, the CEPT tanks can be filled with treated effluent or pumped down when taken out of service.

A liquid polymer system is provided to allow immediate start up of this wet weather treatment train, since dry polymer preparation and aging takes approximately 2 hours. Once the dry polymer has aged, it can be substituted for liquid polymer. Dry polymer has the benefit of taking up less space and having a somewhat longer shelf life than emulsion polymer. A well-designed neat polymer storage tank system provides a shelf life of about six months, while dry polymer generally has a shelf life of 12 months when properly stored in a clean, dry environment. A small liquid polymer system for startup and a dry polymer system following startup are both included in the cost and footprint estimates. For a cost estimate of using liquid polymer only, see Section 9-1.

The other processes in the system are physical or physical/chemical treatment systems that are easily and quickly brought online and will achieve normal levels of treatment efficiency quickly.

6.3.2 Interaction with Main Plant

As described in the previous treatment trains, two waste streams from the gravity thickeners will interact with the existing plant. Thickened sludge will be pumped to the existing storage tanks at an estimated rate of 0.6 to 6.4 mgd, depending on the flow capacity of the treatment train. The overflow from the thickeners, ranging from 3 to 32 mgd, is recycled back to the head of the plant for distribution across the main plant and the wet weather treatment train.

6.3.3 Impact on Plant Operations

CEPT requires the addition of chemicals, ferric chloride and polymer, that are not currently used at the SE WPCP. Storage of these new chemicals will need to be monitored to ensure that they are not degraded over time, especially during long periods of shutdown. The system effluent may need to be recycled to the head of the existing plant until the unit process is stabilized.

6.4 Cost Analyses

The estimated capital, O&M, and lifecycle costs for each flow scenario are shown in Exhibit 6-3. Total capital costs and the capital costs per volume treated are also shown in Exhibits 6-4 and 6-5. Estimated O&M costs by category are shown in Exhibit 6-6. A more detailed breakdown of these costs is presented in Attachment SE-3.1.

7.0 Treatment Train #4 - CEPT with Plate Settlers

7.1 Process Flow Diagram

Building upon Treatment Train #3, this train utilizes the addition of plate settlers in the primary clarifiers to increase the effective settling area of the tank. With chemical addition and the increased settling area, the surface overflow rate is estimated to increase from 3000 gpd/sf for CEPT only, to 7000 gpd/sf with the addition of plates. To prevent the plate settlers from clogging, fine screening is included as an additional process in this train (Exhibit 7-1).

7.2 Conceptual Design and Site Layouts

Conceptual designs were developed at three different flow scenarios for this train: 80, 200, and 900 mgd. Key design parameters at these flows are shown in Exhibit 7-1. Due to the higher surface loading rate of these tanks, a 900 mgd facility will be able to fit on the existing site (Exhibit 7-2).

7.3 Operational and Technology-Specific Issues

7.3.1 Startup and Shutdown

The requirements for startup and shutdown are similar to those for the CEPT treatment train.

7.3.2 Interactions with Main Plant

The waste streams from the gravity thickeners will be similar in flow to the CEPT treatment train. An estimated thickened sludge flow of 0.6 to 6.4 mgd, depending on the flow capacity of the treatment train, will be pumped to the existing sludge storage tanks. The overflow from the thickeners, ranging from 3 to 32 mgd depending on the flow capacity of the treatment train, will be recycled back to the head of the entire plant.

7.3.3 Impact on plant operations

In addition to the same impacts on plant operations associated with CEPT, plate settlers require regular cleaning to maintain performance, especially due to the sticky nature of the solids that are typically present in wastewater. There will also be additional maintenance associated with the set of fine screens as well.

8.0 Treatment Train #5 - Ballasted Flocculation

The final treatment train uses ballasted flocculation to achieve removal efficiencies beyond that of CEPT. Ballasted flocculation, often referred to as “high rate treatment,” creates extremely dense flocs with high settling velocities that can be removed efficiently even at very high surface overflow rates. Two proprietary systems that use ballasted flocculation are the DensaDeg and Actiflo systems. The DensaDeg system uses chemical sludge produced within it (recirculated from the clarifier underflow to the system influent) as a ballasting agent. The Actiflo system uses microsand as the ballasting agent. Both systems can achieve TSS removals in the range of 85 to 95 percent.

Actiflo requires separate gravity thickeners to process the sludge it generates, while Densadeg recirculates its sludge within its own process and therefore produces a thicker sludge not requiring thickening. The overall cost differential is not significant in most cases, however, since Densadeg has a lower overflow rate (40 gpm/sf compared with 60 gpm/sf) and larger footprint (CH2M HILL, 2007b).

Since the overall cost of the Actiflo and DensaDeg systems have been found to be similar, only one system was chosen for evaluation for this treatment train. The Actiflo system was selected in order to show the possibility of adding gravity thickeners to the plant layout. Pilot testing should be performed to determine the system best suited for the plant, while providing other benefits such as:

- Identification of influent wastewater constituents that may affect performance of either technology
- Determining suitable chemical dosages for the ballasted flocculation system
- Providing effluent quality information that can be used for design of downstream disinfection processes
- Assessing treatment performance at typical design overflow rates
- Providing better understanding of system operation through pilot testing.

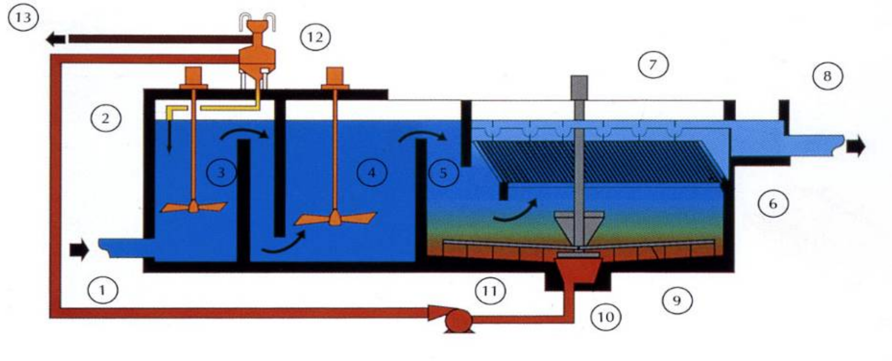
8.1 Process Flow Diagram

In the ballasted flocculation treatment train, wet weather flow passes through bar screening, influent pumps, grit removal, and fine screening before entering the ballasted flocculation system (Exhibit 8-2). A schematic of the Actiflo system is shown in Exhibit 8-1.

Using the numbers in the Exhibit, the wastewater enters at point (1) along with the coagulant (ferric chloride) to the flash mixing zone (3) where microsand is also added (2). Addition of the coagulant enhances flocculation by destabilizing suspended solids in the wastewater. Compartment (4) is a gentle mixing zone where polymer is added to promote formation of strong flocs around the microsand. The flocculated solids flow to compartment (5), the clarification zone. Most of the solids settle at the bottom of this compartment, but this zone also has lamella settling modules (6) to enhance removal of suspended solids that may be present in the wastewater. The solids accumulated at the bottom of the clarification compartment (10) are recycled to a hydrocyclone (12), where the sludge is separated from the microsand. The microsand is recycled back to the flash mixing zone (3), and the sludge leaves the system by stream (13).

As shown in Exhibit 8-2, the sludge from the ballasted flocculation process is pumped to gravity thickeners to be thickened from 0.3 percent solids to 3-4 percent solids.

EXHIBIT 8-1
Schematic of the ACTIFLO High-Rate Primary Clarifier (scanned from vendor's brochure)



8.2 Conceptual Design and Site Layouts

Conceptual designs using the ballasted flocculation system were developed for flow capacities of 80, 200, 900, and 1,200 mgd. The 1,200 mgd scenario was developed to show the maximum flow that can be treated using the available land onsite. The key design parameters are presented in Exhibit 8-2. As seen in the conceptual layouts in Exhibit 8-3, the space requirements of this treatment train are minimal compared to the other alternatives. This is due to its extremely high surface overflow rate of 60 gpm/sf.

8.3 Operational and Technology-Specific Issues

8.3.1 Startup and Shutdown

Ballasted flocculation systems stabilize quickly, with Actiflo taking less than 20 minutes and DensaDeg less than 45 minutes to start producing good quality effluent based on demonstration testing. Infilco Degremont indicated that the DensaDeg process will produce design effluent immediately if left filled with chlorinated plant effluent. However, based on piloting studies, a connection should be provided for discharging wet weather effluent to the head of the existing plant during startup or until ballasted flocculation system performance stabilizes. To facilitate startup, the ballasted flocculation system should also be underloaded initially.

Shutdown can occur at the operator’s convenience. Typically, equipment will simply need to be switched off. The hydrocyclones should be pumped down before being turned off. The tanks themselves can either be filled with treated effluent, or drained down. To prevent freezing during cold weather, any system that is not totally enclosed should have a constant flow of water, or be drained down. The cost estimate does not include a building for the ballasted flocculation units since they are able to be effectively operated in an outdoor environment, and the inclusion of a building would add unnecessary capital costs to this alternative.

The advantage of leaving the basins filled with water is that the startup time is substantially reduced and the basins reach their design effluent quality much more quickly. This reduces the volume of partially treated water that must be returned to the existing treatment plant. Running a small flow through the tanks also helps in maintaining equipment, such as the tank mixers. Actiflo’s manufacturer recommends leaving the sand in the tanks only if the tanks are filled with effluent. With sand readily available in the tanks, treatment can begin sooner. If the system were fully drained, the sand within the Actiflo system would require removal and disposal to prevent freezing. Upon startup, sand would have to be reintroduced into the treatment flow using the bulk sand feed system. Infilco Degremont indicates that solids should be removed from the DensaDeg system within six hours to prevent septicity. The DensaDeg system can then be left filled with chlorinated plant effluent.

8.3.2 Interaction with Main Plant

During startup, effluent from the ballasted flocculation system will be discharged to the head of the main plant until system performance stabilizes.

Similar to the other treatment trains, recycle flows from the screenings washer/compactor and grit classifier will be conveyed to the ballasted flocculation system with the wet weather treatment train. The overflow streams from the gravity thickeners, however, must be sent to the head of the main plant for distribution across both the wet weather treatment train and the existing plant. Since this treatment train has the highest removal efficiency, it generates the highest sludge and overflow volumes. In addition, the solids content of the sludge is thinner compared to primary clarifier sludge as a result of the cyclones used to separate the ballast from the sludge. The estimated overflow volume is 6 to 86 mgd, depending on the flow capacity of the treatment train. Thickened sludge will be pumped to the existing sludge storage tanks at a rate of 0.6 to 9.6 mgd.

8.3.3 Impact on plant operations

To simplify routine operation, Actiflo and Densadeg typically have automated routine startup and shutdown sequences with PLC programming and adjustable timers (service interval, tank fill, equipment run, shutdown, and tank drain). However, operator attention will be necessary to monitor or optimize performance, and to confirm successful facility startup. The operators will have the following responsibilities:

- Start the process train
- Monitor coagulant and polymer dose and perform jar tests to optimize chemical dosing.
- Manage the loading of screenings and grit dumpsters.
- Observe equipment operation and contact maintenance if equipment malfunctions.

8.3.4 Other Issues

Foaming – Foaming may occur due to the addition of coagulants and polymer settling aids, and should be investigated in pilot studies. For example, during startup of the Actiflo unit at Lawrence WWTP in Lawrence, Kansas, the observed foaming resulted from the reaction of ferric chloride with biodegradable surfactants in the incoming wastewater. Foaming can be controlled using silica-based defoamers such as Tramfloc 110, Chemco DF, and Neo Solutions NS-8454 at low dosages.

Floc Carryover and Microsand Loss – Floc carryover is an issue for the DensaDeg system that should be investigated through pilot tests. As flows approach the design SOR, sludge densities may decrease, sending large flocs of sludge out in the effluent. These large flocs not only affect effluent quality in terms of TSS and BOD levels, but may also decrease effectiveness of the disinfection process downstream.

Regarding the Actiflo system, a certain degree of microsand loss is expected from normal operation of the system. The manufacturer indicates that about 8 pounds of microsand are lost for each million gallons of wastewater treated. The sand must be replaced for optimal operation of the system. According to information gathered during the team’s site visit to the Cincinnati Metropolitan Sewer District, the SSO 700 Facility loses 350 lbs of sand per 15 mg wet weather event. In the conceptual design of this treatment train, adequate storage space was provided in the chemical buildings for 10 day storage of sand. Additionally, the microsand needs to be maintained in the system in case rapid startup is required, and the sand must be prevented from freezing during the winter so that the unit can start up quickly if needed during the cold season. The DensaDeg unit is totally drained when the system is shut down, and no chemical sludge is maintained in the system when it is not in use.

Sludge Concentration - One important difference between Actiflo and Densadeg is the sludge concentration that they produce. Sludge from the DensaDeg system can be four to five times more concentrated than sludge from the Actiflo system. Since the two systems are expected to produce the same mass of sludge, because they operate with similar coagulant dosages, it is expected that the volume of sludge produced in the ACTIFLO system will be four to five times greater than that in the DensaDeg unit. Gravity thickeners have been included in the conceptual design for the Actiflo treatment train to thicken the sludge to 3-4 percent solids. These thickeners may not be necessary if the Densadeg system is chosen.

8.4 Cost Analyses

The estimated capital, O&M, and lifecycle costs for each flow scenario are shown in Exhibit 8-4. Total capital costs and the capital costs per volume treated are also shown in Exhibits 8-5 and 8-6. Estimated O&M costs by category are presented in Exhibit 8-7. A more detailed breakdown of these costs is presented in Attachment SE-3.1.

EXHIBIT 8-4
Cost Summary for Ballasted Flocculation: Treatment Train #5

	Wet Weather Flow (mgd)			
Cost	**80**	**200**	**900**	**1200**
Capital Cost ($M)	$159	$278	$837	$1,050
Annual Operations and Maintenance Cost ($M)	$2.1	$3.4	$6.2	$7.0
Present Value of the Cost ($M)	$191	$331	$934	$1,159

EXHIBIT 8-5
Capital Costs for Treatment Train #5: Ballasted Flocculation

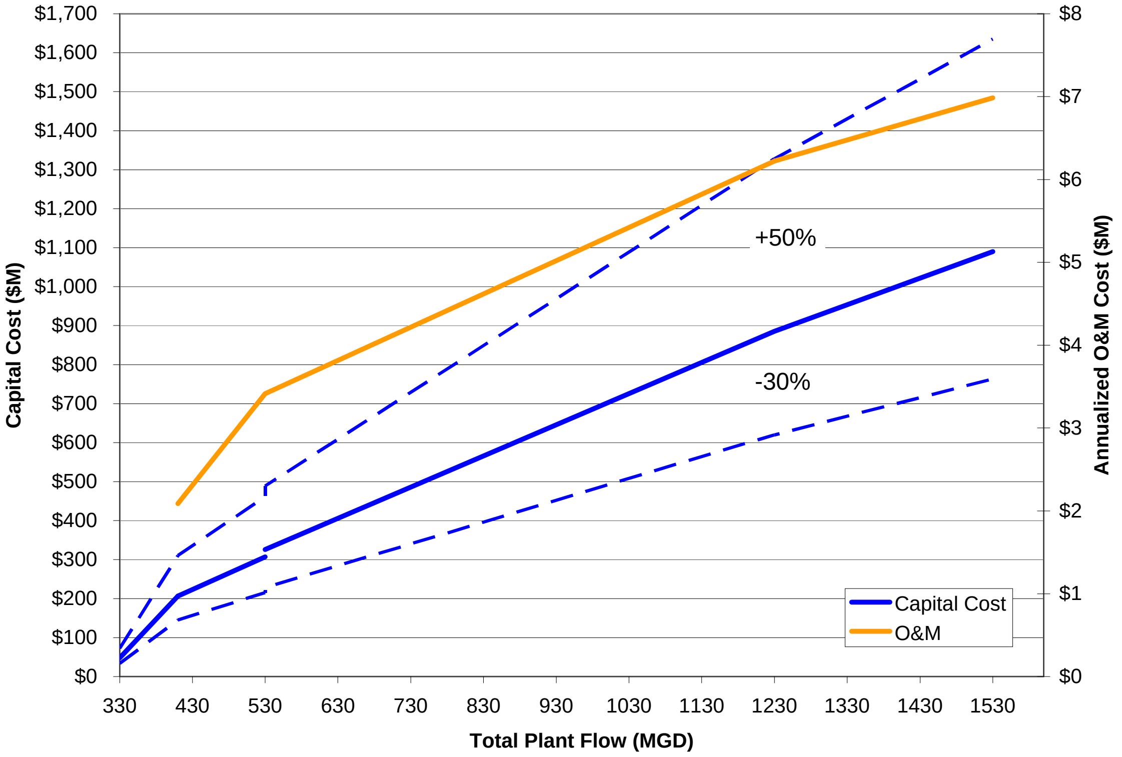

EXHIBIT 8-6
Capital Costs per Gallon Treated for Treatment Train #5: Ballasted Flocculation

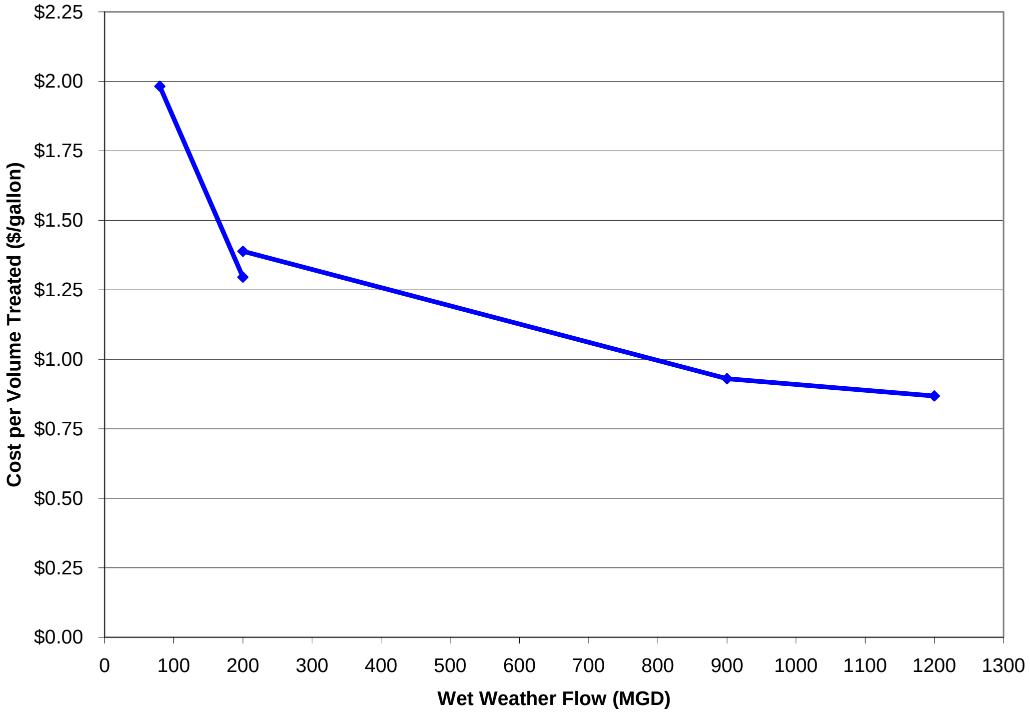

EXHIBIT 8-7
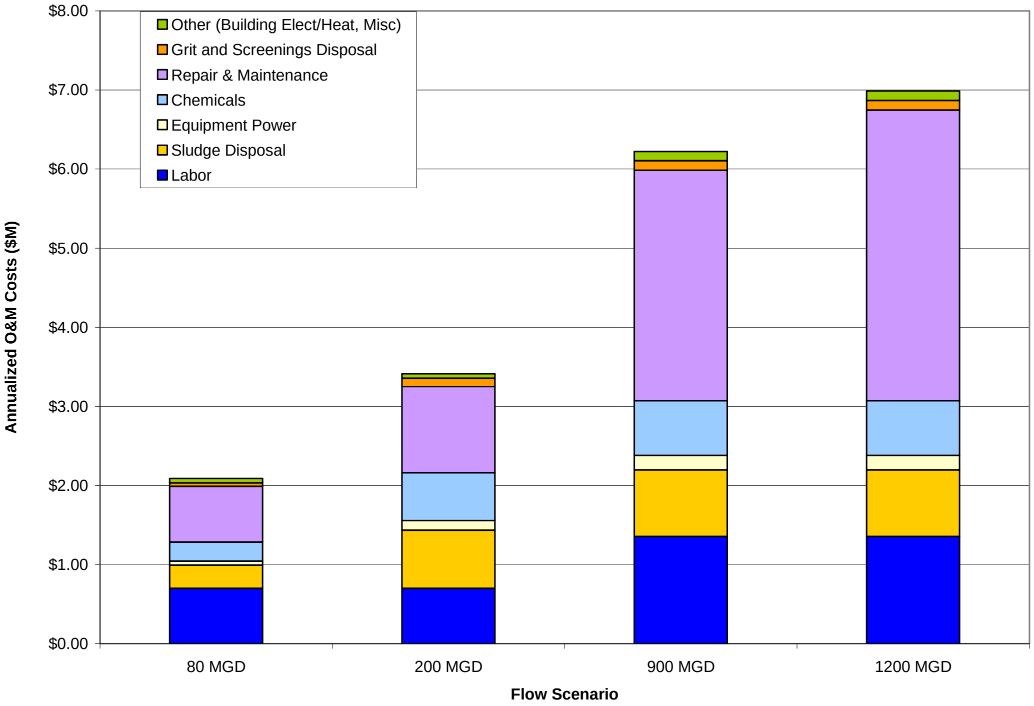
Operations and Maintenance Costs by Category for Treatment Train #5: Ballasted Flocculation



9.0 Alternatives for Optimizing Capital Costs

9.1 Polymer Usage

For Trains #3-#5, polymer is added as a flocculant to the wet weather flow. The capital costs presented for these trains include the cost for both a liquid polymer system and a dry polymer feed system. The liquid polymer system is sized for a 20-hour storage of 40 percent emulsion polymer, and would be used during the first two hours of start up of the wet weather treatment facility. This allows time for the dry polymer to be mixed and aged. The dry polymer system would include a hopper and solution tank(s) for mixing and aging. Ten day storage of dry polymer supersacks would be maintained on site.

An alternative to using dry polymer would be to maintain a 10-day storage of the liquid polymer in bulk storage tanks. The capital cost savings from using liquid polymer only for various flow scenarios is presented in Exhibit 9-1.

EXHIBIT 9-1
Capital Cost of Using Liquid Polymer Only

	Total Capital Cost ($)		
Flow (mgd)	**Liquid and Dry Polymer**	**Liquid Polymer Only**	**Cost Differential**
80	$2,142,080	$1,088,080	$1,054,000
200	$3,538,778	$1,424,771	$2,114,007
470	$5,085,895	$2,574,029	$2,511,866
900	$7,016,125	$3,355,787	$3,660,338

Note: 40% active liquid emulsion polymer assumed.

The capital cost savings are mostly due to the high cost of the dry polymer feed equipment. The main advantage of dry polymer systems is the reduction in chemical costs, which contribute significantly to the operations and maintenance costs of the plant. Dry polymer is $3400 per dry ton, which is approximately 15% cheaper than liquid polymer ($3983 per dry ton for 40 percent active emulsion). Dry polymer also has a 12-month shelf life, which is double that for liquid polymer. This is useful for systems where wet weather events occur less frequently or predictably.

Since the chemical cost of dry polymer is lower than liquid polymer, but the capital costs are higher for the dry polymer system, there is not a significant difference in the life cycle cost of the two alternatives. Thus, selection of the polymer system often depends on operational preferences. Liquid polymer systems are easier to maintain than dry polymer systems, which have the risk of clogging in the hopper and feed-lines. Having only one system to operate also reduces the complexity of the chemical feed system.

9.2 Digesters at the SW WPCP

The capital cost of one digester was included for each of the treatment trains and flow scenarios described in previous sections. Since sludge from the SE WPCP is currently transferred to the SW WPCP for treatment, the new digester is assumed to be located in the SW WPCP also.

According to PWD, as discussed in Workshop No. 3, the existing digesters at the SW WPCP may have adequate capacity to treat the wet weather flow. Since there will be gravity thickeners in the new wet weather treatment facility, the thickness and pumping rate of the sludge transferred to the SW WPCP can be controlled. Sludge can also be stored in the gravity thickeners and metered to the SW WPCP at the desired flow-rate.

The need to expand the digestion capacity of the SW WPCP for treatment of primary sludge from the SE WPCP will be determined after further analysis of the digesters and the wet weather treatment trains in SW WPCP. The costs of the digester (without markups) are included as separate line items in the detailed cost tables in Attachment SE-3.1 and can be subtracted from the total if necessary.

9.3 Ballasted Flocculation

As mentioned in Section 8, the costs presented for Treatment Train #5, Ballasted Flocculation, are based on the Actiflo system, which is similar in cost to Densadeg, the other proprietary high rate treatment technology. If the ballasted flocculation treatment train is selected, a cost estimate for the Densadeg system should be developed to examine the cost differential. The main contributions to the cost differential will include:

- **Reduction in number of thickeners** - Densadeg maintains a 3-4 percent sludge thickness for its ballast, compared to the 0.3 percent sludge thickness in the Actiflo system.
- **Increase in footprint** – Densadeg has a 40 gpm/sf loading rate, compared to Actiflo’s 60 gpm/sf loading rate.
- **Elimination of fine screening** – Actiflo requires fine screening to protect the hydrocyclones in the system, which separate sand from sludge. Since Densadeg uses sludge only as its ballast, it does not require fine screening upstream.

Implications to operations and maintenance should also be examined between the two systems. For example, Actiflo requires sand as the ballasting agent, which requires storage and maintenance.

9.4 Refined Design Assumptions via Influent Sampling

Influent sampling at the plant during wet weather events will shed light on the wastewater characteristics of the wet weather flow, as well as the flow regime during events. More concrete numbers for influent TSS, BOD, and flow can be used to refine process design parameters, which may lead to a reduction in the size and cost of the treatment trains.

10.0 Comparison of Treatment Alternatives

10.1 Effluent Water Quality

While each flow scenario for each treatment train evaluated above is capable of producing blended effluent concentrations that meet permit limits, the resulting water quality differs widely between different scenarios. The TSS and BOD concentrations of the blended effluent for each treatment train and flow scenario is presented in Exhibit 10-1 and 10-2, respectively.

EXHIBIT 10-1
Blended Effluent TSS Concentrations

Treatment Train	**Wet Weather Treatment Train Effluent Conc. (mg/L)**	**Blended Effluent TSS Concentration (mg/L)**						
		Wet Weather Treatment Train Flow (mgd)						
		80	***200***	***380***	***470***	***540***	***900***	***1200***
#1) Vortex/Swirl Concentrators								
High Loading Rate:	154	59	81	99				
Low Loading Rate:	77	44	51				66	
#2) Conventional Clarifiers	99	48	60			75	82	
#3) CEPT w/ Conventional Clarifiers	44	38	39		41		42	
#4) CEPT w/ Plate Settlers	42	37	38				40	
#5) Ballasted Flocculation	21	33	30				25	24

Notes: Based on the 95th percentile wet weather TSS concentration of 36 mg/L and a maximum of 330 MGD through the existing plant. Allowable daily blended effluent TSS concentration on wet weather days is 99 mg/L, based on permit limits.

EXHIBIT 10-2
Blended Effluent BOD Concentrations

		Blended Effluent BOD Concentration (mg/L)						
		Wet Weather Treatment Train Flow (mgd)						
Treatment Train	**Wet Weather Treatment Train Effluent Conc. (mg/L)**	***80***	***200***	***380***	***470***	***540***	***900***	***1200***
#1) Vortex/Swirl Concentrators								
High Loading Rate:	100	38	52	64				
Low Loading Rate:	63	31	38				52	
#2) Conventional Clarifiers	74	38	52			71	79	
#3) CEPT w/ Conventional Clarifiers	47	28	32		37		41	
#4) CEPT w/ Plate Settlers	46	28	32				40	
#5) Ballasted Flocculation	36	26	28				33	33

Notes: Based on the 95th percentile wet weather BOD concentration of 23 mg/L and a maximum of 330 MGD through the existing plant. Allowable daily blended effluent BOD concentration on wet weather days is 106 mg/L, based on permit limits.

It should be noted that at wet weather flows higher than 200 mgd, the blended effluent BOD concentrations for Trains #1 and #2 exceed the NPDES permit Instantaneous (daily composite) Maximum Discharge Limitation of 60 mg/L (Exhibit 10-2). While this limit is stated in the permit, there are currently no reporting requirements for this specific data point.

In addition, with an estimated removal efficiency of 30 percent at high loading rates, the vortex/swirl treatment train does not meet removal efficiencies of primary clarification (55 percent).

As described in Section 3.1, the maximum flow through all the treatment trains, with the exception of the vortex swirl at high loading rates, is unlimited if the number of wet weather days is less than 7 days per month. To illustrate the risk of exceeding permit limits at these design flows, Exhibit 10-3 presents the maximum number of days that the wet weather treatment train can operate at its maximum capacity without exceeding monthly TSS permit limits.

A frequency plot of the number of wet weather events per month and the duration of each event is shown in Exhibits 10-4 and 10-5 for comparison purposes. As shown, wet weather events have occurred at a historical maximum of 15 per month. This suggests that CEPT, CEPT with Plates, and Ballasted Flocculation have a very low probability of exceeding permit limits. Exhibit 10-5 also shows that approximately 95% of events do not last as long as 24 hours, which is the event duration assumed in this study. It should be noted that a continuous simulation-based approach would give a more accurate estimate of risk, and more detailed analyses should be performed during the facility planning and design phases.

EXHIBIT 10-3
Allowable Number of Operating Days of Wet Weather Treatment Train

	Maximum Allowable Number of Operating Days per Month[(1)]						
	Wet Weather Treatment Train Flow (mgd)

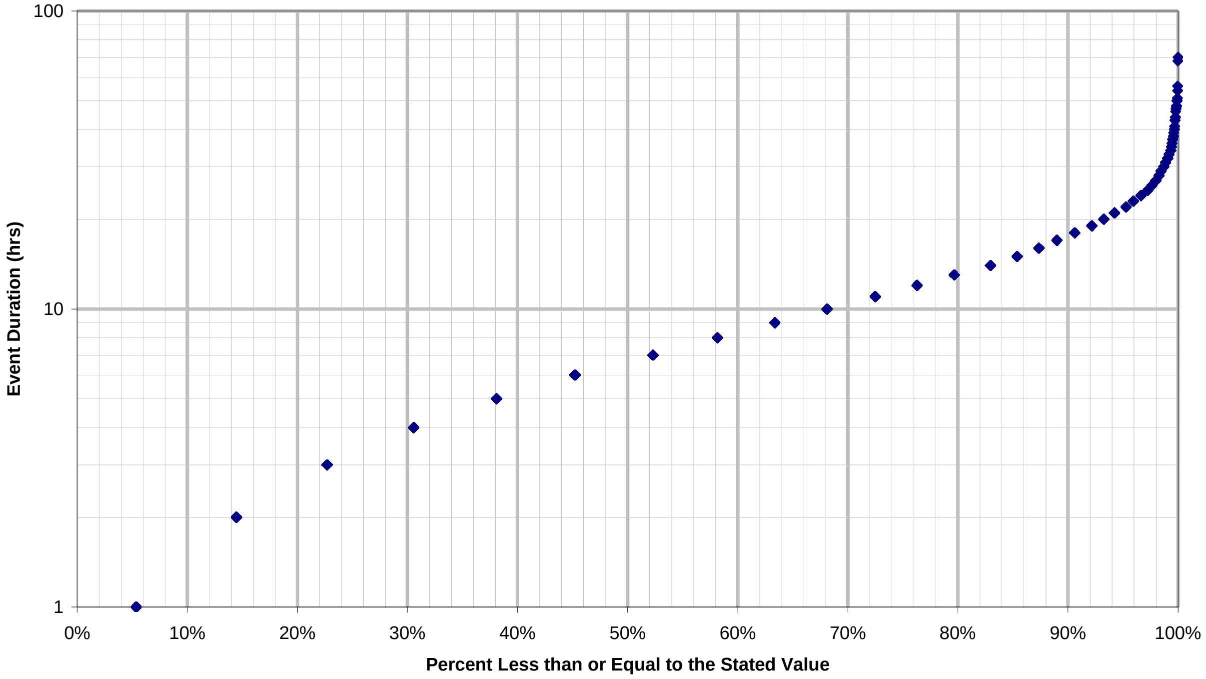
EXHIBIT 10-5
Cumulative Frequency Plot of Wet Weather Event Duration



10.2 Capital, O&M and Life-Cycle Costs

The capital cost estimates for the five treatment trains are shown in Exhibit 10-6. Train #4, CEPT with Plates, is the most expensive, followed by Train #1, vortex/swirl at low loading rates. Trains #2, 3, and 5 appear to have similar costs throughout the entire flow range, with Train 5 being slightly less costly. Translated into a cost per volume treated, all trains appear to become more cost effective as flow capacity increases (Exhibit 10-7).

The comparison of O&M costs for each treatment train is shown in Exhibit 10-8. As expected, the O&M costs are lowest for vortex swirls at high loading and conventional clarifiers, which do not require chemical settling aids. Vortex swirls at low loading rates has the highest O&M costs for repair and maintenance of the large number of vortex units and gravity thickeners required.

Taking construction, non-construction, and O&M costs into consideration, Exhibit 10-9 shows the present value of the total cost of each wet weather treatment train. Train #4, CEPT with Plates, remains most costly since it requires the highest capital and O&M costs. Train #1, vortex/swirl concentrators, appears to be least costly from the life-cycle cost perspective, especially at lower flows. This is due to its low chemical usage and minimal operations and maintenance needs.

10.3 Overall Comparison

Aside from capital, O&M, and lifecycle costs, there are numerous other criteria by which the treatment trains should be evaluated, including:

- Reliability of the system
- Community and environmental impacts or perception
- Ability to handle large variations in flow
- Land requirements
- Constructability
- Requirements for maintenance and operator attention
- Sustainability

These evaluation criteria were discussed in Workshop No. 2B, and are presented in TM-SE2 for various wet weather treatment technologies (CH2M HILL, 2008). Several key advantages and disadvantages of Treatment Trains #1 - #5, as evaluated in this report, are described in Exhibit 10-10.

EXHIBIT 10-10
Summary of Pros and Cons for Each Wet Weather Treatment Train

Treatment Train	Pros	Cons
Train #1: Vortex/Swirl Concentrators	• Simple operation • Low maintenance requirements – no moving parts	• Only cost competitive at high loading rates and low removal efficiencies. • Maximum design flow may decrease if the assumed number of operating days is greater than 7.
Train #2: Conventional Clarifiers	• Simple operation • Same technology as existing plant –operators familiar with equipment	• Space limited • May exceed instantaneous blended effluent BOD concentration at high flows • Maximum design flow may decrease if the assumed number of operating days is greater than 7.
Train #3: CEPT	• Lower chlorine dose possible due to high TSS removal efficiencies	• Operators unfamiliar with technology • Space limited • Uses chemicals • Can treat less flow on existing site than conventional clarifiers • Operators unfamiliar with technology

EXHIBIT 10-10
Summary of Pros and Cons for Each Wet Weather Treatment Train

Treatment Train	Pros	Cons
Train #4: CEPT with Plates	• Can treat 900 mgd with available land on site • Lower chlorine dose possible due to high TSS removal efficiencies • Unlimited number of operating days per month	• Highest capital and O&M costs • Operators unfamiliar with technology • Labor intensive to clean plants • Uses chemicals
Train #5: Ballasted Flocculation	• Can treat up to 1200 mgd with available land on site • Highest removal efficiencies • Unlimited number of operating days per month • Lower chlorine dose possible due to high TSS removal efficiencies	• Operators unfamiliar with technology • Second most labor intensive • Uses chemicals

The costs for wet weather treatment at the SE WPCP should be analyzed with the costs of other wet weather treatment alternatives, such as improvements in the collection system, to determine which treatment train alternatives and flow regimes should be evaluated further. Treatment trains that are selected for further evaluation should undergo more detailed design and costing methods, water quality sampling, and bench and pilot scale testing, so that removal efficiencies, land requirements, capital costs, and O&M costs can be further refined.

Notes:
1. Contractor markups - use 1.516 multiplier (see TM-SE3 Section 3.3)
2. Escalation - multiplier depends on duration of construction (see Exhibit 3-7 in TM-SE3 Section 3.3)
3. Local Adjustment Factor - use 1.152 multiplier (see TM-SE3 Section 3.3)
4. Market Adjustment Factor - use 1.15 multiplier (see TM-SE3 Section 3.3)
5. Non-construction costs - use 1.3 multiplier (see TM-SE3 Section 3.3)
6. For 200 mgd flow scenarios, cost assumes construction of new outfall conduits. The total capital cost of the 200 mgd scenario assuming no new outfall conduits is provided in the last line item of this table.

	1200	$1,354,994	$843,401	$182,122	$15,759	$692,347	$3,674,634	$121,219	$101,639	$6,986,114	17,357

Notes:

1. All O&M costs are annualized costs based on escalation through a 30-year period. For flows of 470 mgd and higher, costs are based on an average flow of 337.5 mgd (see TM-SE3 Section 3.3)
2. Power costs are estimated based on the total horsepower requirements and the average-to-max flow ratio.
3. "Other" costs cover miscellaneous costs for vehicles, lab tests, office equipment, etc.

Percentage of Costs by Category

	Flow (mgd)	Labor	Sludge Disposal	Equipment Power	Building Electrical/ Heating	Chemicals	Repair & Maintenance	Grit and Screenings Disposal	Other
Train #1: Vortex/Swirls (low loading)	80	35.2%	8.1%	2.0%	0.2%	3.0%	47.2%	1.8%	2.6%

Executive Summary

Background and Project Summary

As part of the series of memoranda prepared for the Philadelphia Water Department's (PWD) Combined Sewer Overflow (CSO) Long Term Control Plan (LTCP) update, this report presents the conceptual design and cost analyses for four wet weather treatment alternatives for the Southwest Water Pollution Control Plant (SW WPCP). The wet weather treatment technologies for the SW WPCP evaluated in this report are as follows:

1. Vortex Swirl Concentrators
2. Conventional Clarifiers
3. Chemically Enhanced Primary Treatment (CEPT) with Conventional Clarifiers
4. Ballasted Flocculation (includes fine screening)

Conceptual treatment trains were developed for each treatment technology at various wet weather flows ranging from 220 million gallons per day (mgd) to 1740 mgd and cost curves for capital, operations and maintenance (O&M), and lifecycle costs were generated for each treatment train alternative.

Existing Plant and the New Wet Weather Treatment Facility

Currently, the SW WPCP has a flow capacity of 400 mgd. With several process and hydraulic modifications, as identified in the 2001 Stress Testing Report, the capacity of the existing plant can potentially reach 540 mgd (CH2M HILL, 2001). In sizing the wet weather treatment trains, it was assumed that these upgrades, costing $64.6 million, will have been completed, increasing the plant's capacity to a minimum of 540 mgd (Section 2). Any wet weather flow in excess of 540 mgd would be diverted to the new wet weather facility.

The new wet weather facility is sited in two tracts of land currently utilized by the Biosolids Recycling Center (BRC), the Upper and Lower BRC areas. Due to the likely infeasibility in routing a new outfall conduit from the BRC area through the Philadelphia International Airport to the Delaware River, a new outfall conduit to the Schuylkill River is proposed to be constructed for the new wet weather treatment facility. Unlike the Southeast and Northeast WPCPs, effluent from the wet weather facility will not commingle with the effluent from the conventional plant. This means that the regulating agencies may view the new facility as a separate wet weather treatment facility requiring a new discharge permit.

If blending of the two plant effluents is required or desired, the outfall for the existing plant could be relocated to the Schuylkill by constructing a new outfall conduit. The cost of this conduit, and thus comingling, is estimated at $155 million. Despite the difference in outfall locations, this report assumes that the SW WPCP and its new wet weather facility will operate as one system.

Flow Scenarios

Conceptual designs and cost estimates were developed for the design flows for each wet weather treatment train under evaluation (Exhibit ES-1). These flows were selected based on the ability to meet permit requirements (assuming commingling with existing plant), the capacity of the existing collection system, the land area available at the Upper and Lower BRC sites, and the maximum expected flow from the upgraded collection system, as described in Section 4.

EXHIBIT ES-1
Design Flows Evaluated for each Wet Weather Treatment Train

Treatment Train	Design Flows Evaluated (mgd)
#1) Vortex/Swirl Concentrators	220, 702
#2) Conventional Clarifiers	220, 600, 1200
#3) CEPT w/ Conventional Clarifiers	220, 550, 1000
#4) Ballasted Flocculation	220, 980, 1740

Comparison of Treatment Alternatives

Effluent Water Quality

Due to the varying removal efficiencies of each candidate treatment train, the resulting water quality differs widely between different trains. The TSS and cBOD concentrations of the effluent for each wet weather treatment train and flow scenario is presented under Section 10 in Exhibits 10-1 and 10-2, respectively. In general, ballasted flocculation provides the best treatment, achieving TSS and cBOD concentrations even lower than the existing plant.

Capital and O&M Costs

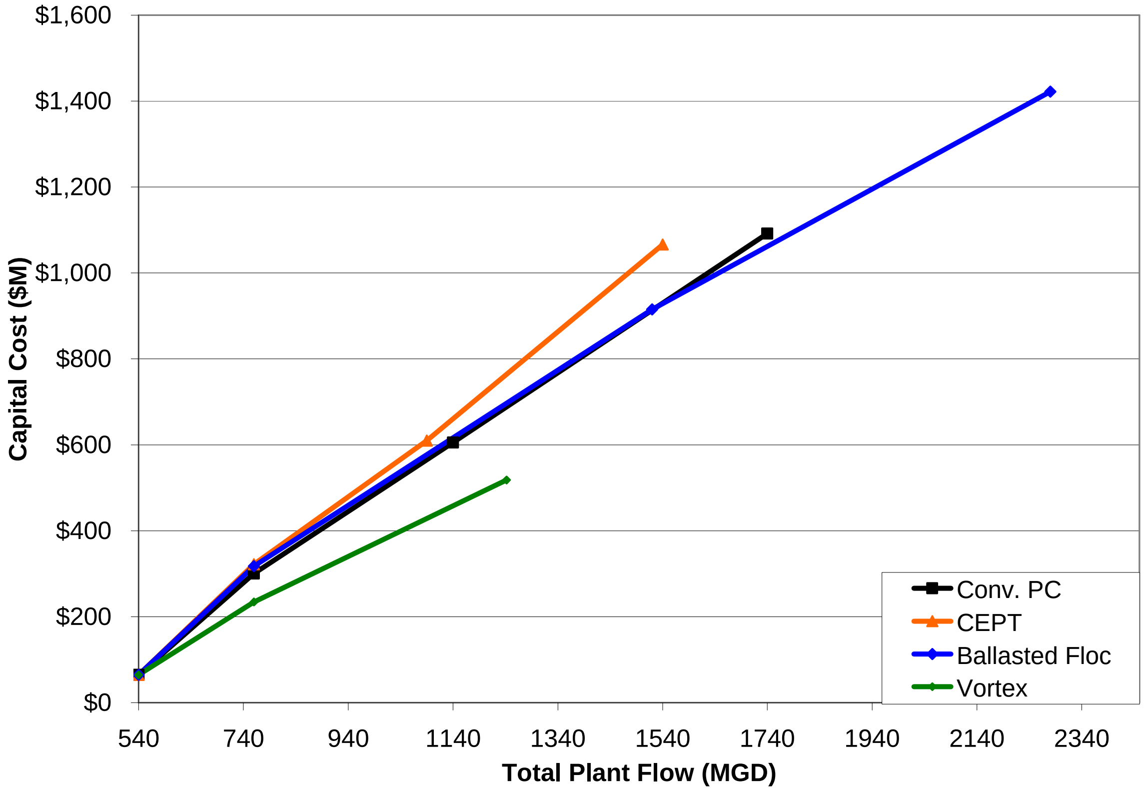
The capital cost estimates for the four treatment trains are shown in Exhibit ES-2. Train #3, CEPT, is the most expensive, followed by Trains #2 and #4, Conventional Clarification and Ballasted Flocculation, which appear similar in cost. The cost of Train #1, Vortex/Swirl, is significantly less expensive than the other three trains. Translated into capital cost per volume treated, all trains appear to become more cost effective as flow capacity increases (Exhibit ES-3).

The reason that CEPT is more expensive than Ballasted Flocculation for the SW WPCP wet weather facility is likely due to the limited length and increased number of its clarifiers, as described in Section 7.2, as well as the increased cost for piles.

The comparison of O&M costs for each treatment train is shown in Exhibit ES-5. As expected, the O&M costs for vortex swirls and conventional clarifiers, which do not require chemical settling aids, are the lowest. Ballasted Flocculation has the highest O&M costs due to its chemical usage and the complexity of its system.

Taking construction, non-construction, and O&M costs into consideration, Exhibit ES-6 shows the present value of the total cost of each wet weather treatment train. Again, CEPT and Ballasted Flocculation remain most costly due to their high capital and O&M costs. Train #1, vortex/swirl concentrators, is significantly less expensive compared with other technologies from the life-cycle cost perspective. This is due to its low chemical usage and minimal operations and maintenance needs.

EXHIBIT ES-2
Comparison of Capital Costs for All Treatment Trains



Note: Capital cost presented includes cost of improvements recommended in the Stress Testing Report ($64.6 million). Total plant flow includes flow from both the conventional plant and the wet weather treatment facility.

EXHIBIT ES-3
Comparison of Capital Cost Effectiveness for all Treatment Trains

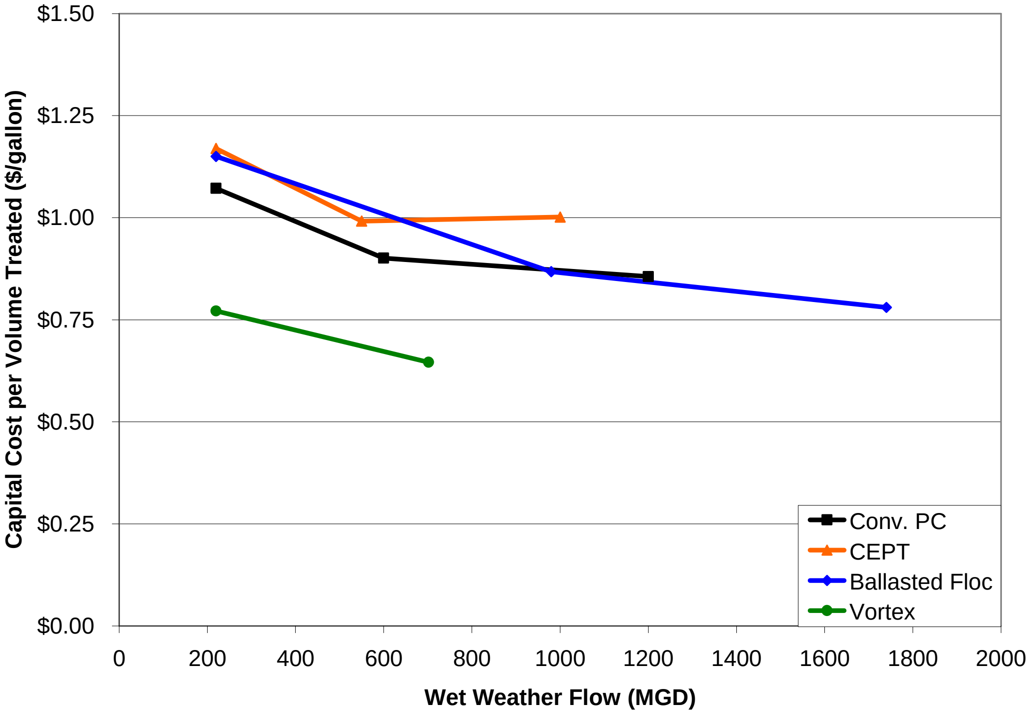


EXHIBIT ES-4
Comparison of Operations and Maintenance Costs for all Treatment Trains

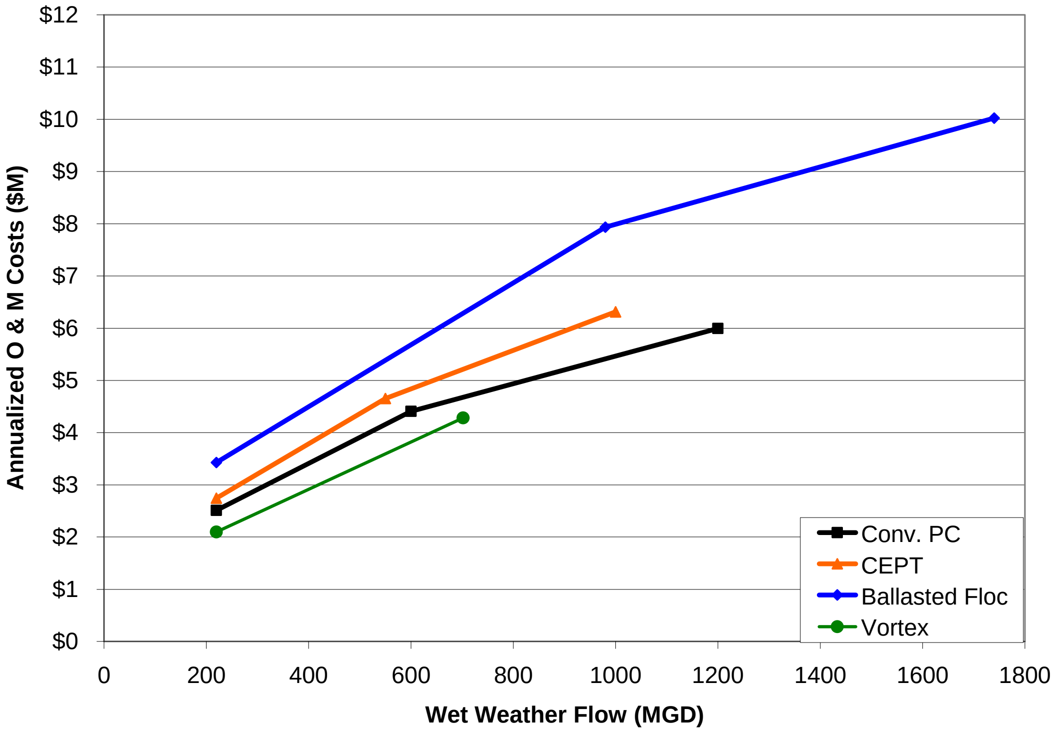

EXHIBIT ES-5
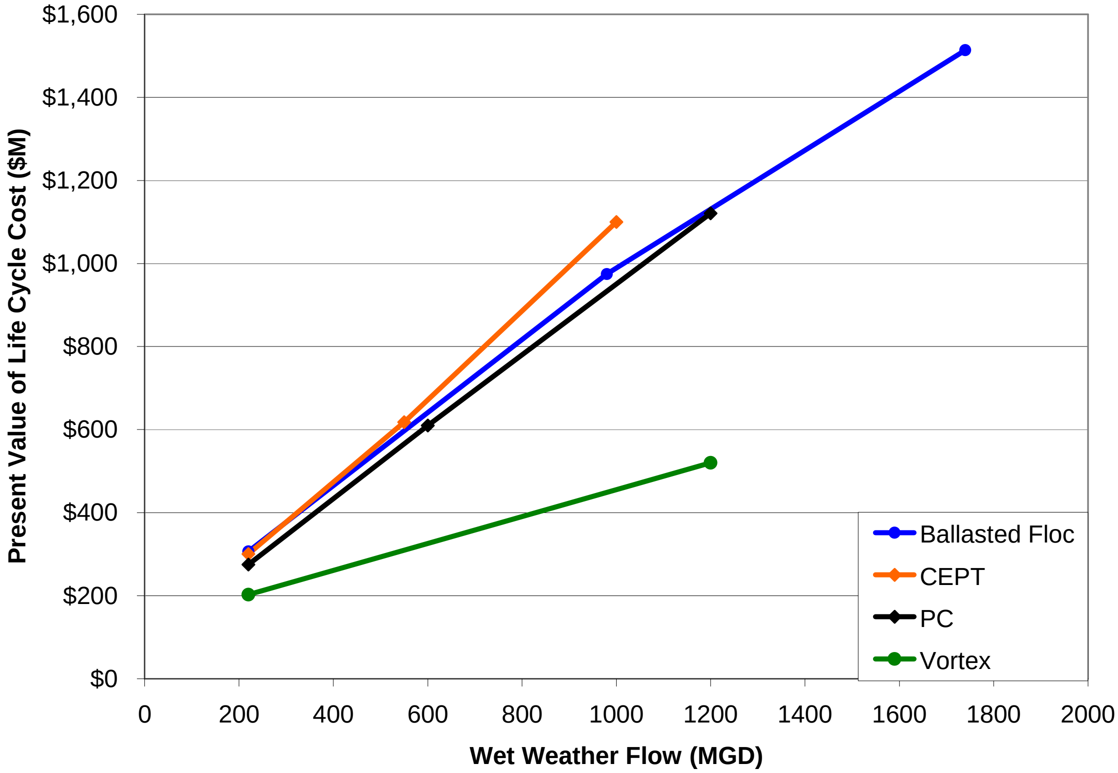
Comparison of Life-Cycle Costs for all Treatment Trains



Overall Comparison

Aside from capital, O&M, and lifecycle costs, there are numerous other criteria by which the treatment trains should be evaluated, including system reliability, community impacts, the ability to handle large variations in flow, land requirements, constructability, requirements for maintenance and operator attention, and sustainability. The main advantages and disadvantages for Treatment Trains #1 - #4, as evaluated in this report, are described in Exhibit ES-6.

EXHIBIT ES-6
Summary of Pros and Cons for Each Wet Weather Treatment Train

Treatment Train	Pros	Cons
Train #1: Vortex/Swirl Concentrators	• Simple operation • Low maintenance requirements – no moving parts	• Maximum design flow may decrease if the assumed number of operating days per month is greater than 7. • Unless operated at lower loading rates, removal efficiency may not be high enough to operate alone without blending effluent with main plant effluent.

EXHIBIT ES-6
Summary of Pros and Cons for Each Wet Weather Treatment Train

Treatment Train	Pros	Cons
Train #2: Conventional Clarifiers	• Simple operation • Same technology as existing plant –operators familiar with equipment	• Space limited • Maximum design flow may decrease if the assumed number of operating days is greater than 9 per month.
Train #3: CEPT	• Lower chlorine dose possible due to high TSS removal efficiencies • May be operated as Conventional Clarifiers if chemicals found to be unnecessary	• Operators unfamiliar with technology • Space limited • Can treat less flow on land available than conventional clarifiers • Uses two additional chemical systems for coagulation and flocculation
Train #4: Ballasted Flocculation	• Can treat up to 1740 mgd with available land on site • Highest removal efficiencies • Unlimited number of operating days per month • Lower chlorine dose possible due to high TSS removal efficiencies	• Operators unfamiliar with technology • Most labor intensive and complex system • Uses two additional chemical systems for coagulation and flocculation

The costs for wet weather treatment at the SW WPCP should be analyzed with the costs of other wet weather treatment alternatives, such as improvements in the collection system, to determine which treatment train alternatives and flow regimes should be evaluated further. Treatment trains that are selected for further evaluation should undergo more detailed design and costing methods, water quality sampling, and bench and pilot scale testing, so that removal efficiencies, land requirements, capital costs, and O&M costs can be further refined.

1.0 Introduction

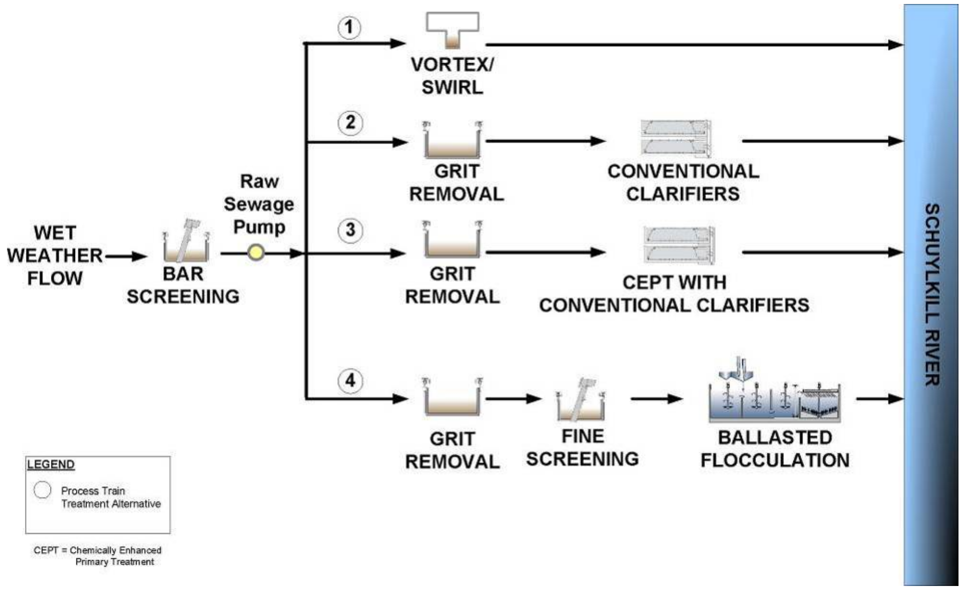
As part of the series of memoranda prepared for the Philadelphia Water Department's (PWD) Combined Sewer Overflow (CSO) Long Term Control Plan (LTCP) update, this report presents the conceptual design and cost analyses for four wet weather treatment alternatives for the Southeast Water Pollution Control Plant (SW WPCP). These treatment alternatives were short listed from previous evaluations by the LTCP team (PWD, CDM, and CH2M HILL) based on information from: water quality data analysis and review of available land for SW WPCP; survey of various potential wet weather treatment technologies; and site visits to three existing wet weather treatment facilities in Ohio (CH2M HILL, 2008b). A treatment train utilizing CEPT with Plate Settlers was evaluated for the Southeast WPCP, but was subsequently eliminated due to its extremely high cost (CH2M HILL, 2008c).

The wet weather treatment technologies for the SW WPCP evaluated in this report are as follows:

1. Vortex Swirl Concentrators
2. Conventional Clarifiers
3. Chemically Enhanced Primary Treatment (CEPT) with Conventional Clarifiers
4. Ballasted Flocculation (includes fine screening)

Conceptual treatment trains were developed for each treatment technology at various wet weather flows ranging from 220 million gallons per day (mgd) to 1740 mgd (Exhibit 1-1). Cost curves for both capital and operations and maintenance (O&M) costs were generated for each treatment train alternative. This report presents the conceptual design parameters, site layouts, cost estimates, and potential issues of each treatment train alternative.

EXHIBIT 1-1
Schematic View of Treatment Trains Evaluated



2.0 Improvements to Existing Plant

In order to increase the flow capacity of the SW WPCP for wet weather conditions, the potential of maximizing flow through the existing plant was evaluated. From 2004 to 2007, the SW WPCP treated an average daily flow of 193 mgd, a maximum daily flow of 432 mgd, and an instantaneous peak flow of 489 mgd. The maximum plant flow sustained over 12 hours was 466 mgd (CH2M HILL, 2008b).

According to stress testing results and recommendations, the SW WPCP's firm capacity can potentially reach 540 mgd with several process and hydraulic modifications (Exhibit 2-1). The necessary improvements to achieve this flow were identified in the 2001 Stress Testing Report and are based on results of stress tests on unit processes, long-term monitoring of the plant, hydraulic modeling, and input from SW WPCP plant staff (CH2M HILL, 2001).

In sizing the wet weather treatment trains, it was assumed that the upgrades proposed in the Stress Testing Report and identified in Table 2-1 will have been completed, increasing the plant's capacity to a minimum of 540 mgd. Thus, the baseline cost that is used in the wet weather treatment train cost estimates is $64.5 million (Exhibit 2-1). This is reflected in the cost curves for each treatment train, presented in latter sections of the report.

EXHIBIT 2-1
Cost Summary of Potential Improvements for Existing SW WPCP

	Improvement Description	Cost(1)
1	Replace caulking on secondary clarifier launders to improve flow distribution	Complete
2	Provide preliminary treatment for the BRC centrate that is recycled to the plant	$17,585,962
3	Modify existing RAS system in the secondary clarifiers	$8,717,624
4	Provide four gravity thickeners for thickening of primary sludge (tentative location west of the Final Sedimentation Tanks)	$25,165,565
5	Resolve hydraulic limitations between primary clarifiers and aeration basin	$11,121,009
6	Provide an additional effluent pump at the effluent pumping station	$1,981,532
	TOTAL	$64,571,692

(1) Assume escalation factor of 19.8% - based on 9/1/2009 start date and 2-year construction duration.

3.0 New Facility Location

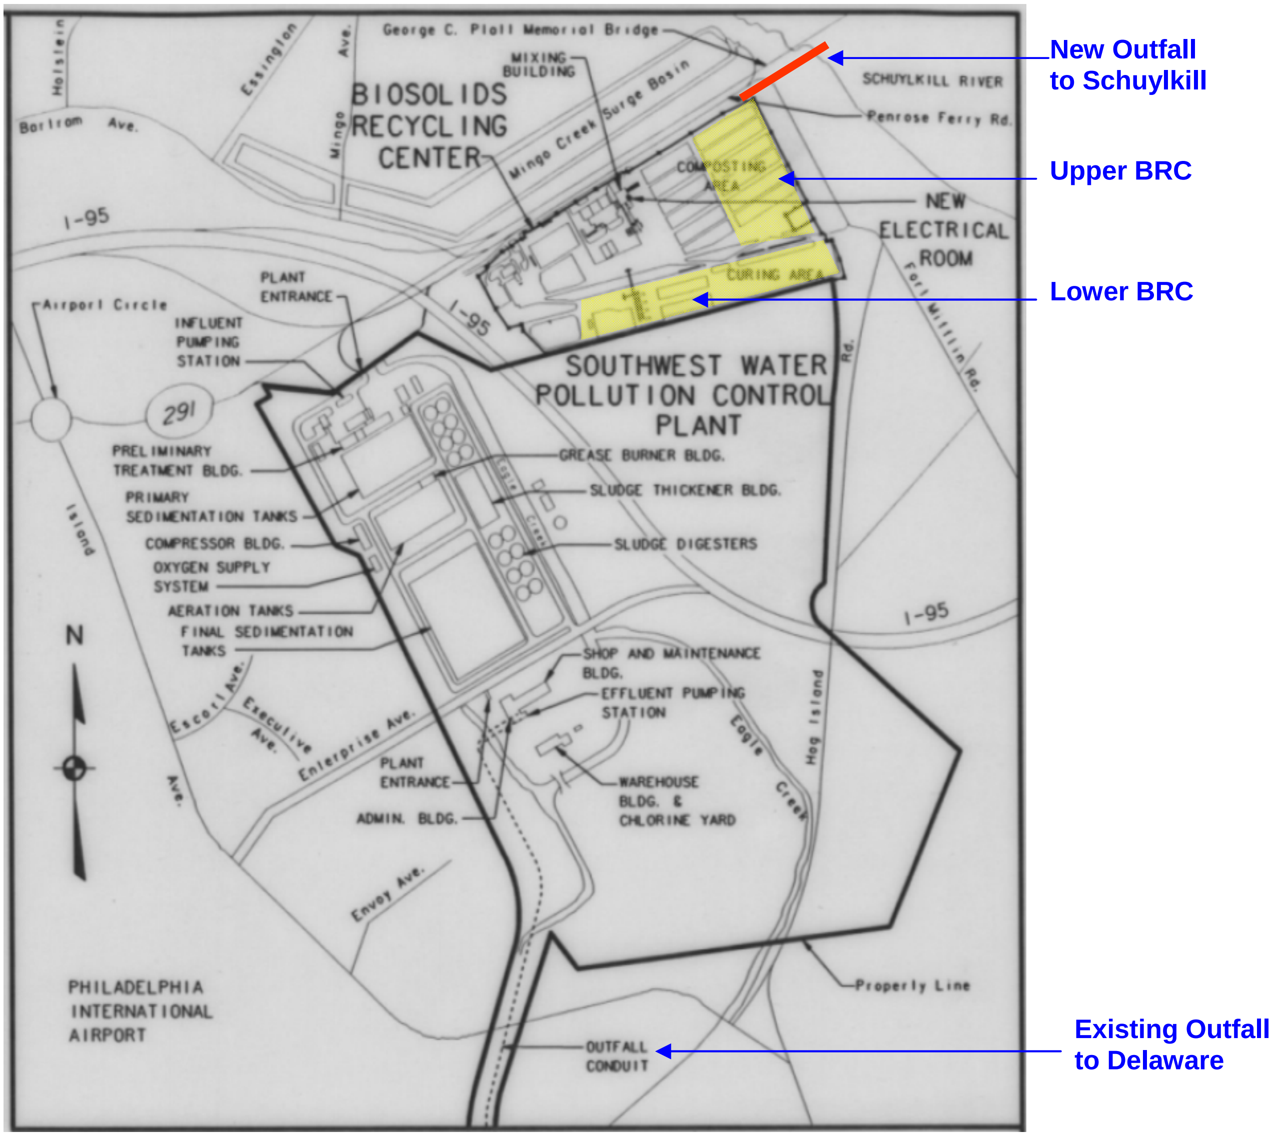
The existing SW WPCP is located east of the Philadelphia International Airport, near the confluence of the Schuylkill and Delaware Rivers. Due to proposed construction activities by both the Federal Aviation Authority (FAA) and the Army Corps of Engineers (ACOE) in the vicinity, the land area available for plant expansion is limited. While the impact of the proposed projects by the FAA and the ACOE is presently undetermined, it was decided that the wet weather treatment facility should be located in an area least likely to be affected by projects proposed by those entities. The area north of the lagoons, currently utilized by the Biosolids Recycling Center (BRC) for composting and curing, was chosen as a suitable location for the new wet weather treatment facility. This L-shaped area is comprised of two tracts of land referred to as the Upper BRC and the Lower BRC (Exhibit 3.1).

3.1 New Outfall to the Schuylkill

The outfall conduit for the existing SW WPCP passes underneath the airport as it runs southward from the plant to the Delaware River. Since it runs under an airport runway on FAA property, the expansion of this existing conduit is considered infeasible. Alternate routes to the Delaware also appear difficult for construction. Given the new wet weather facility's proximity to the Schuylkill River, the most logical alignment for the new outfall conduit is eastward along Penrose Avenue, terminating at the Schuylkill River near the George Platt Memorial Bridge (Figure 3.1).In order to construct a new outfall to the Schuylkill, a new discharge permit will need to be negotiated for the new wet weather treatment facility. Unlike the Southeast and Northeast WPCPs, effluent from the wet weather facility will not commingle with the effluent from the conventional plant. This means that the regulating agencies may view the new facility as a separate wet weather treatment facility, not as an expansion of a WPCP requiring secondary treatment.

If blending of the two plant effluents is required or desired, the outfall for the existing plant could be relocated to the Schuylkill by constructing a new outfall conduit. The cost of this conduit, and thus comingling, is estimated at $155 million. Since the value of comingling is questionable, the cost of this blending option is not included in the cost curves. In terms of plant operation, this report will treat the new wet weather facility as part of the SW WPCP, despite the difference in outfall locations.

EXHIBIT 3-1
New Wet Weather Facility Location for the SW WPCP



4.0 Wet Weather Treatment Alternatives: Evaluation Methodology

As described above, the new wet weather facility for the SW WPCP will be designed to treat all flows that cannot be treated by the conventional plant. As such, wet weather flows in excess of 540 mgd will be diverted to the new facility. The four wet weather treatment trains under evaluation for the new facility are:

1. Vortex Swirl Concentrators
2. Conventional Clarifiers
3. Chemically Enhanced Primary Treatment (CEPT) with Conventional Clarifiers
4. Ballasted Flocculation (includes fine screening)

Conceptual designs and cost estimates were performed for each treatment train at different design flows. This section describes the development of the various design flows and the key assumptions for design and cost estimating.

4.1 Design Flows

The design flows that were selected for evaluation for each treatment train are shown in Exhibit 4-1 and are described below in further detail.

EXHIBIT 4-1
Design Flows Evaluated for each Wet Weather Treatment Train

Treatment Train	Design Flows Evaluated (mgd)
#1) Vortex/Swirl Concentrators	220, 702
#2) Conventional Clarifiers	220, 600, 1200
#3) CEPT w/ Conventional Clarifiers	220, 550, 1000
#4) Ballasted Flocculation	220, 980, 1740

4.1.1 Minimum Design Flow: 220 MGD

The 220 mgd flow point reflects the capacity of the wet weather treatment train required to bring the treatment capacity of SW WPCP to the same level as the existing collection system capacity. In a technical memorandum provided by CDM, it was noted that the existing collection system can deliver 760 mgd to the SW WPCP assuming all process and hydraulic limitations in the plant are removed (Myers, 2007). With the assumption that 540 mgd can be treated by upgrading the existing plant, the new wet weather treatment train will need a minimum capacity of 220 mgd.

4.1.2 Design Flow by Permit Limits: 702 MGD

Unlike the Northeast and Southeast plants, no physical blending of the effluents from the conventional and wet weather plants at SW WPCP will actually occur (Section 2). For the purposes of this evaluation, we have considered the existing plant and its new wet weather facility as one system and have based the maximum allowable system flows on the water quality of the commingled flow. This allows for the determination of the maximum allowable flow through each wet weather treatment train for the system to continue meeting NPDES permit limits for weekly and monthly TSS and cBOD concentrations (Exhibit 4-2, CH2M HILL, 2008b).

With the exception of the Vortex/Swirl train, the flows through the candidate wet weather treatment trains were unlimited by permit requirements, assuming that the wet weather treatment facility operates for no more than seven days per month. The maximum allowable flow through the Vortex/Swirl train is 702 mgd. The maximum flows for the "unlimited" trains are bounded by other conditions as described in Sections 4.1.4 and 4.1.5.

It should be noted that if PWD were to negotiate a new discharge permit to the Schuylkill for the wet weather treatment facility, the maximum allowable flows through each wet weather treatment train would also need to be negotiated. Thus, the flow points analyzed in this report were used for the development of cost curves, but may not reflect what will be allowable under the regulatory framework.

EXHIBIT 4-2
Maximum Allowable Flow of Wet Weather Treatment Trains to Meet NPDES Permit Requirements

Treatment Train	TSS Removal Efficiency[1] (%)	Achievable Effluent TSS Concentration of Wet Weather Train[2] (mg/l)	Maximum Allowable Flow Through Wet Weather Train[3] (mgd)
#1) Vortex/Swirl Concentrators	30%	158	702
#2) Conventional Clarifiers	55%	102	Unlimited*
#3) CEPT w/ Conventional Clarifiers	80%	45	Unlimited*
#4) Fine Screening -> Ballasted Floc	91%	21	Unlimited*

*These flows are unlimited assuming the wet weather treatment train operates for no more than seven days per month, an estimate provided by CDM (CH2M HILL, 2008b).

(1) TSS removal efficiencies are based on industry standards. Specific references are provided in TM-SE2 (CH2M HILL, 2008a).

(2) Achievable effluent concentrations based on 95th percentile influent wet weather TSS concentration (226 mg/L)

(3) Maximum flow determined by NPDES Monthly TSS Limit assuming blending between conventional and wet weather plant. The allowable daily "blended" effluent TSS concentration during wet weather was calculated to be 99 mg/L (CH2M HILL, 2008b).

4.1.3 Design Flows by Available Land – Upper BRC: 550 MGD, 600, 980 MGD

While both the Upper and Lower BRC areas are available for the new wet weather facility, the two strips of land are separated by Penrose Ferry Road. To keep both the new wet weather facility and the BRC on the same side of the road, the use of the Upper BRC alone was assessed. It was found that a 550-mgd CEPT facility, a 600-mgd Conventional Clarification facility, or a 980-mgd Ballasted Flocculation could fit on the Upper BRC site alone. The 702-mgd vortex facility described above is also able to fit on this site.

4.1.4 Design Flows by Available Land – Upper and Lower BRC: 1000, 1200 MGD

Making full use of the land available in both the Upper and Lower BRC areas, it was found that either a 1000-mgd CEPT facility or a 1200-mgd Conventional Clarification facility could fit on the entire site.

4.1.5 Maximum Design Flow: 1740 MGD

According to CDM's assumptions on the capacity of the upgraded collection system, the collection system capacity for the SW WPCP could reach 2,280 mgd after transmission improvements, equivalent to three times the existing collection system capacity. Assuming the existing plant will be able to handle 540 mgd, the maximum flow to the new wet weather facility will be 1,740 mgd. The maximum design flow point used for the ballasted flocculation was thus 1,740 mgd. This facility will be able to fit on the Upper and Lower BRC areas.

4.2 Key Design Assumptions

4.2.1 Average Design Flow

In the previous section, the design flow capacities were identified for each treatment train based on permit limits, available land area, and collection system capacity. These flows are the peak flows that the wet weather facilities are designed to treat under each scenario.

The average flow that the wet weather facility will receive, however, depends on conditions in the collection system. Preliminary model simulations have been performed for the Southwest Drainage district (SWDD) under several deep tunnel and plant expansion scenarios (CDM, 2008). Simulation results suggest that the average flow delivered to the wet weather facility increases as the capacity of the facility increases, and is not highly sensitive to the volume of storage in the collection system (Exhibit 4-3).

Model runs for a 540-mgd and a 1,080-mgd wet weather facility generated an average flow of 362-mgd and 472-mgd, respectively, assuming the largest storage tunnel scenario. Based on these model results, the maximum average design flow assumed for the new wet weather treatment trains evaluated in this report is 472-mgd. For the Conventional Clarification 600-mgd and the CEPT 550-mgd scenarios, an average flow of 362-mgd was assumed. For trains with peak capacities less than 362 mgd, the average flow is assumed to be equivalent to the peak flow of the facility (Exhibit 4-4).

EXHIBIT 4-3
Average Annual Wet Weather Treatment Rates Under Various Deep Tunnel and Plant Expansion Scenarios

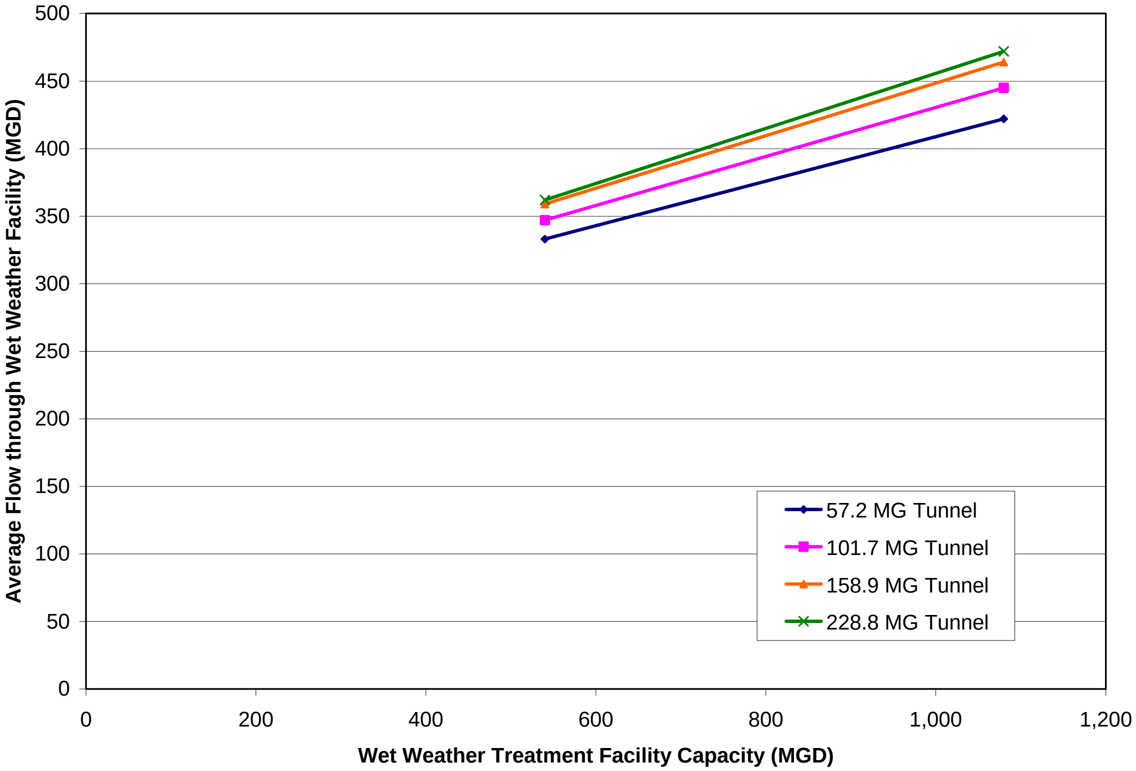


EXHIBIT 4-4
Average Design Flows

Maximum Design Flow (mgd)	Average Design Flow (mgd)
220	220
550, 600	362
980, 1000, 1200, 1740	472

4.2.2 Process

The process design described herein is based on conceptual design parameters and will require refinement as the planning and design efforts progress. For the purposes of developing capital costs, sizing of most facilities was based on maximum design flows. The average design flow, as described above, was used for sizing chemical storage facilities, storage for screenings and grit, and sludge handling facilities.

Preliminary Treatment

Each wet weather train evaluated in this report was sized to treat influent flow in excess of the plant's flow capacity of 540 mgd. A new influent conduit will divert excess wet weather flow to the new preliminary treatment building (PTB) of the wet weather treatment facility. The new PTB will contain an influent wet well at a similar elevation to the existing wet well, bar screens, influent pumps, and screenings and grit handling systems. The influent pumps were designed to increase the hydraulic grade line so that the wet weather flow can discharge to the river outfall by gravity from the wet weather treatment facilities. The screenings and grit handling systems include screenings washers and compactors, as well as grit concentrators and classifiers. This system will handle screenings from both the bar screens and the fine screens when required.

From the PTB, the wet weather flow will continue on to further treatment through processes dependent on each treatment train. These are described in further detail in Sections 5 through 8.

Disinfection

The final process of all treatment trains is chlorination and dechlorination. The wet weather flow will be dosed with sodium hypochlorite at the head of the new chlorine contact chamber. For all facilities with capacities of 600-mgd or less, the chlorine contact chamber is sized to provide a 20-minute detention time at peak flow. For facilities with higher capacities, the chamber is sized for a 10-minute detention time at peak flow, and it is assumed that the chlorine dosage will be increased correspondingly to provide adequate disinfection. Sodium bisulfite is then used for dechlorination at the end of the chlorine contact chamber. A new 700-ft long outfall conduit will convey the treated effluent to the Schuylkill River.

Chemical Feed

For CEPT and Ballasted Flocculation, which provide chemically-enhanced clarification, a coagulant and flocculant are added as settling aids. For CEPT, Train #3, these chemicals are added to a rapid mixer and flocculation basin upstream of the sedimentation tank. In the ballasted flocculation, Train #4, the settling aids are added to mixing zones that are part of the ballasted flocculation unit.

Ferric chloride was selected as the coagulant for all trains since it is currently used at PWD's water treatment plants. However, if there are concerns with the iron affecting the digestion process downstream, aluminum sulfate (alum) can be used as a substitute. Liquid polymer is used as the flocculant for all trains.

Ten-day storage at average flow was assumed for all chemicals.

Sludge Handling

Primary sludge from all treatment trains is pumped to gravity thickeners, where the solids concentration is expected to increase to a minimum of 3 percent. The thickeners are sized to handle the average wet weather flow (as presented in Exhibit 4-4) with a 95 percentile influent solids concentration (226 mg/L) for a continuous period of 24 hours.

The thickened sludge will be pumped to the plant's digesters for treatment. The sludge will be screened through StrainPress® sludge cleaners to remove inert solids before entering the digesters. Capital costs for each treatment train include the cost of extra digesters that may be required at the SW WPCP, assuming a maximum of seven wet weather days in one month. The digesters were sized to provide 20-day storage for solids, assuming average flow, a 95 percentile influent solids concentration (226 mg/L), an average wet weather event duration of five hours, and five events in 20 days. The new digesters will be located in the vacant area south of the existing digesters at the SW WPCP. The digesters needed for the SE WPCP wet weather facility will also be located in this area.

The design parameters that were assumed for all the treatment train processes are summarized in Exhibit 4-5. The process flows are described in further detail in each of the treatment train sections.

EXHIBIT 4-5
Key Process Design Assumptions for Wet Weather Treatment Trains(1)

Preliminary Treatment			
Bar Screens	Opening Size	15	mm (0.59 in)
	Screenings Production(2)	3.5	cf/mg
Influent Pumps	Type	Vertical End-Suction	
	Total Dynamic Head (TDH)	60	ft (match SW WPCP wet well elevations)
Fine Screens	Opening Size	6	mm (0.24 in)
	Screenings Production(2)	2.5	cf/mg
	Screenings Compaction Factor	2	
Grit Removal	Type	Vortex Grit Unit	
	Grit Production(2)	4	cf/mg
Screenings and Grit	Number of Days Storage	1	day
Primary Clarifiers	Type	Rectangular Basin	
	Sludge Collection Mechanism	Chain-and-flight	
Flocculation Tank	Detention Time (at max flow)	10	min
	Number of Stages	3	
Wet Weather Treatment Technology	**Surface Overflow Rate (gpd/sf)**		
Vortex/Swirl	36,000 (25 gpm/sf)		
Conventional Clarifiers	2,400 (3)		
CEPT	3,000		
Ballasted Flocculation	84,600 (60 gpm/sf)		
Chlorine Contact			

EXHIBIT 4-5
Key Process Design Assumptions for Wet Weather Treatment Trains(1)

Chlorine Contact Chamber	Detention Time (at avg flow)	20	min

Chemical Feed

Chemical	Purpose	Concentration	Storage (at avg flow)
Ferric Chloride	Coagulation	60 mg/L	10 days
Liquid Polymer	Flocculation	2 mg/L	10 days
Sodium Hypochlorite	Chlorination	5 mg/L	10 days
Sodium Bisulfite	De-chlorination	1.5 mg/L(4)	10 days

Primary Sludge Generation(5)

Train	% TSS Removal	% Solids in Sludge
#1: Vortex/Swirl	30%	0.07%(6)
#2: Conventional Clarifiers	55%	0.5%
#3: CEPT	80%	0.5%
#4: Ballasted Floc	90%	0.3%

Sludge Thickening

Gravity Thickeners	Max Hydraulic Loading Rate (limiting factor for Trains #1 and #5)	900	gal/sf/day
	Max Solids Loading Rate (limiting factor for Trains #2, #3, and #4))	30.7	lb/sf/day
	% Solids of Thickened Sludge	3	% minimum
StrainPress® Sludge Screens	Sludge Throughput	200 – 400	gpm

Digesters

Anaerobic Digesters	Detention Time	20	days
	Diameter	115	ft
	Side Water Depth	25	ft
	Volatile Solids Destruction	50	%

(1) Unless otherwise noted, all design parameters are based on standard textbook values.

(2) Estimated from 2004-2005 grit and screenings disposal records from the SE WPCP (CH2M HILL, 2008c).

(3) Based on stress testing results on existing primary clarifiers

(4) Assumes 1 mg/L residual chlorine concentration at the end of the chlorine contact chamber

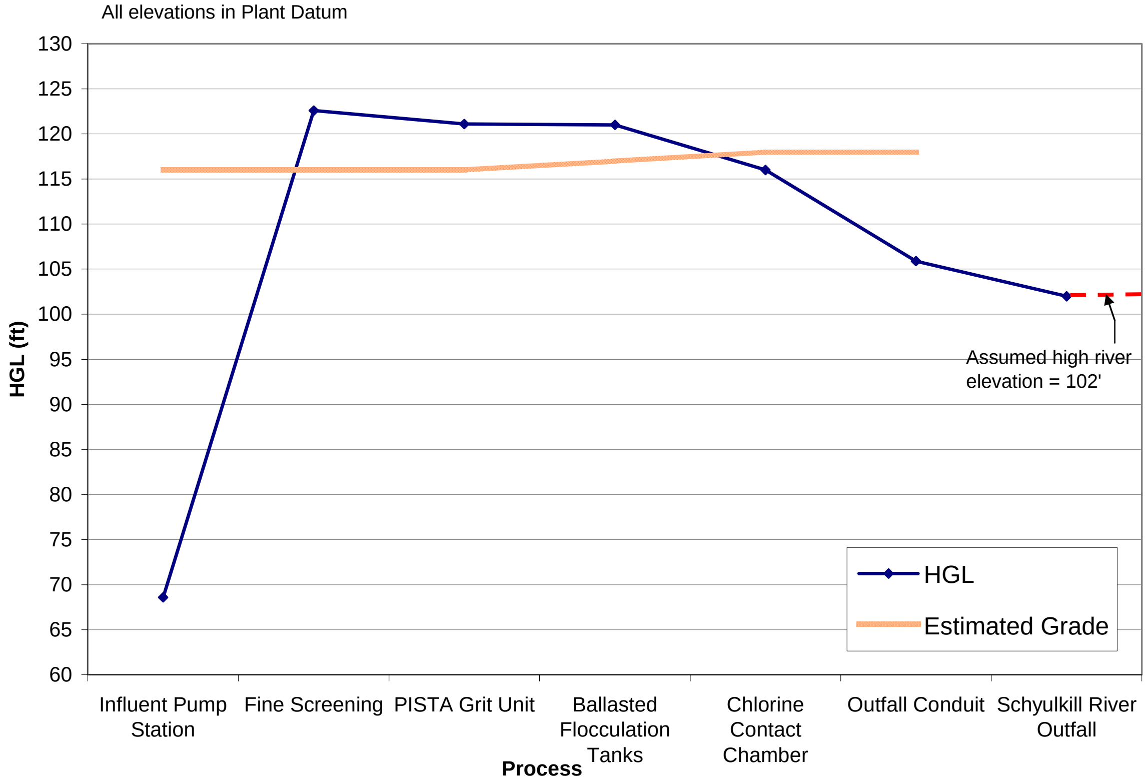
(5) Assumes 95 percentile influent TSS concentration of 226 mg/L, and volatile solids percentage of 70%

(6) Based on a 10% underflow from the vortex/swirl concentrator

4.2.3 Hydraulics

To eliminate the need for a new effluent pump station, the elevations of the new wet weather treatment trains were set to allow gravity flow to the new Schuylkill River outfall. A preliminary hydraulic profile for the ballasted flocculation train at 980 mgd is shown in Exhibit 4-6.

EXHIBIT 4-6
Preliminary Hydraulic Gradeline for the Ballasted Flocculation Treatment Train at 980 MGD



As an initial condition, the high river elevation was assumed to be 102 feet. This is similar to the assumption made for the Delaware River in the Southeast WPCP memo (CH2M HILL, 2008c). It is also based on the assumption that the Schuylkill River levels and the Delaware River levels are equal at their point of confluence.

The water surface level of the chlorine contact chamber was assumed to be 2 feet below grade (116 feet). Since the ground elevation at the Upper BRC site is much higher than the maximum river level, there is an approximate 10-ft drop between the chlorine contact chamber and the beginning of the outfall conduit. Headloss through the outfall conduit is estimated at 3.9 ft (using Manning's Equation).

The elevation of the chlorine contact chamber sets the elevations of the upstream unit processes. As shown in Exhibit 4-6, the tank walls may rise above grade by several feet. To be conservative, however, the capital cost estimates assume complete burial of all tanks.

4.2.4 Site Conditions

Two main assumptions were made on the site and soil conditions at the Upper and Lower BRC sites:

- Piles will be needed for foundations of all structures. A pile density and depth of 0.069 piles/sf and 30 feet were used for all water-bearing structures on site. A pile density and depth of 0.089 piles/sf and 50 feet were used for the outfall conduit going out to the Schuylkill River. These numbers were based on existing pile plans for the Northeast WPCP, since there are no similar structures at the existing BRC (CH2M HILL, 2008d). A pile density and depth of 0.0006 piles/sf and 30 feet were used for all other structures, based on drawings of the existing sludge dewatering facility at the BRC.
- Dewatering will be required for most buried structures. According to plant drawings, the groundwater elevation is approximately 10 to 15 feet below grade at the SW WPCP.

4.3 Cost Estimating Assumptions

CH2M HILL's costing model was used to develop conceptual level estimates of both capital and life-cycle costs for each of the treatment trains and flows. This tool was supplemented by budgetary quotes from vendors for all major pieces of equipment. These estimates are defined as Class 4 estimates by the Association for the Advancement of Cost Engineers (AACE) and have an expected level of accuracy of +50 to -30 percent.

4.3.1 Capital Costs

Construction Costs

Construction costs were developed using the costing model for each building or unit process of a treatment train, and were based on estimated materials, labor, equipment, and installation costs. Contractor markups applied to the construction subtotal costs are presented in Exhibit 4-7. The percentages used are industry standards and are in agreement with CDM's assumptions. The escalation factors applied are based on a construction start-date of September 1, 2009, and the estimated construction duration of each scenario (Exhibit 4-8). This start-date was chosen since PWD's LTCP Update must be submitted by this date. A location adjustment factor of 15.2 percent was applied to the escalated construction cost, which is in agreement with the ENR 20-city Construction Cost Index (CCI).

Lastly, a market adjustment factor of 15 percent was applied to account for: busy contractors; contractors selectively bidding jobs; contractors selectively choosing which Owners they want to do jobs for; premium wages to keep skilled workers and management staff; availability of crafts/trades; immigration impacts and uncertainty; abnormal fuel impacts and uncertainty; and abnormal material impacts of the last two years.

EXHIBIT 4-7
Contractor Markups Assumed in Capital Cost Estimates

Contractor Markups	%	Applied to:
Overhead (OH)	10%	Subtotal of Construction Cost
Profit (P)	5%	Subtotal of Construction Cost + OH
Mobilization, Bonds, and Insurance (MOB)	5%	Subtotal of Construction Cost + OH&P
Contingency	25%	Subtotal of Construction Cost + OH&P + MOB

EXHIBIT 4-8
Escalation Factors for Various Construction Scenarios

Flow Capacity of Wet Weather Treatment Train (mgd)	Estimated Construction Duration (months)(1)	Escalation Factor(2)
220	27	21.2%
550, 600, 702	36	23.9%
980, 1000, 1200, 1740	48	28.2%

(1) Escalation factors are based on mid-point of construction with a construction start-date of 9/1/2009.

(2) Construction durations were estimated based on facilities of similar size, and need to be refined through each stage of design.

Non-Construction Costs

A factor of 30 percent was applied to the total construction costs to estimate non-construction costs related to the project. The breakdown of these factors is shown in Exhibit 4-9.

EXHIBIT 4-9
Non-Construction Cost Factors

Non-Construction Expenditure	Factor*
Permitting	2%
Engineering	10%
Services During Construction	10%
Commissioning and Startup	3%
Legal/Administration	5%

*Each factor was applied to the total construction cost of the project, including all markups and escalation.

4.3.2 O&M and Life Cycle Cost Analysis

Life cycle and O&M costs of each treatment train at each flow were also estimated using CH2M HILL's costing model and were based on financial and operational assumptions as listed in Exhibit 4-9. The O&M costs cover labor, power for equipment and buildings, chemicals, and repair, maintenance and replacement of structures and equipment. The average flows that were assumed for the O&M costs are shown in Exhibit 4-4, as described in Section 4.2.1.

The additional labor required for each treatment train is dependent on the flow capacity of the train, as shown in Exhibit 4-11. It was assumed that new maintenance workers and operators would be hired for the new wet weather facility, working full time throughout the year. For some flow scenarios, it was assumed that a portion of the labor requirements during wet weather events could be met by increasing the number of shifts for existing operators, who would work overtime at a rate of 1.5 times their normal wage. It was assumed that the operators on overtime would work one 8-hour shift per wet weather event.

A detailed break down of the O&M costs and the energy requirements for each train are presented in Attachment SW-2.1. It should be noted that all O&M costs presented for the treatment trains are annualized O&M costs that include escalation over the 30-year period.

Life cycle costs were calculated using the total capital cost, including construction and non-construction costs, and O&M costs. The present value of the life cycle costs are presented in the cost summary section of each train.

EXHIBIT 4-10
Assumed Factors for Life Cycle Cost Estimates

Factor	Value	
Financial		
Annual Discount Rate	4.875	%
Life-Cycle Calculation Period	30	Years
Inflation Rate	4	%(1)
Operation		
Days of operation of wet weather treatment train	48	days(2)
Duration of wet weather event	5	Hours(2)
Labor		
Hourly wage for plant operator	$50.44	including fringe benefits
Hourly wage for plant operator on overtime	$75.65	including fringe benefits
Hourly wage for maintenance worker	$52.35	including fringe benefits
Fringe benefits and overhead multiplier	2.7	applied on top of raw hourly rate
Number of working hours for full time operators at wet weather facility	2,080	hours per year per operator
Number of working hours for operators on overtime at wet weather facility	408	hours per year per operator (16 hours per event)
Number of working hours for maintenance workers at wet weather facility	2,080	hours per year per worker

EXHIBIT 4-10
Assumed Factors for Life Cycle Cost Estimates

Factor	Value	
Power for Buildings		
Building Electrical Cost Assumed	$0.10	$/kwh
Building Electrical Requirements	2	watts/sf of building area
Building Heating Requirements	1.2	BTU/hr/surface area of building
Natural gas cost assumed	$14	per MBTU
Power for Equipment(3)	$0.10	$/kwh
Chemicals(4)		
Ferric Chloride	$310	$/dry ton
Liquid Polymer	$3983	$/dry ton
Sodium Hypochlorite	$1450	$/dry ton
Sodium Bisulfite	$1000	$/dry ton
Repair, Maintenance, and Replacement		
	Percentage assumed for annual O&M cost	
Finishes	2%	of finishes cost during construction
Equipment	1%	of capital cost of equipment
Instrumentation and Controls	5%	of capital cost of I&C
Mechanical	0.1%	of capital cost of mechanical work (incl. valves)
Electrical	1%	of capital cost of electrical equipment
Disposal		
Grit and Screenings Disposal and Hauling Costs	$100	per cubic yard
Final Sludge Disposal Costs(5)	$75	per wet ton
Other		
Other O&M Costs (including vehicles, lab tests, office equipment and other miscellaneous costs)	$10,000	per additional full-time operator and maintenance worker
Contingency		
Contingency applied to O&M costs	20	%

(1) Based on CCI Index

(2) Based on hydraulic model simulations for the SW WPCP (CDM, 2008).

(3) Equipment power costs estimated by PWD.

(4) Based on existing costs at the plant (McKeon, 2008)

(5) Final sludge mass assumes 30% dewatered cake.

EXHIBIT 4-11
Additional Labor Requirements for each Flow Scenario

Treatment Train Flow Capacity	Number of Additional Full-Time Operators(1)	Number of Existing Operators on Overtime(2)	Number of Additional Maintenance Workers(1)
220	1	1	2
550, 600, 702	2	0	4
980, 1000, 1200	2	1	4
1740	2	3	4

(1) Full-time operators and maintenance workers are new hires who work 2080 hours per year. Maintenance workers include different trades required for the facility (e.g. electricians, instrument technicians, mechanics, etc..)

(2) Existing operators on overtime work 8 hours per wet weather event, or 408 hours per year.

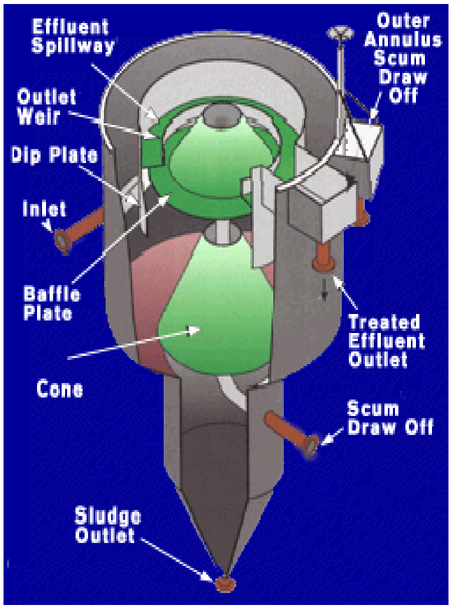
5.0 Treatment Train #1- Vortex/Swirl Concentrators

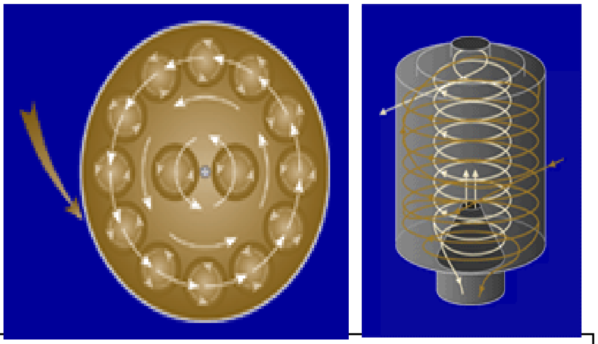
5.1 Process Flow Diagram

The first treatment train under evaluation utilizes the vortex separation technology as its main treatment process. After passing through bar screens and influent pumping at the PTB, the wet weather flow will enter the primary vortex/swirl concentrators. Vortex/swirl concentrators are flow-through structures with no moving parts. The wet weather flow enters the cylindrical structure tangentially, producing a swirling motion that concentrates the solids in the center (Exhibit 5-1). An underflow drain in the center of the unit continually draws the solid materials out of the flow.

The treated effluent flows out of the top of the vessel, continuing on to the chlorine contact chamber. The solids underflow, typically 10 percent of the influent, undergoes grit removal through a vortex grit unit before settling and thickening in gravity thickeners. The conceptual process flow diagram for this treatment train is shown in Exhibit 5-2.

EXHIBIT 5-1
Diagrammatic Cutaway of Vortex/Swirl Device
(Storm King®, H.I.L. Technologies)





Flow Pattern Plan and Profile Views (H.I.L. Technologies)
The flow in vortex/swirl devices initially follows a path around the perimeter of the unit and is then directed into an inner swirl pattern with a lower velocity than the outer swirl. Solids separation is achieved by both centrifugal force and gravity because of the long flow path and inertial separation due to the circular flow pattern. The concentrated underflow passes through an outlet in the bottom of the vessel while the treated effluent flows out of the top of the vessel.

5.2 Conceptual Design and Site Layouts

The main design parameters for each flow scenario of this treatment train are shown in Exhibit 5-2. A conceptual site layout for the maximum flow scenario of 702 mgd is shown in Exhibit 5-3. The conceptual design in this report is based on a loading rate on the vortex/swirls of approximately 25 gpm/sf, providing an estimated removal efficiency of 30 percent.

As Exhibit 5-3 shows, a 702-mgd facility does not fully occupy the Upper BRC area, and does not utilize the Lower BRC area at all. This provides the option of designing vortex swirls with lower loading rates in order to achieve high removals. According to a study performed in Columbus, Georgia, the vortex swirl can achieve removal efficiencies of up to 70 percent at a 5 gpm/sf loading rate (WERF, 2003). This option may be considered if regulating agencies require removal efficiencies equivalent to that of primary treatment for the new wet weather facility.

5.3 Operational and Technology-Specific Issues

The effectiveness of vortex/swirl concentrators greatly depends on the hydraulic loading rate on the unit and the characteristics of the solids entering the unit. The optimal loading rate must be determined through pilot or operational testing. In order to operate the vortex/swirl at its optimal operating rate or “sweet spot”, the vortex/swirl units can be brought online one by one as the influent flow increases. Alternatively, an equalization basin can be constructed to maintain a specific flow-rate into the units. An equalization basin was not included in the cost estimates, but conservative hydraulic loading rates were assumed for facility sizing.

5.3.1 Startup and Shutdown

The pretreatment processes (bar screens, influent pumps, and grit removal) can be brought online quickly at the start of a wet weather event. Vortex/ swirl concentrators would be empty at the start of a wet weather event. At small flows, the wet weather flow will exit through the underflow. As flows increase, the vessel will fill due to the increased hydraulic load and begin discharging treated effluent to the outfall.

During shutdown, the vortex/swirl and grit units will be emptied by pumping from the underflow sections to SW WPCP’s existing influent wet well. The influent wet well in the new PTB would also be pumped down to the plant’s existing wet well using dewatering pumps (Exhibit 5-2).

For long term shutdown, the chlorine contact chamber could be pumped down, with the flow recycled to the head of the main plant.

5.3.2 Interaction with Main Plant

The waste streams generated by the screenings washer/compactor and the grit classifiers are sent to the gravity thickeners of the wet weather treatment train and will not affect the main plant.

The overflow from the gravity thickeners is conveyed to the head of the entire plant. The estimated overflow range from wet weather thickeners only ranges from 21 to 69 mgd, depending on the size of the plant. To minimize the effect of this volume, the overflow is recycled back to both the main plant and the wet weather facility so that it can be distributed across all units in operation.

5.3.3 Impact on plant operations

Since the vortex/swirl unit has no moving parts, it is expected to have little operations and maintenance requirements. However, operators' attention may be necessary to monitor the hydraulic loading rates into the vortex/swirls to ensure that the "sweet spot" is maintained. The treatment train also includes grit pumps, concentrators, and classifiers, as well as sludge pumps and other equipment, all of which require maintenance. In addition, the new chemical building will include storage of sodium hypochlorite and bisulfite, which are fed to the new chorine contact chamber. Storage of hypochlorite will need to be monitored, since it degrades over time. In addition, the hypochlorite feed-lines should be flushed or degassed periodically.

5.4 Cost Analyses

The estimated capital, O&M, and lifecycle costs for each flow scenario are presented in Exhibit 5-4. Total capital costs and the capital costs per volume treated for all scenarios are shown in Exhibits 5-5. The estimated O&M costs by category are also presented in Exhibits 5-6. A more detailed breakdown of these costs is presented in Attachment SW-2.1.

EXHIBIT 5-4
Cost Summary for Vortex/Swirl Treatment Train #1

	Wet Weather Flow (mgd)	
Cost	**220**	**702**
Capital Cost ($M)	$170	$453
Annual Operations and Maintenance Cost ($M)	$2.1	$4.3
Present Value of the Cost ($M)	$202	$520

Capital Costs per Gallon Treated for Treatment Train #1: Vortex/Swirl

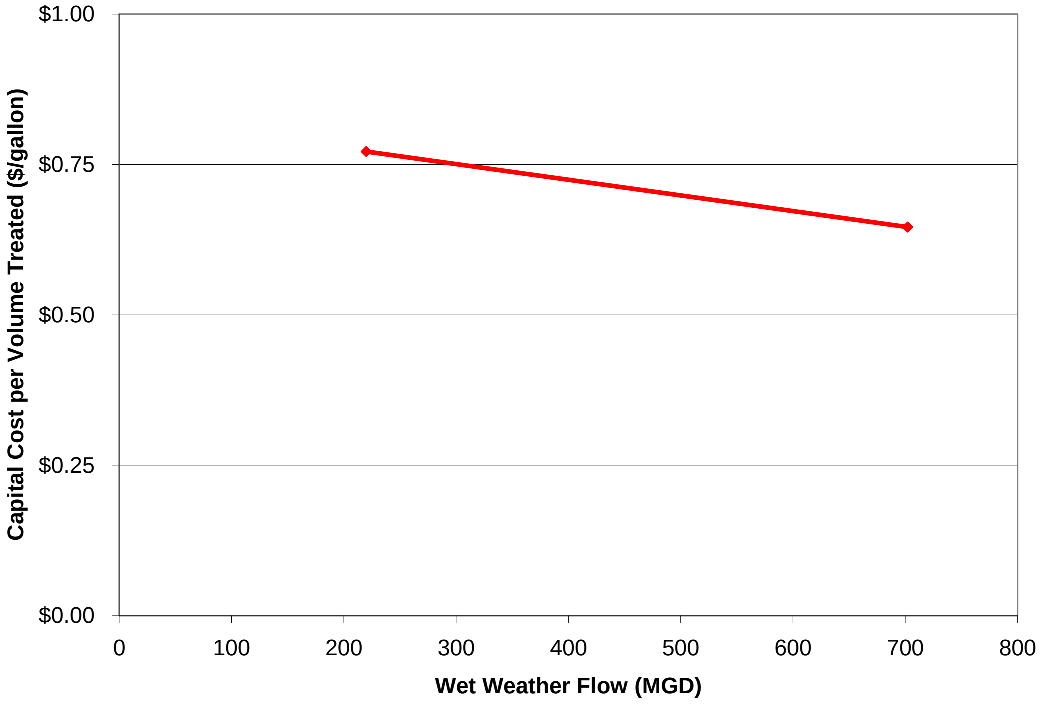

EXHIBIT 5-7
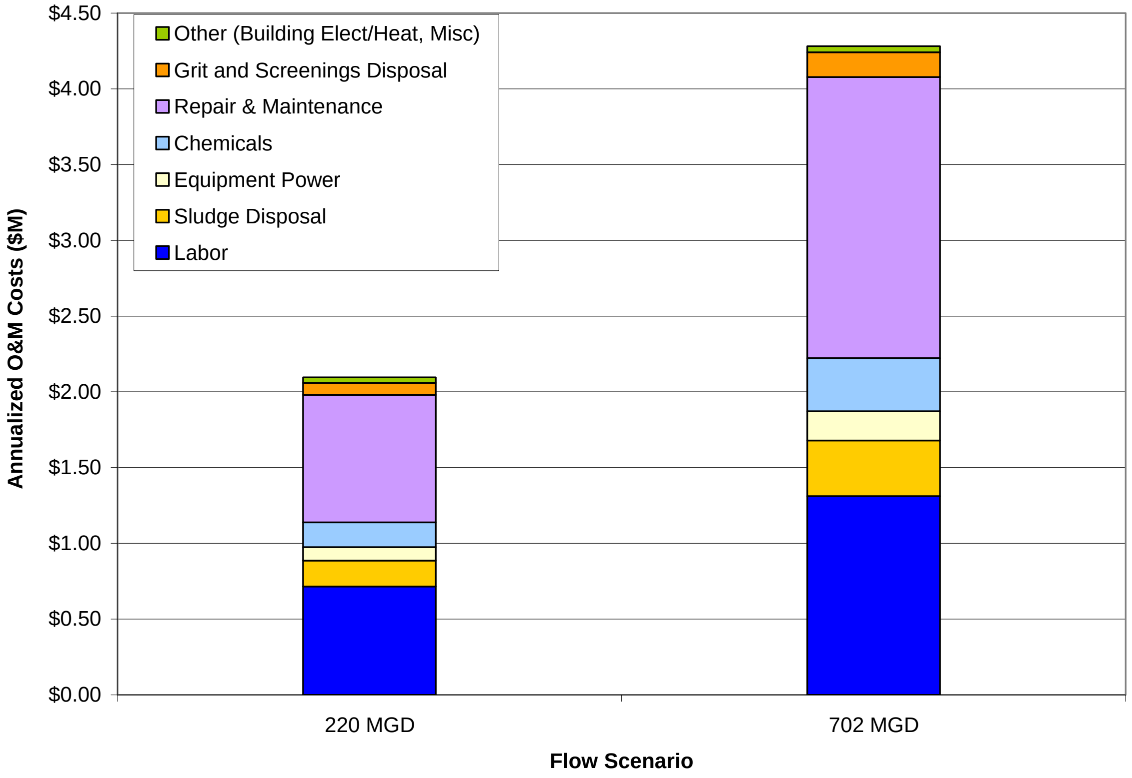
Operations and Maintenance by Category for Treatment Train #1: Vortex/Swirl



6.0 Treatment Train #2 - Conventional Clarifiers

6.1 Process Flow Diagram

Through treatment train #2, the wet weather flow undergoes essentially the same level of primary treatment as the flow through the existing SW WPCP. After preliminary treatment through the bar screens and grit removal, the wet weather flow passes through conventional primary clarifiers at a maximum loading rate of 2400 gpd/sf. This is the overflow rate achievable by the plant's existing primary clarifiers, as shown through stress testing (CH2M HILL, 2001). Primary sludge is collected by chain and flights in the clarifier tanks and is pumped to the gravity thickeners for thickening. The process flow diagram for this treatment train is shown in Exhibit 6-1.

6.2 Conceptual Design and Site Layouts

Conceptual designs were developed at three different flow scenarios for this train: 220, 600, and 1200 mgd. Key design parameters at these flows are shown in Exhibit 6-1. The conceptual layouts for the 600 and 1200 mgd scenarios are shown in Exhibit 6-2. The 600-mgd facility can fit on the Upper BRC area only, and the 1200-mgd facility utilizes the entire Upper and Lower BRC areas available.

6.3 Operational and Technology-Specific Issues

6.3.1 Startup and Shutdown

When the wet weather facility is initially put into service, it will take 2-3 hours before the conventional clarifiers begin to discharge treated wet weather flow. This is equivalent to the time needed to displace the existing wastewater in the tanks, or to fill the tanks if they are empty.

For shut down, the tanks may be filled with treated effluent, or drained down to the existing plant if freezing becomes an issue.

6.3.2 Interaction with Main Plant

The waste streams generated by the screenings washer/compactor and the grit classifiers are sent to the primary clarifiers of the wet weather treatment train and will not affect the main plant. As with the other treatment trains, the overflow from the gravity thickeners will be conveyed to the head of the entire plant. The estimated overflow from wet weather thickeners only ranges from 4 to 25 mgd, depending on the size of the plant. To minimize the effect of this volume, the overflow is recycled back to the head of the entire plant so that it can be distributed across all units in operation.

6.3.3 Impact on Plant Operations

The operations and maintenance requirements for this treatment train should be similar to those needed for corresponding processes at the existing plant.

6.4 Cost Analyses

The estimated capital, O&M, and lifecycle costs for each flow scenario are shown in Exhibit 6-3. Total capital costs and the capital costs per volume treated are also shown in Exhibits 6-4 and 6-5. Estimated O&M costs by category are presented in Exhibit 6-6. A more detailed breakdown of these costs is presented in Attachment SW-2.1.

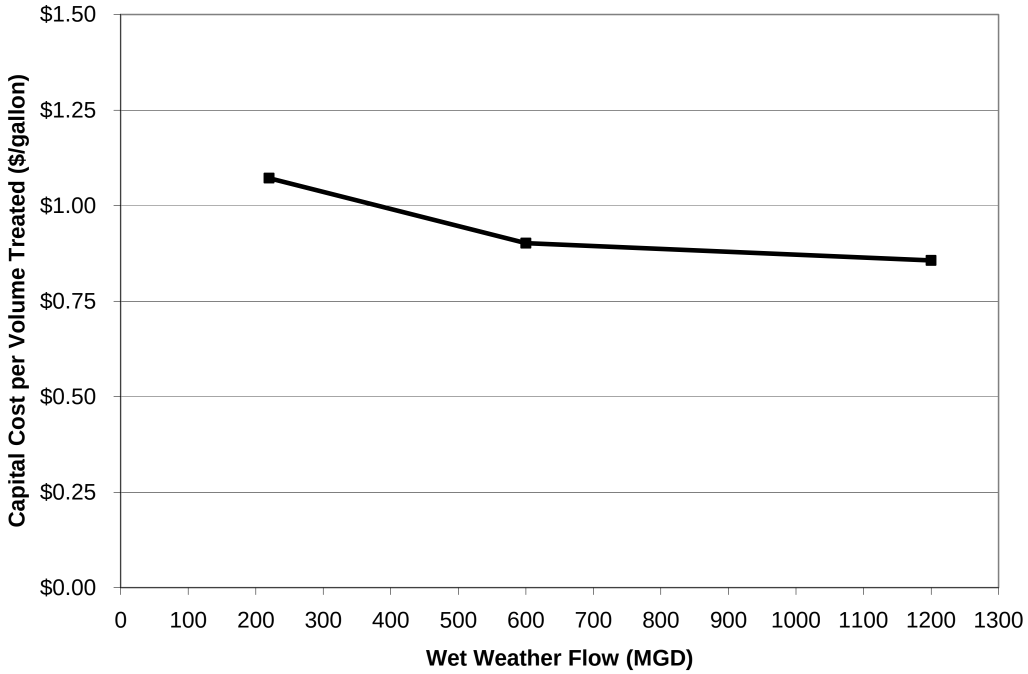

EXHIBIT 6-6
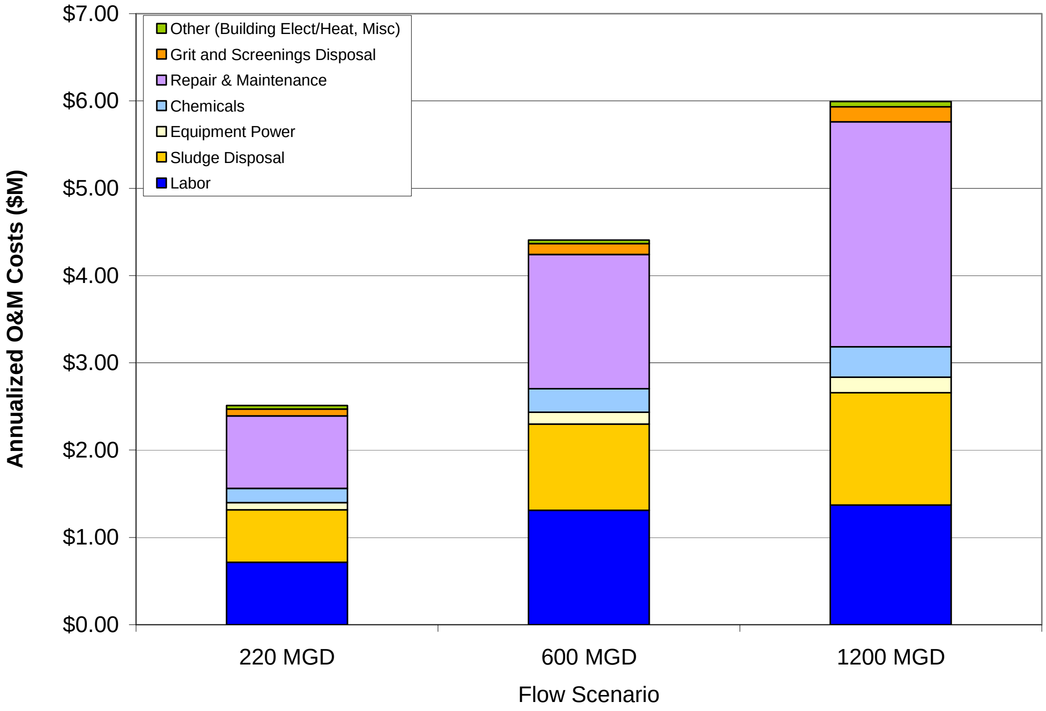
Operation and Maintenance Costs by Category for Treatment Train #2: Conventional Clarifiers



7.0 Treatment Train #3 - Chemically Enhanced Primary Treatment (CEPT)

7.1 Process Flow Diagram

Chemically enhanced primary treatment (CEPT) improves the removal efficiency of TSS and BOD through the addition of coagulants and flocculants to primary clarifiers. With chemical enhancement, the surface overflow rate of the primary clarifier is expected to increase from 2400 gpd/sf to 3000 gpd/sf, and the removal efficiency from 55 percent to 80 percent. As shown in the process flow diagram in Exhibit 7-1, the flow path is similar to Treatment Train #2. The only difference is the addition of rapid mixers and flocculation basins upstream of the primary clarifiers, along with their associated chemical feed and storage systems.

7.2 Conceptual Design and Site Layouts

Conceptual designs were developed at three different flow scenarios for this train: 220, 550, and 1000 mgd. Key design parameters at these flows are shown in Exhibit 7-1. The 550-mgd facility fits on the Upper BRC site alone, and the 1000-mgd facility utilizes both the Upper and Lower sites. As seen in Exhibit 7-2, the 1000-mgd requires more clarifiers per volume treated because the width of the Lower BRC tract limits the length of the clarifier tank to approximately 170-ft. Without this constraint, the length of the clarifiers in other flow scenarios can reach 250-ft.

The flow capacities in this train are lower than for Conventional Clarification due to the increased number of gravity thickeners required to treat the solids removed through CEPT.

7.3 Operational and Technology-Specific Issues

7.3.1 Startup and Shutdown

When the wet weather facility is initially put into service, it will take 2-3 hours before the clarifiers begin to discharge treated wet weather flow. This is equivalent to the time needed to displace the existing wastewater in the tanks, or to fill the tanks if they are empty.

For shut down, the tanks may be filled with treated effluent, or drained down to the existing plant if freezing becomes an issue.

The other processes in the system are physical or physical/chemical treatment systems that are easily and quickly brought online and will achieve normal levels of treatment efficiency quickly.

7.3.2 Interaction with Main Plant

As described in the previous treatment trains, the overflow from the thickeners, ranging from 8 to 36 mgd depending on the flow scenario, is recycled back to the head of the plant for distribution across the main plant and the wet weather treatment train.

7.3.3 Impact on Plant Operations

CEPT requires the addition of chemicals, ferric chloride and polymer, that are not currently used at the SW WPCP. Storage of these new chemicals will need to be monitored to ensure that they are not degraded over time, especially during long periods of shutdown. The system effluent may need to be recycled to the head of the existing plant until the unit process is stabilized.

7.4 Cost Analyses

The estimated capital, O&M, and lifecycle costs for each flow scenario are shown in Exhibit 7-3. Total capital costs and the capital costs per volume treated are also shown in Exhibits 7-4 and 7-5. Estimated O&M costs by category are shown in Exhibit 7-6. A more detailed breakdown of these costs is presented in Attachment SW-2.1.

8.0 Treatment Train #4 - Ballasted Flocculation

The final treatment train uses ballasted flocculation to achieve removal efficiencies beyond that of CEPT. Ballasted flocculation, often referred to as "high rate treatment," creates extremely dense flocs with high settling velocities that can be removed efficiently even at very high surface overflow rates. Two proprietary systems that use ballasted flocculation are the DensaDeg and Actiflo systems. The DensaDeg system uses chemical sludge produced within it (recirculated from the clarifier underflow to the system influent) as a ballasting agent. The Actiflo system uses microsand as the ballasting agent. Both systems can achieve TSS removals in the range of 85 to 95 percent.

Actiflo requires separate gravity thickeners to process the sludge it generates, while Densadeg recirculates its sludge within its own process and therefore produces a thicker sludge not requiring thickening. The overall cost differential is not significant in most cases, however, since Densadeg has a lower overflow rate (40 gpm/sf compared with 60 gpm/sf) and larger footprint (CH2M HILL, 2007b).

Since the overall cost of the Actiflo and DensaDeg systems have been found to be similar, only one system was chosen for evaluation for this treatment train. The Actiflo system was selected in order to show the possibility of adding gravity thickeners to the plant layout. Pilot testing should be performed to determine the system best suited for the plant, while providing other benefits such as:

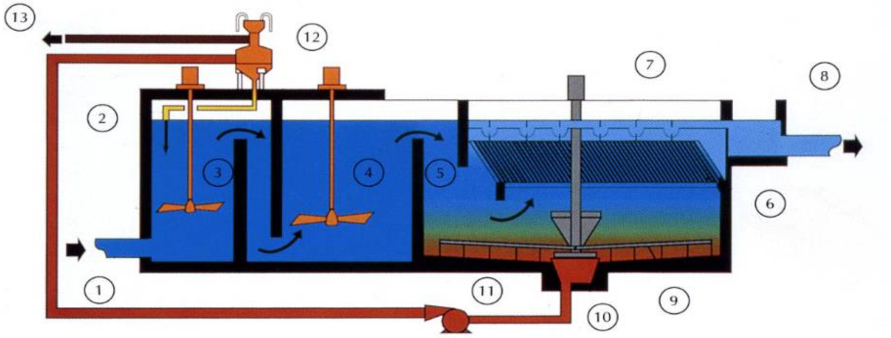
- Identification of influent wastewater constituents that may affect performance of either technology
- Determining suitable chemical dosages for the ballasted flocculation system
- Providing effluent quality information that can be used for design of downstream disinfection processes
- Assessing treatment performance at typical design overflow rates
- Providing better understanding of system operation through pilot testing.

8.1 Process Flow Diagram

In the ballasted flocculation treatment train, wet weather flow passes through bar screening, influent pumps, grit removal, and fine screening before entering the ballasted flocculation system (Exhibit 8-2). A schematic of the Actiflo system is shown in Exhibit 8-1.

Using the numbers in the Exhibit, the wastewater enters at point (1) along with the coagulant (ferric chloride) to the flash mixing zone (3) where microsand is also added (2). Addition of the coagulant enhances flocculation by destabilizing suspended solids in the wastewater. Compartment (4) is a gentle mixing zone where polymer is added to promote formation of strong flocs around the microsand. The flocculated solids flow to compartment (5), the clarification zone. Most of the solids settle at the bottom of this compartment, but this zone also has lamella settling modules (6) to enhance removal of suspended solids that may be present in the wastewater. The solids accumulated at the bottom of the clarification compartment (10) are recycled to a hydrocyclone (12), where the sludge is separated from the microsand. The microsand is recycled back to the flash mixing zone (3), and the sludge leaves the system by stream (13).

EXHIBIT 8-1
Schematic of the ACTIFLO High-Rate Primary Clarifier



As shown in Exhibit 8-1, the sludge from the ballasted flocculation process is pumped to gravity thickeners to be thickened from 0.3 percent solids to 3-4 percent solids.

8.2 Conceptual Design and Site Layouts

Conceptual designs using the ballasted flocculation system were developed for flow capacities of 220, 980, and 1740 mgd. The key design parameters are presented in Exhibit 8-2. As seen in the conceptual layouts in Exhibit 8-3, the space requirements of this treatment train are minimal compared to the other alternatives. The 980-mgd facility fits on the Upper BRC site alone, utilizing the same area as a 550-mgd CEPT or 600-mgd Conventional Clarification plant. This is due to its extremely high surface overflow rate of 60 gpm/sf.

8.3 Operational and Technology-Specific Issues

8.3.1 Startup and Shutdown

Ballasted flocculation systems stabilize quickly, with Actiflo taking less than 20 minutes and DensaDeg less than 45 minutes to start producing good quality effluent based on demonstration testing. Infilco Degremont indicated that the DensaDeg process will produce design effluent immediately if left filled with chlorinated plant effluent. However, based on piloting studies, a connection should be provided for discharging wet weather effluent to the head of the existing plant during startup until such time as the ballasted flocculation system performance stabilizes. To facilitate startup, the ballasted flocculation system should also be underloaded initially.

Shutdown can occur at the operator's convenience. Typically, equipment will simply need to be switched off. The hydrocyclones should be pumped down before being turned off. The tanks themselves can either be filled with treated effluent, or drained down. To prevent freezing during cold weather, any system that is not totally enclosed should have a constant flow of water, or be drained down. The cost estimate does not include a building for the ballasted flocculation units since they are able to be effectively operated in an outdoor environment, and the inclusion of a building would add unnecessary capital costs to this alternative.

The advantage of leaving the basins filled with water is that the startup time is substantially reduced and the basins reach their design effluent quality much more quickly. This reduces the volume of partially treated water that must be returned to the existing treatment plant. Running a small flow through the tanks also helps in maintaining equipment, such as the tank mixers. Actiflo's manufacturer recommends leaving the sand in the tanks only if the tanks are filled with effluent. With sand readily available in the tanks, treatment can begin sooner. If the system were fully drained, the sand within the Actiflo system would require removal and disposal to prevent freezing. Upon startup, sand would have to be reintroduced into the treatment flow using the bulk sand feed system. Infilco Degremont indicates that solids should be removed from the DensaDeg system within six hours to prevent septicity. The DensaDeg system can then be left filled with chlorinated plant effluent.

8.3.2 Interaction with Main Plant

During startup, effluent from the ballasted flocculation system will be discharged to the head of the main plant until system performance stabilizes.

Similar to the other treatment trains, recycle flows from the screenings washer/compactor and grit classifier will be conveyed to the ballasted flocculation system with the wet weather treatment train. The overflow stream from the gravity thickeners, however, must be sent to the head of the main plant for distribution across both the wet weather treatment train and the existing plant. Since this treatment train has the highest removal efficiency, it generates the highest sludge and overflow volumes. In addition, the solids content of the sludge is thinner compared to primary clarifier sludge as a result of the cyclones used to separate the ballast from the sludge. The estimated overflow volume is 16 to 128 mgd, depending on the flow capacity of the treatment train.

8.3.3 Impact on plant operations

To simplify routine operation, Actiflo and Densadeg typically have automated routine startup and shutdown sequences with PLC programming and adjustable timers (service interval, tank fill, equipment run, shutdown, and tank drain). However, operator attention will be necessary to monitor or optimize performance, and to confirm successful facility startup. The operators will have the following responsibilities:

- Start the process train
- Monitor coagulant and polymer dose and perform jar tests to optimize chemical dosing.
- Manage the loading of screenings and grit dumpsters.
- Observe equipment operation and contact maintenance if equipment malfunctions.

8.3.4 Other Issues

Foaming – Foaming may occur due to the addition of coagulants and polymer settling aids, and should be investigated in pilot studies. For example, during startup of the Actiflo unit at Lawrence WWTP in Lawrence, Kansas, the observed foaming resulted from the reaction of ferric chloride with biodegradable surfactants in the incoming wastewater. Foaming can be controlled using silica-based defoamers such as Tramfloc 110, Chemco DF, and Neo Solutions NS-8454 at low dosages.

Floc Carryover and Microsand Loss – Floc carryover is an issue for the DensaDeg system that should be investigated through pilot tests. As flows approach the design SOR, sludge densities may decrease, sending large flocs of sludge out in the effluent. These large flocs not only affect effluent quality in terms of TSS and BOD levels, but may also decrease effectiveness of the disinfection process downstream.

Regarding the Actiflo system, a certain degree of microsand loss is expected from normal operation of the system. The manufacturer indicates that about 8 pounds of microsand are lost for each million gallons of wastewater treated. The sand must be replaced for optimal operation of the system. According to information gathered during the team's site visit to the Cincinnati Metropolitan Sewer District, the SSO 700 Facility loses 350 lbs of sand per 15 mg wet weather event. In the conceptual design of this treatment train, adequate storage space was provided in the chemical buildings for 10 day storage of sand. Additionally, the microsand needs to be maintained in the system in case rapid startup is required, and the sand must be prevented from freezing during the winter so that the unit can start up quickly if needed during the cold season. The DensaDeg unit is totally drained when the system is shut down, and no chemical sludge is maintained in the system when it is not in use.

Sludge Concentration - One important difference between Actiflo and Densadeg is the sludge concentration that they produce. Sludge from the DensaDeg system can be four to five times more concentrated than sludge from the Actiflo system. Since the two systems are expected to produce the same mass of sludge, because they operate with similar coagulant dosages, it is expected that the volume of sludge produced in the ACTIFLO system will be four to five times greater than that in the DensaDeg unit. Gravity thickeners have been included in the conceptual design for the Actiflo treatment train to thicken the sludge to 3-4 percent solids. These thickeners may not be necessary if the Densadeg system is chosen.

8.4 Cost Analyses

The estimated capital, O&M, and lifecycle costs for each flow scenario are shown in Exhibit 8-4. Total capital costs and the capital costs per volume treated are also shown in Exhibits 8-5 and 8-6. Estimated O&M costs by category are presented in Exhibit 8-7. A more detailed breakdown of these costs is presented in Attachment SW-2.1.

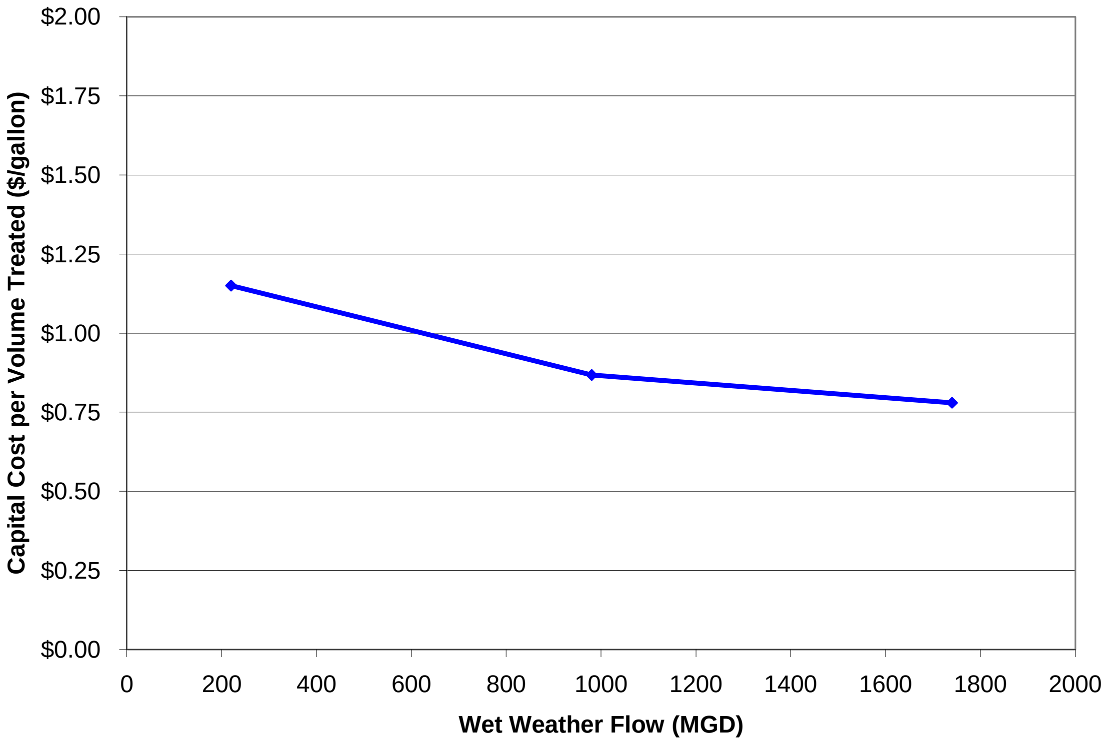

EXHIBIT 8-7
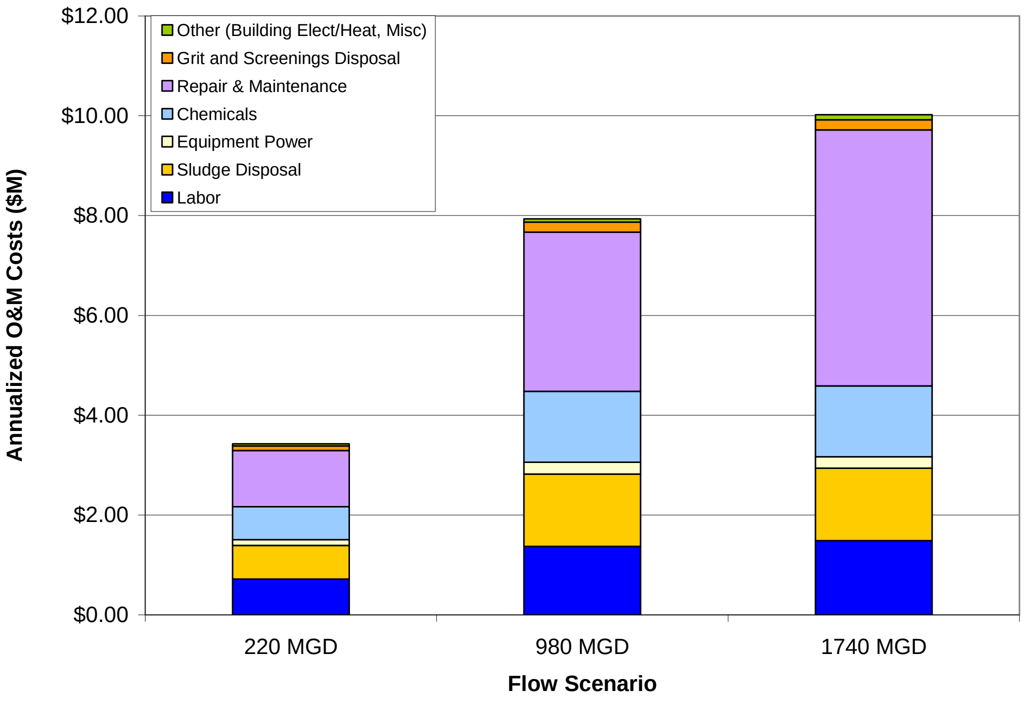
Operations and Maintenance Costs by Category for Treatment Train #5: Ballasted Flocculation



9.0 Alternatives for Optimizing Capital Costs

9.1 Ballasted Flocculation

As mentioned in Section 8, the costs presented for Treatment Train #5, Ballasted Flocculation, are based on the Actiflo system, which similar in cost to Densadeg, the other proprietary high rate treatment technology. If the ballasted flocculation treatment train is selected, a cost estimate for the Densadeg system should be developed to examine the cost differential. The main contributions to the cost differential will include:

- **Reduction in number of thickeners** - Densadeg maintains a 3-4 percent sludge thickness for its ballast, compared to the 0.3 percent sludge thickness in the Actiflo system.
- **Increase in footprint** – Densadeg has a 40 gpm/sf loading rate, compared to Actiflo’s 60 gpm/sf loading rate.
- **Elimination of fine screening** – Actiflo requires fine screening to protect the hydrocyclones in the system, which separate sand from sludge. Since Densadeg uses sludge only as its ballast, it does not require fine screening upstream.

Implications to operations and maintenance should also be examined between the two systems. For example, Actiflo requires sand as the ballasting agent, which requires storage and maintenance.

9.2 Refined Design Assumptions via Influent Sampling

Influent sampling at the plant during wet weather events will shed light on the wastewater characteristics of the wet weather flow, as well as the flow regime during events. More concrete numbers for influent TSS, BOD, and flow can be used to refine process design parameters, which may lead to a reduction in the size and cost of the treatment trains.

10.0 Comparison of Treatment Alternatives

10.1 Effluent Water Quality

As discussed in Section 3, effluent from the wet weather treatment facility will discharge to a new outfall at the Schuylkill River and will not commingle with the effluent from the main plant, which currently discharges into the Delaware River. It is likely that a new NPDES permit will need to be negotiated for this new discharge. If treated as a separate wet weather facility, it is clear that the effluent water quality in order from best to worst will come from: Ballasted Flocculation, CEPT, Conventional Clarification, and finally the Vortex/Swirl train (Exhibits 10-1 and 10-2).

10.1.1 Effluent Water Quality – Assuming Blending

An alternative way of analyzing water quality is to consider the new wet weather facility and the main SW WPCP as one system with a single discharge permit. In this system, the effluent from the two plants is “blended” before discharge into the water body, and this “blended” effluent must meet permit limits. This is similar to the water quality analyses performed for the Southeast and Northeast WPCPs.

The TSS and cBOD concentrations of the “blended” effluent for each treatment train and flow scenario is presented in Exhibit 10-1 and 10-2, respectively.

EXHIBIT 10-1

Blended Effluent TSS Concentrations

Treatment Train	**Wet Weather Treatment Train Effluent Conc. (mg/L)**	**Blended Effluent TSS Concentration (mg/L)**							
		Wet Weather Treatment Train Flow (mgd)							
		220	***550***	***600***	***702***	***980***	***1000***	***1200***	***1740***
#1) Vortex/Swirl Concentrators	158	61			99				
#2) Conventional Clarifiers	102	45		64				77	
#3) CEPT w/ Conventional Clarifiers	45	29	34				37		
#4) Ballasted Flocculation	21	22				21			21

Notes: Based on the 95th percentile wet weather TSS concentration of 22 mg/L and a maximum of 540 MGD through the existing plant. Allowable daily blended effluent TSS concentration on wet weather days is 112 mg/L, to meet monthly TSS permit limits.

EXHIBIT 10-2

Blended Effluent cBOD Concentrations

Treatment Train	Wet Weather Treatment Train Effluent Conc. (mg/L)	Blended Effluent cBOD Concentration (mg/L)							
		Wet Weather Treatment Train Flow (mgd)							
		220	***550***	***600***	***702***	***980***	***1000***	***1200***	***1740***
#1) Vortex/Swirl Concentrators	75	27			46				
#2) Conventional Clarifiers	64	24		37				47	
#3) CEPT w/ Conventional Clarifiers	54	21	31				38		
#4) Ballasted Flocculation	49	20				34			39

Notes: Based on the 95th percentile wet weather cBOD concentration of 8 mg/L and a maximum of 540 MGD through the existing plant.

As described in Section 4.1, the maximum flow through all the treatment trains, with the exception of the vortex swirl, is unlimited if the number of wet weather days is less than 7 days per month. To illustrate the risk of exceeding permit limits at these design flows, Exhibit 10-3 presents the maximum number of days that the wet weather treatment train can operate at its maximum capacity without the system exceeding monthly TSS permit limits. The ballasted flocculation train is unlimited in frequency of operation since its effluent quality (30 mg/L TSS) surpasses permit limits without blending.

EXHIBIT 10-3

Allowable Number of Operating Days of Wet Weather Treatment Train

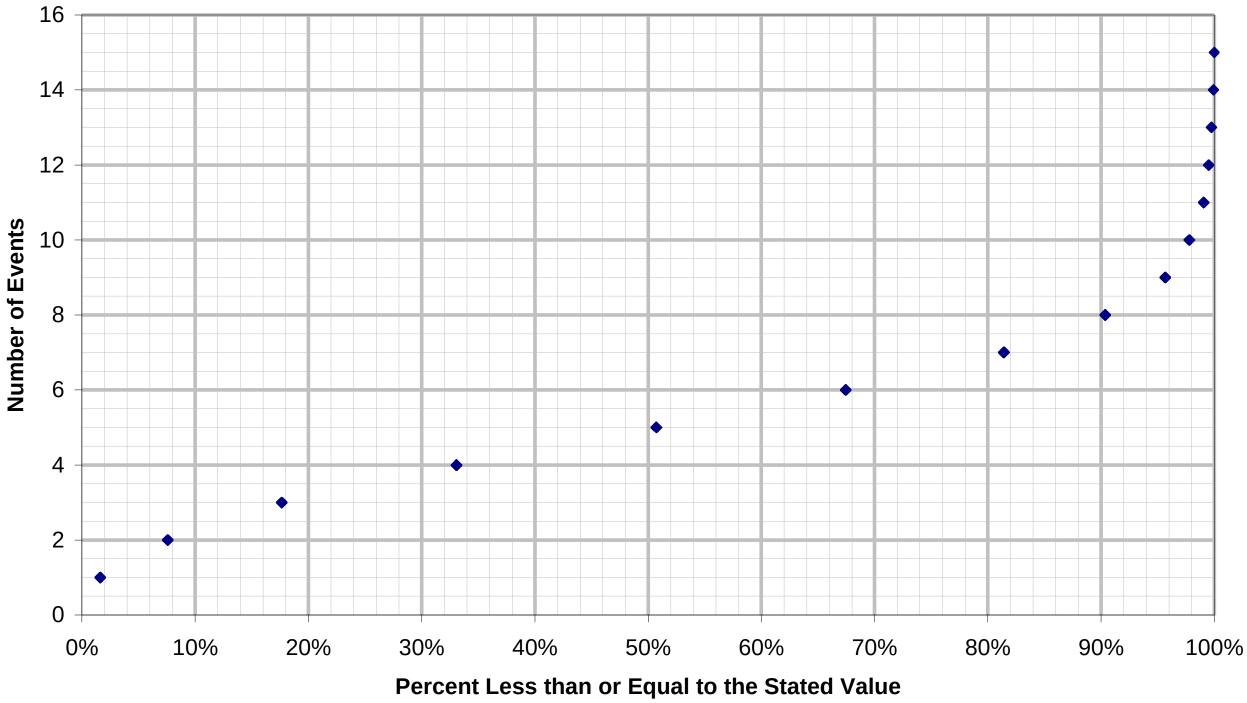
Treatment Train	Maximum Allowable Number of Operating Days per Month(1)							
	Wet Weather Treatment Train Flow (mgd)							
	220	***550***	***600***	***702***	***980***	***1000***	***1200***	***1740***
#1) Vortex/Swirl Concentrators	12			7				
#2) Conventional Clarifiers	17		11				9	
#3) CEPT w/ Conventional Clarifiers	UNLIMITED	25				22		
#4) Ballasted Flocculation	UNLIMITED							

Notes:
(1) Allowable number of operating days without exceeding permit limits for monthly TSS concentrations. Assumes entire plant operates at maximum capacity during every wet weather event.

A frequency plot of the number of wet weather events per month and the duration of each event is shown in Exhibits 10-4 and 10-5 for comparison purposes (Myers, 2008b). As shown, wet weather events have occurred at a historical maximum of 15 per month. This suggests that CEPT, and Ballasted Flocculation have a very low probability of exceeding permit limits. It should be noted that the wet weather event referred to in this plot occurs whenever rainfall exceeds 0.1 inch, and does not necessarily correspond to operation of the new wet weather treatment train. If the flow does not exceed the capacity of the conventional plant, the wet weather treatment train will not come online. Thus, the new wet weather treatment train is expected to operate less than 15 times per month.

It should be noted that a continuous simulation-based approach would give a more accurate estimate of risk, and more detailed analyses should be performed during the facility planning and design phases.

EXHIBIT 10-4
Cumulative Frequency Plot of the Number of Wet Weather Events per Month



Notes: Based on Philadelphia International Airport NOAA Rain Gauge Hourly Data from1902-2000. Minimum Interevent Time = 4 hrs, Minimum Storm = 0.1 Inches (provided by CDM)

10.1.2 Capital, O&M and Life-Cycle Costs

The capital cost estimates for the four treatment trains are shown in Exhibit 10-5. Train #3, CEPT, is the most expensive, followed by Trains #2 and #4, Conventional Clarification and Ballasted Flocculation, which appear similar in cost. The cost of Train #1, Vortex/Swirl, is significantly less expensive than the other three trains. Translated into a cost per volume treated, all trains appear to become more cost effective as flow capacity increases (Exhibit 10-6).

The reason that CEPT is more expensive than Ballasted Flocculation for the SW WPCP wet weather facility is likely due to the limited length and increased number of its clarifiers, as described in Section 7.2, as well as the increased cost for piles.

The comparison of O&M costs for each treatment train is shown in Exhibit 10-7. As expected, the O&M costs for vortex swirls and conventional clarifiers, which do not require chemical settling aids, are the lowest. Ballasted Flocculation has the highest O&M costs due to its chemical usage and the complexity of its system.

Taking construction, non-construction, and O&M costs into consideration, Exhibit 10-8 shows the present value of the total cost of each wet weather treatment train. Again, CEPT and Ballasted Flocculation remain most costly due to their high capital and O&M costs. Train #1, vortex/swirl concentrators, is significantly less expensive compared with other technologies from the life-cycle cost perspective. This is due to its low chemical usage and minimal operations and maintenance needs.

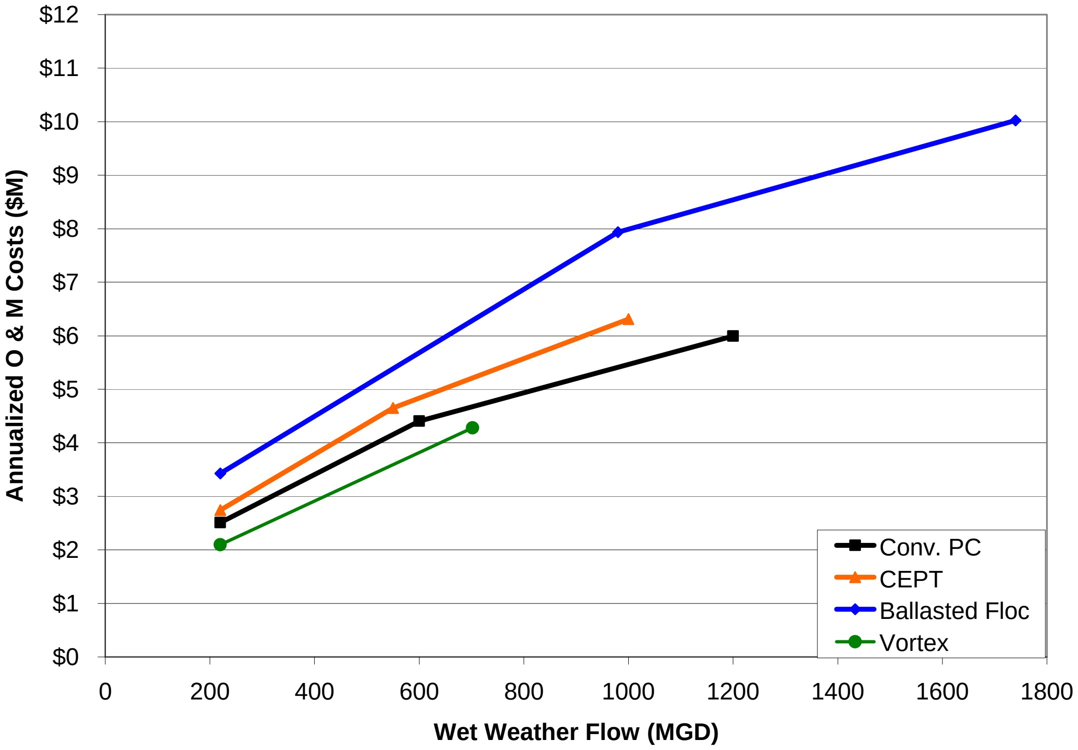

EXHIBIT 10-8
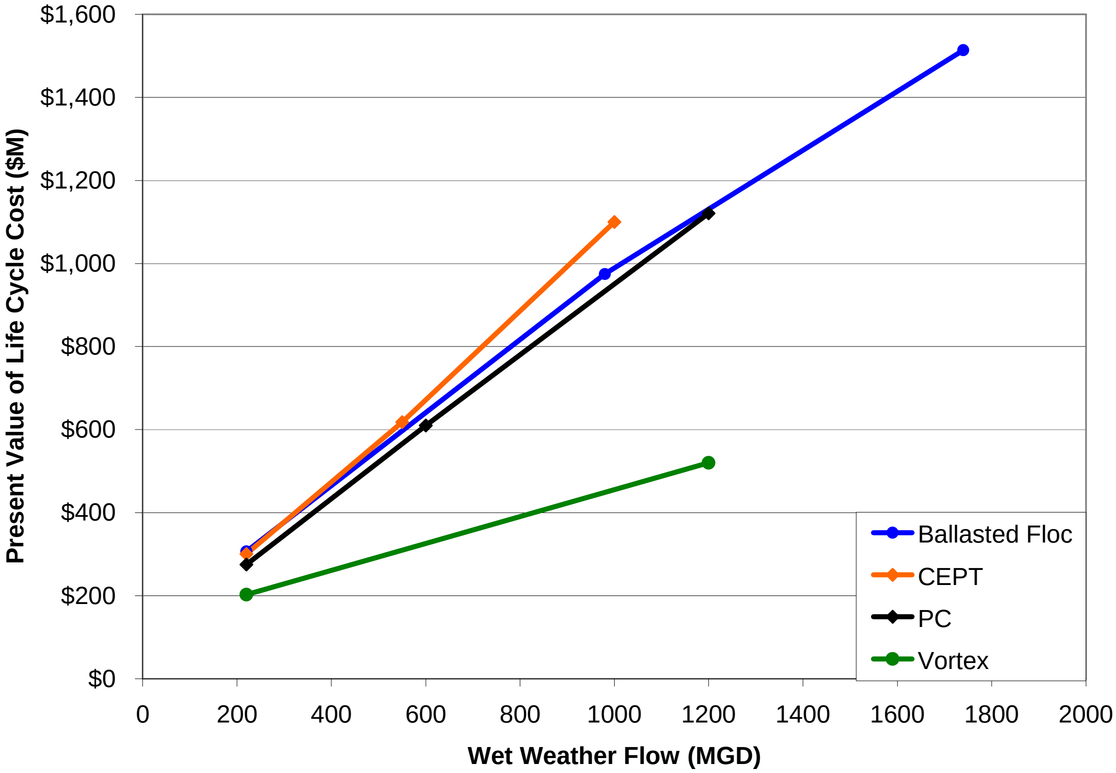
Comparison of Life-Cycle Costs for all Treatment Trains



10.2 Overall Comparison

Aside from capital, O&M, and lifecycle costs, there are numerous other criteria by which the treatment trains should be evaluated, including:

- Reliability of the system
- Community and environmental impacts or perception
- Ability to handle large variations in flow
- Land requirements
- Constructability
- Requirements for maintenance and operator attention
- Sustainability

These evaluation criteria were discussed in Workshop No. 2B, and are presented in TM-SE2 for various wet weather treatment technologies (CH2M HILL, 2008a). Several key advantages and disadvantages of Treatment Trains #1 - #4, as evaluated in this report, are described in Exhibit 10-9.

EXHIBIT 10-9
Summary of Pros and Cons for Each Wet Weather Treatment Train

Treatment Train	Pros	Cons
Train #1: Vortex/Swirl Concentrators	• Simple operation • Low maintenance requirements – no moving parts	• Maximum design flow may decrease if the assumed number of operating days per month is greater than 7. • Unless operated at lower loading rates, removal efficiency may not be high enough to operate alone without blending effluent with main plant effluent.
Train #2: Conventional Clarifiers	• Simple operation • Same technology as existing plant – operators familiar with equipment	• Space limited • Maximum design flow may decrease if the assumed number of operating days is greater than 9.
Train #3: CEPT	• Lower chlorine dose possible due to high TSS removal efficiencies • May be operated as Conventional Clarifiers if chemicals found to be unnecessary	• Operators unfamiliar with technology • Space limited • Can treat less flow on land available than conventional clarifiers
Train #4: Ballasted Flocculation	• Can treat up to 1740 mgd with available land on site • Highest removal efficiencies • Unlimited number of operating days per month • Lower chlorine dose possible due to high TSS removal efficiencies	• Operators unfamiliar with technology • Most labor intensive and complex system • Uses two additional chemical systems for coagulation and flocculation

The costs for wet weather treatment at the SW WPCP should be analyzed with the costs of other wet weather treatment alternatives, such as improvements in the collection system, to determine which treatment train alternatives and flow regimes should be evaluated further. Treatment trains that are selected for further evaluation should undergo more detailed design and costing methods, water quality sampling, and bench and pilot scale testing, so that removal efficiencies, land requirements, capital costs, and O&M costs can be further refined.

Cost Efficiency ($/gallon)	**$0.77**	**$0.65**	**$1.07**	**$0.90**	**$0.86**	**$1.17**	**$0.99**	**$1.00**	**$1.15**	**$0.87**	**$0.78**

Notes:
1. Contractor markups - use 1.516 multiplier (see TM-SW2 Section 4.3)
2. Escalation - multiplier depends on duration of construction (see Exhibit 4-7 in TM-SW2 Section 4.3)
3. Local Adjustment Factor - use 1.152 multiplier (see TM-SW2 Section 4.3)
4. Market Adjustment Factor - use 1.15 multiplier (see TM-SW2 Section 4.3)
5. Non-construction costs - use 1.3 multiplier (see TM-SW2 Section 4.3)

Notes:

1. All O&M costs are annualized costs based on escalation through a 30-year period. See TM-SW2 Section 4.2.1 for description of average flows
2. Power costs are estimated based on the total horsepower requirements and the average-to-max flow ratio.
3. "Other" costs cover miscellaneous costs for vehicles, lab tests, office equipment, etc.

Percentage of Costs by Category

	Flow (mgd)	Labor	Sludge Disposal	Building Electrical & Heating	Chemicals	Other	Grit and Screenings Disposal	Equipment Power	Repair & Maintenance
Train #1: Vortex/Swirls	220	34.1%	8.2%	0.2%	7.8%	1.6%	3.8%	4.3%	40.1%

Introduction

To meet the regulatory requirements and long-term goals of its CSO, stormwater, and drinking water source protection programs, The Philadelphia Water Department (PWD) has embraced a comprehensive watershed characterization, planning, and management program. Watershed management fosters the coordinated implementation of programs to control sources of pollution, reduce polluted runoff, and promote managed growth in the city and surrounding areas, while protecting the region's drinking water supplies, fishing and other recreational activities, and preserving sensitive natural resources such as parks and streams. PWD has helped form watershed partnerships with surrounding urban and suburban communities to explore regional cooperation based on an understanding of the impact of land use and human activities on water quality.

Coordination of these different programs has been greatly facilitated by PWD's creation of the Office of Watersheds (OOW), which is composed of staff from the PWD's planning and research, CSO, collector systems, laboratory services, and other key functional groups. One of OOW's responsibilities is to characterize existing conditions in local watersheds to provide a basis for long-term watershed planning and management.

OOW is developing a series of watershed management programs for each of the city's watersheds. Cobbs Creek was the first watershed for which an integrated watershed management plan was completed; the Tookany/Tacony-Frankford Watershed Partnership was second to complete a plan. This Comprehensive Characterization Report contains a series of technical documents that form the scientific basis for the Tookany/Tacony-Frankford Integrated Watershed Management Plan (TTFIWMP), released in 2005. The report characterizes the land use, geology, soils, topography, demographics, meteorology, hydrology, water quality, ecology, fluvial geomorphology, and pollutant loads found in the watershed. It presents and discusses data collected through the end of 2004. This report is intended as a single compilation of background and technical documents that can be periodically updated as additional field work or data analyses are completed. Sections of this report were completed at different times by different authors.

Section 2
Characterization of the Study Area

2.1 Watershed Description and Demographics

The Tookany/Tacony-Frankford Watershed is defined as the land area that drains to the mouth of Tacony Creek at the Delaware Estuary, encompassing approximately 36 square miles in southeastern Pennsylvania. This area includes portions of Montgomery and Philadelphia Counties. Figure 2-1 includes the watershed boundaries, hydrologic features, and political boundaries. Much of the information is based on the U.S. Census Bureau's TIGER (Topologically Integrated Geographic Encoding and Referencing) database.

The Tookany/Tacony-Frankford Watershed discharges to the Delaware River, and is made up of three linked stream segments: the Tookany Creek in the headwaters, which drains into the Tacony Creek, which becomes the Frankford Creek in the lower reaches. Named tributaries of the Tookany Creek include Mill Run, Rock Creek and Jenkintown Creek.

In a relatively undisturbed watershed, watershed boundaries follow topographic high points or contours. The U.S. Geological Survey (USGS) has subdivided the Tookany/Tacony-Frankford Watershed based on topography, as shown in Figure 2-2. These USGS subwatersheds are determined from the land area draining to a particular point of interest, such as a stream confluence or gauging site. These boundaries allow initial determinations of drainage areas and modeling elements. However, adjustments are made where necessary to include the effects of man-made alterations to the natural drainage patterns.

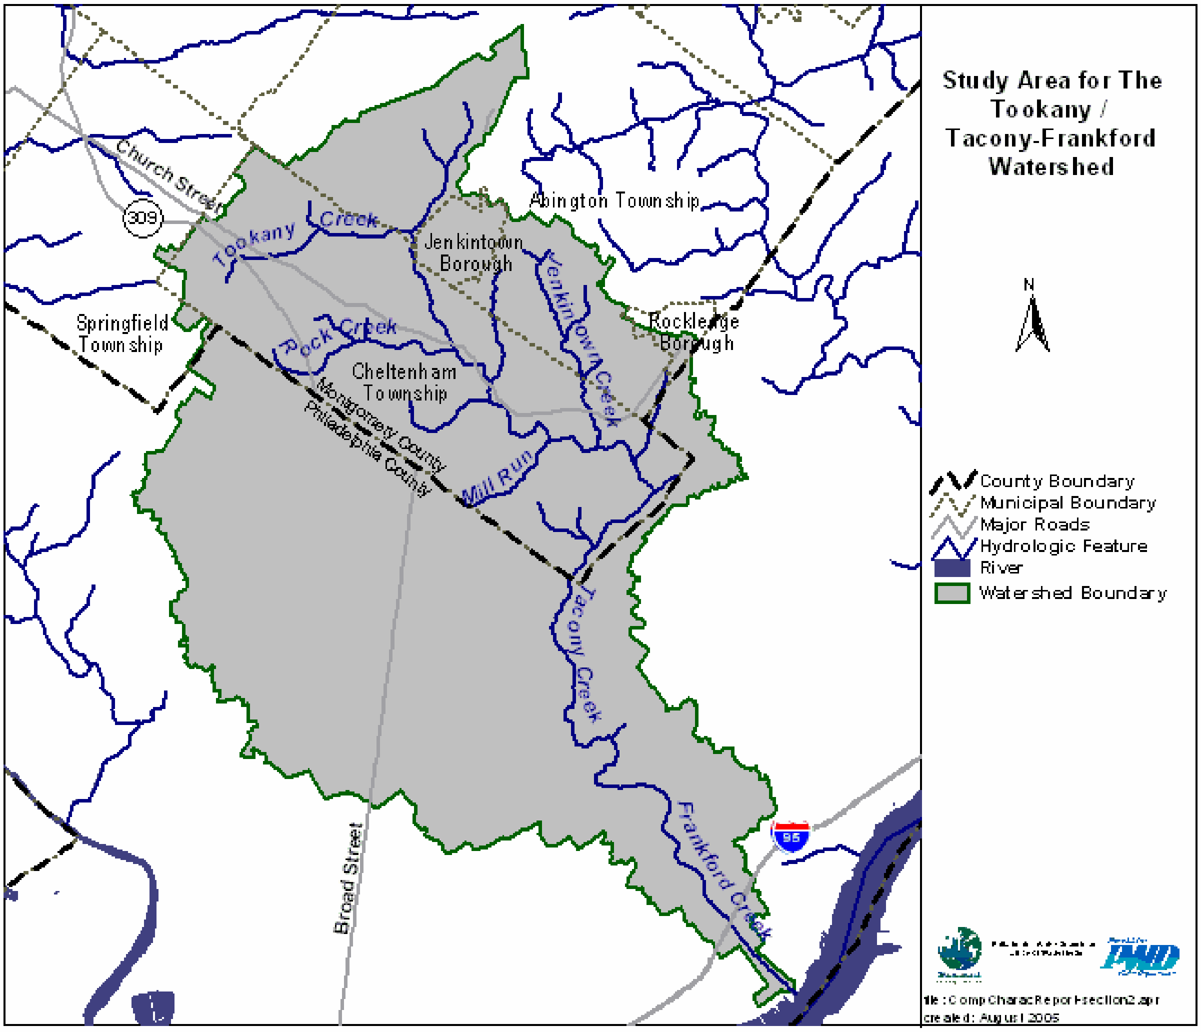

Figure 2-1 Tookany/Tacony-Frankford Study Area

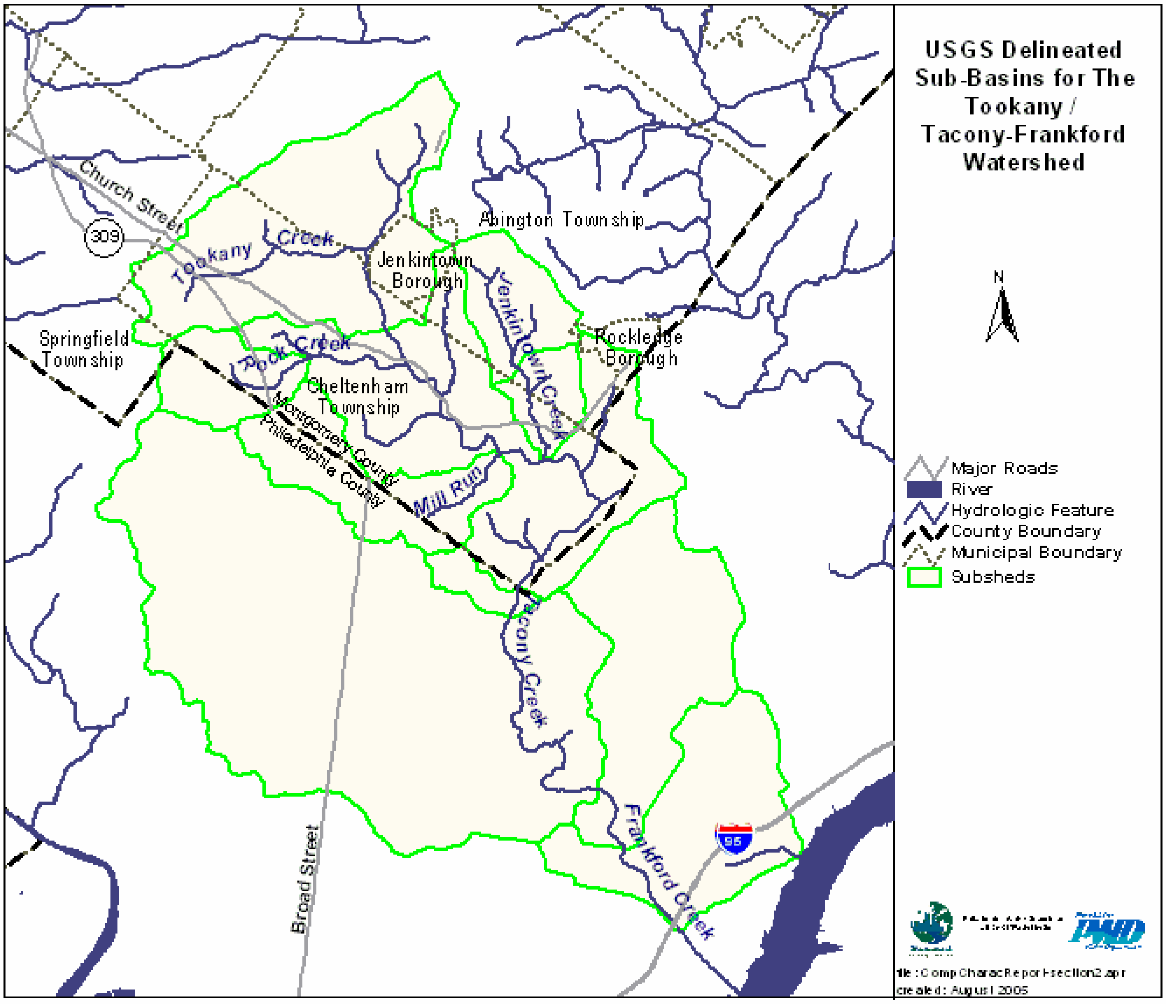

Figure 2-2 USGS Topographic Subwatersheds of the Tookany/Tacony-Frankford Watershed

2.2 Demographic Information

Population density and other demographic information in the watershed are available from the results of the 2000 census. Approximately 357,000 people live within the drainage area of the Tookany/Tacony-Frankford Watershed. Figure 2-3 shows the population density in the watershed at the census block level. Spatial trends in population correspond closely to land use, with multi-family row homes displaying the greatest population density of 20 people per acre or more, single-family homes displaying a lower density, and other land use types displaying the lowest density. In addition to population data, the U.S. Census Bureau provides a range of socioeconomic data that are often useful in watershed planning and general planning studies. Median household income and mean home value (Figures 2-4 and 2-5) are two of the many sample datasets provided.

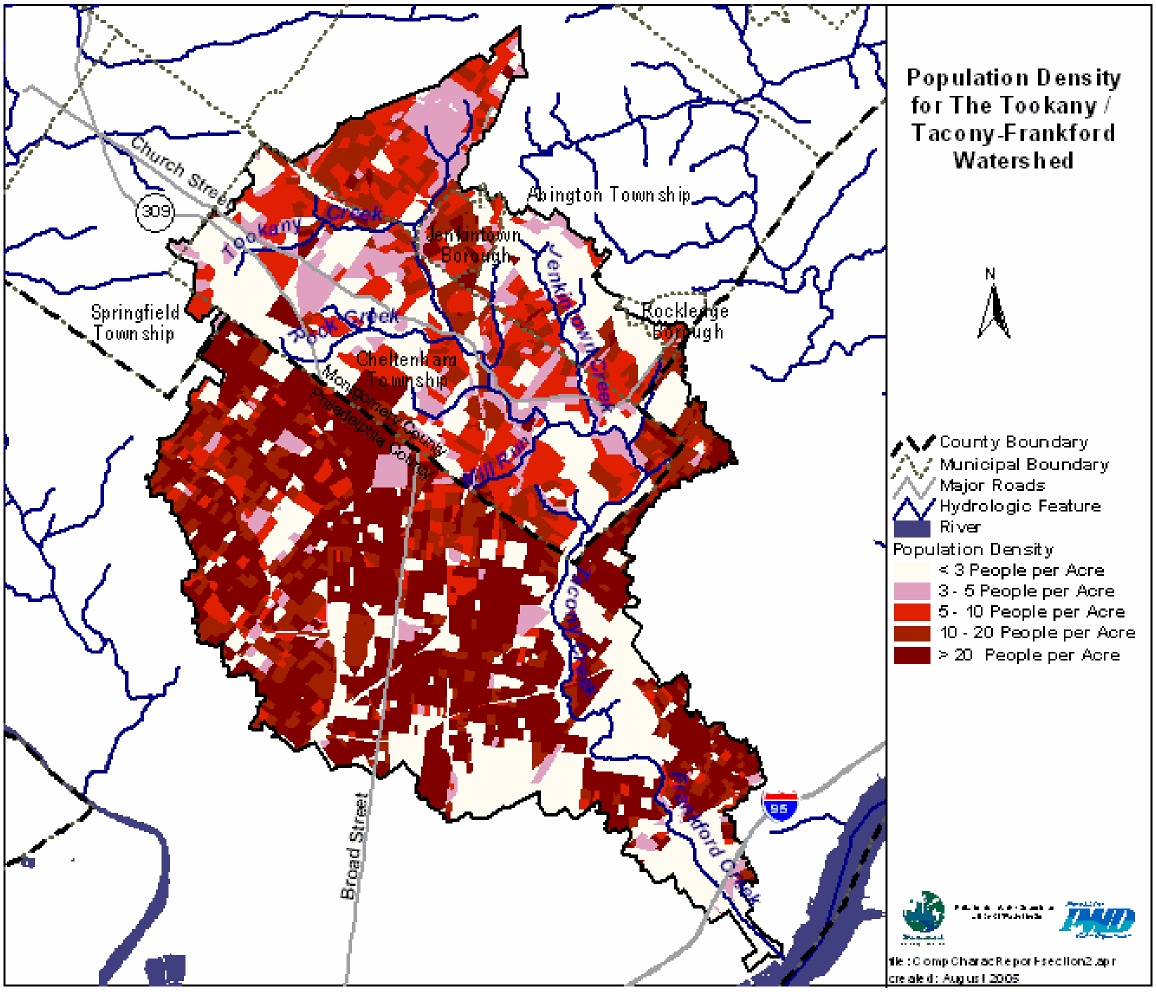

Figure 2-3 Population Density in Tookany/Tacony-Frankford Watershed by Census Block Group (Source: U.S. Census, 2000)

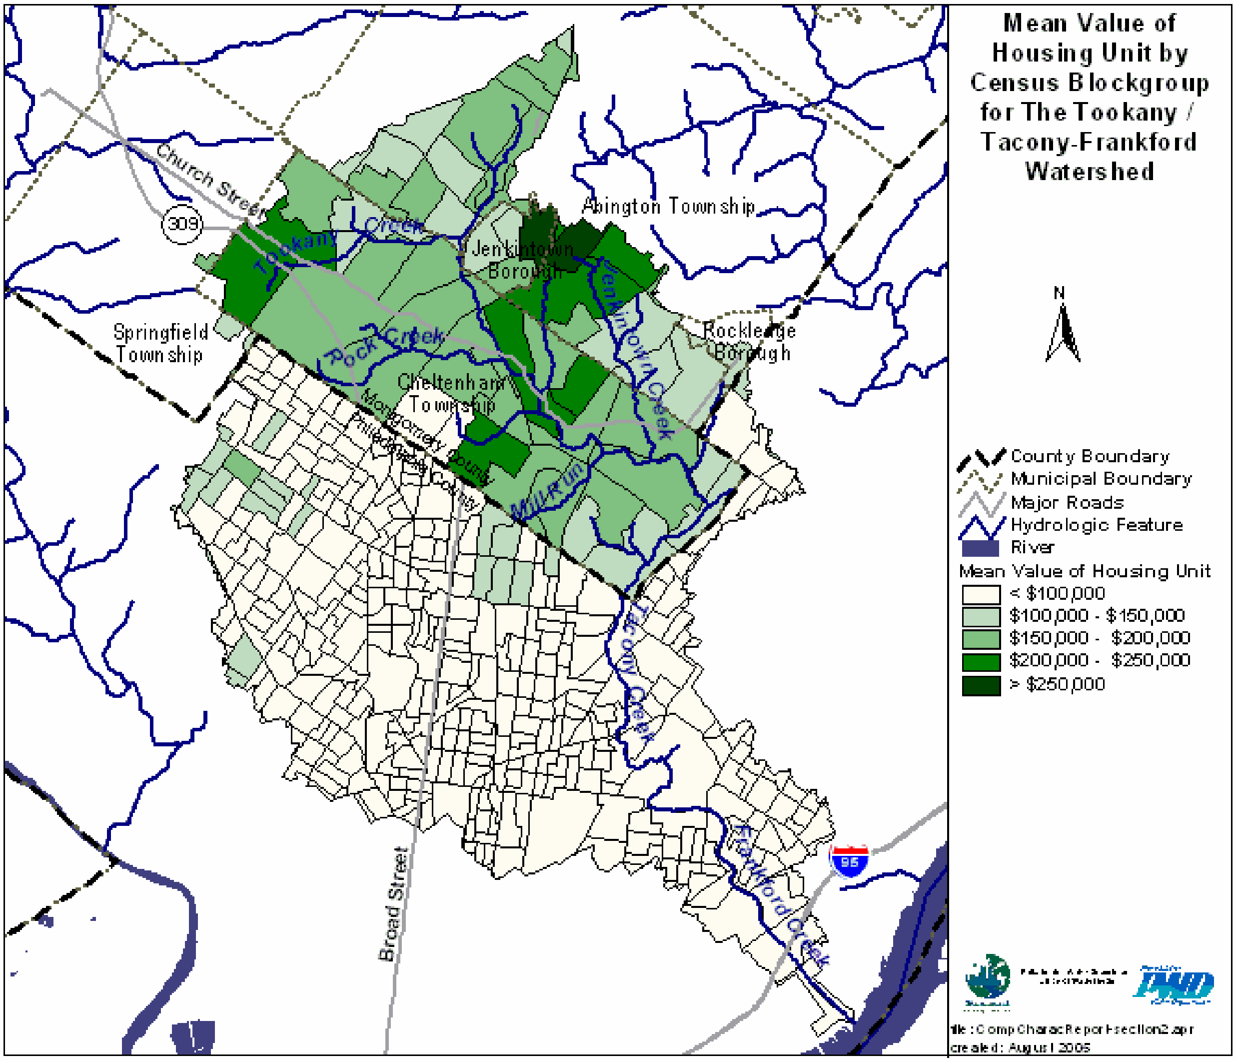

Figure 2-4 Mean Value of Housing Units in Tookany/Tacony-Frankford Watershed by Census Block Group (Source: U.S. Census, 2000)

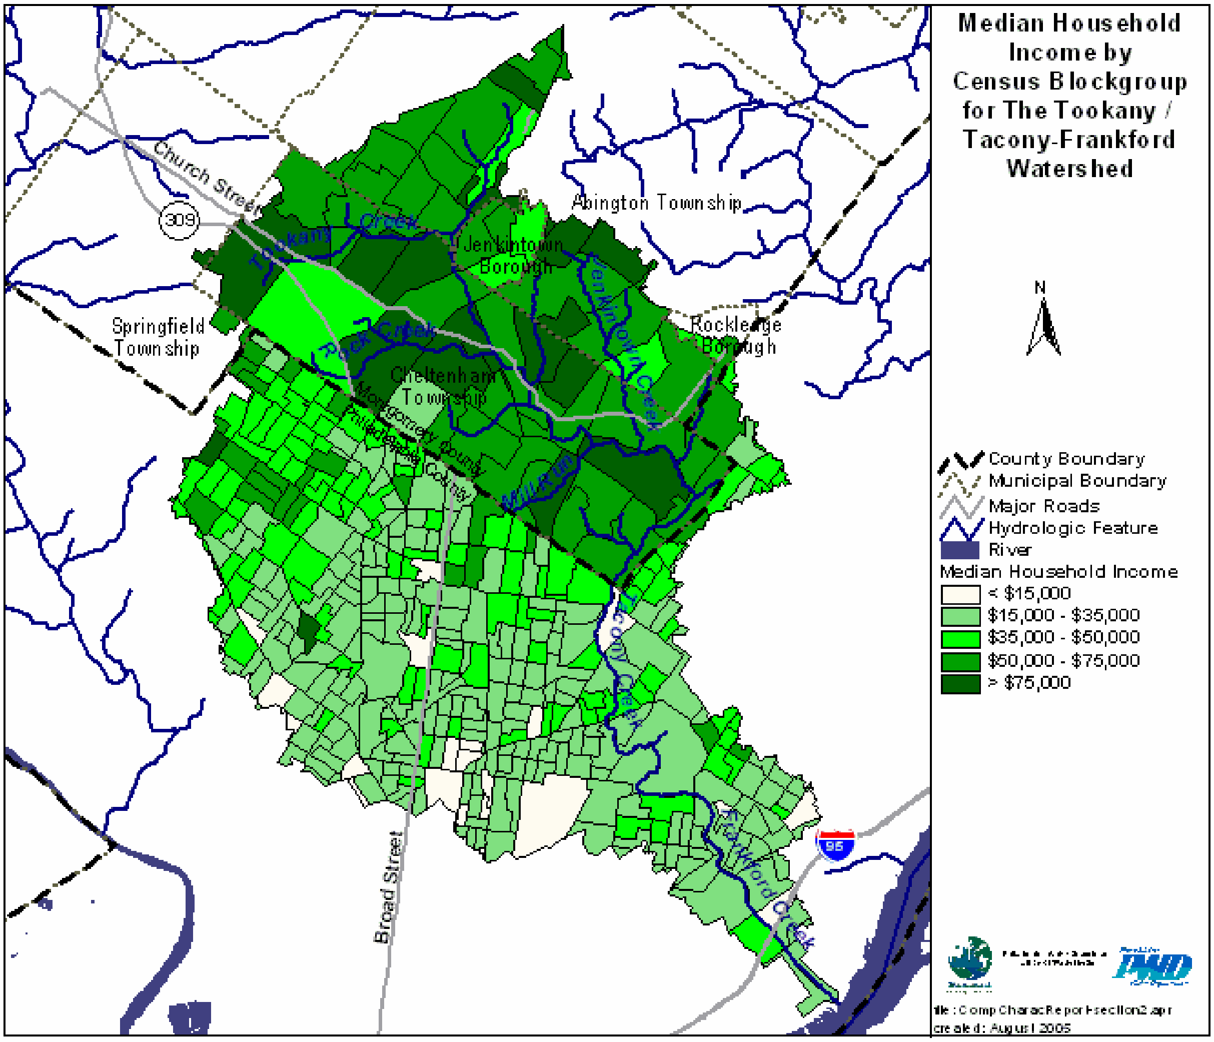

Figure 2-5 Median Household Income in Tookany/Tacony-Frankford Watershed by Census Block Group (Source: U.S. Census, 2000)

2.3 Land Use

Land use information for the Tookany/Tacony-Frankford Watershed was obtained from the Delaware Valley Regional Planning Commission (DVRPC). Figure 2-6 is the 1996 land use map for the study area. The upper reaches and headwaters of the Tookany/Tacony-Frankford Watershed are characterized primarily by a mix of multiple-family and detached single-family residential areas, golf courses and parkland. The lower portions of the Tookany/Tacony-Frankford Watershed are primarily high-density residential areas in the City of Philadelphia, with commercial areas along highway corridors. Riparian lands within the City consist mainly of relatively undisturbed parkland.

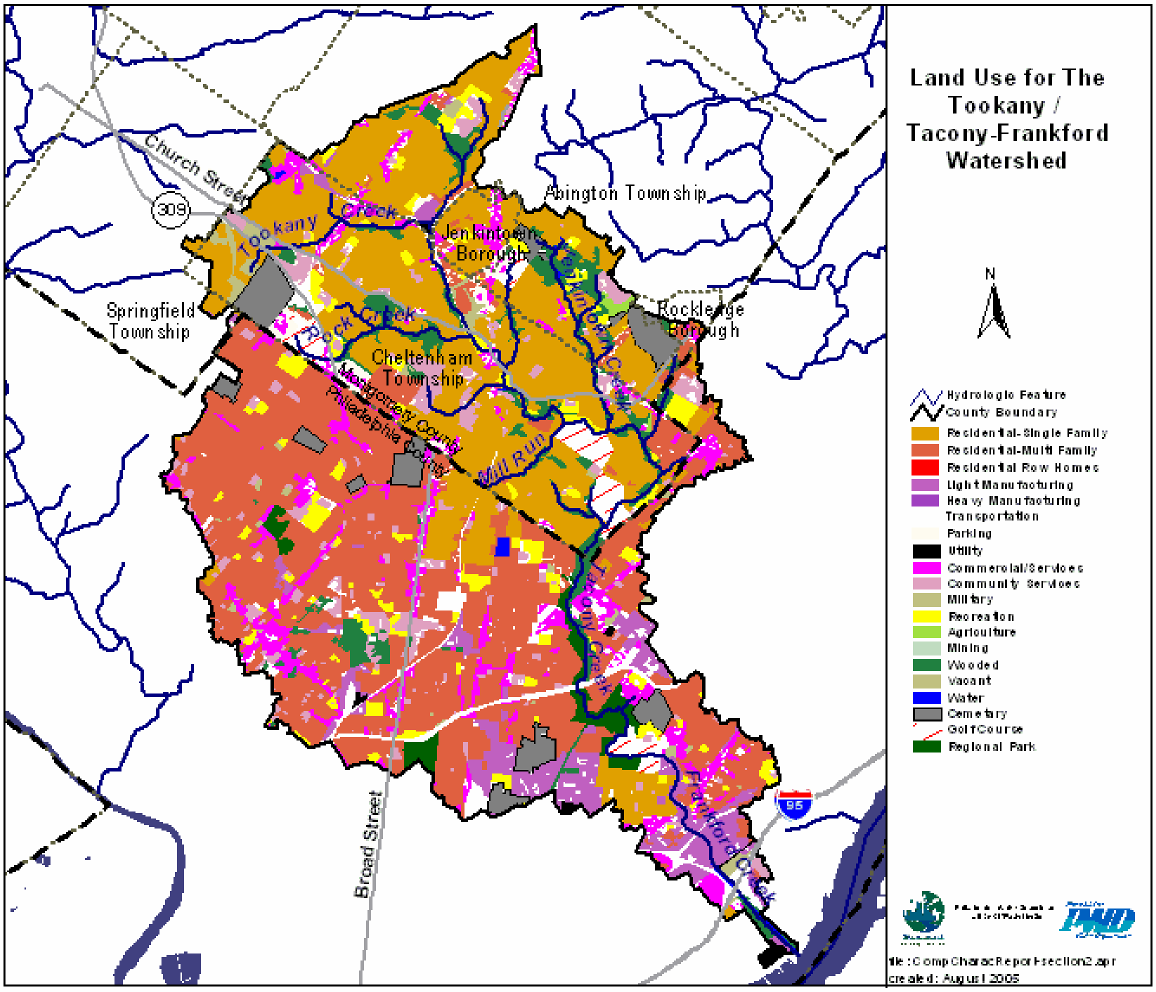

Figure 2-6 Land Use in the Tookany/Tacony-Frankford Watershed (Source: DVRPC 1995)

One of the primary indicators of watershed "health" is the percentage of impervious cover within the watershed. Based on numerous research efforts, studies and observations, a general categorization of watersheds has been widely applied to watershed management based on percent impervious cover (Schueler 1995). Percent impervious cover and other indicators of stream health are summarized in Table 2-1. Table 2-2 illustrates that the entire watershed has greater than 25% impervious cover, placing it in the "Non-Supporting" category of stream health.

Table 2-1 Impervious Cover as an Indicator of Stream Health (Schueler 1995)

Characteristic	Sensitive	Degrading	Non-Supporting
Percent Impervious Cover	0% to 10%	11% to 25%	26% to 100%
Channel Stability	Stable	Unstable	Highly Unstable
Water Quality	Good to Excellent	Fair to Good	Fair to Poor
Stream Biodiversity	Good to Excellent	Fair to Good	Poor
Pollutants of Concern	Sediment and temperature only	Also nutrients and metals	Also bacteria

Table 2-2 Estimated Total Impervious Cover

Watershed	County	Total Area (ac)	Acres Impervious	Percent Impervious
Tacony-Frankford	Philadelphia	10,844.5	5810.0	53.6
Tookany	Montgomery	10,226.7	2808.6	27.5

Table 2-3 summarizes several of the impacts of traditional development on streams and watersheds, most of which are created by the addition of impervious cover across the portions of the land surface. Figure 2-7 illustrates the changes to the volume and duration of runoff before and after development. Figure 2-7 also illustrates the benefits of using various BMPs and low impervious techniques to manage stormwater.

Table 2-3 Impacts of Traditional Development on Watershed Resources (from Schueler 1995)

Changes in Stream Hydrology ▪ Increased magnitude/frequency of severe floods ▪ Increased frequency of erosive bankfull and sub-bankfull floods ▪ Reduced ground water recharge ▪ Higher flow velocities during storm events	**Changes in Stream Morphology** ▪ Channel widening and downcutting ▪ Streambank erosion ▪ Channel scour ▪ Shifting bars of coarse sediments ▪ Imbedding of stream substrate ▪ Loss of pool/riffle structure ▪ Stream enclosure or channelization
Changes in Stream Water Quality ▪ Instream pulse of sediment during construction ▪ Nutrient loads promote stream and lake algae growth ▪ Bacteria contamination during dry and wet weather ▪ Higher loads of organic matter ▪ Higher concentrations of metals, hydrocarbons, and priority pollutants ▪ Stream warming ▪ Trash and debris jams	**Changes in Stream Ecology** ▪ Reduced or eliminated riparian buffer ▪ Shift in external production to internal production ▪ Reduced diversity of aquatic insects ▪ Reduced diversity of fish ▪ Creation of barriers to fish migration ▪ Degradation of wetlands, riparian zones and springs ▪ Decline in amphibian populations

2.4 Geology and Soils

Geology and soils play a role in the hydrology, water quality, and ecology of a watershed. The Tookany/Tacony-Frankford Watershed is located primarily within the Piedmont physiographic province. Geologic formations on the surface in the area include gneiss and schist in most of the watershed; sand is dominant in the lower reaches of the watershed (as shown in Figure 2-8). Soils in the upper portions of the Tacony Creek subwatershed include stony and silty loams, as shown in Figure 2-9. Soil in much of the rest of the watershed is classified as urban or made land and is not representative of the original undisturbed soil.

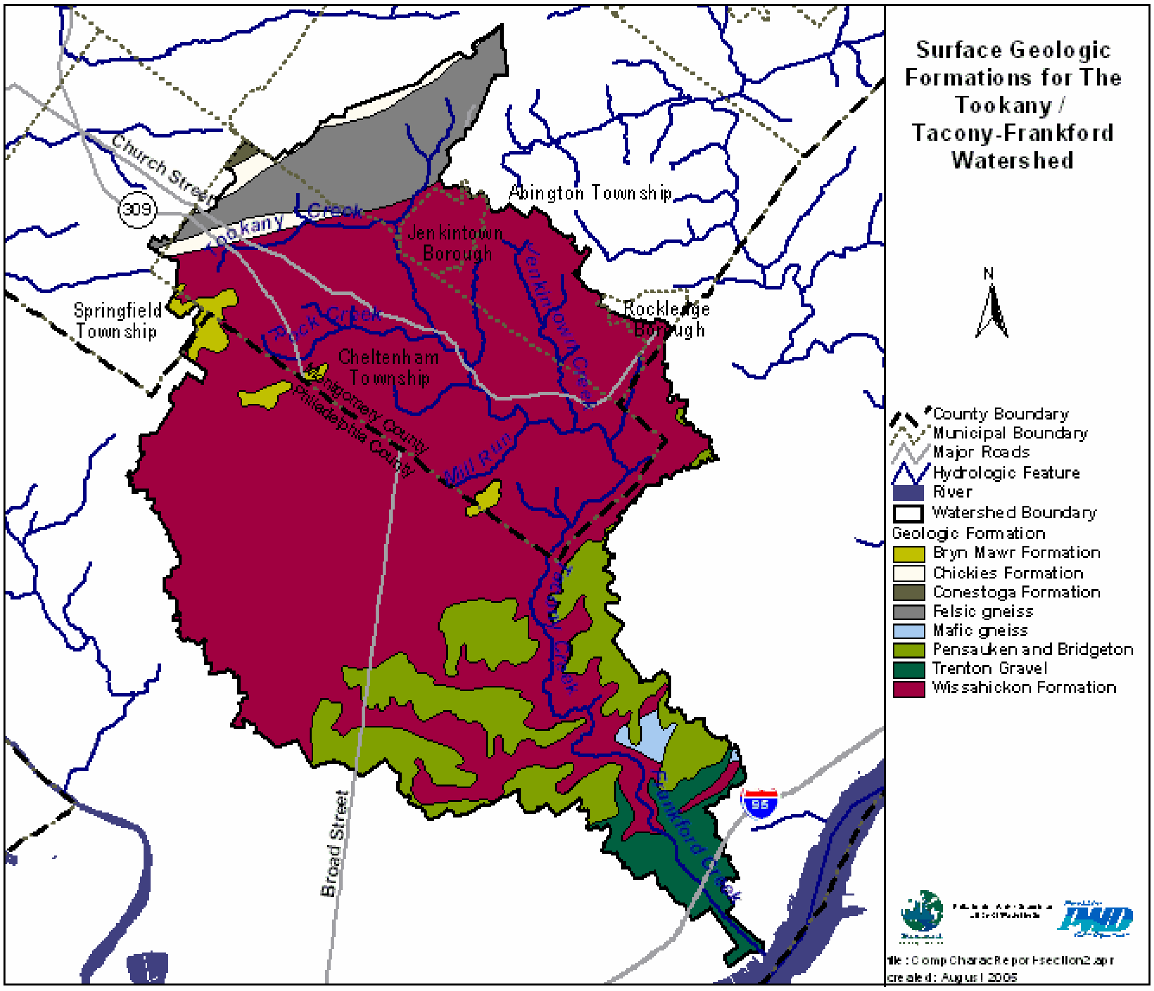

Figure 2-8 Surface Geologic Formations of the Tookany/Tacony-Frankford Watershed (Source: USGS)

Section 3
Sampling and Monitoring Program Methods

3.1 Background

PWD's Office of Watersheds (OOW) has carried out an extensive sampling and monitoring program to characterize conditions in the Tookany/Tacony-Frankford Watershed. The program is designed to document the condition of aquatic resources and to provide information for the planning process needed to meet regulatory requirements imposed by EPA and PA DEP. The program includes hydrologic, water quality, biological, habitat, and fluvial geomorphological aspects. OOW is well suited to carry out the program because it merges the goals of the city's stormwater, combined sewer overflow, and source water protection programs into a single unit dedicated to watershed-wide characterization and planning.

Under the provisions of the Clean Water Act, the National Pollutant Discharge Elimination System (NPDES) requires permits for point sources that discharge to waters of the United States. In the Tookany/Tacony-Frankford Watershed, stormwater outfalls and wet weather sewer overflow points discharging to surface waters are classified as point sources and are regulated by NPDES.

EPA's Combined Sewer Overflow Control Policy, published in 1993, provides the national framework for regulation of CSOs under NPDES. The Policy guides municipalities and state and Federal permitting agencies in meeting the pollution control goals of the CWA in as flexible and cost-effective a manner as possible. As part of the program, communities serviced by combined sewer systems are required to develop long-term CSO control plans (LTCPs) that will result in full compliance with the CWA in the long term, including attainment of water quality standards. PWD completed its LTCP in 1997 and is currently implementing its provisions. The strong focus of the National CSO Policy on meeting water quality standards is a main driver behind PWD's water quality sampling and monitoring program.

Regulation of stormwater outfalls under the NPDES program requires operators of medium and large municipal stormwater systems or MS4s, such as the separate-sewered portions of the Tookany/Tacony-Frankford Creek watershed, to obtain a permit for discharges and to develop a stormwater management plan to minimize pollution loads in runoff over the long term. Partially in administration of this program, PA DEP assigns designated uses to water bodies in the state and performs ongoing assessments of the condition of the water bodies to determine whether the uses are met and to document any improvement or degradation. These assessments are performed primarily with biological indicators based on the EPA's Rapid Bioassessment Protocols (RBPs) for benthic invertebrates and physical habitat. The Tookany/Tacony-Frankford Creek is listed by the PA DEP as impaired for one or more designated uses, not requiring a TMDL.

The Tookany/Tacony-Frankford Creek and its tributaries are designated warm water fisheries. All of the Tookany portion of the watershed plus tributaries, and the upper, non-tidal portion of the Tacony Creek are classified as unattained by PA DEP. For this reason, the stormwater permit for the City of Philadelphia specifies that the state of the aquatic resource must be evaluated periodically. Because PA DEP has endorsed biomonitoring as a means of determining attainment of uses, PWD periodically performs RBPs in the Tookany/Tacony-Frankford Creek.

OOW is responsible for characterization and analysis of existing conditions in local watersheds to provide a basis for long-term watershed planning and management. The extensive sampling and monitoring program described in this section is designed to provide the data needed for the long-term planning process.

3.2 Summary of Physical and Chemical Monitoring

PWD's Office of Watersheds (OOW) and Bureau of Laboratory Services (BLS) have planned and carried out an extensive sampling and monitoring program to characterize conditions in the Tookany/Tacony-Frankford Creek watershed. The program includes hydrologic, water quality, biological, habitat, and fluvial geomorphological components. Again, because the OOW has merged the goals of the city's stormwater, combined sewer overflow, and source water protection programs into a single unit dedicated to watershed-wide characterization and planning, it is uniquely suited to administer this program.

Sampling and monitoring follow the Quality Assurance Project Plan (QAPP) and Standard Operating Protocols (SOPs) as prepared by BLS. These documents cover the elements of quality assurance, including field and laboratory procedures, chain of custody, holding times, collection of blanks and duplicates, and health and safety. They are intended to help the program achieve a level of quality assurance and control that is acceptable to regulatory agencies.

Tables 3-1 and 3-2 summarize the types, amounts, and dates of recent sampling and monitoring performed by PWD, PA DEP, and USGS. A river mile-based naming convention is followed for sampling and monitoring sites located along waterways in the watershed. The naming convention includes three letters and three or more numbers which denote the watershed, stream, and distance from the mouth of the stream. For example, site TFJ110 is named as follows:

- "TF" indicates the Tookany/Tacony-Frankford watershed.
- "J" indicates Jenkintown Creek, a tributary to Tookany Creek.
- "110" places the site 1.10 miles upstream of the confluence of Jenkintown Creek and Tookany Creek.

3.3 Water Quality Sampling and Monitoring

A range of water quality samples were collected between 1999 and 2004 at 9 sites in the watershed. The sites are listed in Table 3-2 and are shown on Figure 3-1. Three different types of sampling were performed as discussed below. Parameters were chosen based on state water quality criteria or because they are known or suspected to be important in urban watersheds. The parameters sampled during each type of sampling are listed in Table 3-4. Water quality in each reach and section of the watershed is characterized in Section 5.

The sampling and analysis program meets AMSA (2002) *et al.* recommendations for the minimum criteria that should form the basis for impairment listings:

- Data collected during the previous five years may be considered to represent current conditions.
- At least ten temporally independent samples should be collected and analyzed for a given parameter.
- A two-year minimum data set is recommended to account for inter-year variation, and the sample set should be distributed over a minimum of two seasons to account for inter-seasonal variation.
- No more than two-thirds of the samples should be collected in any one year.
- Samples collected fewer than four days apart at the same river location should be considered one sample event.
- Samples collected within 200 meters [about 0.1 miles] of each other will be considered the same station or location. This convention was followed except where two sampling sites were chosen to represent conditions upstream and downstream of a modification such as a dam.

3.3.1 Discrete Interval Sampling

Discrete, or "grab" samples were collected at nine sites on a weekly basis for four weeks during three seasonal monitoring periods (Fall/winter, spring and summer). Samples were collected regardless of flow or precipitation. Each site along the stream was sampled once during the course of a few hours, to allow for travel time and sample processing/preservation. The purpose of discrete sampling was initial characterization of water quality under both dry and wet conditions and identification of parameters of possible concern. Discrete sampling followed the Standard Operating Protocol (SOP) "Field Procedures for Grab Sampling".

3.3.2 Continuous Monitoring

Continuous data were collected at eight sites for a total of over 44,000 hours. During continuous sampling, data for selected parameters were collected at 15-minute increments by a submerged instrument (YSI Sonde 6600) over approximately two weeks. The instrument measured parameters using voltage and diffusion-based probes rather than physically collecting samples. Parameters measured included stage, dissolved oxygen, temperature, pH, and turbidity. This method produces 96 measurements per parameter every 24 hours, but cost and quality control are more challenging compared to discrete sampling. The SOP for continuous sampling describes the extensive quality control and assurance procedures applied to the data.

3.3.3 Wet Weather Event Sampling

At eight sites, a series of samples was collected over the course of several wet weather events. During wet weather sampling, several discrete samples were collected just before and during the course of a wet weather event. The data allow characterization of water quality responses to stormwater runoff and wet weather sewer overflows.

3.3.4 PWD/USGS Cooperative Water Quality Monitoring Program (1970-1980)

In the early 1970s, the Philadelphia Water Department began a study in cooperation with the U.S. Geological Survey (USGS) titled, "Urbanization of the Philadelphia Area Streams." The purpose of this study was to quantify the pollutant loads in some of Philadelphia's streams and possibly relate the degradation in water quality to urbanization. PWD and the USGS established six stream gauging stations in Tookany/Tacony-Frankford Watershed and conducted monthly water quality sampling from 1971 to 1980 at 5 of these locations. Of six original gauges, only the gauge at Castor Avenue (01467087) remains operational today. Monthly "snapshot" water quality samples were collected at each site and analyzed for conductivity, BOD_5, total phosphate, ammonia, nitrite, nitrate, and fecal coliform. The program collected about ten years of monthly samples. Figure 3-2 and table 3-4 show the locations of the monitoring stations from the PWD/USGS Cooperative Program.

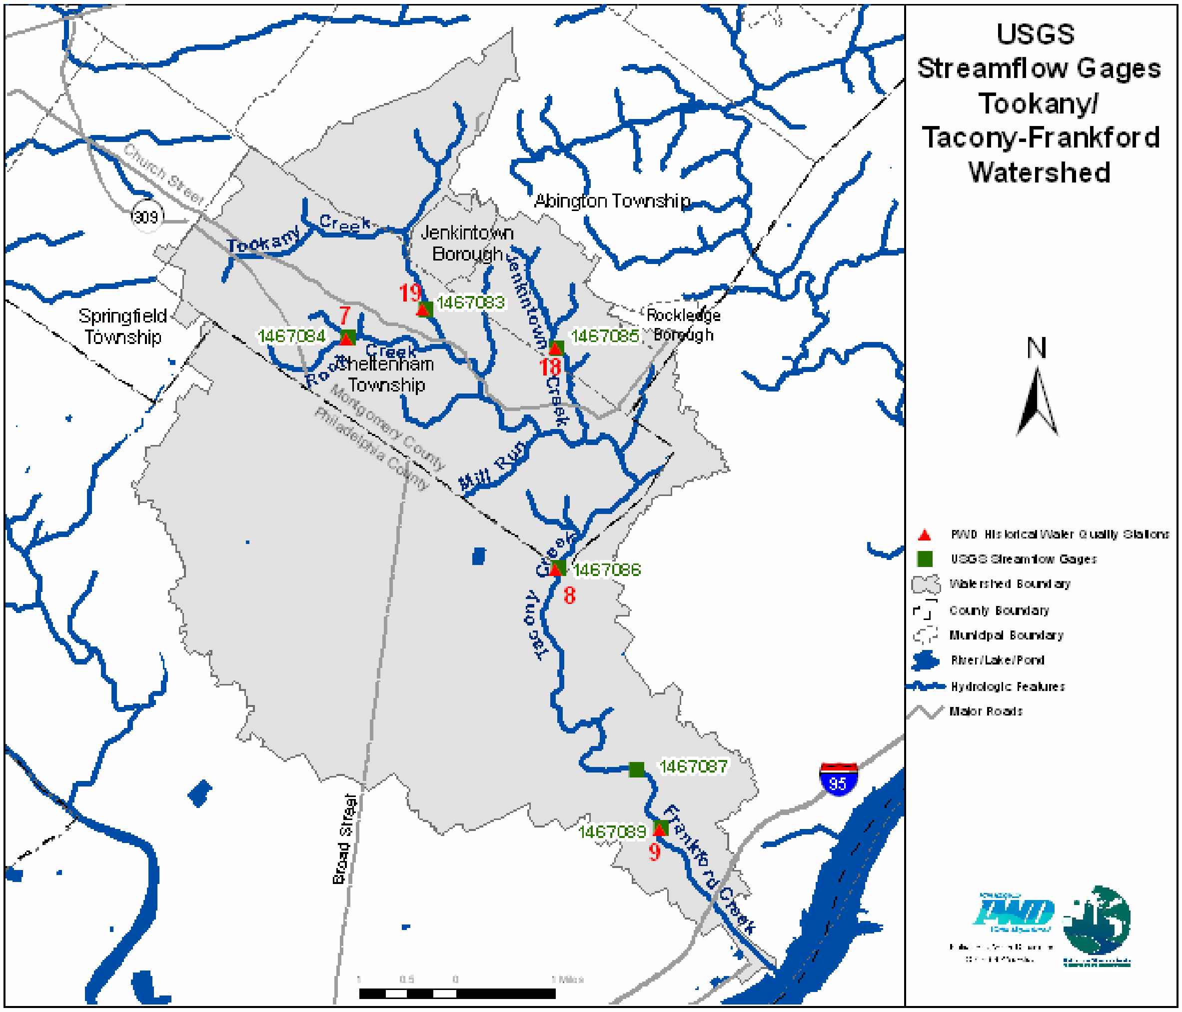

Figure 3-2 PWD/USGS Cooperative Program Water Quality Stations in the Tookany/Tacony-Frankford Watershed

Stream discharge was recorded at the time samples were collected, enabling comparisons to present day water quality. Historic samples were characterized as wet or dry based on a flow frequency analysis conducted in 2001. Spring and winter flows were typically higher than summer and fall flows, so samples were analyzed by season. For each season, a sample was determined to be wet if the instantaneous flow was greater than the estimated wet/dry weather flow break point. Some samples with discharge below the break point that had noticeably lower conductivity and greater TSS concentration were also characterized as "wet". Despite this check, it is assumed that many samples were collected within 48 hours of a rain event but classified as "dry".

3.4 Hydrologic and Outfall Monitoring

Hydrologic monitoring included a system of precipitation gauges and measurement of flows at stream gauges and at points within the sewer system (outfalls and CSO regulators). Characterization of hydrologic and hydraulic data is presented in Section 4.

3.4.1 Precipitation Data

Precipitation data are available from the National Oceanography and Atmospheric Administration (NOAA) and from local gauges operated by PWD and other organizations. NOAA's gauge at the Philadelphia International Airport, located in southeastern Philadelphia, has over 100 years of hourly precipitation data; the period of record runs from January 3, 1902 through the present. Additional precipitation data can be obtained from PWD's network of 24 rain gauges throughout the city; these data are available in 15-minute increments from the early 1990s to the present. Nine of the City gauges are located in or near the Tookany/Tacony-Frankford Creek watershed, as shown in Figure 3-3.

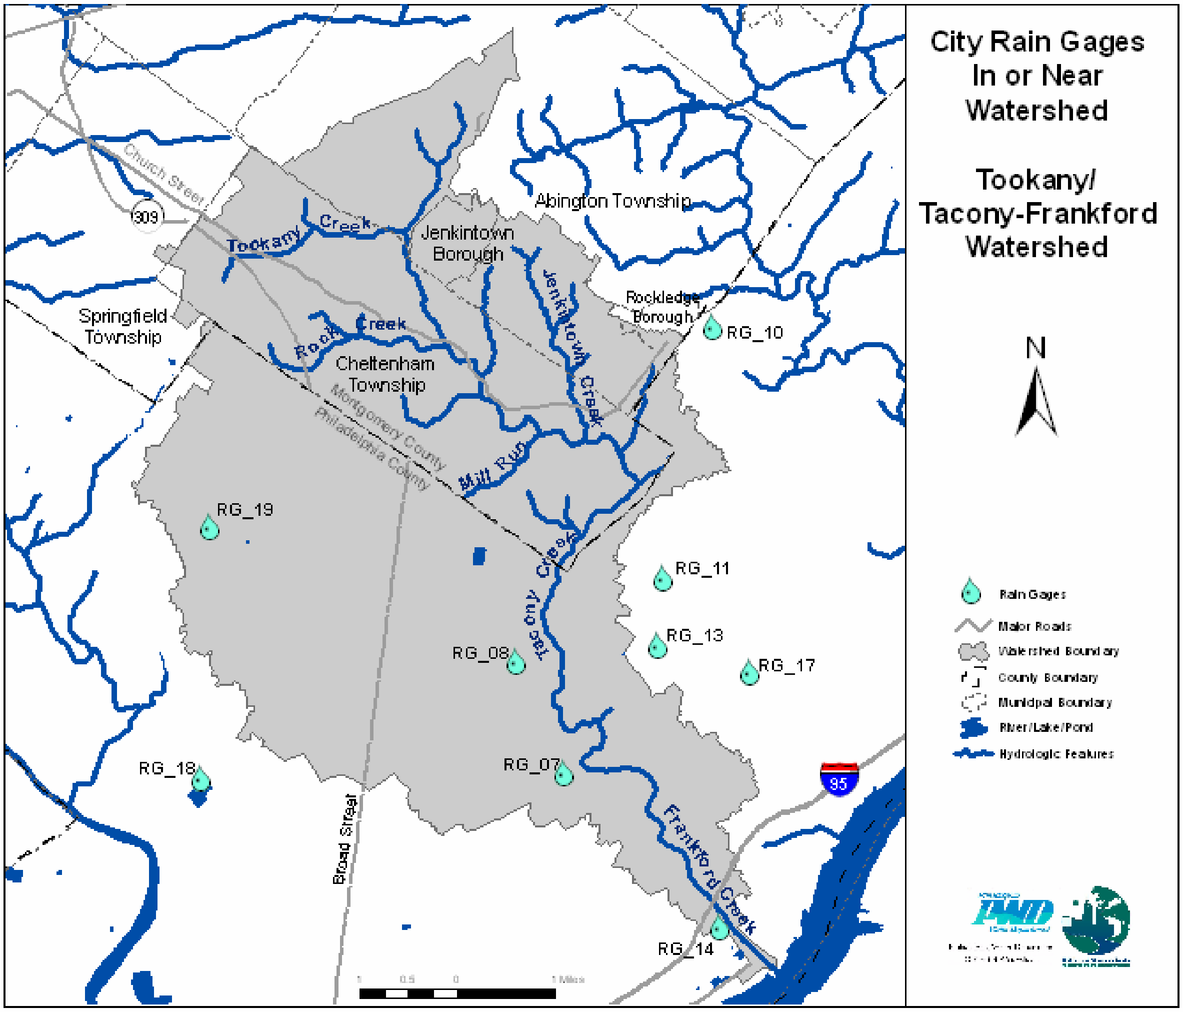

Figure 3-3 PWD Rain Gauges located in or near Tookany/Tacony-Frankford Watershed

3.4.2 Sewer Flow Instrumentation

PWD maintains real-time level monitors in the Tacony-Frankford Creek sewer system. At these points, monitors are typically present in the trunk sewer just above the regulator and in the outfall pipe itself. The magnitude of discharges from the city's CSO outfalls are estimated using a combination of this monitored data and calibrated computer models.

3.4.3 Streamflow Data

PWD and the USGS augmented the existing stream gauging network in the watershed as part of the Cooperative sampling program, establishing three new stream gauges from 1971 to 1973. A gauge was established at Castor Avenue in 1982, which is the only gauge still in operation. However, PWD and USGS are in the process of re-establishing the former gauge at the city line. Table 3-5 contains summary information for each of the six gauging stations for their respective periods of record. Historical stage-discharge rating curves are available for four of the stations and are shown in Figure 3-4.

Table 3-4 Periods of Record for Flow and Water Quality Data

Station ID	Location	Quality Data (Period)	Streamflow Data (Period)
01467089	Frankford Creek at Torresdale Ave.	10/9/67 - 3/7374	10/1/64 - 6/29/82, 5/14/82 – 6/29/82
01467087	Frankford Creek at Castor Ave.*	9/24/25 - 8/24/76	7/1/82 - 9/30/03

01467085	0.14	2.07	45
01467084	0.33	2.51	87
01467083	1.6	9.74	207

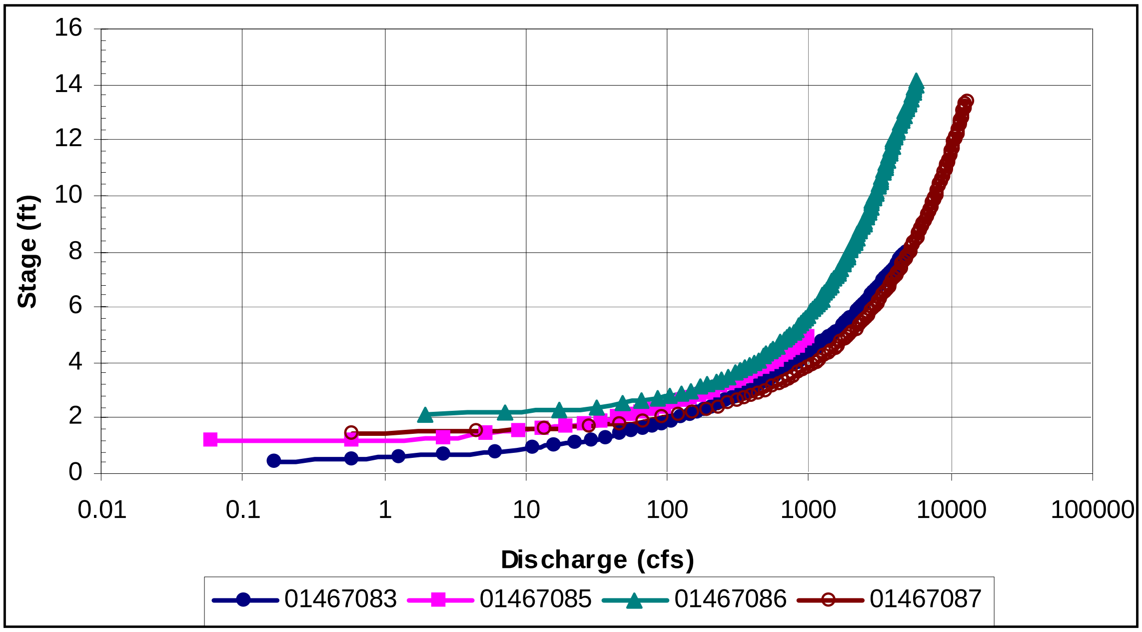

Figure 3-4 Historical stage-discharge rating curves available for four stations

3.4.5 STORET

The majority of the data available from STORET, USEPA's water quality database, for the Tookany/Tacony-Frankford Watershed were from the PWD/USGS Cooperative Program, "Urbanization of the Philadelphia Area Streams." The STORET inventory of water quality data within the Tookany/Tacony-Frankford Creek Watershed will be attached as an Appendix at a later date.

3.5 Benthic Macroinvertebrate Sampling

During 3/24/04 to 4/1/04, the Philadelphia Water Department conducted Rapid Bioassessment Protocols (RBP III) at twelve (n=12) locations within the Tookany/Tacony-Frankford Watershed (Figure 3-5). Using EPA guidelines, macroinvertebrates were collected by placing a standard ($1m^2$) kicknet at the downstream portion of a riffle. The substrate was then kicked and scraped manually one meter from the net aperture to remove benthic invertebrates. Four rocks of varying size were randomly chosen within the sampling sites and manually scraped to remove benthic invertebrates. This procedure was repeated at another riffle location with less flow. Specimens were then preserved in 70% ETOH (ethyl alcohol) and returned to the laboratory in polyethylene containers. In the laboratory, samples were placed in an 11" x 14" gridded (numbered) pan and random subsamples, or "plugs" were examined until 100 individuals were collected. Macroinvertebrates were identified to genus, with the exception of mollusks, aquatic worms, chironomids, crayfish, and leeches, which were identified to the family level.

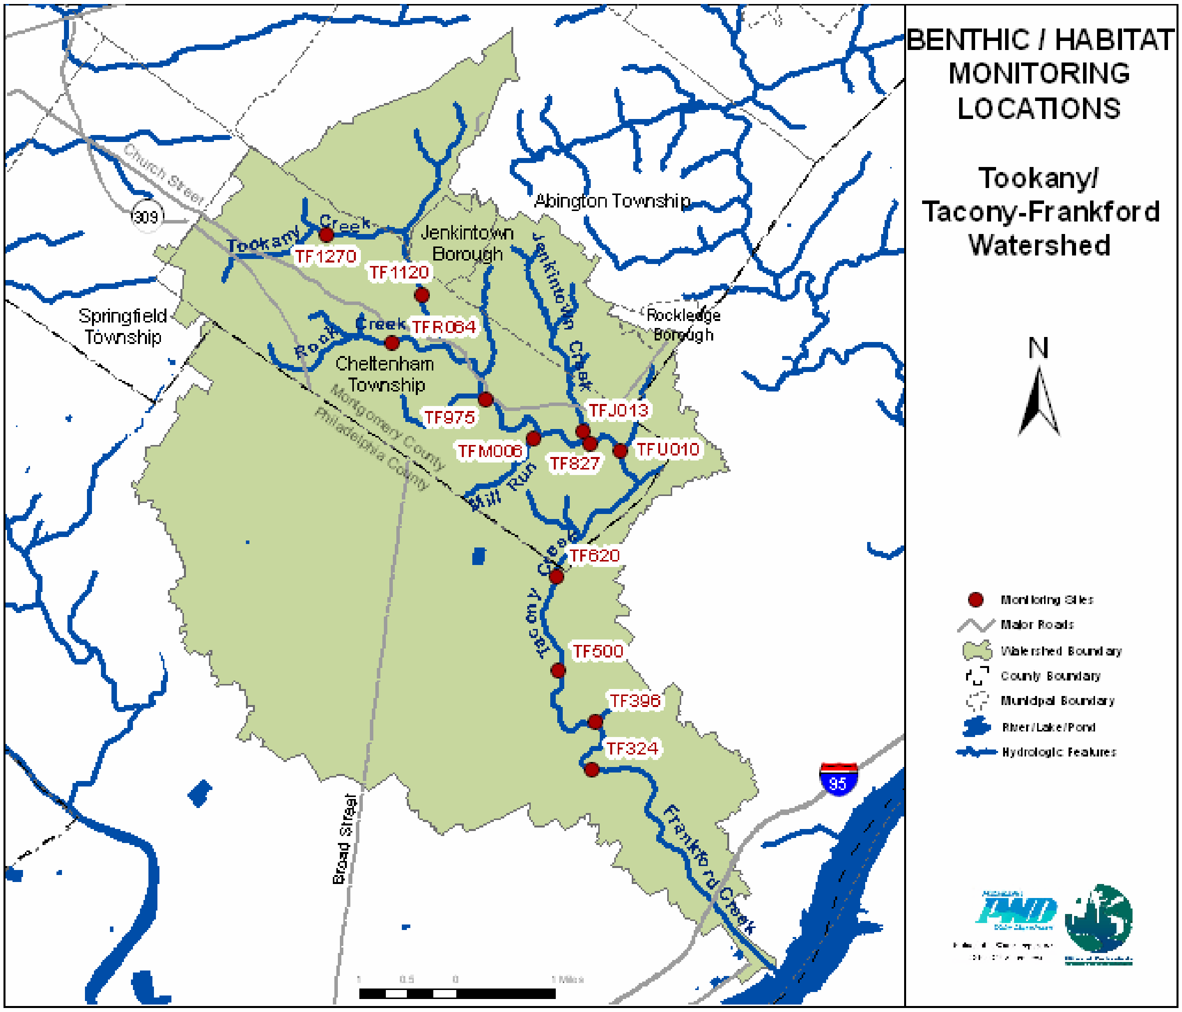

Figure 3-5 Benthic Macroinvertebrate Monitoring and EPA Habitat Assessment Sites in the Tookany/Tacony-Frankford Watershed, 2004

3.5.1 Metrics:

Biological integrity and benthic community composition of the 12 sites were assessed using the metrics in table 3-6. (EPA guidelines for RBP III and PA DEP Modified Rapid Biological Assessments)

Table 3-6 Biological Condition Scoring Criteria for RBP III

Metric	Biological Condition Scoring Criteria			
	6	4	2	0
Taxa Richness (a)	>80%	79-70%	69-60%	<60%
Hilsenhoff Biotic Index (Modified) (a)	<0.71	0.72-1.11	1.12-1.31	>1.31
Modified EPT Index (a)	>80%	79-60%	59-50%	<50%
Percent Contribution of Dominant Taxon (a)	<10	11-16	17-22	>22
Precent Modified Mayflies (a)	<12	13-20	21-40	>40
Ratio of Scrapers/Filter (b) Collectors	>50%	35-50%	20-35%	<20%
Community Loss Index (b)	<0.5%	0.5-1.5	1.5-4.0	>4.0
Ratio of Shredders/Total (b)	>50%	35-50%	20-35%	<20%

[a] Metrics used to quantify scoring criteria (PA DEP)
[b] Additional metrics used for qualitative descriptions of sampling locations (EPA)

Upon completion of the total biological scoring criteria, each site was compared to a reference site according to its drainage area and geomorphologic attributes. The reference sites chosen were French Creek, located at Coventryville, and Rock Run, a tributary of French Creek. Using the following chart, benthic quality of each site was established to identify spatial trends of impairment along the river continuum (Table 3-7).

Table 3-7 Biological Condition Categories for RBP III

% Comparison to Reference Score (a)	Biological Condition Category	Attributes
>83%	Nonimpaired	Comparable to the best situation within an ecoregion. Balanced trophic structure. Optimum community structure for stream size and habitat quality.
54-79%	Slightly impaired	Community structure less than expected. Species composition and dominance lower than expected due to loss of some intolerant forms. Percent contribution of tolerant forms increases.
21-50%	Moderately impaired	Fewer species due to loss of most intolerant forms. Reduction in EPT index.
<17%	Severely impaired	Few species present. If high densities of organisms, then dominated by one or two taxa.

(a) Percentage values obtained that are intermediate to the above ranges will require subjective judgment as to the correct placement. Use of the habitat assessment and chemical data may be necessary to aid in the decision process.

3.6 Ichthyofaunal (Fish) Sampling

3.6.1 Fish Collection in Non-Tidal Portions

Between 6/2/04 and 6/16/04, PWD biologists conducted fish assessments at seven (n=7) locations within the Tookany/Tacony-Frankford Watershed (Figure 3-5). Fish were collected by electrofishing as described in EPA's Rapid Bioassessment Protocol V (RBP V) (Barbour *et al*., 1999). Depending on stream conditions, Smith-Root backpack or tote barge electrofishers were used to stun fish. A 100m reach of the stream was blocked at the upstream and downstream limits with nets to prevent immigration or emigration from the study site. Each reach was uniformly sampled, and all fish captured were placed in buckets for identification and counting. An additional pass without replacement was completed along the reach to ensure maximum likelihood population and biomass estimates.

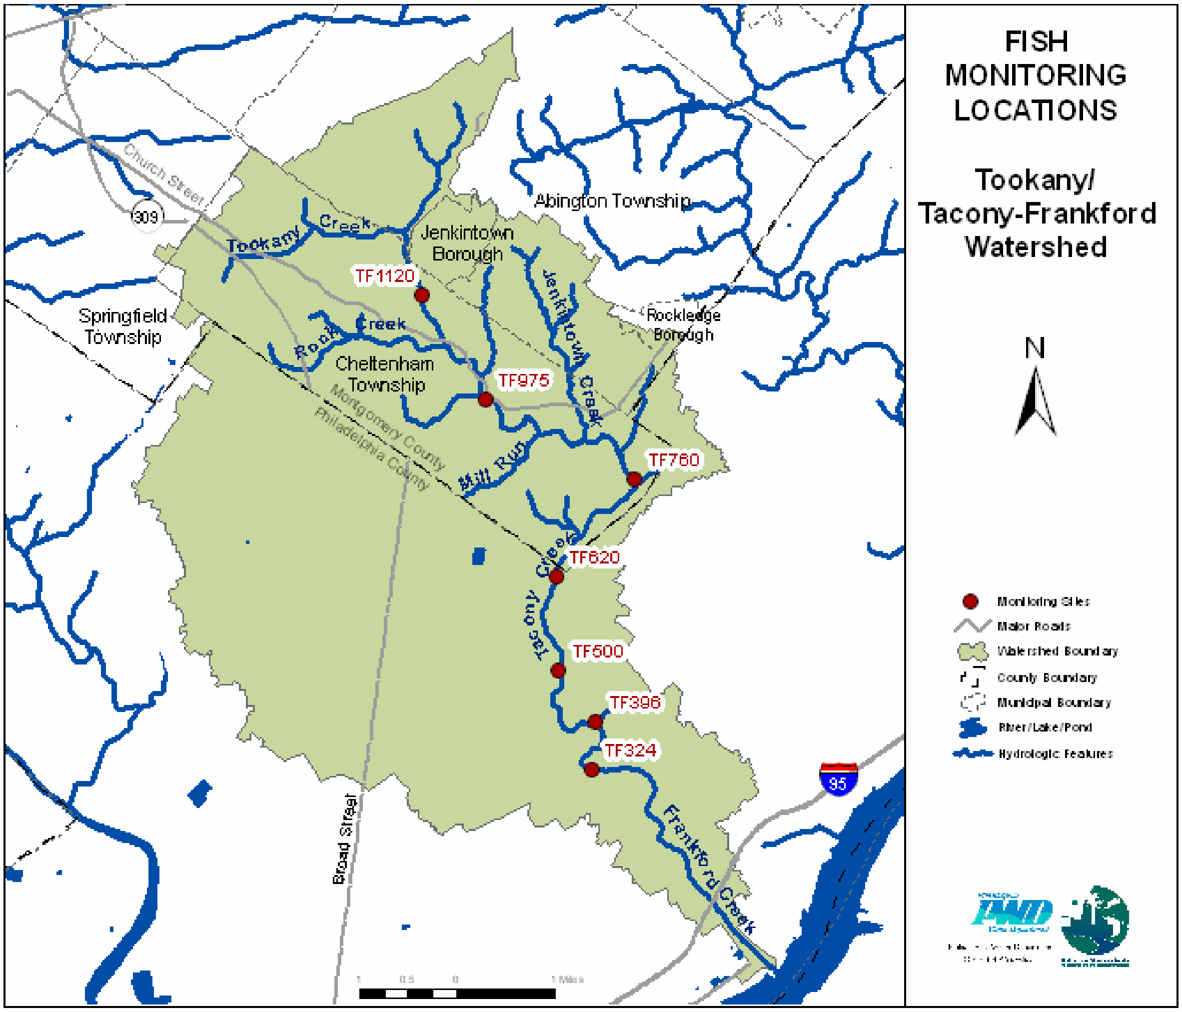

Figure 3-5 Non-Tidal Fish Monitoring Sites in the Tookany/Tacony-Frankford Watershed, 2004

3.6.2 Fish Collection in Tidal Portions

Between 8/1/04 and 8/8/04, staff biologists completed fish assessments at two (n=2) tidal locations in the Tookany/Tacony-Frankford Watershed (Figure 3-6). Fish inhabiting tidal portions of Frankford Creek were collected with Smith-Root electrofishing apparatus mounted aboard a small aluminum-hulled johnboat. Electrofishing was conducted for ten-minute intervals in a downstream direction, targeting areas with suitable fish habitat. It was not feasible to install block nets or otherwise prevent net movement of fish into or out of the sampling area.

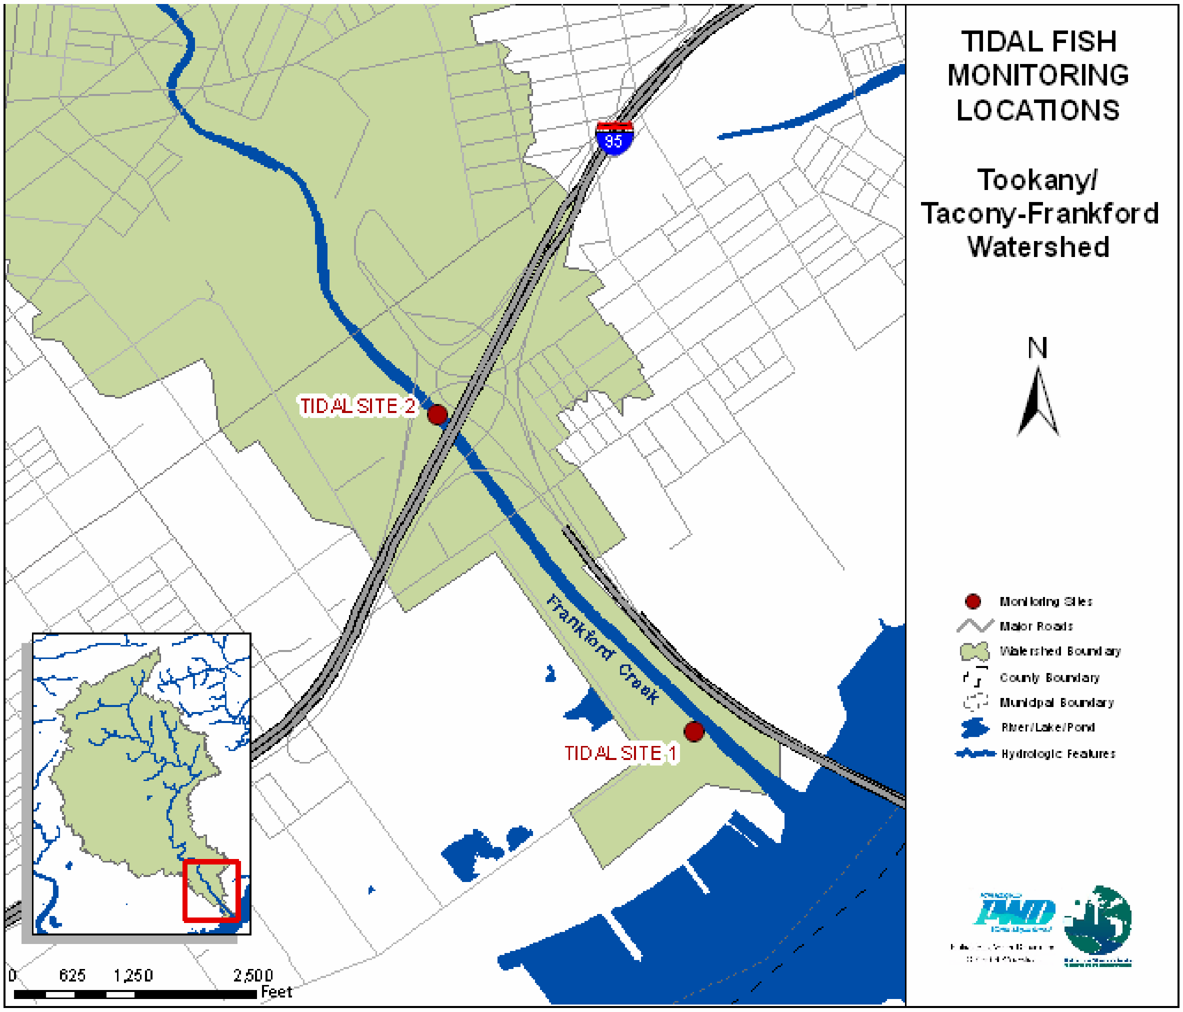

Figure 3.6 Tidal Fish Monitoring Sites in Frankford Creek, 2004

3.6.3 Sample Processing

Fish were identified to species, weighed (± 0.01 g) with a digital scale (Model Ohaus Scout II) and measured to the nearest 0.1 cm using a Wildco fish measuring board. Large fish that exceeded the digital scale's capacity were weighed using spring scales (Pesola). Any external deformations, lesions, tumors, cysts, or disease were noted during processing. Species that could not be identified in the field (*e.g.*, small or juvenile cyprinids) were preserved with 10% formalin solution and stored in polyethylene bottles for laboratory identification.

To facilitate the process of acquiring total fish biomass and to reduce field time, a simple linear regression was developed between weight (g) and length (cm). Approximately 20 individuals of each species were weighed, and total lengths were measured. Once 20 individuals of each species were measured (both weight and length), biomass (g) for each fish was calculated using the regression analysis. Similar procedures were conducted at the reference locations (*i.e.*, French Creek and Rock Run) to obtain a discrete measure of the condition of the fish assemblages at each assessment location.

3.6.4 Fish IBI Metrics:

The health of fish communities in Tookany/Tacony-Frankford Watershed was assessed based on the technical framework of the Index of Biological Integrity (IBI) developed by Karr (1981). The analysis entailed the definition of "ecoregional-specific" metrics pertinent to the fish assemblages located in the lower Schuylkill River Drainage. Standardized metrics (*i.e.*, indices) were then integrated to provide an overall indication of the condition of fish assemblages at each assessment location. Individual metrics within the fish IBI framework were also used to provide quantitative information regarding a specific attribute of the respective assessment location (*e.g.*, pollution tolerance values). In addition to IBI metrics, other metrics were incorporated into the design to evaluate the overall ecological health of fish assemblages and as a means of comparison of each assessment site. Tables 3-8 and 3-9 describe the various indices and scoring criteria used for the IBI metrics in the Tookany/Tacony-Frankford Watershed. Additional metrics used in the analysis are displayed in Table 3-10.

Table 3-8 Metrics Used to Evaluate the Index of Biological Integrity (IBI) at Representative Sites.*

Metric	Scoring Criteria		
	5	3	1
1. Number Of Native Species	>67%	33-67%	<33%
2. Number Of Benthic Insectivore Species	>67%	33-67%	<33%
3. Number Of Water Column Species	>67%	33-67%	<33%
4. Percent white sucker	<10%	10-25%	>25%
5. Number Of Sensitive Species	>67%	33-67%	<33%
6. Percent Generalists	<20%	20-45%	>45%
7. Percent Insectivores	>45%	20-45%	<20%
8. Percent Top Carnivores	>5%	1-5%	<1%
9. Proportion of diseased/anomalies	<1%	1-5%	>5%
10. Percent Dominant Species[a]	<40%	40-55%	>55%

* Metrics used are based on modifications as described in Barbour, *et al*., 1999.

[a] Metric based on USGS NAWQA study (2002).

Table 3-9 Index of Biological Integrity (IBI) Score Interpretation.*

IBI	Integrity Class	Characteristics
45-50	Excellent	Comparable to pristine conditions, exceptional assemblage of species
37-44	Good	Decreased species richness, intolerant species in particular
29-36	Fair	Intolerant and sensitive species absent; skewed trophic structure
10-28	Poor	Top carnivores absent or rare; omnivores and tolerant species dominant
<10	Very Poor	Few species and individuals present; tolerant species dominant; diseased fish frequent

* IBI score interpretation based on Halliwell, *et al*., 1999.

Table 3-10 Additional Metrics Used to Evaluate Fish Assemblage Condition

Metric	Assessment Type
Species Diversity	Shannon (H') Diversity Index
Trophic Composition	Percentage of Functional Feeding Groups
Tolerance Designations	Percentage of Pollution Tolerant, Moderate And Intolerant Species
Modified Index Of Well-Being	MIwb Index

3.6.5 Species Diversity:

Species diversity, a characteristic unique to the community level of biological organization, is an expression of community structure (Brower *et al.*, 1990). In general, high species diversity indicates a highly complex community. Thus, population interactions involving energy transfer (*e.g.*, food webs), predation, competition and niche distribution are more complex and varied in a community of high species diversity. In addition, many ecologists support species diversity as a measure of community stability (*i.e.*, the ability of community structure to be unaffected by, or recover quickly from perturbations). Using the Shannon (H') Diversity Index formula, species diversity was calculated at each sampling location:

$$H' = -\Sigma\, n_i/N * \ln (n_i/N): \qquad \text{(eq. 1)}$$

where n_i is the relative number of the *i*th taxon and N is the total number of all species.

3.6.6 Trophic Composition and Tolerance Designations:

Trophic composition metrics were used to assess the quality of the energy base and trophic dynamics of the fish assemblages (Plafkin *et al.*, 1989). The trophic composition metrics offer a means to evaluate the shift toward more generalized foraging that typically occurs with increased degradation of the physiochemical habitat (Barbour *et al.*, 1999). Pollution tolerance metrics were also used to distinguish low and moderate quality sites by assessing tolerance values of each species identified at the sampling locations. This metric identifies the abundance of tolerant, moderately tolerant and pollution intolerant individuals at the study site. Generally, intolerant species are first to disappear following a disturbance. Species designated as intolerant or sensitive should only represent 5-10% of the community; otherwise the metric becomes less discriminatory. Conversely, study sites with fewer pollution intolerant individuals may represent areas of degraded water quality or physical disturbance. For a more detailed description of metrics used to evaluate the trophic and pollution designations of fish assemblages, see Barbour *et al.*, (1999).

3.6.7 Modified Index of Well-Being (MIwb):

Modified Index of Well-Being (MIwb) is a metric that incorporates two abundance and two diversity measurements. Modifications from the Ohio EPA (1987), which eliminate pollution tolerant species, hybrids and exotic species, were incorporated into the study in order to increase the sensitivity of the index to a wider array of environmental disturbances. MIwb is calculated using the following formula (equation 2):

$$MIwb = 0.5*\ln N + 0.5*\ln B + H_N + H_B \quad \text{(eq. 2)}$$

where;

N = relative numbers of all species
B = relative weight of all species
H_N = Shannon index based on relative numbers
H_B = Shannon index based on relative weight

3.7 Algae Sampling

Between 8/17/2004 and 9/17/2004, replicate algae samples were collected from three (n=3) sites within the Tookany/Tacony-Frankford Watershed (Figure 3-7). Samples were collected on six occasions to determine the biomass of benthic algae in terms of chlorophyll-*a* (chl-*a*), spatial variation in biomass within and between sites, the scouring effects of high flows, and algal accrual rates following a high flow event.

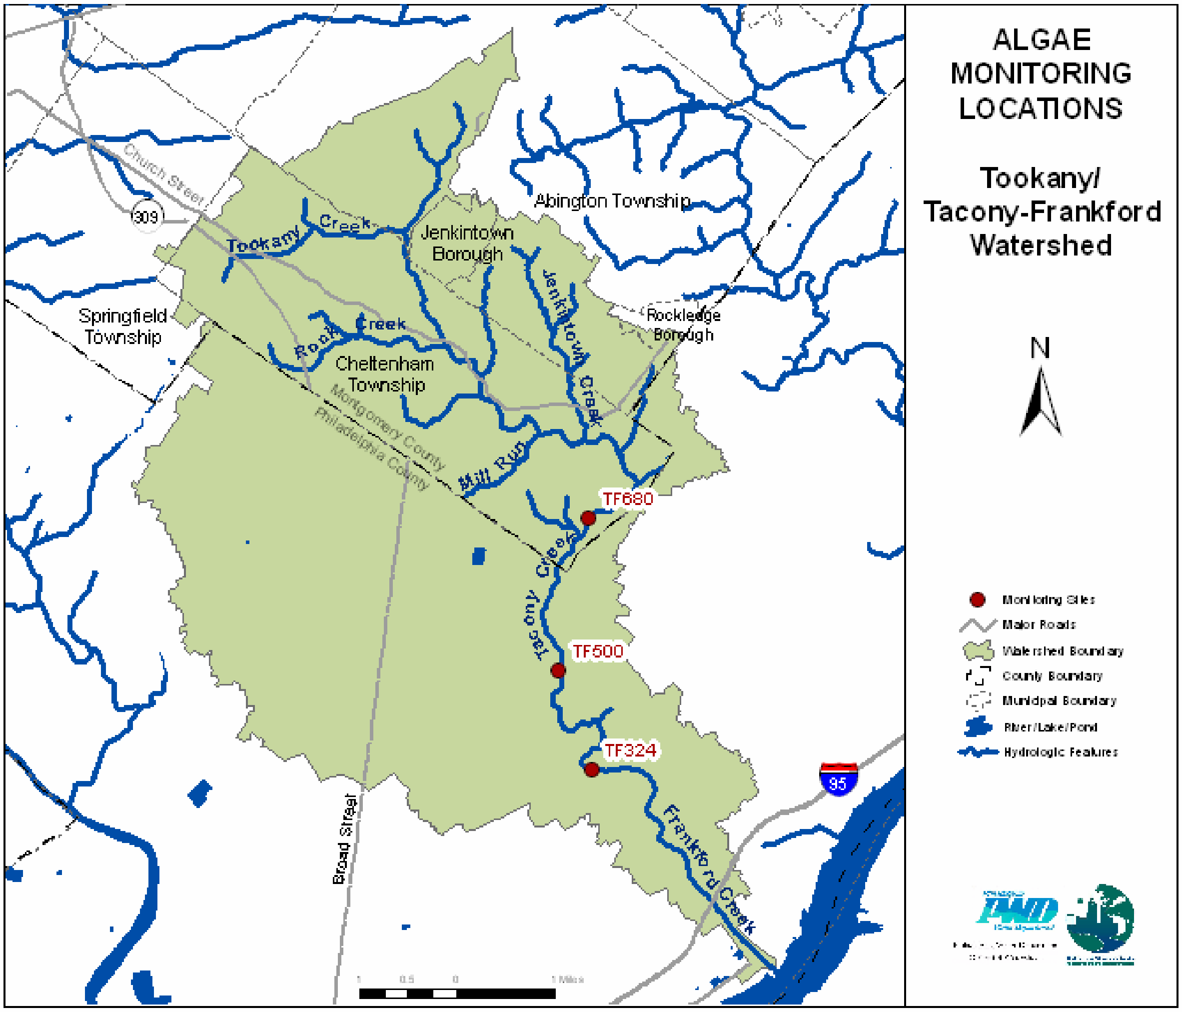

Figure 3-7 Algae Monitoring Locations in the Tookany/Tacony-Frankford Watershed, 2004

3.7.1 Periphyton Collection Procedure

Sampling was conducted on the main channel of the Tookany/Tacony-Frankford Creek at or near stations where continuous water quality parameters (*i.e.*, DO, temperature, pH, conductivity) were recorded. During the course of the study, TF280, TF500, and TF620 were the only stations that had continuously recording sondes. Because of heavy shading and different habitat conditions (*e.g.*, deeper water, slower flow) at TF500 than at TF280 and TF620, sampling focused on the latter two sites. Samples were collected near site TF280 at site TF324 and near site TF620 at site TF680. On one occasion, algal samples were also collected from TF500 (8/19/2004). The total number of samples collected with respect to site and date are shown in Table 3-11.

Table 3-11 Number of Periphyton Samples Collected with Respect to Site and Date from the Tookany/Tacony-Frankford Watershed, 2004

Date	Site	Sampling Program	# samples chl-*a*
8/19/04	TF324	Monitor	8
	TF500	Monitor	5
	TF680	Monitor	8
8/23/04	TF324	Monitor	5
	TF680	Monitor	5
8/26/04	TF324	Monitor	5
	TF680	Monitor	5
9/8/04	TF324	Monitor	0
	TF680	Monitor	4
	TF680	Scour	4
9/13/04	TF324	Monitor	4
	TF324	Scour	4
	TF680	Monitor	4
	TF680	Scour	4
9/17/04	TF324	Monitor	4
	TF324	Scour	4
	TF680	Monitor	4
	TF680	Scour	4

Because we were interested in determining how algal biomass was reduced following scouring by a high flow event, we attempted to collect initial algal samples near a predicted rain event, and additional algal samples following the rain event. However, during the sampling period, a rain event adequate to cause scouring did not occur. Because we were concerned that seasonal changes in biomass would occur before a sufficient scouring event did, we artificially simulated effects of a high flow event by removing algae from approximately 50 rocks at TF324 and TF680 and placing them back in the stream. Algal material was removed by scrubbing the rocks with plastic scouring pads. Algal material was sampled at TF680 on the same date for "pre-scour" data. "Pre-scour" samples could not be collected at TF324 because of elevated stream levels from a brief rain event. Subsequent "post-scour" samples were collected from both TF324 and TF680 on 9/13/2004 (Day 5) and 9/17/2004 (Day 9). Scoured substrates on day 0 were presumed to have chl-*a* concentrations less than 5 mg/m^2 and daily accrual rates for each site determined by dividing the net gain or loss of algae by time (days).

All samples were collected using the same methods. Composite algal samples (2-6 rocks) were collected from randomly selected rocks by brushing and scraping using toothbrushes and scalpels or other scraping tools. Material from each composite sample was placed in a separate container, labeled, and placed on ice in darkened containers until arrival at the laboratory. Composite algal samples were collected rather than individual rocks because when algal biomass is low or coverage is heterogeneous, sampling at the rock scale can artificially increase within-site variation and reduce the power of the data collected. To ensure adequate algal biomass and reduce within-site variation, all replicate algal samples were a composite of material from 2-6 rocks.

The area sampled was determined by wrapping the sampled area in aluminum foil. The 3-dimensional foil mold was carefully removed from the rock and cut with scissors so the foil lay as flat as possible. The area of the foil was then digitized using Scion Image (Beta 4.0.2), a windows version of NIH Image for the Macintosh, to calculate surface area.

In addition to algal biomass samples, samples were collected for quantitative taxonomic analysis. Composite samples were collected in the same manner as biomass samples and algal material removed by brushing and scraping. Algal material for each sample was placed in a separate container and preserved in 5-10% formalin for taxonomic identification of soft algae and diatoms. These samples will be analyzed by the Phycology Section at the Academy of Natural Sciences, but data will not be presented in this report.

3.7.2 Laboratory Procedures

Composite algal samples were processed by homogenizing the sample in a blender. The sample was measured in a graduated cylinder and the total volume brought to 1 L with deionized water. A 15 mL sub-sample for chl-*a* analyses was filtered through a 47 mm glass fiber filter (Whatman, 0.7-µm nominal pore size). For a subset of samples, an algal sub-sample was filtered through a weighed, pre-combusted glass fiber filter to determine percent solids and percent organic matter. Filters for both measures were stored frozen.

Algal samples were analyzed for chl-*a* according to Standard Methods for fluorometry (APAH 1992). Percent solids and percent organic matter were determined by drying the filters to a constant weight at 105ºC for 24 h (mass of solids) and burning the sample in a muffle oven at 550ºC for 1 h (APAH 1992). However, laboratory errors resulted in questionable AFDM data and these data are not reported.

3.7.3 Data Analyses

Spatial and temporal variation in algal biomass was examined using ANOVA (SYSTAT 10.2.01, 2002). Two-factor ANOVA was used to examine differences in chl-*a* with respect to site and sampling date for the general monitoring program. Because samples were only collected at TF500 on one occasion, these data were not included in the analyses. A three-factor ANOVA identified differences in chl-*a* between "scoured" and natural rocks with respect to site and date.

3.8 Habitat Assessment

3.8.1 EPA Habitat Assessment

Prior to benthic macroinvertebrate sampling procedures, habitat assessments at twelve (n=12) sites (Figure 3-5) were completed based on the Environmental Protection Agency's *Rapid Bioassessment Protocols for Use in Wadeable Streams and Rivers* (Barbour *et al*., 1999). Reference conditions were used to normalize the assessment to the "best attainable" situation. Habitat parameters are separated into three principal categories: (1) primary, (2) secondary, and (3) tertiary parameters. Primary parameters are those that characterize the stream "microscale" habitat and have greatest direct influence on the structure of indigenous communities. Secondary parameters measure "macroscale" habitat such as channel morphology characteristics. Tertiary parameters evaluate riparian and bank structure and comprise three categories: (1) bank vegetative protection, (2) grazing or other disruptive pressure, and (3) riparian vegetative zone width. Table 3-12 lists the various parameters addressed during habitat assessments.

Table 3-12 Habitat assessment criteria used at benthic monitoring stations.

Condition/Parameter	Condition			
	Optimal	**Suboptimal**	**Marginal**	**Poor**
Epifaunal Substrate/Available Cover	16-20	11-15	6-10	0-5
Pool Substrate Characterization	16-20	11-15	6-10	0-5
Pool Variability	16-20	11-15	6-10	0-5
Sediment Deposition	16-20	11-15	6-10	0-5
Embeddedness	16-20	11-15	6-10	0-5
Velocity/Depth Regime	16-20	11-15	6-10	0-5
Frequency of Riffles (or bends)	16-20	11-15	6-10	0-5
Channel Flow Status	16-20	11-15	6-10	0-5
Channel Alteration	16-20	11-15	6-10	0-5
Channel Sinuosity	16-20	11-15	6-10	0-5
Bank Stability*	9-10	6-8	3-5	0-2
Vegetative Protection*	9-10	6-8	3-5	0-2
Riparian Vegetative Zone Width*	9-10	6-8	3-5	0-2

*Both right and left banks are assessed separately.

3.8.2 Habitat Suitability Index (HSI) Model Methods

3.8.2.1 Model History and Assumptions

Prior to the development of Instream Flow Incremental Methodology (IFIM), a number of Habitat Suitability Index (HSI) models were developed by the U.S. Fish and Wildlife Service (USFWS). Based on empirical data and supported by years of research and comprehensive review of scientific literature, these models present numerical relationships between various habitat parameters and biological resources, particularly gamefish species and species of special environmental concern. Through evaluation of various input parameters, models arrive at a final index value between 0 and 1, a score of 1 corresponding to the ideal habitat condition, and zero indicating that some aspect of the habitat is unsuitable for supporting a naturally reproducing population of the species of interest.

Numerous assumptions are inherent with use and interpretation of the models. First and foremost is the assumption that habitat features alone are responsible for determining abundance or biomass of the species of interest at the study site. Clearly, no species exists in a vacuum; aside from habitat variables, other ecological and environmental interactions can strongly influence biological communities. HSI indices assume that users will use good professional judgment, consult with regional experts when necessary, and consider the possible effects of other factors (*e.g.*, competition, predation, toxic substances and other anthropogenic factors) when interpreting model output.

3.8.2.2 Model Data Requirements

Most types of data required by HSI models were available for all sites within Tookany/Tacony-Frankford Watershed. However, a number of habitat parameters were not directly measured in a fashion best suited for use with HSI models and required additional interpretation or normalization. Few water quality parameters were measured with equal sampling effort across all sites; some parameters were measured with continuous monitoring instruments at some sites and grab samples or hand-held meters at other sites. Some variables were not directly measured at some sites. To facilitate HSI analysis at these sites, (conservative) values were substituted based on sampling conducted at nearby sites and reference sites in neighboring watersheds. Turbidity data were excluded from the analyses entirely because all HSI were developed using Jackson Turbidity Units (JTU), which cannot be converted to/from modern Nephelometric Turbidity Unit (NTU) data. Any other significant modifications to the variables or the modeling approach are explained in Section 5.3.5 (Habitat Suitability Indices). A list of all HSI input variables for the seven HSI models applied to Tookany/Tacony-Frankford Watershed appears in Table 3-13.

Table 3-13 Habitat Suitability Index (HSI) variable matrix.

HSI Model Variable Matrix	Variable Type	Blacknose Dace	Common shiner	Creek Chub	Fallfish	Longnose Dace	Redbreast Sunfish	Smallmouth Bass
Total number of HSI variables		**16***	**9**	**20**	**6**	**6**	**10**	**13***
Average Temperature during growing season (May-Oct.)	**temperature**	X						X
Average Temperature in spawning season**		X	X		X		X	X
Maximum temperature sustained for 1 week			X			X	X	
Average Summer Temperature (Jul-Sep)				X	X			
Average temperature during spring (May-Jun)				X				
Average Turbidity (JTU)***	**water quality**	X	X	X	X		X	X
Average yearly pH value			X					X
Least suitable pH value (instantaneous)							X	
pH fluctuation classification				X				
Minimum dissolved oxygen concentration				X			X	X
Minimum dissolved oxygen conc. During spring				X				
Percent instream cover during average summer flow	**general stream characteristics**			X		X	X	X
Instream cover classification					X			
Percent shading of stream between 1000 and 1500 hrs.		X		X				
Percent vegetative cover							X	
Availability of thermal refugia (winter) (Y/N)				X				
Stream gradient (m/Km)		X		X				X
Average stream velocity during average summer flow				X		X		
Dominant substrate characterization					X		X	
Stream width		X		X			X	
Mode of stream depth during average summer flow					X			
Water level fluctuations								X
Stream margin substrate characterization (Y/N)		X						
Average velocity along stream margins		X		X				
Stream margin vegetation characterization				X				
Substrate food production potential				X				
Percent riffles	**riffles**					X		
Riffle substrate characterization		X	X	X		X		
Average velocity in riffles		X	X	X				
Average depth of riffles		X						
Average maximum depth of riffles						X		
Percent pools	**pools**	X	X	X			X	X
Pool substrate characterization		X						X
Pool classification			X	X				
Average depth of pools				X				X
Average velocity at 0.6 depth in pools		X	X					

* Some variables used more than once, applied to different life stages
**Spawning season varies by species. Common Shiner and Fallfish use a Y/N index.
*** Turbidity relationships developed using Jackson candle units; cannot be converted to NTU values

3.8.2.3 Suitability Index Expressions

HSI models use three major types of Suitability Index (SI) expressions or mathematical relationships to compute the suitability of a given habitat variable; they are (in increasing order of complexity): 1) categorized relationships, 2) linear equations (or more commonly, series of linear equations bounded by inflection points), and 3) suitability curves. Categorized relationships are used for a limited number of HSI variables in which the relationship between the habitat feature and suitability for the species of interest is fairly simple. Substrate size categorization is one example; many HSI models use dominant substrate type categories (*e.g.*, silt, sand, gravel, cobble, boulder, bedrock). Other SI variables that may be defined by simple categorization are temperature, dissolved oxygen, pH or, or in some cases, the variability of these measurements (Figure 3-8). Categorized data were processed directly within Microsoft Excel spreadsheet HSI models.

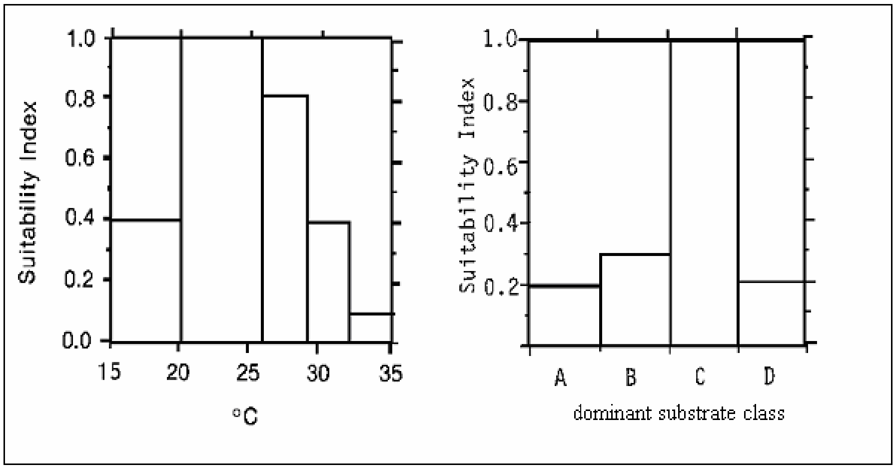

Figure 3-8 Categorized expressions in HSI models.

Many SI variables are defined by a series of linear relationships bounded by inflection points (*i.e.*, a collection of linear relationships that roughly approximate a curve). Many of these relationships include a range of unsuitable (SI=0) values, a range of ideal (SI =1.0) values, or both. Although all types of SI variables were, in some cases, defined by series of linear relationships (Figure 3-9), these expressions were less likely to be employed as models increased in complexity. As models become more complex, there is a corresponding increased focus on development of SI curves. SI variables defined by linear relationships were processed using linear equations and Boolean commands directly in Excel spreadsheet models.

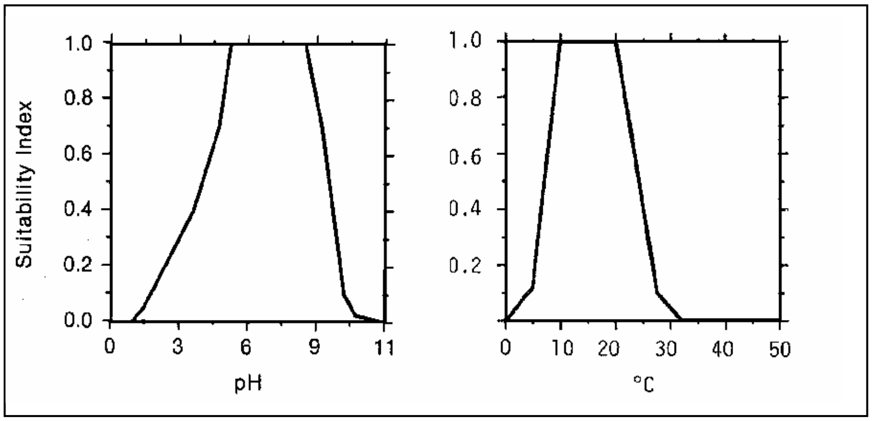

Figure 3-9 Linear expressions in HSI models.

SI curve relationships are considered the most precise and continuous of SI relationships, and therefore, appear more frequently in more complex HSI models. For example, curves allow models to accurately represent the non-linear, sub-asymptotic change in SI expected as a habitat variable approaches complete unsuitability or ideal suitability (SI score 0 or 1 respectively). Two general SI curve shapes were common, modified parabolae and "s-curves", though there was considerable variation in actual curve shape between different SI variables (Figure 3-10). As curve equations were not provided with HSI model documentation, lookup tables were generated by scanning curves with data extraction software (Data Thief). Subsequent data processing was handled in Excel.

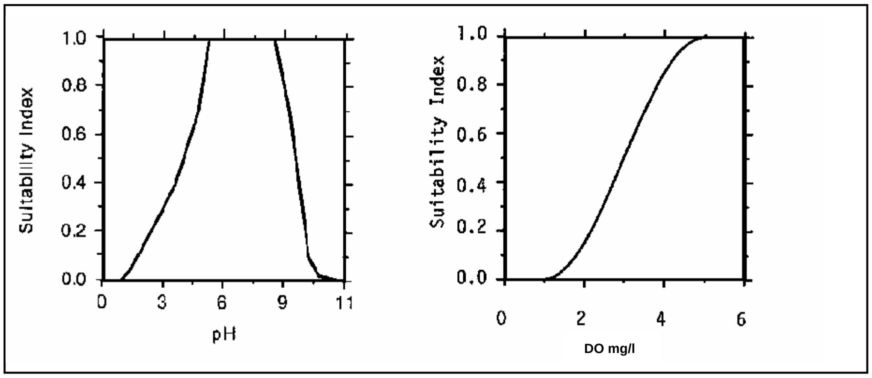

Figure 3-10 Curve relationships in HSI models.

3.8.2.4 Model Evaluation

HSI model output for each site was compared to EPA habitat data results. With the exception of longnose dace, smallmouth bass and fallfish HSI data, HSI model output was compared to observed fish abundance and biomass with correlation analyses. Several habitat models likely require modification in order to be useful in guiding or evaluating stream habitat improvement activities. While time constraints precluded the modification of models to better suit Tookany/Tacony-Frankford Watershed, it is hoped that such modifications will increase the usefulness of these models in the future.

3.9 Chemical Assessment

3.9.1 Fixed Interval Chemical Sampling

Bureau of Laboratory Services staff collected surface water grab samples at eight (n=8) locations within Tookany/Tacony-Frankford Watershed for chemical and microbial analysis (Figure 3-11). Samples from sites TF620 and TF680 were combined for analysis and considered TF620. Sampling events were planned to occur at each site at weekly intervals for one month during three separate seasons. Actual sampling dates were as follows: "winter" samples collected 1/15/04, 1/22/04, 1/29/04, and 2/5/04; “spring” samples collected 4/21/04, 4/29/04, 5/6/04, and 5/13/04; “summer” samples collected 8/5/04, 8/12/04, 8/19/04 and 8/26/04. A total of 96 discrete samples, comprising 3552 chemical and microbial analytes, were collected and recorded during the 2004 assessment of the Tookany/Tacony-Frankford Watershed. To add statistical power, additional discrete water quality samples from PWD's wet-weather chemical sampling program were included in analyses when appropriate. Sites TF280, TF500, TF620, TF760, TF975, TF1120 and TFJ110 were included in PWD's baseline chemical assessment of Tookany/Tacony-Frankford

Watershed in 2000. A single new site (TFM006), located on Mill Run and the Tacony Creek confluence was added for 2004.

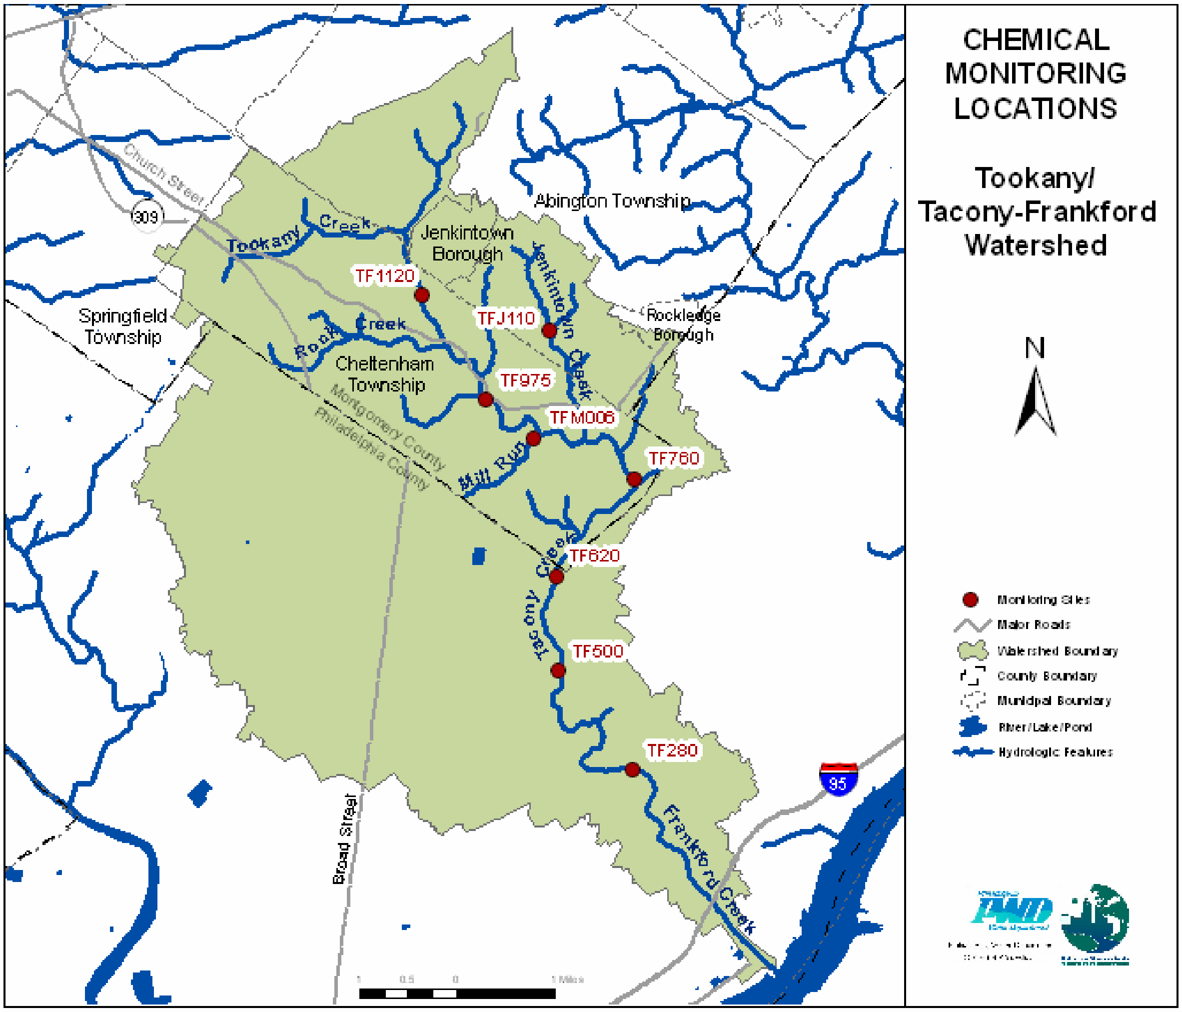

Figure 3-11 Fixed Interval Chemical Sampling Locations in the Tookany/Tacony-Frankford Watershed, 2004

Discrete sampling was conducted on a weekly basis and was not specifically designed to target wet or dry weather flow conditions. Depending on which definition of "dry weather" was used (*i.e.*, 48 hr interval or 72 hr interval), between 6-7 sampling events occurred during dry weather- this data is most pertinent to Target A of the Watershed Management Plan (Dry Weather Water Quality and Aesthetics). Specifically addressed are indicators 7 and 8 – chemical and microbial constituents that are influential in shaping communities of aquatic systems or that are indicative of anthropogenic degradation of water quality in the watershed.

3.9.2 Wet-Weather Targeted Sampling

Target C of the Watershed Management Plan addresses water quality in wet weather. Yet characterization of water quality at several widely spatially distributed sites simultaneously over the course of a storm event presents a unique challenge. Automated samplers (Isco, Inc.) were used to collect samples during nine runoff producing rain events in 2003 and 2004. Seven events took place in 2003 on 10/14/03, 5/2/03, 5/5/03, 5/7/03, 5/15/03, 7/10/03, and 9/23/03 and were monitored from four locations. Two events took place in 2004 on 7/7/04 and 8/30/04 and were monitored from six locations (Figure 3-12). Samples from sites TF620 and TF680 were combined for analysis and considered TF620.

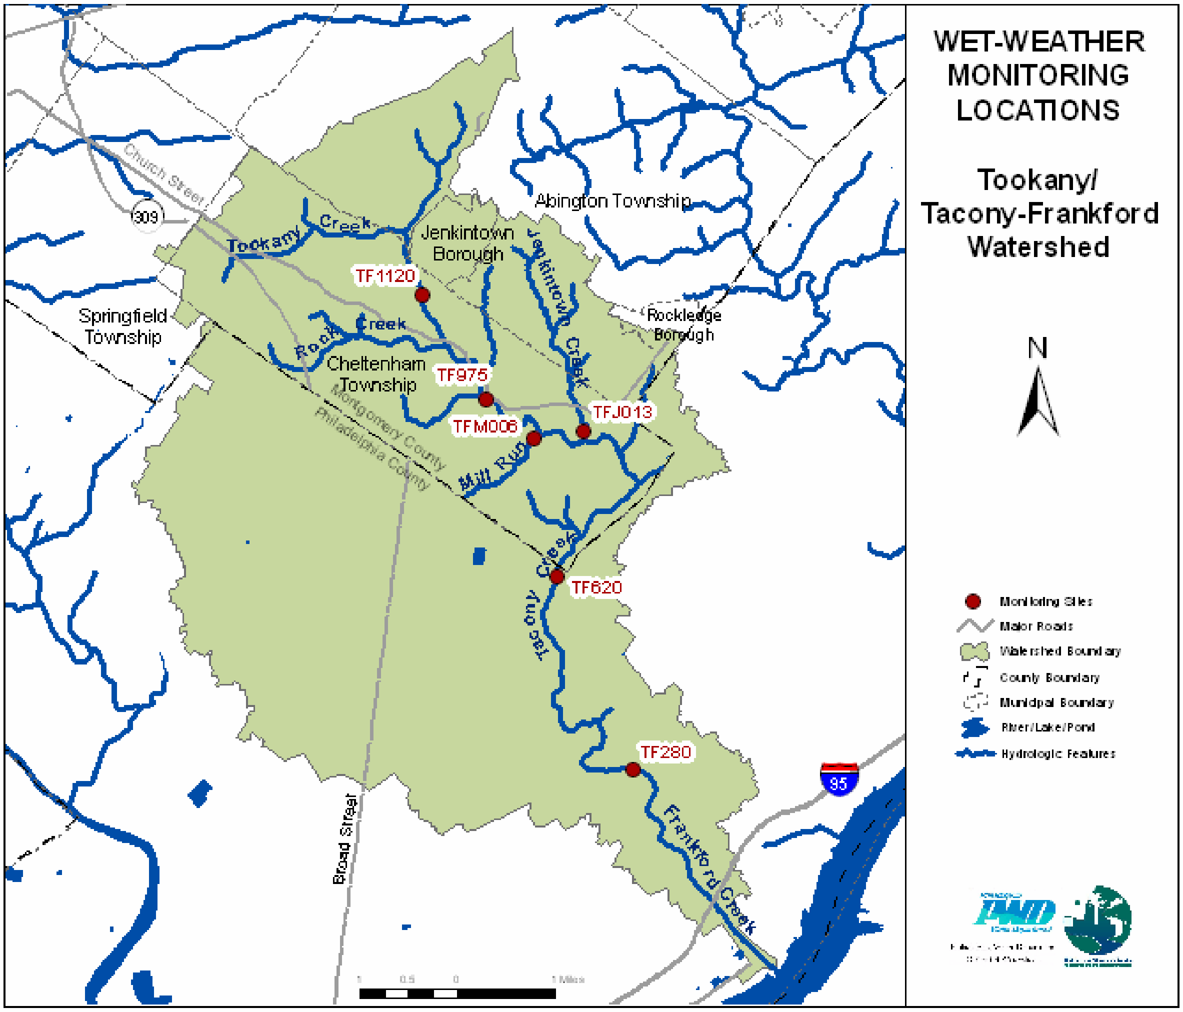

Figure 3-12 Wet Weather Sampling Sites in the Tookany/Tacony-Frankford Watershed, 2004

The automated sampler system obviated the need for BLS team members to manually collect samples, thereby greatly increasing sampling efficiency. Automated samplers were equipped with vented instream pressure transducers that allowed sampling to commence beginning with a small (0.1ft.) increase in stage. Once sampling was initiated, a computer-controlled peristaltic pump and distribution system collected the first 4 grab samples at 20 minute intervals and the remaining samples at 1.5 hr. intervals.

Use of automated samplers allows for a greater range of flexibility in sampling programs, including flow-weighted composite sampling based on a user defined rating curve, but stage discharge rating curves at these sites were poorly defined for larger flows. Though some difficulties were encountered due to a combination of mechanical failure, individual site characteristics, and/or vandalism, the 20 minute and 1.5 hour intervals were found to be generally satisfactory in collecting representative samples over the course of a storm event.

3.9.3 Continuous Water Quality Monitoring

Physicochemical properties of surface waters are known to change over a variety of temporal scales, with broad implications for aquatic life. Several important, state-regulated parameters (*e.g.*, dissolved oxygen, temperature, and pH) may change considerably over a short time interval, and therefore cannot be measured reliably or efficiently with grab samples. Self-contained data logging continuous water quality monitoring Sondes (YSI Inc. Models 6600, 600XLM) were deployed between 3/20/2001 and 10/5/2004 at seven (n=7) sites within Tookany/Tacony-Frankford Watershed in order to collect DO, pH, temperature, conductivity and depth data (Figure 3-13). Samples from sites TF620 and TF680 were combined for analysis and considered TF620. Sondes continuously monitored conditions and discretized the data in 15 min increments.

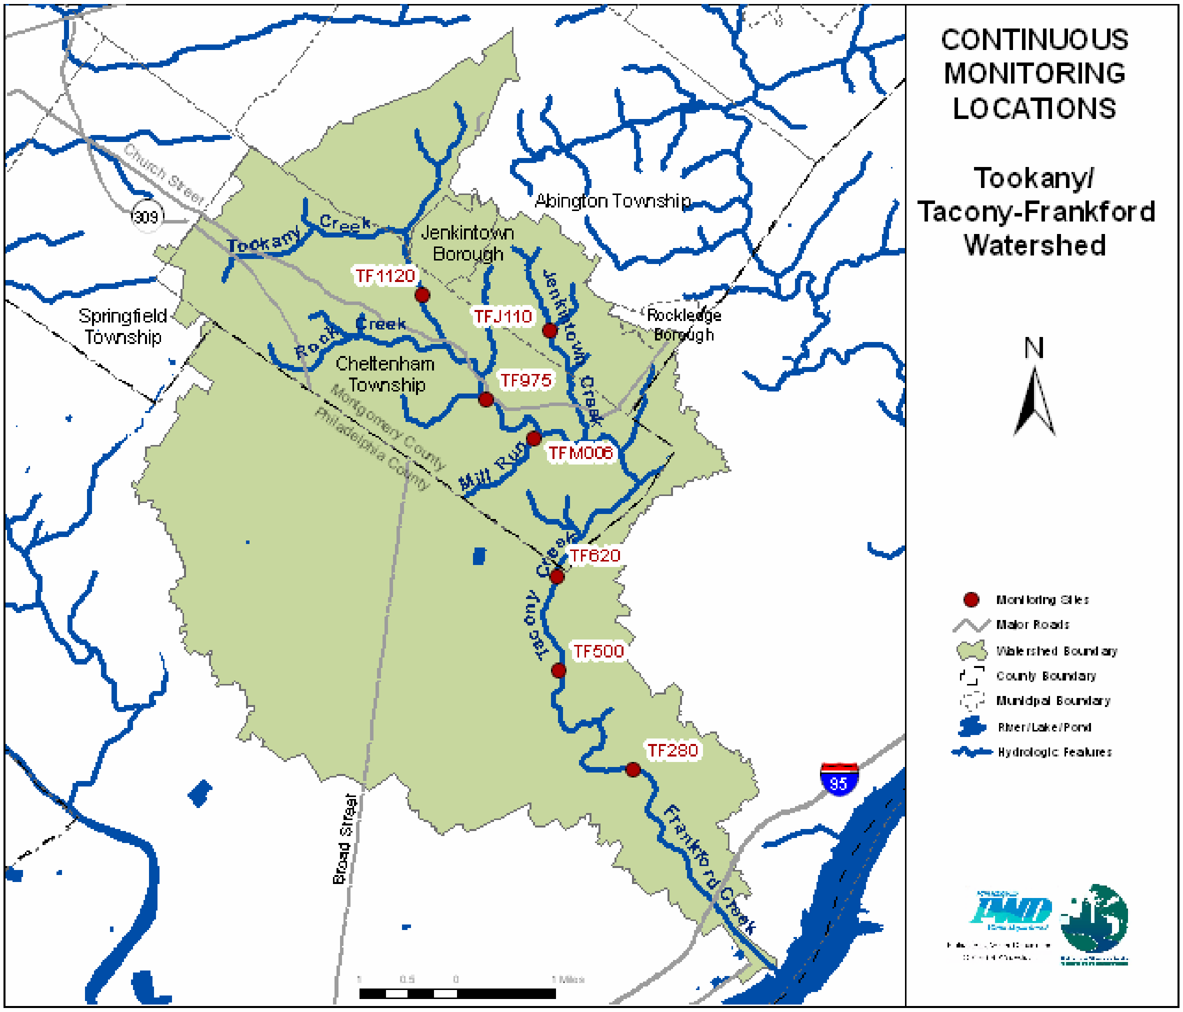

Figure 3-13 Continuous Water Quality Monitoring Sites in Tookany/Tacony-Frankford Watershed, 2004

Extended deployments of continuous water quality monitoring instruments in urban streams present challenges: drastic increases in stream flow and velocity, probe fouling due to accumulation of debris and algae, manpower required for field deployment and maintenance, and the need to guard against theft or vandalism. With refinements to Sonde enclosures and increased attention to cleaning and maintenance, PWD's Bureau of Laboratory Services has made wide-reaching improvements in the quality and recoverability of continuous water quality data, particularly dissolved oxygen (DO) data. Despite improvements, some DO data was rejected (Table 3-14) (See Appendix B). All pH and Temperature data was acceptable.

Table 3-14 Total Sonde hours and rejected DO data.

3.9.4 RADAR Rainfall Data and Analysis

Because storm events are inherently variable and do not evenly distribute rainfall spatially or temporally, PWD contracted with Vieux and Associates to obtain discretized measurements of rainfall intensity during storm events targeted by wet weather sampling. For each 15 minute interval, RADAR tower-mounted equipment measured high frequency radio wave reflection in the atmosphere above Tookany/Tacony-Frankford watershed. This information was provided to PWD as a series of relative reflectivity measurements for individual 1km^2 blocks. The resulting grid allowed for the summing of relative rainfall intensity within the sub-shed served by each sampling site over the course of each individual storm event (Figure 3-14). Individual intensity measurements were also graphed and arranged sequentially to produce animated time-series rainfall accumulation graphics. This analysis, combined with data from the PWD rain gauge network and stream stage measurements logged by the automated sampler, allowed for more thorough analysis of water quality data, particularly in determining whether some areas or sub-sheds may have contributed more runoff than others.

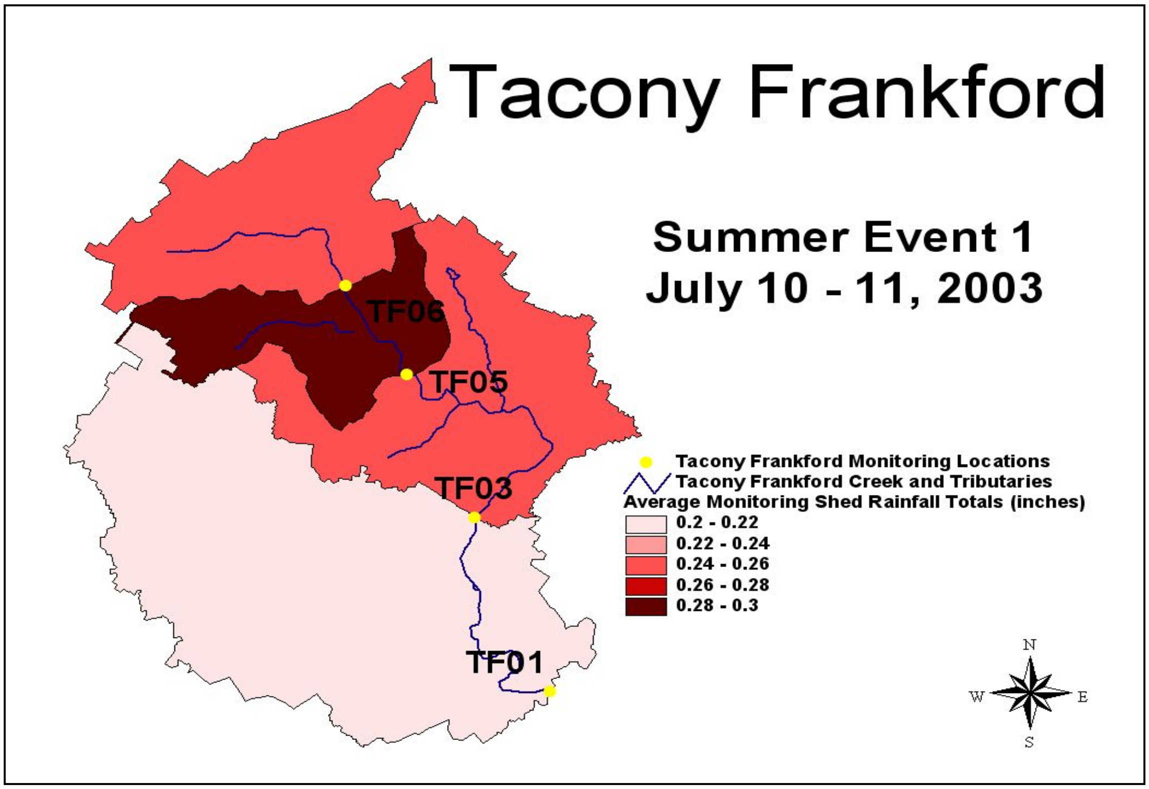

Figure 3-14 RADAR Rainfall Totals by Subshed (7/10/03-7/11/03)

3.10 Fluvial Geomorphological (FGM) Analysis

Between December 2003 and March 2004, Philadelphia Water Department staff conducted FGM analysis on the Tookany/Tacony-Frankford Creek and its tributaries. Analysis was conducted in order to characterize channel morphology, disturbance, stability, and habitat parameters as well as to provide a template for hydrologic and hydraulic modeling and serve as a baseline for assessing channel bank and bed changes.

3.10.1 Watershed Characterization

Philadelphia Water Department staff collected existing information from key stakeholders including existing maps, GIS layers, aerial photographs, studies, and documents. Topographic information, geological maps, soils maps, and aerial photographs were reviewed to identify key features along the stream corridor that may not be apparent in the field. Regional curve data developed for the Northeast was used to determine ranges of hydraulic geometry relationships based on the bankfull discharge. This information was used strictly for field calibration purposes and comparison to actual observations.

3.10.2 Stream Survey

Philadelphia Water Department staff cruised 30 miles of streams within the study area. Cruising consisted of a team of environmental engineers and biologists walking the entire length of Tookany/Tacony-Frankford Creek and its tributaries and characterizing channel morphology, disturbance, stability, and habitat parameters. Philadelphia Water Department staff also performed a qualitative habitat assessment using customized parameters from the *Rapid Steam Assessment Technique* (RSAT, Washington Metropolitan council of Governments) and the *Qualitative Habitat Evaluation Index* (Ohio). Data was recorded on a *Measured Reach Stream Morphology, Channel Stability, and Habitat Evaluation Field Form*. Digital photographs were taken at strategic points throughout the cruised reaches and coded for reference. Base maps were used to mark stream classification boundaries, channel stability zones, and habitat features.

A *Cruised Reach Field Form* and a *Watershed Data Summary Spreadsheet* was completed for each reach. Data from the field forms was entered into a *Watershed Data Summary Spreadsheet.* The spreadsheet was programmed to generate qualitative ratings on bank and bed erosion conditions, shear stresses, channel stability and habitat value.

3.10.3 Stream Cross Sections

Philadelphia Water Department staff surveyed cross sections of Tookany/Tacony-Frankford Creek to characterize the morphological features of the channel, provide a template for hydrologic and hydraulic modeling, and serve as a baseline for assessing channel bank and bed changes (erosion and sediment accretion). Approximately 4 cross sections were surveyed per mile (102 cross sections). Each cross section extended a minimum of 25′ beyond the top of bank on both sides of the stream. Features surveyed included breaks in slope, bankfull stage, water surface and thalweg. A permanent monument (5/8″ reinforcing bar with a color cap) was established on one side of the cross section to mark the location and relative elevation. The approximate location of each cross section was also coded and mapped. Three digital photographs of each cross section were taken (upstream, downstream, and across the stream) to photo-document existing conditions.

Using the elevations established, cross section data was entered into an excel spreadsheet to provide an illustration of the cross section along with defining certain morphological characteristics.

3.10.4 Bank Pins and Scour Chains

Bank pins and scour chains have not been installed in Tookany/Tacony Creek; however they may be installed in the future. Bank pins and scour chains will provide PWD the opportunity to measure stream bank erosion rates and observe streambed degradation/aggradation.

3.10.5 Guiding Principles for Fluvial Geomorphologic Restoration of Tacony Creek

3.10.5.1 Identification Ranking and Analysis of Stream Impacts

A Geographic Information System (GIS) map and associated relational database for the information collected in the field was created. This system was used to assess the geographic distribution of impacted and vulnerable areas. Stream impacts were ranked on a comparative subwatershed basis as to their impacts and relative magnitude of contribution to overall water quality deterioration in the entire watershed. Impacts were ranked by both type of problem and by subwatershed. Rankings are shown in Tables 3-15 and 3-16.

Section 4
Characterization of Watershed Hydrology

This section examines the components of the hydrologic cycle for the Tookany/Tacony-Frankford Watershed. The hydrologic cycle includes precipitation, evaporation, infiltration into soil, stormwater runoff over the land surface and in the sewer system, surface water flow in streams, and groundwater. The different types of sewer systems that serve the area are discussed in this section because they are an important part of the hydrologic cycle in the urban environment.

4.1 Components of the Urban Hydrologic Cycle

One way to develop an understanding of the hydrologic cycle is to develop a water balance. The balance is an attempt to characterize the flow of water into and out of the system by assigning estimated rates of flow for all of the components of the cycle. It is also important to understand that the natural water cycle components including precipitation, evapotranspiration (ET), infiltration, stream baseflow, and stormwater runoff must be supplemented by the many artificial interventions related to urban water, wastewater, and stormwater systems.

The first step in developing a water balance for the urban hydrologic cycle is to identify the system boundaries and the pathways that allow water to cross those boundaries. For the Tookany/Tacony-Frankford Watershed, the system includes: the land surface within the watershed boundaries, structures and vegetation on the surface, and the subsurface beneath the watershed. Inputs to the system are precipitation and outside sources of potable water. Outflows from the system include streamflow through the system outlet, evaporation and transpiration losses to the atmosphere, and flows of wastewater to the system outlet. In addition, it is possible for subsurface exchanges to occur across the boundary.

Precipitation that falls on the land surface may evaporate, be taken up by plants and be lost through transpiration, or flow directly to a water body over land or through a storm sewer system. Flow in streams consists of stormwater runoff, combined sewer overflow, delayed wet weather inputs through shallow groundwater, and a baseflow component due to the discharge of groundwater to the creek during dry weather and wet weather. A portion of potable water pumped in from outside the watershed enters the sanitary sewer system and is sent to outside treatment plants, and a portion is lost to consumptive uses.

The system inflows and outflows can be split into a number of components. These are shown below as a simple, "input equals output" water balance with the many natural and anthropogenic components of a typical urban water cycle.

Inflows: ***P + OPW + WW/IND Rech + EDR + WW Disch***

Outflows: ***RO + SWW + GWW + EDW + BF + OWD + ET***

where:

P is the average precipitation at the Philadelphia gage,

OPW is the outside potable water brought in,

WW/IND Rech is the wastewater and industrial discharge back to groundwater,

EDR is the estimated domestic recharge from private septic systems,

WW Disch is the discharge of water to creeks from larger wastewater plants or industrial facilities,

RO is the surface water runoff component of precipitation,

SWW is the withdrawal of water from the creek, primarily for public water supply and industrial use,

GWW is the groundwater withdrawal from public water supply or industrial wells,

EDW is the estimated domestic withdrawal of groundwater from private wells,

BF is the median baseflow of streams,

OWD is the discharge of wastewater to outside plant, and

ET is the evaporation and transpiration of water and is used to close the equation. It thus contains the sum of errors of the other terms as well as the estimated ET value.

4.1.1 Precipitation

P + OPW + WW/IND Rech + EDR + WW Disch = RO + SWW+ GWW + EDW + BF + OWD + ET

Precipitation is the primary, natural inflow to the hydrologic system. Precipitation data used to estimate this component are available from the National Oceanography and Atmospheric Administration (NOAA) and from local gauges operated by PWD and other organizations. NOAA's gauge at the Philadelphia International Airport, located in southeastern Philadelphia, has over 100 years of hourly precipitation data covering a period of record from January 3, 1902 through the present. The average annual rainfall in the Philadelphia area based upon the airport gauge is 41 inches. Most months have average precipitation totals of 3-4 inches. The driest season is late fall, and the wettest is late summer when thunderstorms are common (Table 4-1). Average temperatures during the winter months are above the freezing point during the day and below the freezing point at night. Snow and snowmelt events occur, but it is rare for a snow pack to accumulate and last through the season.

Additional precipitation data can be obtained from PWD's network of 24 rain gauges throughout the city; these data are available in 15-minute increments from the early 1990s to the present. Nine of the city gauges are located in or near the Tookany/Tacony-Frankford Watershed, as shown in Section 3, Figure 3-1. Data from these gauges provide precipitation at a higher level of spatial and temporal detail.

Table 4-1 Average Monthly Precipitation, Temperature, and Potential Evaporation

Month	Average Precipitation (in)	Average Temperature High (°F)	Average Temperature Low (°F)	Potential Evaporation (in/month)
January	3.3	39.2	24.4	2.1*
February	2.9	42.1	26.1	2.1*

December	3.3	43.5	28.6	2.1*

** estimated*

4.1.2 Outside Potable Water

P + OPW + WW/IND Rech + EDR + WW Disch = RO + SWW+ GWW + EDW + BF + OWD + ET

The watershed is generally supplied with drinking water from sources of water outside the watershed. For the Philadelphia portion of the watershed, water is imported into the watershed through the drinking water distribution system from raw water drawn from the Schuylkill and Delaware Rivers. For the outside communities, most of the water is supplied by Aqua America (formerly Philadelphia Suburban Water Company).

For the Tookany/Tacony-Frankford Watershed, most of this water never leaves the urban infrastructure used to transmit drinking water to and convey wastewater from homes to wastewater treatment plants outside the watershed. In this sense, this component of the watershed water balance is not critical to watershed planning activities.

4.1.3 Wastewater and Industrial Recharge to Groundwater

P + OPW + WW/IND Rech + EDR + WW Disch = RO + SWW+ GWW + EDW + BF + OWD + ET

This component represents water that has been used in homes or industry, has been treated, and is subsequently discharged back to the groundwater, thus making it an "inflow" component. Available data suggest that there are no such discharges within the watershed. For this reason, this component is not included in the table of estimated flows for components of the hydrologic cycle.

4.1.4 Estimated Domestic Recharge

P + OPW + WW/IND Rech + EDR + WW Disch = RO + SWW+ GWW + EDW + BF + OWD + ET

This component represents water that has been used in homes and is subsequently discharged to septic systems. In this way, it represents an inflow component to the groundwater portion of the hydrologic cycle. Although the number of septic tanks within the watershed is hard to accurately quantify; the 1990 census data indicated that about 1075 septic tanks were present in the watershed, 706 of which are within the city of Philadelphia. This number is believed to be a high estimate of the actual number.

Based on this information and an estimate of 50 gallons of sewage per person per day discharged to septic systems, this component represents potential 53,750 gallons per day in the Tookany/Tacony-Frankford Watershed. These flows may also be expressed as approximately 0.03 inches per year for the Tookany/Tacony-Frankford Watershed.

4.1.5 Wastewater Discharges to the Stream

P + OPW + WW/IND Rech + EDR + WW Disch = RO + SWW+ GWW + EDW + BF + OWD + ET

This component represents water that has been used in homes or industry, has been treated, and is subsequently discharged back into the stream, thus making it an "inflow" component. There are believed to be three active industrial point source dischargers and five sites with industrial stormwater permits in the Tookany/Tacony-Frankford Watershed (see Table 9-4). The permit for one facility, Biello Auto Parts Inc., that was once listed as active has expired. This component is assumed to be negligible in comparison to the main inflow components and is not included in the table of estimated flows for components of the hydrologic cycle.

4.1.6 Runoff

P + OPW + WW/IND Rech + EDR + WW Disch = RO + SWW+ GWW + EDW + BF + OWD + ET

Precipitation is the primary natural inflow component of the water cycle. This inflow component generally results in three natural outflow components: evapotranspiration (ET), runoff, and infiltration into the groundwater. Thus runoff is one of the major, natural outflow components to be estimated.

The amount of stormwater runoff depends on a variety of factors, including rainfall intensity, surface ponding of rain, ground slope, and, most importantly, the imperviousness of the ground surface. The amount of impervious cover follows patterns of land use and population density because manmade structures and pavement are the cause of impervious surface. Estimates of imperviousness can be further refined by examining the relative proportion of impervious surfaces on the USGS quadrangles and in aerial photos. Because of the urbanized nature of the watershed, runoff is almost always collected into a sewer system. Depending on the location within the watershed, it can either be discharged through storm sewers or through combined sewers. Therefore, this component is further discussed under the Runoff/Outside Wastewater Discharge component below.

4.1.7 Surface Water Withdrawals

P + OPW + WW/IND Rech + EDR + WW Disch = RO + SWW+ GWW + EDW + BF + OWD + ET

This outflow component represents intakes for water withdrawal for drinking water or industrial use. For the Tookany/Tacony-Frankford Watershed, no permitted withdrawals exist, and this component can be left out of the water balance table.

4.1.8 Groundwater Withdrawals

P + OPW + WW/IND Rech + EDR + WW Disch = RO + SWW+ GWW + EDW + BF + OWD + ET

This outflow component represents groundwater pumping for industrial use or public water supply. There are no public supply or industrial wells of significance in the watershed, and this component can be left out of the water balance table.

4.1.9 Estimated Domestic Withdrawals

P + OPW + WW/IND Rech + EDR + WW Disch = RO + SWW+ GWW + EDW + BF + OWD + ET

The entire watershed is served by a public water supply distribution system. There are no areas where domestic wells form a significant source of supply, and groundwater pumping can be ignored as a significant component of the water balance.

4.1.10 Baseflow

P + OPW + WW/IND Rech + EDR + WW Disch = RO + SWW+ GWW + EDW + BF + OWD + ET

Precipitation results in three natural outflow components: evapotranspiration (ET), runoff, and infiltration into the groundwater. In most shallow groundwater systems, the surface watershed generally corresponds to the recharge and discharge area of the groundwater system. This means that infiltration enters the groundwater aquifer, and flows underground to the stream for eventual discharge as stream baseflow. This allows us to equate infiltration with stream baseflow, making it possible to estimate infiltration through baseflow separation techniques at stream gauges.

In pervious areas, the amount of water that infiltrates the soil, and thus reappears as stream baseflow, depends on soil properties. At the beginning of a storm, when soil pores are usually not saturated, the moisture content of the soil determines the amount of infiltration that can occur. Capillary suction forces caused by surface tension in the pores also affect the infiltration rate. The size, shape, and distribution of soil pores determine the rate at which a soil can transmit flow in both the unsaturated and saturated states. The infiltration rate decreases as soil pores become filled with water during the course of the storm. When the pores become completely saturated, the water transmission rate reaches equilibrium. Sandy soils allow the highest infiltration rates, while soils with high clay content allow very slow infiltration; loams and mixtures of different soil types fall between the two extremes. Table 4-2 lists typical values for saturated hydraulic conductivity, capillary suction, and initial moisture deficit for a range of NRCS soil textures (Handbook of Hydrology, D.R. Maidment, Editor in Chief, McGraw-Hill, Inc., 1993, pp 5.1-5.39.) Soil textures found in the watershed were discussed in Section 1. It is important to remember that in urbanized areas, the original soils have often been disturbed, compacted, or replaced by fill material that may have different hydraulic characteristics from the undisturbed state.

Table 4-2 Typical Hydraulic Properties of Different NRCS Soil Textures

	Saturated Hydraulic Conductivity (in/hr)	Capillary Suction (in)	Initial Moisture Deficit (fraction)
Sand	9.3	2.0	0.35
Loamy Sand	2.4	2.4	0.31
Sandy Loam	0.86	4.3	0.25
Loam	0.52	3.5	0.19
Silt Loam	0.27	6.6	0.17
Sandy Clay Loam	0.12	8.6	0.14
Clay Loam	0.08	8.2	0.15
Silty Clay Loam	0.08	10.8	0.11
Sandy Clay	0.05	9.4	0.091
Silty Clay	0.04	11.5	0.092
Clay	0.02	12.5	0.079

The simplest way to compute infiltration, which is generally difficult to measure and/or model, is to perform baseflow separation on streamflow. In this way, if baseflow is assumed to equal infiltration, then the infiltration component can be directly balanced by the baseflow component. For the Tookany/Tacony Frankford Watershed, this approach results in an annual infiltration/baseflow component ranging from 7.1 to 14.0 inches per year, depending on the gage location within the watershed. Downstream locations on Frankford Creek (1467087 and 1467089) are the most urbanized, and have the lowest baseflow relative to drainage area. Smaller tributaries (Rock Creek, 1467084) are the least impaired and have higher baseflow relative to drainage area. Upstream areas of Tacony Creek (1467086) and Tookany Creek (1467083), as well as Jenkintown Creek (1467085) also have relatively high baseflow relative to drainage area.

4.1.11 Runoff and Outside Wastewater Discharges

P + OPW + WW/IND Rech + EDR + WW Disch = RO + SWW+ GWW + EDW + BF + OWD + ET

Almost the entire watershed is served by sewers. Depending on the area of the watershed, stormwater may enter surface water directly, enter a combined sewer, or enter a separate storm sewer system. Unsewered areas, where runoff flows overland to the stream system, make up approximately 9% of the Tookany/Tacony-Frankford Watershed. These areas are mainly natural areas located along the stream corridor, such as Tacony Creek Park, where storm sewers are not necessary.

Sewered areas within the watershed are served by two types of sewer systems. In areas served by combined sanitary and storm sewers, the sewer system conveys flows to an interceptor sewer and later to a wastewater treatment plant under dry weather conditions. During larger wet weather events, a combined flow regulator structure diverts a portion of the flow to a receiving stream. 47% of the Tookany/Tacony-Frankford Watershed is serviced by combined sewers, all of which is within Philadelphia County. The City of Philadelphia has 31 regulator structures within the watershed, as shown in Figure 4-1. 25 of these structures are instrumented with continuous flow monitors.

Except for park lands, the rest of the watershed area is serviced by separate sanitary and storm sewer systems. In these areas, the storm sewer system conveys most surface runoff directly to a receiving stream. A portion of stormwater, known as infiltration and inflow, enters the sanitary sewer system during wet weather. The occurrence of CSO and the categorization of sampling periods as wet or dry are discussed later in section 4.3.2.

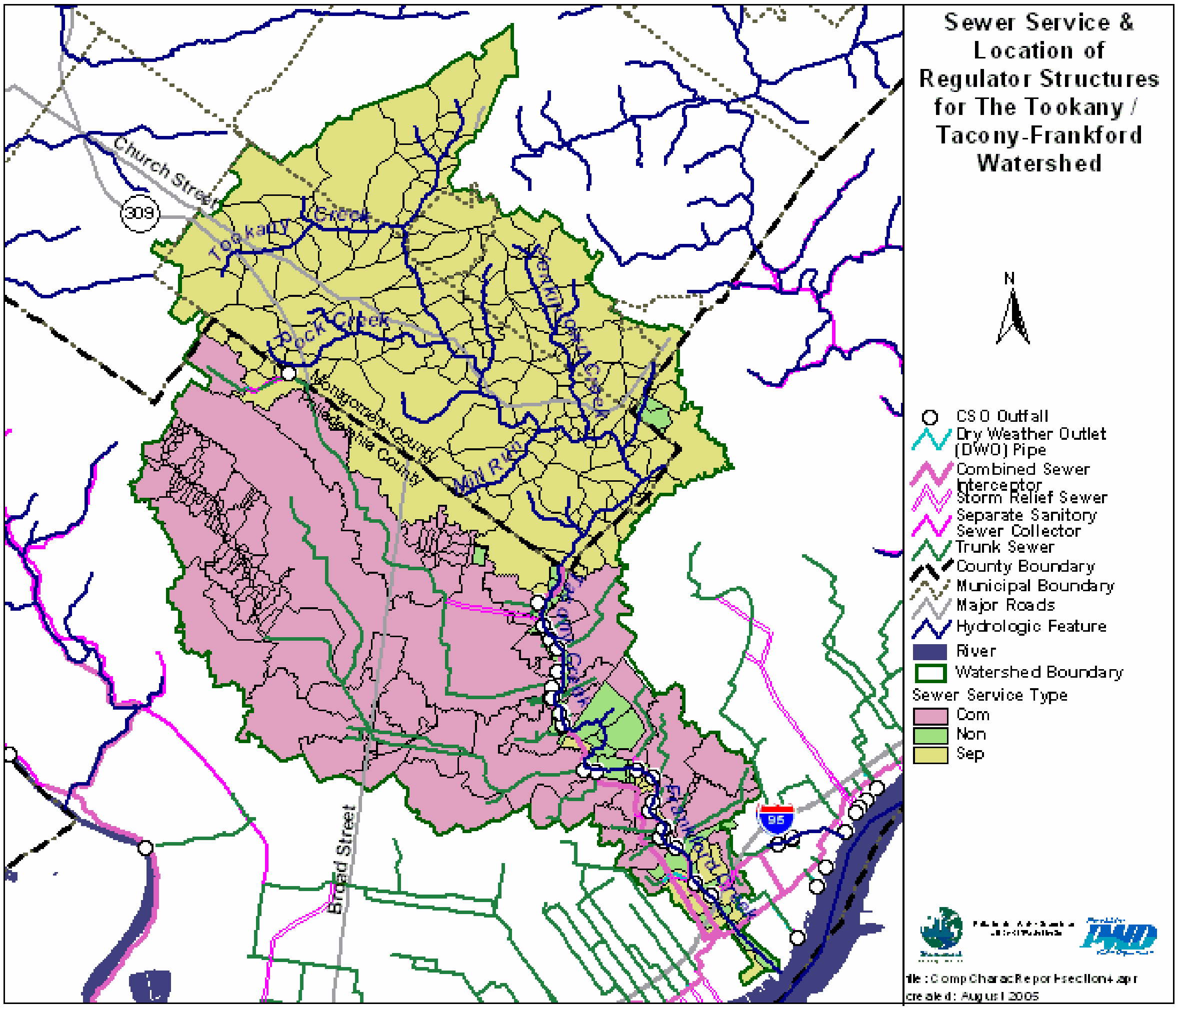

Figure 4-1 Types of Sewer Service and Locations of Regulator Structures

4.1.11 Hydrologic and Hydraulic Modeling

Estimates of the volume, frequency, and duration of combined sewer overflows are based on results from calibrated hydrologic and hydraulic models. Model calibration depends on data from PWD's extensive rainfall gauge network and sewer monitoring program.

The hydraulic and hydrologic model development process focused the greatest detail on the interceptor sewer system, using the USEPA Storm Water Management Model (SWMM)

Extended Transport (EXTRAN) module. The EXTRAN module of SWMM was chosen as the most appropriate tool for the interceptor model. This model is the most widely used and accepted model for interceptor and CSO modeling (Roesner *et al*., 1988). It accurately simulates complex hydraulic conditions that occur in combined sewer interceptors, including unsteady flow, surcharging, branched and looped pipe networks, pumps, orifices, and weirs.

Modeling took place in two tiers or levels of detail. To estimate the treatment rates of the combined sewer regulator structures, or the maximum flow that can pass through the regulator's connector pipe to the interceptor in wet weather, the Tier I sewershed hydrologic representation is in the form of ramp-function hydrographs loaded directly to EXTRAN. Later in the process, the combined sewersheds are modeled in the United States Army Corps of Engineers (USACOE) Storage, Treatment, Overflow, Runoff Model (STORM), providing a more detailed characterization of the hydrologic response of the system with an algorithm for the computation of rainfall excess. STORM thereby provides a wet weather characterization that is useful for assessment of impacts and for planning-level alternatives screening used to establish the direction for detailed facility planning and design.

At the Tier I level, STORM is run in continuous simulation mode using a long-term rainfall record. There is general agreement in the modeling community that single event or design storm simulations are not sufficient for the generation of long-term CSO statistics, including average annual frequency and volume (EPA, 1993). Continuous simulation more thoroughly accounts for antecedent conditions and inter-event conditions within the system. At the Tier II level, sewersheds, interceptors, and regulator structures all are represented in SWMM to support detailed facilities planning and design.

Discharge Monitoring Report and Annual Report Generation

The EXTRAN model is used for the hydraulic characterization of interceptors and regulators to a fine level of detail. The model supports estimates of sewer system overflow characteristics using STORM. This characterization of the combined sewersheds and trunk sewer system is at the correct level of detail for the hydrologic and hydraulic characterization requirements of NPDES permits for CSO and sanitary sewer facilities and for the alternatives analyses required for long term CSO control planning.

Quarterly discharge monitoring reports (DMR's) are required under the NPDES permit system. In addition, the results of the SWMM/NetSTORM model are used to prepare the CSO Annual Report required under Philadelphia's LTCP and Chapter 94 of the Pennsylvania Code. This report details progress on the three phases of the LTCP: implementation of the Nine Minimum Controls, construction of capital projects, and watershed-based planning. The report also summarizes CSO volume, frequency, and capture statistics for the year.

Annual CSO Frequency and Volume Stats

Table 4-3 lists estimated capture percentages for regulator structures in the Tookany/Tacony-Frankford Watershed, based on the modeling results listed in the CSO

Annual Reports. A capture percentage is defined as the percentage of combined sewage (mixed sanitary sewage and stormwater) that is "captured" and sent to a treatment plant during rainfall events over the course of a year. 85% capture is considered to be an ultimate goal for many communities as they implement CSO long term control plans. Based on Table 4-3, capture percentages are generally in the range 40-60% for the Tacony Creek High Level sewer system and 60-80% for the Upper Frankford Creek Low Level sewer system. It is important to note that percent capture for a given year is strongly dependent on the frequency and magnitude of rainfall events during that year. The five years of data listed in Table 4-3 are not sufficient to determine whether an increasing or decreasing trend has taken place. However, as the amount of data increases throughout implementation of the Long Term Control Plan, it will ultimately be possible to evaluate the effectiveness of the control measures.

Table 4-3 Estimated Annual Combined Sewage Capture Percentages

Year	Precipitation (in)	Capture (%) – Lowest and Highest Structure	
		Tacony	Upper Frankford Low Level
2003	46.72	43 - 45	64 - 65
2002	34.11	59 - 64	76 - 79
2001	30.62	51 - 53	70 - 72
2000	43.26	40 - 42	58 - 60
1999	48.6	39 - 40	57 - 59

4.1.12 EvapoTranspiration

P + OPW + WW/IND Rech + EDR + WW Disch = RO + SWW+ GWW + EDW + BF + OWD + ET

Once precipitation reaches the earth's surface, it may take a variety of paths. Typically, a portion enters soil pores through infiltration, a portion returns to the atmosphere through evaporation, and a portion runs off over the land surface (or often into a sewer in urbanized areas). A portion may also be stored temporarily in puddles, in plant parts, through freezing, or in manmade structures designed to detain stormwater; this portion then infiltrates, evaporates, or runs off at a later time.

One of the largest "outflows" of water from the system is evaporation and transpiration. Evapotranspiration includes evaporation, or loss of water to the atmosphere as water vapor, and transpiration, or loss of water to the atmosphere through plants. Evapotranspiration rates depend on temperature, wind speed, solar radiation, type of surface, type and abundance of plant species, and the growing season. Because of these factors, estimated evapotranspiration rates for the Philadelphia region vary seasonally. Neither the Philadelphia Airport nor the Wilmington Airport records evaporation data. One site in New Castle County, Delaware was located which has recorded daily evaporation data from 1956 through 1994. Average daily evaporation rates from this site were developed and are listed in Table 4-4 (City of Philadelphia Combined Sewer Overflow Program: System Hydraulic Characterization).

4.2 Tookany/Tacony-Frankford Watershed Water Cycle Component Tables

The relevant components of the urban water cycle have been estimated for the Tookany/Tacony-Frankford Watershed. Outside Potable Water is assumed to balance Outside Wastewater Discharges, with stormwater and CSOs considered as part of the Runoff component of the water cycle. Table 4-4 shows the results of the analysis, first in inches per year, then in million gallons per day. The inches per year figure simply takes all the flows over an average year, and divides by the area of the watershed. The million gallons per day table takes all the flows over an average year, and divides by 365 days to get an average daily value.

Table 4-4 Water Budget Components

		Inflow		Outflow		
	Period of Record*	P**	EDR	RO	BF	ET+Error
Component (in/yr)	1982 – 2002	42.1	0.085	11.4	7.06	23.7
Component (MGD)	1982 - 2002	66.1	0.134	17.9	11.1	37.3

***Period of Record applies to Runoff and Baseflow.**

****Precipitation uses 100 year rainfall record.**

4.3 Surface Water Characteristics

The above component tables contain values for runoff, ET, and baseflow. These values, however, are complicated by the fact that much of the water is collected in both separate and combined sewers. This section describes, in more detail, the surface water portion of the cycle.

Stormwater runoff ultimately reaches Tookany/Tacony-Frankford Creek and its tributaries through some limited direct surface runoff or through a combined or separate storm sewer. An understanding of the range and frequency of flows, the stage-velocity-discharge relationship, and trends over time is important for a more complete watershed characterization. This information is useful in water quality management, habitat restoration and management, and potable water and flood control applications.

During the USGS/PWD cooperative program in the 1970s, the USGS established streamflow gauging stations at six locations in the Tookany/Tacony-Frankford Watershed. These locations are presented in Section 3, Figure 3-2. Section 3, Table 3-4 contains summary information at each of the gauging stations for their respective periods of record. An historical rating curve is shown in Figure 4-2.

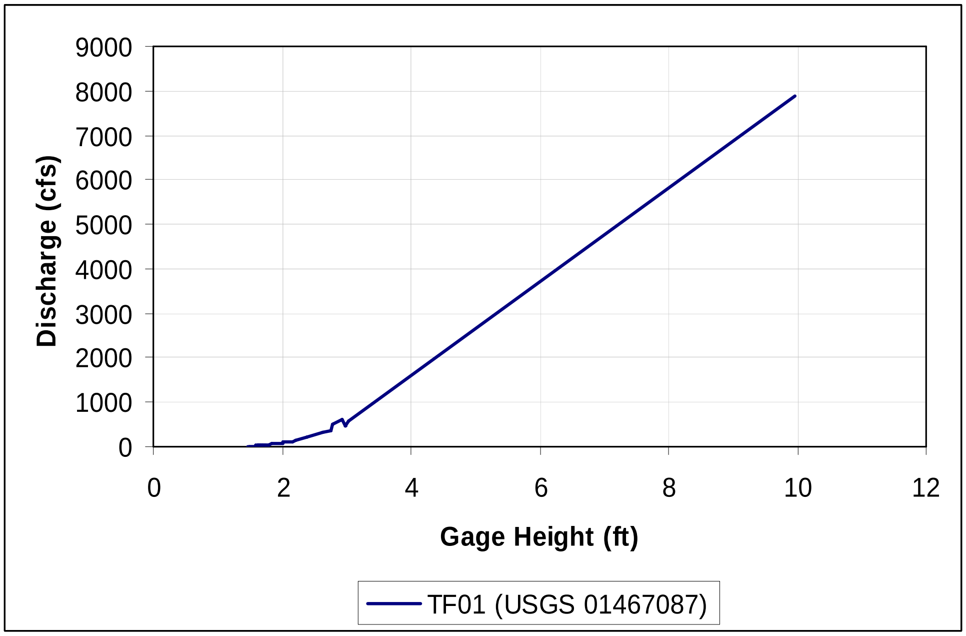

Figure 4-2 Historical Rating Curves for USGS Station 01467087

4.3.1 Evaluation of Total Flow for Trends

Magnitude and Frequency of Flow

Cumulative distribution plots for each of the six gauges listed in Section 3, Table 3-4 are presented in Figure 4-12. A cumulative distribution plot is a plot of discharge versus the percentage of time that a particular flow is not exceeded. These curves are not strictly probability curves because discharge is correlated to successive time intervals and is dependent upon season of the year. However, cumulative distribution plots provide a compact graphical summary of streamflow variability at the different gauging stations.

Trends in Total Flow

Modified Tukey box plots were used to identify seasonal and longer term discharge characteristics for the gauging station at Frankford Creek at Castor Ave. on the Tookany/Tacony-Frankford Creek. Tukey plots display statistical information including median, mean, minimum/maximum values, and selected percentile values as shown in Figure 4-3. Seasonal discharge characteristics are observed for an annual flow cycle using this approach. The discharge plots, discussed above, were used to delineate wet and dry flow regimes. A high flow season earlier in the year and a low flow season occurring later in the year are identified by the peak and trough locations on the plot. Discharges were plotted by weekly time segments, Figures 4-4, monthly in Figure 4-5, annual in, Figures 4-6 and by decade in Figure 4-7. Low flow years in 1985, 1992, and 1999 can be seen on the plots.

Figure 4-7 shows the decade modified Tukey box plots. This plot indicated that although daily flows in the 1980s and 1990s are somewhat lower than flows in the 1970s, the differences are statistically insignificant.

4.3.2 Hydrograph Decomposition Analysis

Areas and Gauges Studied

The Tookany/Tacony-Frankford Watershed is highly urbanized and contains a large proportion of impervious cover. The hydrologic impact of urbanization can be observed through analysis of streamflow data taken from USGS gauges. Table 4-5 lists six gauges with available data, including their locations, periods of record, and drainage areas.

Table 4-5 Data Used for Baseflow Separation

Gauge	Name	Period of Record (yrs)	Drainage Area (sq. mi.)	N (days)	2N* (days)
01467083	Tacony Creek near Jenkintown	6	5.25	1.39	3
01467084	Rock Creek above Curtis Arboretum near Philadelphia	8	1.15	1.03	3
01467085	Jenkintown Creek At Elkins Park	6	1.17	1.03	3
01467086	Tacony Creek at County Line	24	16.6	1.75	3
01467087	Frankford Creek at Castor Ave.	21	30.4	1.98	3
01467089	Frankford Creek at Torresdale Ave.	18	33.8	2.02	5

The interval 2N* used for hydrograph separations is the odd integer between 3 and 11 nearest to 2N. N is calculated based on watershed area.

Baseflow Separation

Baseflow due to groundwater inflow is the main component of most streams in dry weather. Baseflow slowly increases and decreases with the elevation of the shallow aquifer water table. In wet weather, a stormwater runoff component is added to the baseflow. Estimation and comparison of these two components can provide insights into the relationship between land use and hydrology in urbanized and more natural systems.

Baseflow separation was carried out following procedures similar to those found in the USGS "HYSEP" program. The following text is taken from "HYSEP: A COMPUTER PROGRAM FOR STREAMFLOW HYDROGRAPH SEPARATION AND ANALYSIS U.S. GEOLOGICAL SURVEY Water-Resources Investigations Report 96-4040":

"Hydrograph analysis is a useful technique in a variety of water-resource investigations. Separation of streamflow hydrographs into base-flow and surface-runoff components is used to estimate the ground-water contribution to streamflow. Hydrograph-separation techniques also have been used to quantify the ground-water component of hydrologic budgets and to aid in the estimation of recharge rates. In addition, base-flow characteristics determined by hydrograph separation of hydrographs from streams draining different geologic terrains have been used to show the effect of geology on base flow (Sloto *et al*, 1991, p. 29-33).

"The HYSEP program uses three methods to separate the base-flow and surface-runoff components of a streamflow hydrograph—fixed interval, sliding interval, and local minimum. These methods can be described conceptually as three different algorithms to systematically draw connecting lines between the low points of the streamflow hydrograph. The sequence of these connecting lines defines the base-flow hydrograph. The techniques were developed by Pettyjohn and Henning (1979). Hydrograph separations were performed for the streamflow-measurement station French Creek near Phoenixville, Pa., using three methods. Each method is described below.

The duration of surface runoff is estimated using the empirically-defined relation:

$$N=A^{0.2}$$

where N is the number of days after which surface runoff ceases, and A is the drainage area in square miles (Linsley et al. 1982).

"The interval 2N* used for hydrograph separations is the odd integer between 3 and 11 nearest to 2N (Pettyjohn & Henning 1979). For example, the drainage area at the streamflow-measurement station French Creek near Phoenixville, Pa. (USGS station number 01472157), is 59.1 mi2. The interval 2N* is equal to 5, which is the nearest odd integer to 2N, where N is equal to 2.26. The N and 2N* values used for the six gauges in this analysis were listed in Table 4-5.

"The hydrograph separation begins one interval (2N* days) prior to the start of the date selected for the start of the separation and ends one interval (2N* days) after the end of the selected date to improve accuracy at the beginning and end of the separation. If the selected beginning and (or) ending date coincides with the start and (or) end of the period of record, then the start of the separation coincides with the start of the period of record, and (or) the end of the separation coincides with the end of the period of record.

"The sliding-interval method finds the lowest discharge in one half the interval minus 1 day [0.5(2N*-1) days] before and after the day being considered and assigns it to that day. The method can be visualized as moving a bar 2N* wide upward until it intersects the hydrograph. The discharge at that point is assigned to the median day in the interval. The bar then slides over to the next day, and the process is repeated."

Summary Statistics

The results of the hydrograph decomposition exercise support the relationships between land use and hydrology discussed above. For convenience, the flows in Table 4-6 are expressed as a mean volume divided by drainage area over a one-year time period. For reference, one inch per year is approximately equal to one cubic foot per second per acre. Table 4-6 shows streamflow statistics for French Creek as representative of a minimally impaired stream, compared to the six gauges of the Tookany/Tacony-Frankford Watershed. The degree of urban impact to baseflow and runoff can be seen in this table. The upstream portions of the watershed still show reasonable levels of baseflow, similar to those of French Creek (in the 12-13 inches per year range). In the downstream segments of Frankford Creek, baseflow is significantly reduced due to the high degree of impervious cover. Looking at baseflow as a percentage of total flow, the same pattern is evident, however, the effects of urbanization in the upstream areas is more evident using this way of measuring, because it accounts for the higher unit area total flow of the Tookany/Tacony-Frankford Watershed compared with French Creek. The table also indicates the elevated runoff due to urbanization (as a percentage of total rainfall). Again, runoff is generally higher in the downstream areas, and lower in the upstream areas.

Table 4-6 Annual Summary Statistics for Baseflow and Stormwater Runoff

	Baseflow (in/yr/unit area)				**Runoff (in/yr/unit area)**			
	Mean	**Max**	**Min**	**St.Dev.**	**Mean**	**Max**	**Min**	**St.Dev.**
French Creek 01475127	12.9	20.8	5.8	3.8	7.4	15.4	2.9	3.1
Frankford Creek 01467089	7.9	11.5	3.5	2.1	14.9	21.3	8.0	4.3
Frankford Creek 01467087	7.1	13.0	4.5	2.2	11.4	20.3	6.2	3.5
Tacony Creek 01467086	12.6	18.1	7.5	3.2	9.2	13.2	5.2	2.3
Jenkintown Creek 01467085	14.0	18.6	9.5	4.0	9.0	12.0	5.1	2.7
Rock Creek 01467084	12.6	17.0	9.4	3.0	14.9	20.5	10.2	3.6
Tacony Creek 01467083	13.5	18.0	10.8	2.9	10.3	13.6	6.7	2.6

	Baseflow (% of Annual Rainfall)				Runoff (% of Annual Rainfall)			
	Mean	**Max**	**Min**	**St.Dev.**	**Mean**	**Max**	**Min**	**St.Dev.**
French Creek 01475127	31%	44%	15%	7%	17%	30%	7%	5%
Frankford Creek 01467089	18%	24%	9%	4%	34%	46%	21%	7%
Frankford Creek 01467087	18%	25%	11%	4%	29%	39%	17%	6%
Tacony Creek 01467086	29%	40%	19%	6%	21%	27%	13%	3%
Jenkintown Creek 01467085	32%	38%	19%	8%	20%	23%	15%	3%
Rock Creek 01467084	28%	36%	19%	6%	33%	41%	21%	7%
Tacony Creek 01467083	31%	36%	22%	6%	24%	31%	20%	5%

	Baseflow (% of Annual Total Flow)				Runoff (% of Annual Total Flow)			
	Mean	**Max**	**Min**	**St.Dev.**	**Mean**	**Max**	**Min**	**St.Dev.**
French Creek 01475127	64%	75%	53%	5%	36%	47%	25%	5%
Frankford Creek 01467089	35%	48%	27%	5%	65%	73%	52%	5%
Frankford Creek 01467087	38%	49%	26%	6%	62%	74%	51%	6%
Tacony Creek 01467086	58%	67%	48%	5%	42%	52%	33%	5%
Jenkintown Creek 01467085	61%	68%	50%	7%	39%	50%	32%	7%
Rock Creek 01467084	46%	61%	36%	7%	54%	64%	39%	7%
Tacony Creek 01467083	57%	63%	51%	5%	43%	49%	37%	5%

As expected, the quantity of stormwater runoff on a unit-area basis follows patterns of impervious cover in the drainage area. The French Creek watershed, the least developed, has the smallest amount of stormwater runoff both as an annual mean quantity (7.4 in/yr/unit area) and as an annual mean percent of rainfall (17%). As expected, the more highly-developed downstream Frankford Creek has the most runoff both as an annual mean quantity (14.9 in/yr/unit area) and as an annual mean percent of rainfall (34%). Mean runoff from Frankford Creek is twice the mean runoff in the French Creek basin. The more upstream gauges in the Tacony and Tookany have intermediate quantities of stormwater runoff.

Expressing runoff as a percent of annual rainfall as in Table 4-6 provides an estimate of the upper bound of directly connected impervious area (DCIA), that portion of impervious surfaces that are hydraulically connected to the drainage system. In other words, percent DCIA may be less than this number but is no greater. Runoff from impervious surfaces that are not directly connected may ultimately infiltrate or evaporate rather than contributing to stormwater runoff. It is interesting to note that compared to the land use-derived estimates of total impervious cover presented in Section 4 (ranging from 32% to 47% impervious cover as calculated for each municipality), estimated DCIA is generally more than 90% of total impervious area in the watershed. These estimates are calculated as the long-term mean runoff, as a percentage of rainfall, divided by the impervious cover estimate listed in Section 4. For example, runoff in Frankford Creek is 46% of rainfall on an annual mean basis, and impervious cover for the Philadelphia is estimated at 47%. Therefore about 98% of impervious cover appears to be directly connected.

Example Time Series Graphs

Figures 4-8 through 4-10 provide some idea of trends in unit-area flow, baseflow, and runoff from year to year. Although there is considerable variability between years, flows at the six gauges generally follow the same patterns. For example, the Frankford Creek gauges at Castor Avenue and at Torresdale Avenue have the lowest unit-area baseflows and the highest stormwater runoff volumes almost every year of the period of record. This agreement between gauges suggests that the conclusions drawn from long-term mean flows in the previous section are valid for most individual years.

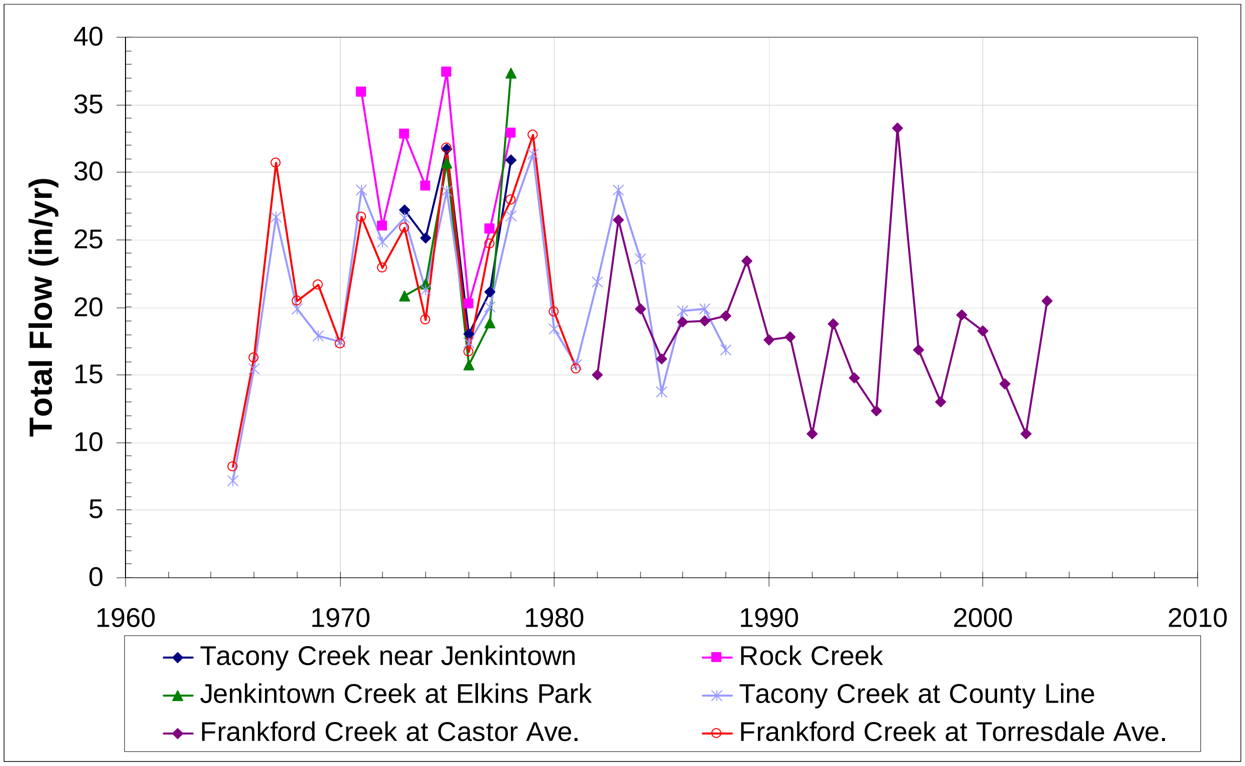

Figure 4-8 Total Flow (in/yr/unit area) Observed at six USGS Gauges in Tookany/Tacony-Frankford Watershed.

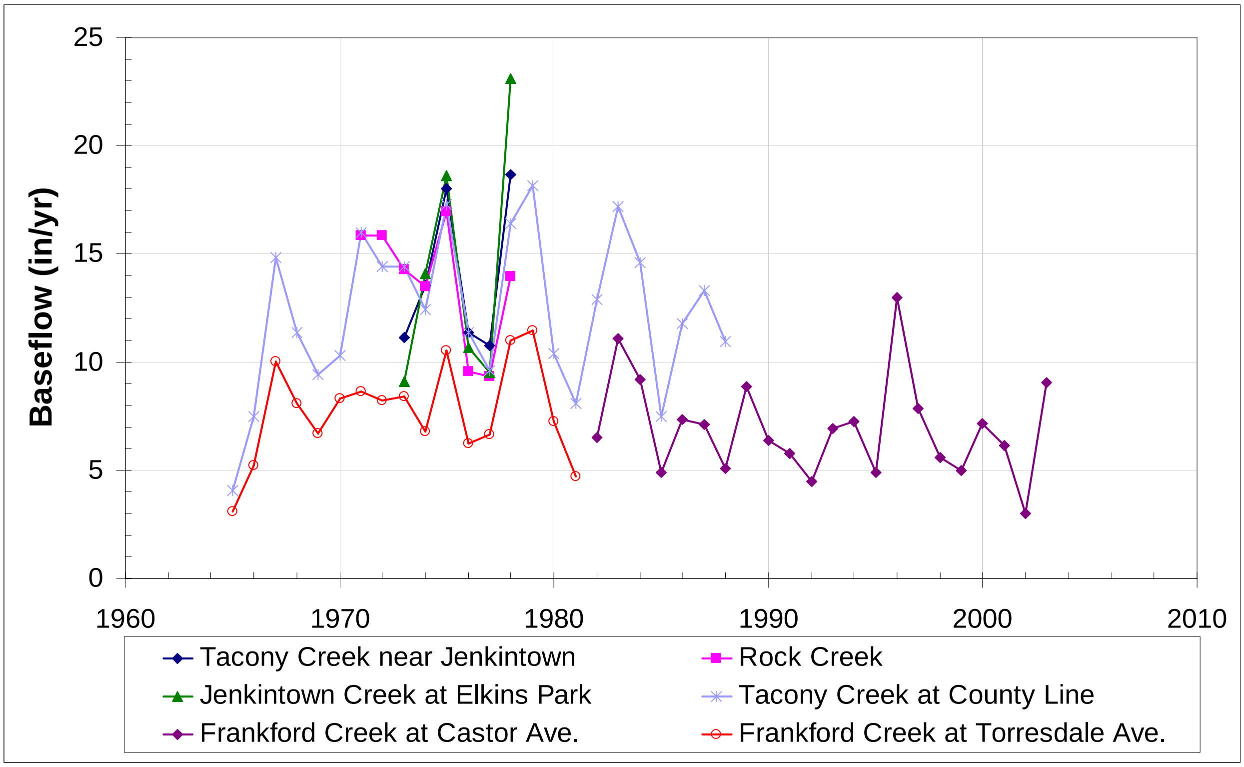

Figure 4-9 Calculated Total Baseflow (in/yr/unit area) at six USGS Gauges in Tookany/Tacony-Frankford Watershed.

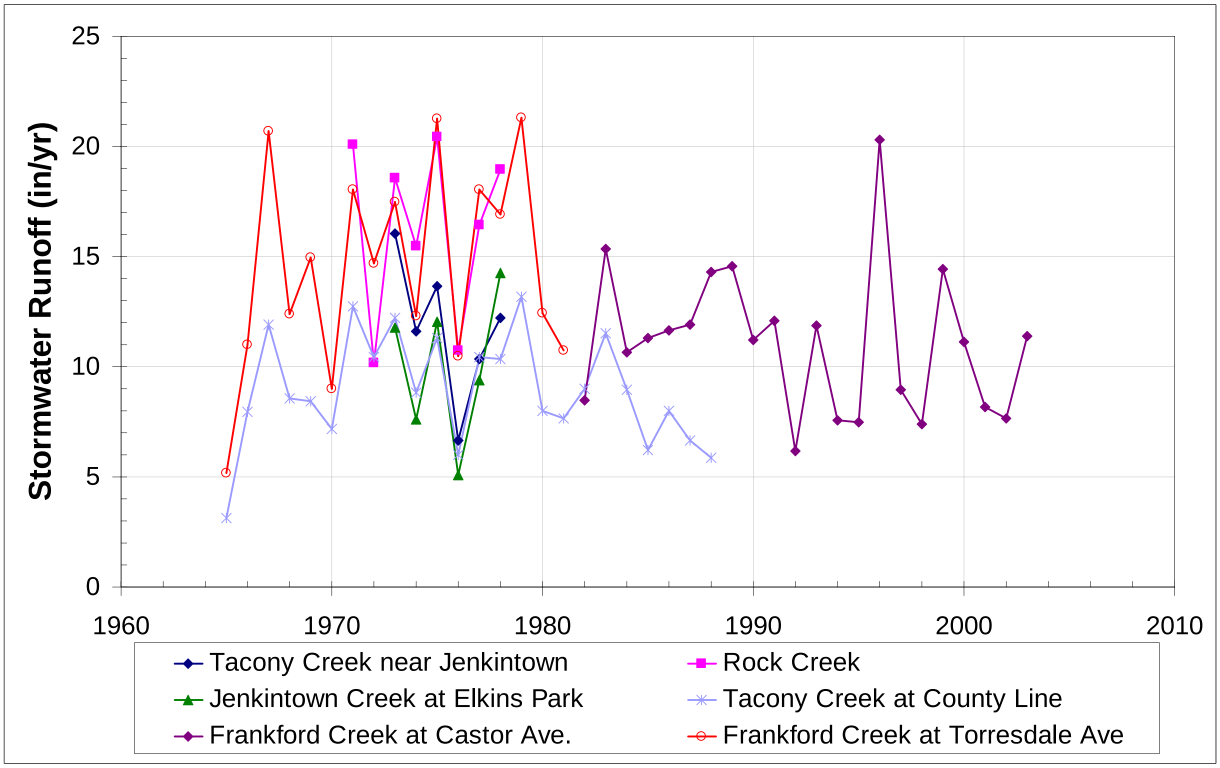

Figure 4-10 Calculated Total Stormwater Runoff (in/yr/unit area) at six USGS Gauges in Tookany/Tacony-Frankford Watershed.

Cumulative Distribution

The cumulative distribution of average daily flow at Tacony Creek near County Line (site TF620/680) and Frankford Creek at Castor Ave. (site TF280) provides more evidence that the Frankford Creek gauge experiences greater extremes of flow. The graph shows the percent of daily flow observations (horizontal axis) that are equal to or less than a given value (on the vertical axis). For example, Figure 4-11 indicates that average daily flow on a unit area basis at the Frankford Creek gauge was less than 0.1 inches on about 90% of days observed. Frankford Creek experiences greater extremes of flow than at the Tacony Creek gauge. On approximately 92% of days, flow at the Frankford Creek gauge is less than flow at the Tacony Creek gauge on a unit-area basis. On the wettest 8% of days, flow at the Tacony Creek gauge is greater than flow at the Frankford Creek gauge on a unit-area basis. These observations strengthen the evidence that downstream reaches of the creek (Frankford Creek) are more influenced by stormwater runoff than upstream reaches (Tacony Creek).

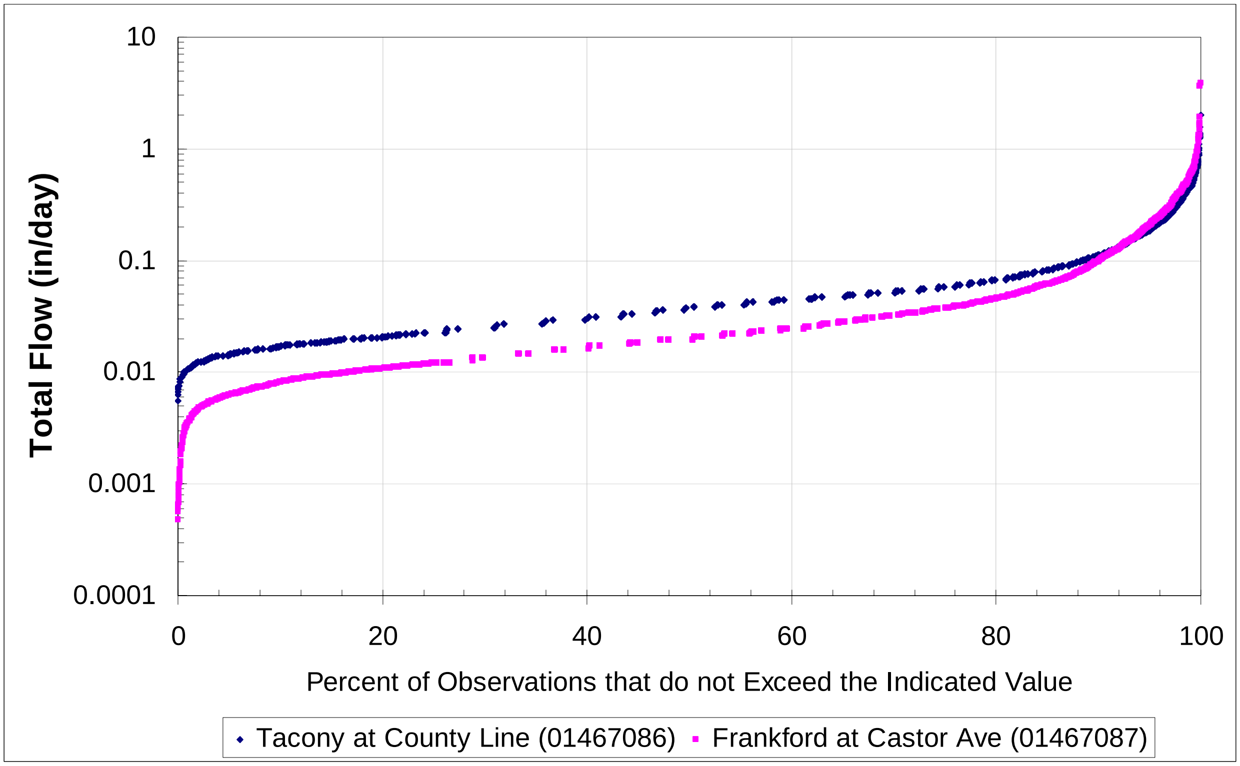

Figure 4-11 Cumulative Distribution Plot of Total Flow at two USGS Gauges in Tookany/Tacony-Frankford Watershed

Characterization of Wet and Dry Weather Sampling Periods

The evaluation of water quality data began with the segregation of water quality observations into wet and dry weather periods. This classification was based upon rainfall. To characterize samples as wet or dry, rainfall for the previous 48 hours was summed and if the total exceeded 0.05 inches the sample was flagged as wet. All samples not meeting this criterion were flagged as dry.

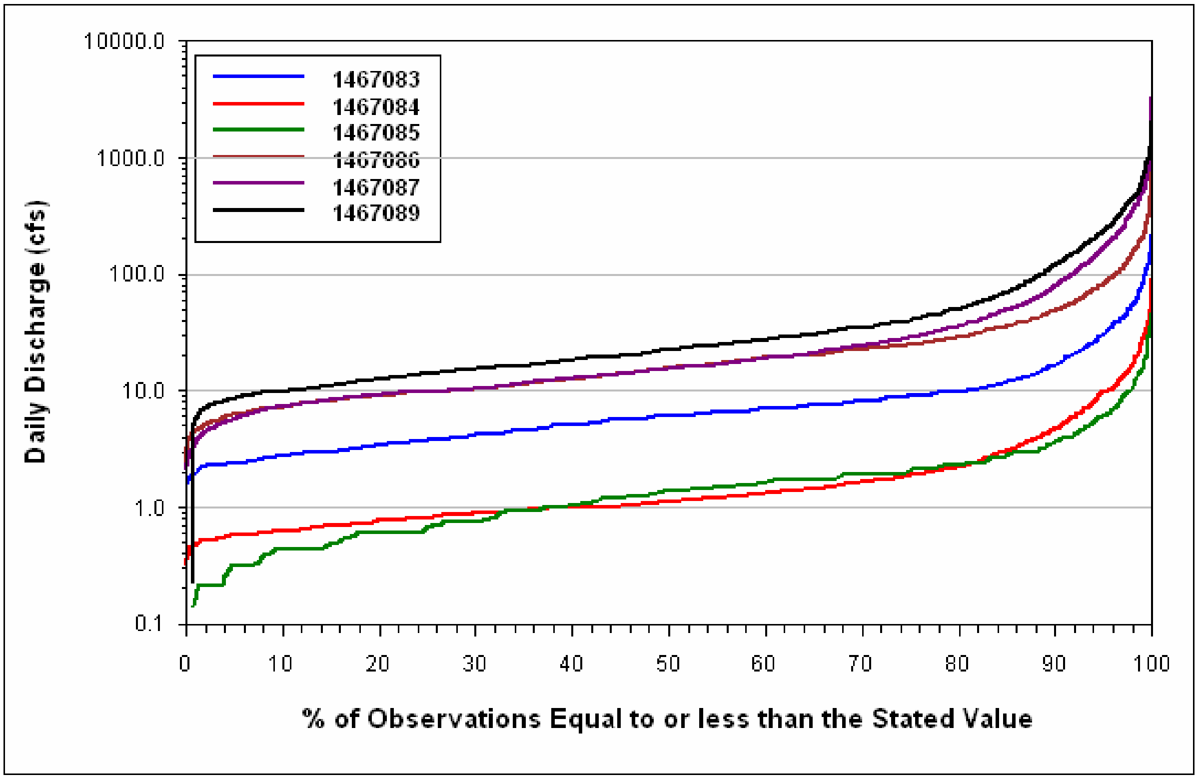

Figure 4-12 Cumulative Distribution Plot of Daily Discharge at six USGS Gauges in Tookany/Tacony-Frankford Watershed

Table 4-7 Wet Weather/Dry Weather Flow Estimates for Historical USGS Gauge Data

Gauge Name	Gauge Number	Season	Q3 (75%) (cfs)

An example of trends in rainfall and corresponding CSOs can be observed in Figures 4-13 and 4-14. Figure 4-13 shows rainfall and CSO data for three CSO outfalls for the period April 12 to 16, 2004. A total of 4.09 inches of rain occurs during the period and CSOs are active. Because CSOs are observed at multiple points in the system, it can be inferred that sampling sites throughout the system are impacted by CSO and stormwater. The discrete sampling conducted during this period would be called wet days. Figure 4-16 shows rainfall and CSO data for the period June 7 to June 11, 2004. This period is classified as dry because neither rainfall nor CSO occurs. Table 4-8 shows the wet or dry categorization of sampling periods when discrete samples were collected. Table 4-9 lists the wet dates in the continuous monitoring or Sonde deployment periods.

4.4 Flooding

4.4.1 Introduction

A stormwater management plan has been initiated in this watershed by the Philadelphia Water Department in partnership with the watershed municipalities in Montgomery County under Pennsylvania's Act 167, the Storm Water Management Act of 1968. The Act 167 planning process and report will identify any "trouble spots" that may exist within the watershed area.

According to the Tookany Creek Watershed Management Plan, "there are several low-lying areas within the watershed that have experienced frequent flooding with damage to homes and businesses. It appears that dwellings were built over time in the floodplain without recognizing the value of the floodplain in attenuating floodwaters. Compounding the problem is the gradual addition of impervious surfaces over decades to the watershed's creeks, thus causing less on-site infiltration and more direct volume flowing quickly into the creeks."

The Tookany Creek Watershed Management Plan additionally discusses the role of floodplains and riparian areas in flood control: "The 100-year floodplain affects the health, safety and welfare of residents. While much of the time the floodplain may be dry, during storms the floodplain stores and conveys large quantities of water. Development within the floodplain reduces the carrying capacity and increases the height and destructive ability of floodwater. In addition to carrying flood waters, the floodplain and stream corridor serve other important functions. The condition of the stream corridor is important in minimizing erosion and water pollution, protecting water quality (temperature and velocity) and providing animal habitat and recreation opportunities."

Frequent damaging flooding does not appear to be a major concern within the study area. However, frequent smaller events of flooding occur in some locations, and damaging flooding has occurred during very large storms.

FEMA Floodplains and Flood Insurance Rate Maps

Information on floodplain extents, historical flooding events, and flood insurance rates is available from FEMA and provides an idea of flood hazards in the study area. The flood insurance rate map (Figure 4-15) provides a quick idea of the areas in the watershed that may experience flooding. As summarized in Table 4-10, Zones A and AE are areas where flooding is likely (1% or greater annual chance of occurrence) and zones X and X500 are areas where flooding is unlikely (less than an annual 1% chance due to elevation or flood protection structures).

Table 4-10 National Flood Insurance Program Zone Designations

Zone	Description
A	Zone A is the flood insurance rate zone that corresponds to the 100-year floodplains that are determined in the FIS by approximate methods. Because detailed hydraulic analyses are not performed for such areas, no base flood elevations or depths are shown within this zone. Flood insurance is generally mandatory in these zones.
AE	Zone AE is the flood insurance rate zone that corresponds to the 100-year floodplains that are determined in the FIS by detailed methods. In most instances, whole-foot base flood elevations derived from detailed hydraulic analyses are shown at selected intervals within this zone. Flood insurance is generally mandatory in these zones.
X and X500	Zone X is the flood insurance rate zone that corresponds to areas outside the 500-year floodplain, areas within the 500-year floodplain but not the 100-year floodplain (X500), and to areas of 100-year flooding where average depths are less than 1 foot, areas of 100-year flooding where the contributing drainage area is less than 1 square mile, and areas protected from the 100-year flood by levees. No base flood elevations or depths are shown within this zone. Flood insurance is generally not mandatory in these zones.

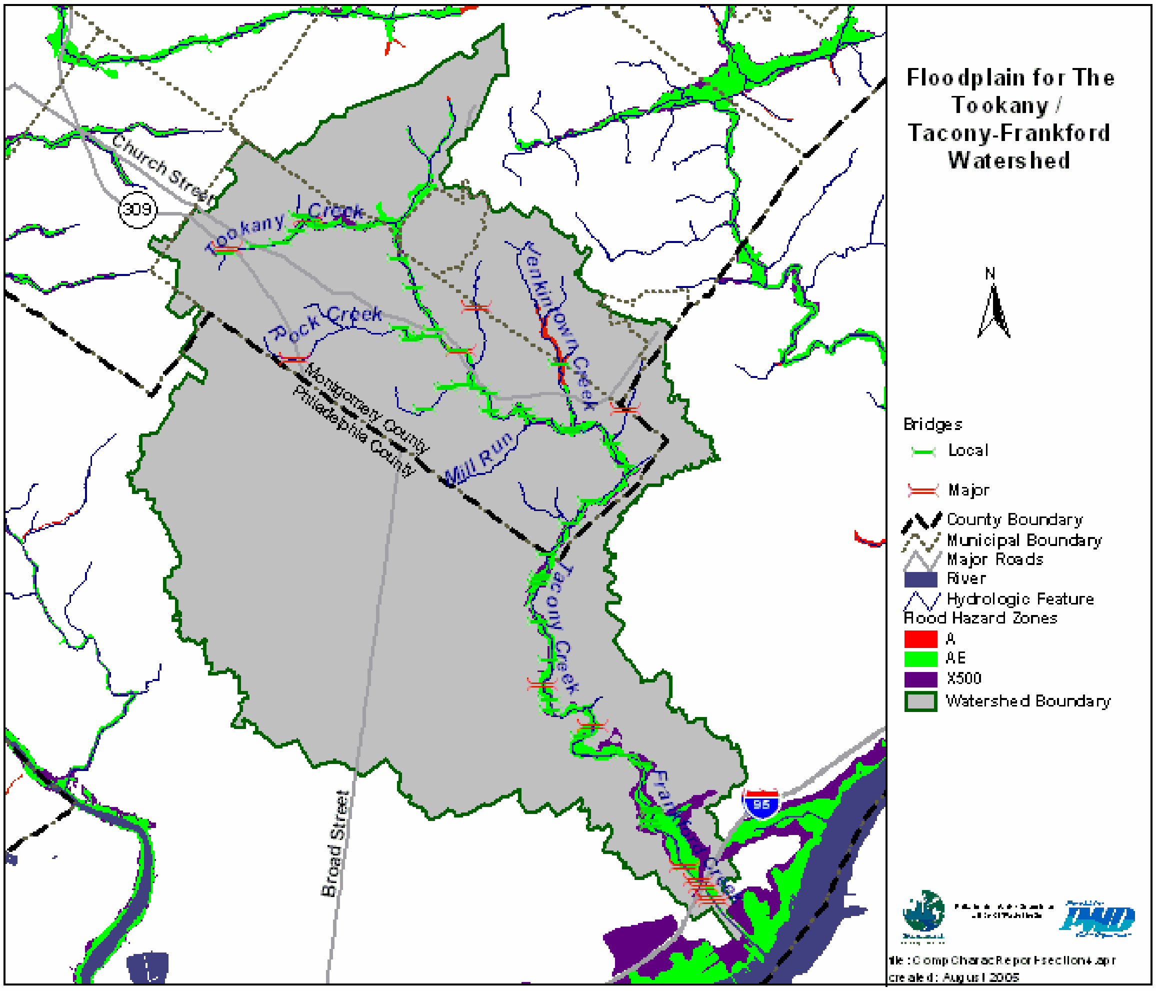

Figure 4-15 FEMA Flood Insurance Rates and Possible Flooding Areas

Table 4-11 Potential Flooding Locations Identified by County FEMA Studies

County	Sheet	Creek	River Mile (ft)	Road Crown/Bridge Deck Below 50-Yr Flood Elevation
Philadelphia	42P	Tacony-Frankford	1,300	Conrail (Partially in 10-yr)

Floodplains and Flooding in the Tookany/Tacony-Frankford Watershed

FEMA's Flood Insurance Study for Philadelphia (FEMA, 1996) indicates that low-lying portions of the greater Philadelphia area have experienced damaging flooding in the past during major tropical events, including Hurricanes Connie and Dianne in August 1955 and Hurricane Agnes in June 1972. A major problem, as the data indicate, is that so much of the

Tookany/Tacony-Frankford Watershed has been developed before the emergence of any floodplain regulations, the most notable of which are the Federal Emergency Management Agency (FEMA) set of minimum floodplain standards, which were modified and made more rigorous in the mid-1990s.

The following text is taken from the Tacony-Frankford Watershed River Conservation Plan:

"Increases in residential development in the upper portion of the watershed, combined with the level topography of the coastal plain, assured that land adjacent to the watershed's streams would experience frequent and devastating floods. Public outcry demanded that the city government address flooding from the Tacony-Frankford Creek and to do something about the deplorable state of the water quality in the stream. Response to this threat to human health and safety resulted in the encapsulation of over half of the watershed into combined sewers that would carry raw sewage and increasing stormwater run-off from the watershed."

According to the Tookany Creek Watershed Management Plan, "In the early 1950s, the PA DEP built a levee along the Tookany Creek to contain the floodwaters to prevent damage to the surrounding homes. This has decreased the severe damage the area once experienced, but the surrounding area roads and some homes continued to flood. In 1978, a pump house was built on Rices Mill Road in Glenside, to curtail the more serious flood events. The Keswick area has experienced flooding as a result of inadequate storm sewer capacity. Many of the storm drains cannot capture and divert the flows in time to prevent flooding in the intersections. Many of the creeks also overflow their banks, causing localized flooding. Abington Township has recently completed a major flood attenuation project in the Baeder Creek sub-watershed due to ongoing and repeated damage."

Section 5
Characterization of Water Quality

5.1 PWD/USGS Cooperative Program (Water Quality and Flow Data)

The purpose of the PWD/USGS study conducted from 1971 to 1980 (described in section 3.4.4) was to quantify the pollutant loads in some of Philadelphia's streams and possibly relate the degradation in water quality to urbanization. Using six stations in the Tookany/Tacony-Frankford Watershed: 01467089 Frankford Creek at Torresdale Ave, 01467087 Frankford Creek at Castor Ave, 01467086 Tacony Creek at County Line, 01467085 Jenkintown Creek at Elkins Park, 01467084 Rock Creek above Curtis Arboretum near Philadelphia, and 01467083 Tacony Creek near Jenkintown (Figure 3-3), monthly "snapshots" of water quality samples were collected and analyzed for conductivity, BOD_5, total phosphate, ammonia, nitrite, nitrate, and fecal coliform.

5.1.1 Qualitative Discussion of PWD/USGS Data

Table 5-1 qualitatively summarizes water quality data collected by the PWD/USGS Cooperative Program. Tables 5-2 and 5-3 present a quantitative summary of this data.

The PWD/USGS Cooperative Program data indicate that total dissolved solids, pH, and nitrite did not appear to have been parameters of concern. Dissolved oxygen concentrations reported represent instantaneous daytime concentrations. This sampling method is not likely to have identified low DO conditions that would have typically occurred in the early morning. Fecal coliform bacteria concentrations often exceeded current standards with mean counts of 10^3 to 10^5 and maximum counts of 10^4 to 10^6. The highest coliform counts were found located furthest downstream at site 9, which correlates with site TF280.

Table 5-1 Qualitative Summary of Water Quality Data Collected 1970-1980

Parameter	Period of Observation	Comments
Discharge	1970-1980	Discharge at the upstream and downstream sites follow the same pattern, with discharge increasing downstream.
Temperature	1970-1980	Water temperature goes through a seasonal cycle and differs very little between cross-sections.
pH	1970-1973	All pH values fall between 6.5 and 8.5.
Specific Conductance	1970-1980	For most measurements, specific conductance was greatest along the mainstem both in and out of the City.
Dissolved Oxygen	1970-1980	Approximately one-quarter of all measurements fell below 6 mg/L in 1970, 1971, 1977, 1978, and 1979. Concentrations at the downstream site were generally lower for all years (the plot from 1980 is based on a small sample size), suggesting that urbanization had an observable affect on dissolved oxygen concentrations during the period. There may have been a slight downward trend in mean concentrations over time.
BOD	1970-1980	Most upstream BOD loads are less than 5 mg/L. Downstream BOD is higher and the mean is around 10 mg/L.
COD	1970-1973	COD concentrations range from about 5 to 37 mg/L at the downstream site and from about 7 to over 200 mg/L at the upstream site.
TOC	1970-1973	TOC concentrations range from about 1 to 11 mg/L at the upstream site and from about 3 to 54 mg/L at the downstream site.
Suspended Solids	1970-1973	Suspended solids are greatest in the downstream location, ranging as high as 800 mg/L. Upstream suspended solids are generally less than 10 mg/L.
Total Dissolved Solids	1970 – 1980	Mean TDS at all sampling sites with data were greater than 230 mg/L.
Organic Nitrogen	1972	The small number of data points available for organic nitrogen concentrations show relatively constant values at all sites with values ranging between 0 .07 and 0.88 mg/L.
Ammonia as Nitrogen	1970-1980	Most ammonia measurements are less than 2 mg/L though downstream peaks have reached as high as 10 mg/L, Downstream values are greater than upstream values for almost all measurements.
Nitrite as Nitrogen	1970-1980	Except for a few peaks, nitrite concentrations were less than 0.1 mg/L at the all locations. Concentrations at downstream locations were higher and reached a maximum of 1 mg/L.
Nitrate as Nitrogen	1970-1980	Nitrate concentrations were greatest at upstream locations with very few exceptions.
Total Phosphate	1970-1980	Concentrations at Site 9 (downstream) are considerably greater than those at Site 8 (upstream), suggesting a considerable input of phosphorus between the two stations. Concentrations at Site 8 appear to have been higher from 1970 to 1972 than later in the decade, with a maximum in 1971 of close to 30 mg/L.
Fecal Coliform	1970-1980	Coliform counts clearly increase from upstream to downstream for all years samples were taken. Upstream counts typically lie between 10^2 and 10^4 col/100 mL, while downstream counts lie between 10^3 and 10^6 col/100 mL. There may have been a slight downward trend over the course of the decade, but very few of the measurements would meet the current standard of 200 mg/L.

Parameter	**Period of Observation**	**Comments**
Aluminum	1970-1973	Few samples of aluminum taken at each location, shows a range of 0.1 to 0.34 mg/L.
Beryllium	1970-1973	All beryllium concentrations measured were less than 0.01 mg/L. (Only 1 sample was available per sampling location)
Cadmium	1970-1973	All cadmium concentrations at the upstream and downstream locations are less than 0.03 mg/L. The upstream samples were greater than the downstream peaks.
Calcium	1970-1973	The upstream and downstream concentrations follow the same pattern. The furthest downstream concentrations are greatest.
Chromium	1970-1973	Upstream and downstream concentrations range from 0.01 to 0.9 mg/L. In 1971, samples from the most downstream location have the highest values. In 1972 and 1973, the upstream location generally has the highest values.
Cobalt	1970-1973	All cobalt concentrations are less than 0.001 mg/L except for one value at the most downstream location of 0.05 mg/L.
Copper	1970-1973	Most of the copper concentrations are less than 0.05 mg/L. The downstream location reached about 0.5 mg/L for one sample.
Iron	1970-1973	All the measured iron concentrations at Sites 7 and 8 are less than 0.6 mg/L except in April 1973. The downstream concentrations are greater than upstream concentrations and reached over 2 mg/L.
Lead	1970-1973	All the measured lead concentrations at Sites 7 and 8 are less than 0.07 mg/L. The downstream concentrations are greater than upstream concentrations and reached 0.7 mg/L.
Magnesium	1970-1972	The concentrations vary between approximately 10 and 18 mg/L. The downstream and upstream concentrations have similar shapes.
Manganese	1972-1973	The upstream concentrations of manganese are generally greater than the downstream concentrations.
Nickel	1970-1973	Measured nickel concentrations are less than 0.01 mg/L (plotted as half the detection limit) during the study period.
Silver	1970-1973	Only 1 silver concentration was measured at each location, all were less than 0.001 mg/L. These values were not graphed.
Zinc	1970-1973	Other than a few peaks at Sites 7 and 8, downstream concentrations of zinc are greatest.

Notes

- Concentrations below the detection limit were most likely reported as equal to the detection limit, resulting in a standard deviation of zero for some parameters.
- N/A indicates that the sample size was too small to calculate a standard deviation.

5.1.2 PWD Water Quality Monitoring Program

To supplement historical data, PWD's Office of Watersheds (OOW) conducted an extensive sampling and monitoring program to characterize the current conditions of the Tookany/Tacony-Frankford Watershed. The program was designed to document the condition of aquatic resources, provide information for the planning process needed to meet regulatory requirements imposed by EPA and PA DEP, and monitor long term trends as implementation of the TTFIWMP proceeds.

Two types of water quality sampling were carried out by PWD in the Tookany/Tacony-Frankford Creek, including discrete sampling before and during wet weather events, and continuous sampling. Figure 5-1 presents the locations of each sampling site and the subshed area draining to that monitoring location. Discrete sampling was performed from June 2000 through December 2004. Wet weather sampling involved the collection of discrete samples before and during a wet weather event, allowing the characterization of water quality responses to stormwater runoff and sanitary and combined sewer overflows. From March 2001 through October 2003, PWD captured data for 12 wet weather events. The second type of sampling to be conducted was continuous water quality monitoring, carried out by introducing YSI 6600 and 600XLM Sondes, shallow depth continuous water quality monitors, and probes that record dissolved oxygen, pH, and turbidity readings. The equipment was deployed to three locations periodically for a number of days to collect continuous data samples and observe water quality fluctuations. The Sonde data for the Tookany/Tacony-Frankford Watershed included over 80 deployments.

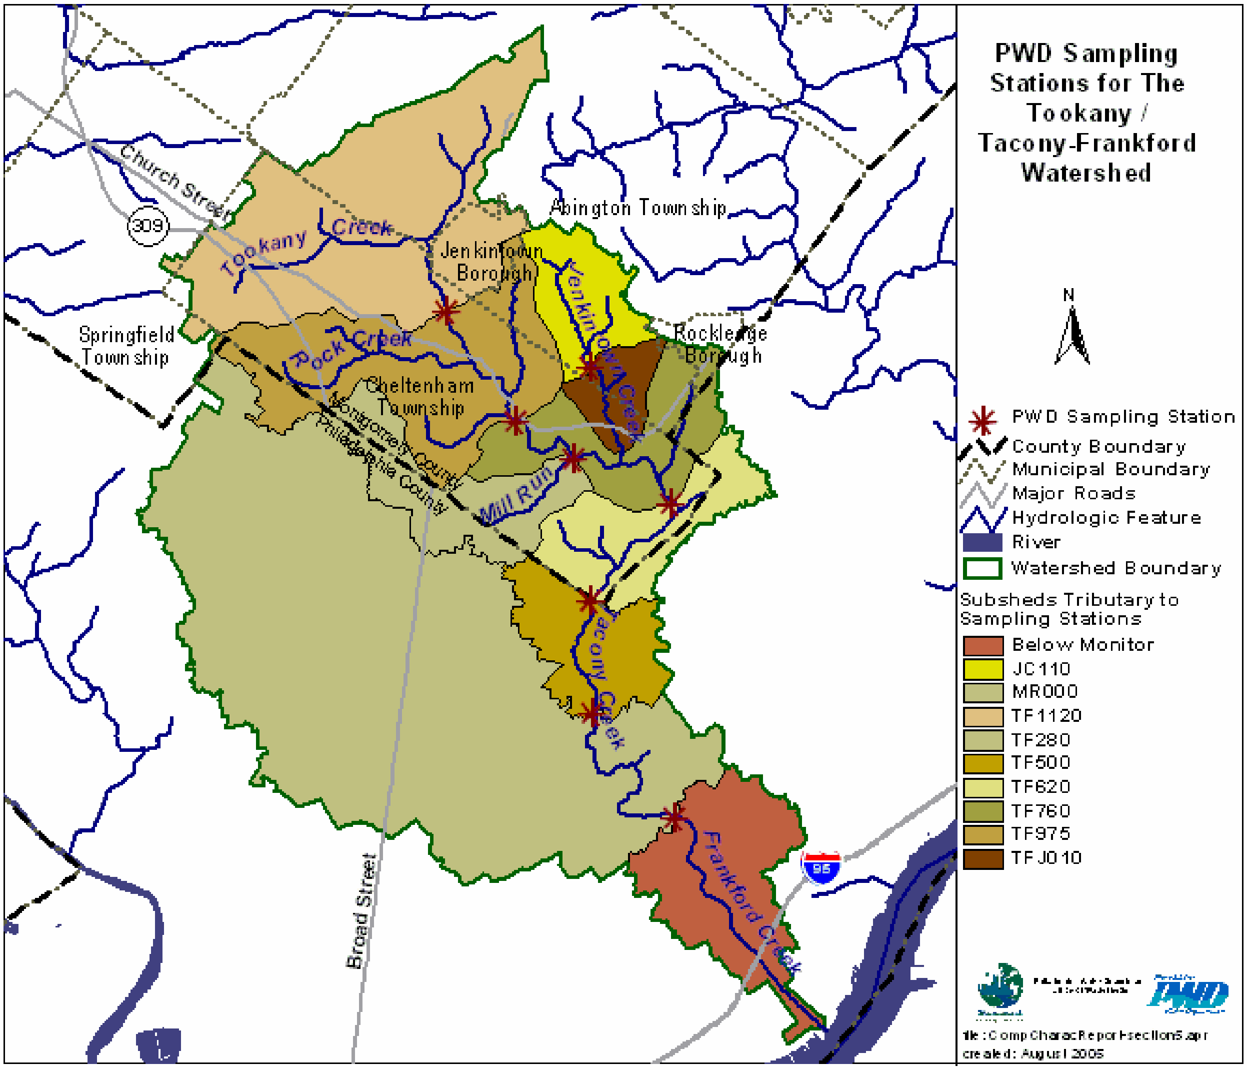

Figure 5-1 Eight Water Quality Monitoring Locations the Tookany/Tacony-Frankford Watershed (Area below monitor represents tidal unassessed portion of the creek)

5.2 Water Quality Analysis for Data Collected from 2000-2004

From 2000 through 2004, PWD has collected water quality data for sampling locations in the Tookany/Tacony-Frankford Watershed. Tables 5-4 thru 5-6 provide a basic, statistical profile of the data from this recent water quality monitoring program. Tables 5-4 and 5-5 provide data from the discrete monitoring program and table 5-6 provides data from the continuous monitoring program. Sample results were compared to relevant PA DEP general water quality criteria to provide an initial impression of which parameters might need further investigation. Applicable relevant standards include water uses to support a potable water supply, recreation and fish consumption, human health, and aquatic life to support warm water fishes.

In addition to the basic statistical profile, Tukey plots of water quality parameters from the 1970s USGS/PWD study and the more recent data are provided in Appendix A.

Table 5-4 Dry Weather Water Quality Summary - Parameters with Standards

5.3 Data Analysis and Water Chemistry

The PWD/USGS Cooperative program recorded a baseline of existing water quality that can now be compared with data collected by PWD from 2000-2004. Sample collection and laboratory techniques were comparable between the two data sets. This comparison allows for a more comprehensive analysis of water quality and the impacts of urbanization on the Tookany/Tacony-Frankford Watershed over the past 30 years.

5.3.1 Dissolved Oxygen

Along with temperature, dissolved oxygen (DO) concentration may be the most important factor shaping heterotrophic communities in streams and rivers. As sufficient DO concentration is critical for fish, amphibians, crustacea, insects, and other aquatic invertebrates, DO concentration is used as a general indicator of a stream's ability to support a balanced ecosystem (TTFIWMP Indicator 9). The Pennsylvania Department of Environmental Protection (PA DEP) has established criteria for both instantaneous minimum and minimum daily average DO concentration. Criteria are intended to be protective of the types of aquatic biota inhabiting a particular lake, stream, river, or segment thereof. Tookany/Tacony-Frankford Watershed is considered a Warm Water fishery (WWF) that cannot support salmonid fish year-round. Furthermore, the stream is not considered appropriate for a put-and-take fishery (*i.e.*, stocking trout to provide recreational opportunities). PA DEP water quality criteria require that minimum DO concentration in a WWF not fall below 4.0 mg/L and that daily averages remain at or above 5.0 mg/L.

Continuous water quality monitoring instruments (YSI Model 6600 and 600XLM Sondes) were deployed periodically at eight sites throughout Tookany/Tacony-Frankford Watershed from 2000 to 2004 to collect data in 15-minute intervals. A total of 1540 days, or the equivalent of over four years of DO data were collected from these monitoring locations. Installing, servicing, and repairing these instruments in an urban environment presented many challenges, as DO membranes were subject to fouling during and after storm events. A protocol for evaluating and rejecting data from intervals when probe failure occurred was developed (Appendix B). Intervals during which probe failure occurred are summarized in Appendix C. Quality of recovered data generally improved as procedures for cleaning and replacing sondes were developed and refined over the course of four years of study (Table 3-12).

When interpreting continuous DO data, one must keep in mind that *in situ* DO probes can only measure dissolved oxygen concentration of water in direct contact with the probe membrane. Furthermore, to obtain accurate measurements, DO probes should be exposed to flowing water or probes themselves must be in motion. Conditions found in urban areas (*e.g.*, severe flows, infrastructure effects, debris accumulation, vandalism, etc.) complicated installation and it was not always possible to situate instruments in ideal locations. Local microclimate conditions surrounding probes and biological growth on probes themselves probably contributed to errors in measurement. It was possible for Sondes situated in subtly different areas of the same stream site to exhibit marked differences in DO concentration due to flow, shading, and local microclimate differences.

DO concentration in Tookany/Tacony-Frankford Watershed was found to be highly variable, both seasonally and spatially, but in general, DO was controlled by temperature, natural community metabolism and inputs of combined sewage and untreated stormwater. As cold water has a much higher capacity for DO than warm water, DO violations were generally restricted to the warmer months. Most serious effects occurred at site TF280, but DO suppression was also observed at sites TF500 and TF620/680 (Table 5-7). Pronounced diurnal fluctuations in DO concentration were observed at sites TF280, TF1120, and TF620/680; most other sites showed only moderate fluctuation due to biological activity. Effects of stream metabolism on DO concentration are addressed in section 5.4-Stream Metabolism.

5.3.2 Biochemical Oxygen Demand (BOD)

Biochemical oxygen demand is an empirical test that measures depletion of oxygen within a water sample over a period of time due to respiration of microorganisms as well as oxidation of inorganic constituents (*e.g.*, sulfides, ferrous iron, nitrogen species) (Greenberg *et al*. 1992). Inhibitors may be used to prevent nitrification in a Carbonaceous Biochemical Oxygen Demand (CBOD) test, and the test may be carried out over the course of thirty or more days to yield ultimate BOD. The BOD_5 test, in which depletion of DO is measured over a five day period, was applied most consistently to water samples from sites in Tookany/Tacony-Frankford Watershed. BOD is one of the most important input parameters for computer simulation of oxygen demand in water quality models. As warm stream water has a limited capacity for DO, excess BOD may preclude warm water streams from meeting WQ criteria despite re-aeration due to diffusion and algal production of DO.

Tookany/Tacony-Frankford Watershed is not affected by municipal wastewater treatment plants or other permitted discharges that would introduce BOD to the stream. Elevated BOD_5 is thus a good indicator of the presence of organic material in stream water that may exert oxygen demand independently of natural stream metabolism. CSO and SSO discharges were believed to be the most important sources of wet weather BOD loading to Tookany/Tacony-Frankford Watershed. Elevated dry weather BOD_5 values were observed frequently at site TF280, and occasionally at sites TF975 and TFM006, suggesting the presence of sewage in dry weather. These results corroborate other sewage indicators observed at these sites (*e.g.*, fecal coliform bacteria, ammonia). Activities recommended to meet target A of the TTFIWMP will address these high priority sources.

Evaluation of BOD_5 results in a watershed where most sources exhibit spatial and temporal variability is difficult. The BOD_5 test provides little information when samples are dilute (MRL= 2mg/L), which is often the case in dry weather samples from streams lacking point source discharges or other sources of organic enrichment (87% of dry weather samples and 28% of wet weather samples had BOD_5 concentration below reporting limits). Analysts must also determine an appropriate series of dilution ratios without *a priori* knowledge of the sample's potential to deplete oxygen. For this reason, 4% of samples were reported as minimum values (*i.e.*, actual values were known to be greater than the value reported but the dilution sequence did not allow computation of an actual value); all samples in which BOD_5 concentration were reported as minimum values were collected in wet weather.

As BOD_5 concentration data were affected by a large number of imprecise values, nonparametric statistics were used in comparing between sites and evaluating wet weather effects. In the latter analysis, data from all sites were combined, non-detects were included as half the method reporting limit (MRL), and minimum values were included as if they were actual values. BOD_5 concentration was found to be significantly greater in wet weather than in dry weather (Mann-Whitney U test, $Z_{2,689} = -7.27$, $p<0.001$), and there was a significant effect of site in wet weather (Kruskal-Wallis ANOVA, $H_{8,565}= 73.32$, $p<0.001$, (Figure 5-2), which is likely due to frequent CSO discharge at site TF280 (mean wet weather BOD_5 11.79±18.22). Though sampling effort was not equal across sites, mean wet weather BOD_5 data suggest CSO discharge at site TF620/680 (5.98±6.55) and occasional SSO discharge or other sources of organic enrichment at sites TFM006 (7.21±7.84), TF975 (4.95±5.74) and TF1120 (4.13±3.89).

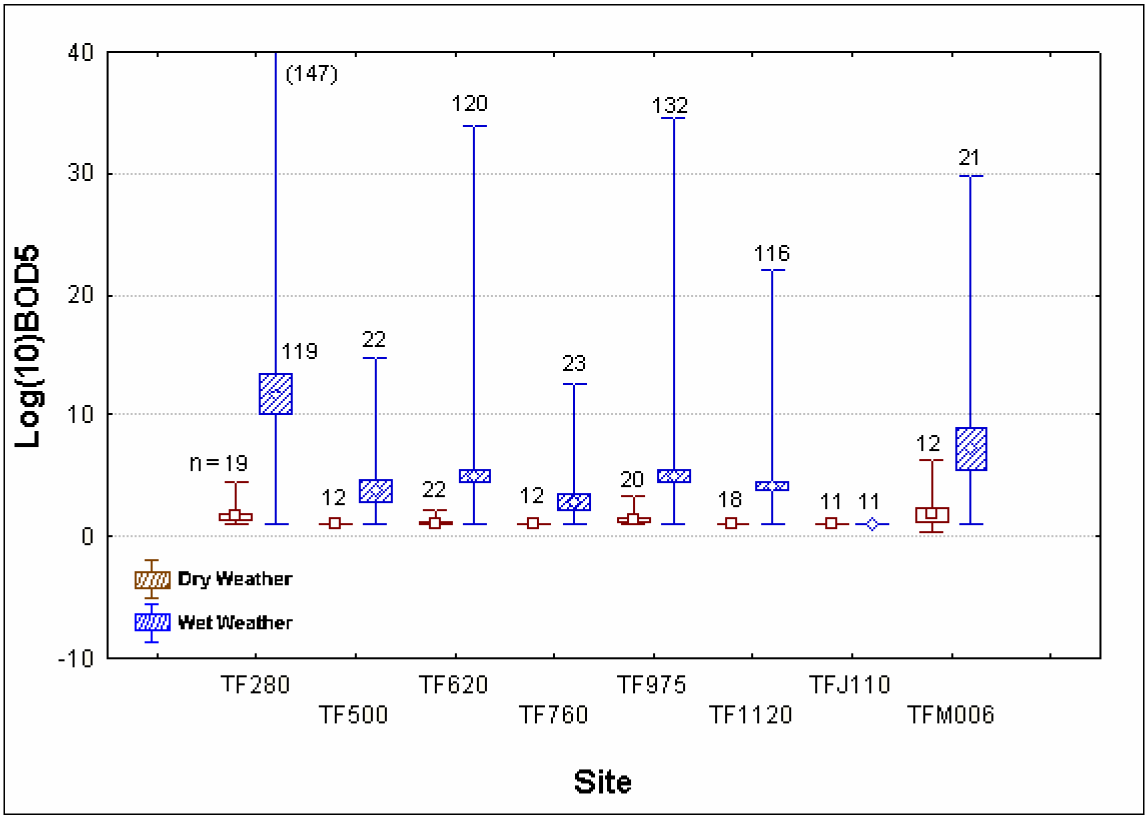

Figure 5-2 Five Day Biological Oxygen Demand of samples collected from 8 sites in Tookany/Tacony-Frankford Watershed in Dry and Wet Weather.

5.3.3 pH

Water quality criteria established by PA DEP regulate pH to a range of 6.0 to 9.0 in Pennsylvania's freshwater streams (Commonwealth of Pennsylvania, 2001). Direct effects of low pH on aquatic ecosystems have been demonstrated in streams affected by acid mine drainage (Butler *et al*. 1973) and by acid rain (Sutcliff and Carrick 1973). Aquatic biota may also be indirectly affected by pH due to its influences on other water quality parameters, such as ammonia. As pH increases, a greater fraction of ammonia N is present as un-ionized NH_3 (gas). For example, ammonia is approximately ten times as toxic at pH 8 as at pH 7. Extreme pH values may also affect solubility and bioavailability of metals (*e.g.*, Cu, Al), which have individually regulated criteria established by PA DEP.

Continuous pH data show that pH fluctuations most often occur at highly productive sites with abundant periphytic algae (Figure 5-3). Pronounced diurnal fluctuations in pH were observed at site TF620, and occasionally at site TF280. These sites occasionally violated water quality criteria by exceeding pH 9.0; minimum pH standards were rarely violated (Table 5-6). pH at shadier sites (*i.e.*, TF500 and sites upstream of site TF680) was probably less strongly influenced by metabolic activity and fluctuations in pH appeared noticeably damped as a result. Algal densities and stream metabolism effects on stream pH are discussed further in section 5.4 Stream Metabolism.

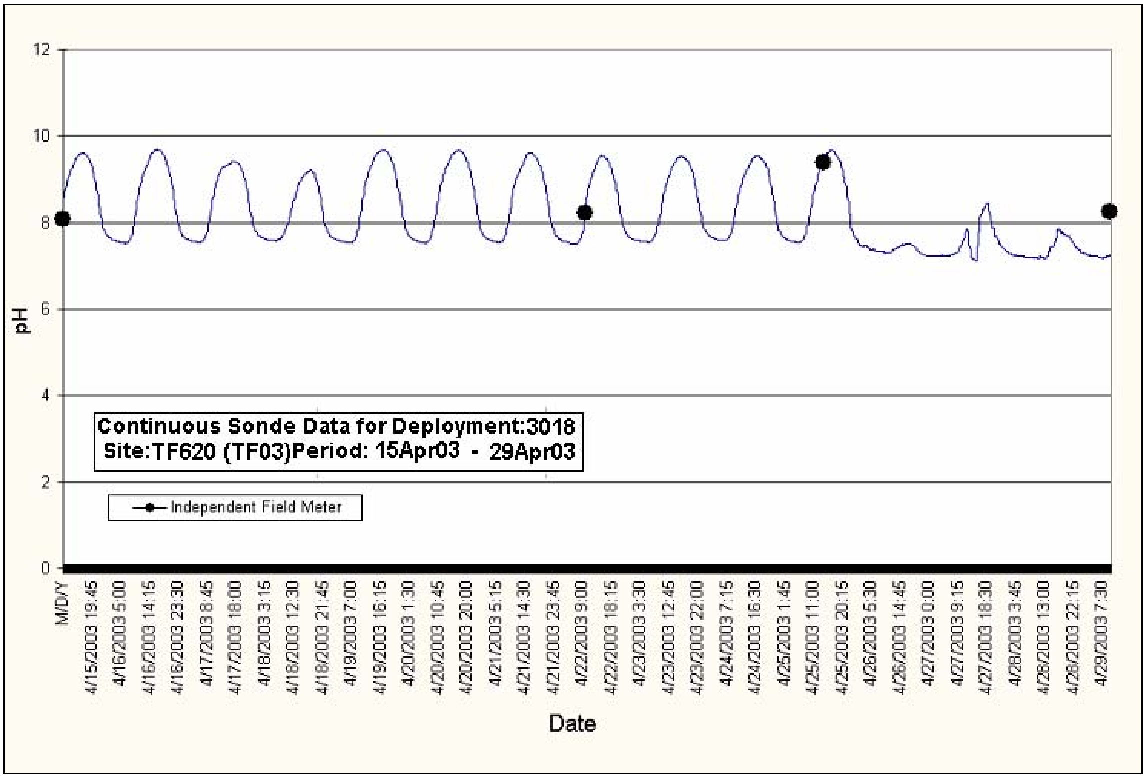

Figure 5-3 Example of pH fluctuations at site TF620, April 2003

Tookany/Tacony-Frankford Watershed is not known to be directly affected by anthropogenic inputs of acids or bases (*e.g.*, acid mine drainage, industrial discharge) that would tend to change stream pH independently of the natural bicarbonate buffer system. Accordingly, the TTFIWMP does not specifically address pH as a separate problem independent of stream eutrophication. Furthermore, as pH problems in Tookany/Tacony-Frankford Watershed are tied closely to DO problems, remediation efforts intended to decrease the frequency and geographic extent of low DO concentrations should generally decrease the severity of pH problems as well. One important caveat, however, is that pH problems may occur at any time of the year when algal production is high. It is possible to have severe fluctuations in DO that do not violate water quality standards due to the greater DO capacity of colder water. While there is a small compensatory effect of lower temperatures on pH toxicity, in general, pH effects may be present under high productivity conditions whenever they occur.

5.3.4 Fecal Coliform and *E. coli* Bacteria

Fecal coliform and *E. coli* bacteria concentrations are positively correlated with point and non-point contamination of water resources by human and animal waste and are used as indicators of poor water quality (Indicator 7, TTFIWMP). PA DEP has established a maximum limit of 200 colony forming units, or "CFU," per 100mL sample during the period 1May - 30Sept, the "swimming season" and a less stringent limit of

2000CFU/100mL for all other times. It should be noted that state criteria are based on the geometric mean of a minimum of five consecutive samples each sample collected on different days during a 30-day period (Commonwealth of Pennsylvania, 2001). As bacterial concentrations can be significantly affected by rain events and otherwise may exhibit high variability, individual samples are not as reliable as replicate or multiple samples taken over a short period.

Based on data from numerous sources (*e.g.*, EPA, USGS, USDA-NRCS, volunteer monitoring organizations, etc.), it appears likely that many, if not most, southeastern PA streams would be found in violation of water quality criteria for fecal coliform bacteria concentration during the swimming season given sufficient sampling effort. PWD has expended considerable resources toward documenting concentrations of fecal coliform bacteria and *E. coli* in Philadelphia's watersheds. The sheer amount of data collected allows for more comprehensive analysis and a more complete picture of the impairment than does the minimum sampling effort needed to verify compliance with water quality criteria. In keeping with the organizational structure of the watershed management plan, fecal coliform bacteria analysis has been separated into dry (Target A) and wet weather (Target C) components, defined by a period with at least 48 hours without rain as measured at the nearest gauge in PWD's rain gauge network.

5.3.4.1 Dry Weather Fecal Coliform Bacteria (Target A)

The geometric mean of 63 fecal coliform bacteria concentration samples collected from Tookany/Tacony-Frankford Watershed in dry weather during the non-swimming season from 2000-2004 did not exceed 2000CFU/100mL (Table 5-8). Only one sample, collected from site TF280, exceeded 2000CFU/100mL (estimated fecal coliform concentration 2100CFU/100mL). In contrast, dry weather geometric mean fecal coliform concentration exceeded water quality criteria of 200CFU/100mL during the swimming season at all sites except TFJ110 (Table 5-9). An improvement in mean fecal coliform concentration can be seen in both swimming and non-swimming season when data from 2000-2004 is compared to historical data from 1970-1980 (t-test $F_{2,140}$= 5.6, p <0.05; $F_{2,163}$ =3.76,p <0.05 respectively)

TFM006	8	447	354	365	90	900	298

Collectively, mean fecal coliform bacteria concentration of sites in the City of Philadelphia were significantly higher during the swimming season than during the non-swimming season ($F_{2,68}$= 1.48, p=.000016). Sites in Montgomery County follow the same temporal pattern and have a significantly higher mean during the swimming season ($F_{2,64}$=1.83, p <0.05). This could be due to higher temperatures during the swimming season. Increased temperatures may allow bacteria to persist longer in the water column and in sediments. Additionally, bacteria load may increase in warmer weather as a result of wildlife and dog walking activity. Drought and decreased storm duration/intensity during summer months may also partially explain temporal variability in mean fecal coliform concentration. Greater amounts of rain and snow melt during the non-swimming season may dilute fecal coliform concentrations.

With the exception of intense sampling upstream and downstream of a point source, surface water grab samples do not usually allow one to determine source(s) of fecal contamination. Research has shown that fecal coliform bacteria may adsorb to sediment particles and persist for extended periods in sediments (VanDonsel *et al.* 1967, Gerba 1976). At sites where dry weather inputs of sewage are not indicated, presence of persistent background concentrations of bacterial indicators in dry weather may thus more strongly reflect past wet weather loadings than dry weather inputs (Dutka and Kwan, 1980). Clearly, there exist several possible sources of fecal coliform bacteria within the watershed, all or combinations of which may be acting within different spatial and temporal dimensions. PWD is piloting a Bacterial Source Tracking (BST) program that may eventually be useful in identifying the sources of fecal coliform bacteria collected in dry weather. Of particular interest is the relative proportion of the total bacterial load from human sources vs. domestic and wildlife animal sources.

5.3.4.2 Wet Weather Fecal Coliform Bacteria Concentration (Target C)

Wet weather fecal coliform concentration of 480 samples collected during the swimming season (*i.e.*, 5/1 - 9/30) and 140 samples collected during the non-swimming season were estimated. Geometric mean fecal coliform concentration of all samples collected in wet weather during the swimming season exceeded the 200 CFU/100mL water quality criterion (table 5-10, figure 5-4). All sites except TFJ110 had geometric mean fecal coliform concentration greater than $3\text{x}10^3$ CFU/100mL. Sites TF280 and TFM006 showed evidence of severe wet weather sewage impacts (estimated geometric mean fecal coliform concentration 23,773 and 13,787 CFU/100mL respectively).

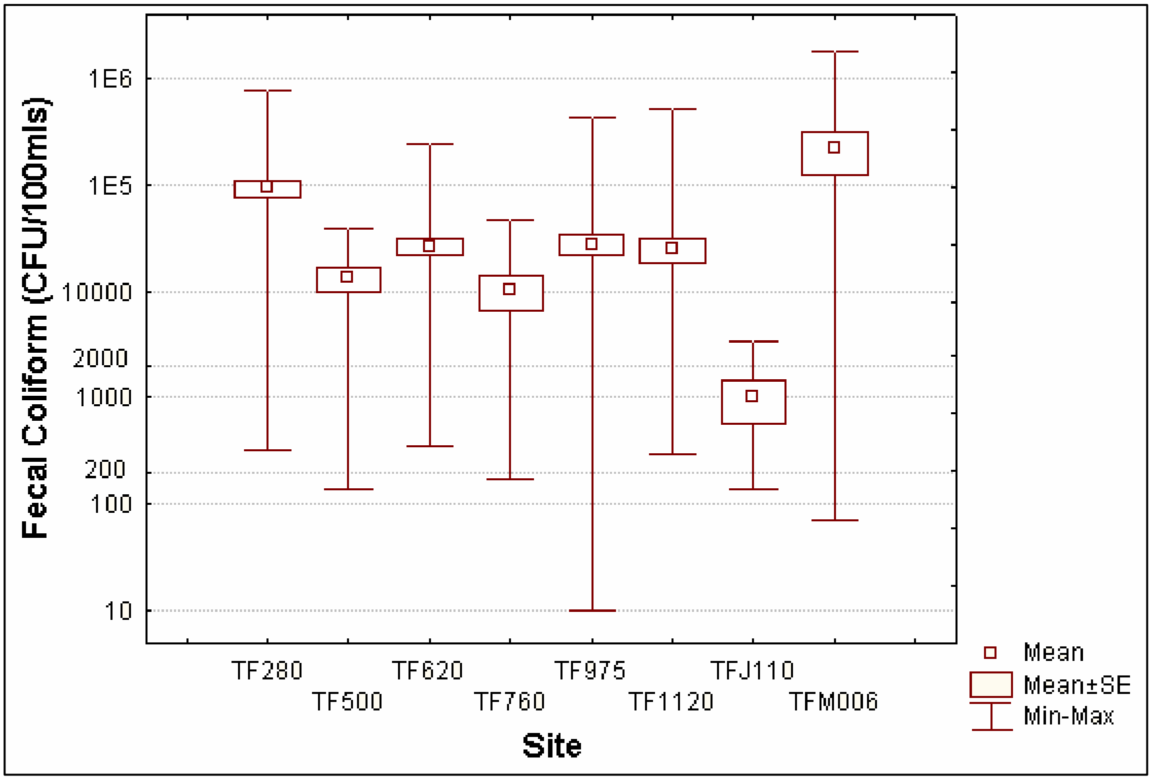

Figure 5-4 Fecal Coliform Bacteria Concentrations of Samples Collected from 8 sites in Tookany/Tacony Frankford Watershed in Wet Weather during the Swimming Season, 2000-2004.

The latter site is located on Mill Run, a historic stream with a drainage area of ca 1mi^2, 52% of which is estimated to be impervious surface. This stream is encapsulated in a storm sewer in Philadelphia, and presently surfaces at stormwater outfall T-88. From 1994 to 1995 PWD investigated 3500 homes within the Mill Run collection area for crossed connections and defective sanitary lateral pipes; although 130 problems were identified and corrected, sewage problems continued. In 2002, PWD sewer maintenance crews installed 6 slot regulators to allow contaminated baseflow in branch storm sewers to be routed to the sanitary sewer. Though subsequent outfall samples collected by PWD's Industrial Waste Unit showed reduced dry weather concentrations of fecal coliform bacteria, large sewage discharges are still reported periodically at the site.

Table 5-10 Fecal Coliform Concentration (CFU/100mL) Wet Weather, Swimming Season (1 May - 30 Sept.)

	Valid N	Mean	Geometric Mean	Median	Minimum	Maximum	Std. Dev.
TF280	104	95132	23774	32000	320	780000	163153

TF1120	110	25256	5503	4850	290	520000	66313
TFJ110	8	1004	580	455	140	3500	1219
TFM006	27	223534	15049	11200	70	1820000	497239

Surface water samples collected at site TFM006 in dry weather (n=6) do not indicate severe problems, however, results from a targeted wet weather sampling event 8/30/04-9/1/04 suggest that sewage impacts in wet weather are still a serious problem at this stormwater outfall (Figure 5-5). Source(s) of these sewage inputs remain unknown. PWD's Waterways Restoration Team (WRT) completed a streambank restoration project at this outfall in 2005, and removal of a large plunge pool was one component of the restoration design. It is hoped that reduction of stagnant water will reduce the influence of small wet weather sewage impacts on dry weather fecal coliform concentrations.

Mean wet weather fecal coliform concentration during the swimming season was significantly greater than that of the non-swimming season both within the City of Philadelphia ($F_{2,316}$= 1.11, p <0.05) and in Montgomery County ($F_{2,302}$= 1.35, p= 0.002). However geometric mean fecal coliform concentrations during the non-swimming season exceeded 2,000 CFU/100mL at sites TF280, TF500, TF620, TF975 and TF1120 (tables 5-10 and 5-11 and Figure 5-5). Although few samples were collected in wet weather during the non-swimming season, Sites TFM006 (geometric mean 137, n=2) and TFJ110 (geometric mean 51, n=3) did not exceed water quality standards. Improvements in mean fecal coliform concentration were observed in both the swimming (historical n=22, modern n=482) and non-swimming season when data from 2000-2004 was compared with historical data from 1970-1980 (t-test $F_{2,502}$=1.08, p=.004 and $F_{2,164}$=1.24, p=.002 respectively).

5.3.5 Temperature

Temperature has a very strong influence on the structure of aquatic communities, determining the saturation concentration of dissolved oxygen and the rate of many biological and physicochemical processes. Though aquatic organisms generally have enzymes capable of working over a range of temperatures, thermal preferenda and tolerance values determine, to a large degree, the range of many species' distributions. This effect is especially true of larger vertebrates, such as fish. Thermal WQ criteria for Tookany/Tacony-Frankford are based on the warm water fishery (WWF) designation, and reflect the fact that the watershed is not expected to have appropriate habitat for maintenance of self propagating populations of coldwater fish (*e.g.*, trout species).

Maximum temperature criteria for WWF vary temporally, but require stream temperatures below 87°F (30.5°C) for the warmest months of the year (*i.e.*, July through August). Heated wastes, such as industrial cooling waters, can neither cause stream temperature to exceed the maximum temperature criterion for a given time period, nor can they result in an increase of 2°F (~1.1°C) over one hour. Continuous water quality monitoring results suggest that temperatures in Tookany/Tacony-Frankford rarely exceed maximum WQ criteria, but increases of 2°F over a one hour period are common due to natural temperature fluctuations (Table 5-6). Flow modifications have probably reduced the influence of groundwater on baseflow water temperature. Dam construction and riparian buffer removal have also probably resulted in enhanced solar heating of stream water. Effects of temperature on fish populations are also discussed briefly in section 8.3 Fish Habitat Indices.

5.3.6 Other Physicochemical Parameters

5.3.6.1 Total Suspended Solids

Sediment transport in small streams is dynamic and difficult to quantify. Numerous factors can affect a stream's ability to transport sediment, but generally sediment transport is related to streamflow and sediment particle size. Stable streams are generally capable of maintaining equilibrium between sediment supply and transport, while unstable streams may be scoured of smaller substrate particles or accumulate fine sediments. The latter effect is particularly damaging to aquatic habitats. PA DEP has identified the cause of impairment in Tookany/Tacony-Frankford to be a combination of "Water/Flow

Variability", "Flow Alterations", and "Other Habitat Alterations". "Siltation" was not listed as a cause of impairment, but the effects of sediment deposition, where and when they occur, are probably addressed by "Other Habitat Alterations".

Water sampling techniques that are adequate to characterize most water quality parameters (*e.g.*, grab samples, automated sampling) are not generally appropriate for evaluating sediment transport in fluvial systems (Edwards and Glysson 1988); errors related to sampling technique should preclude computation of sediment transport during severe storm events that mobilize large streambed particles. TSS concentration (Log transformed) was significantly greater in wet weather than in dry weather ($F_{2,286}$= 8.72, p<0.001).

Maximum daily TSS concentration (log transformed) was found to be significantly positively correlated to average daily streamflow at site TF280 ($r_{(33)}$= 0.85, p<0.001, (Figure 5-6) and instantaneous TSS concentration (log transformed) was positively significantly correlated with instantaneous discharge at all gauged sites in the PWD Historical water quality database (unpublished data). These comparisons of TSS concentration to stream discharge supported the use of TSS concentration as a surrogate measure of the intensity of streamflow and the presence of eroded soil and streambed particles for the purpose of comparing concentrations of certain water quality parameters (*i.e.*, Phosphorus, Nitrate, toxic metals) with intensity of streamflow and soil erosion at stations where USGS gauges have been eliminated.

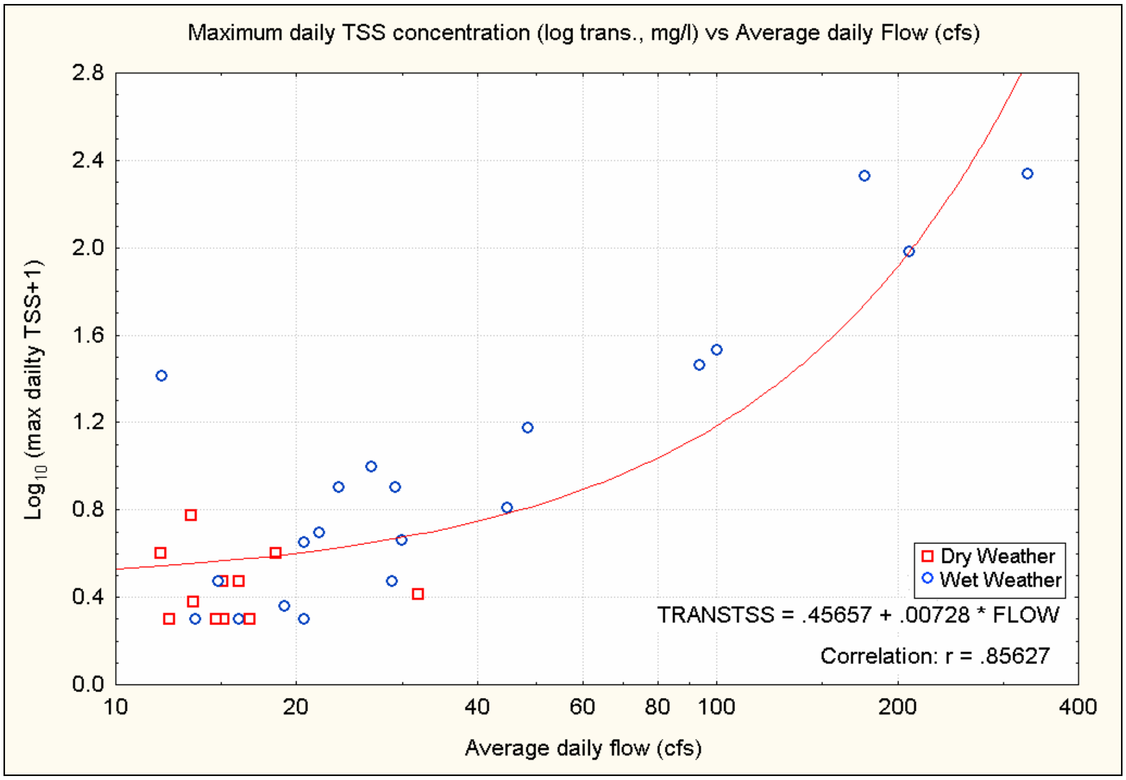

Figure 5-6 Maximum Daily Total Suspended Solids Concentration and Corresponding Average Daily Flow at site TF280.

5.3.6.2 Turbidity

Turbidity is a measure of the light scattering properties of particles suspended in water. In streams, turbidity can come from many sources, but the chief cause of increased turbidity is suspended sediment. While a correlation between turbidity and TSS certainly exists, the relationship between turbidity and TSS may differ between water bodies and even among different flow stages/seasons in the same water body due to sediment characteristics. Consistently turbid waters often show impairment in aquatic communities. Light penetration is reduced, which may result in decreased algal production; suspended particles can clog gills and feeding apparatus of fish, benthic invertebrates, and microorganisms. Feeding efficiency of visual predators may also be reduced.

PA DEP has not established numeric WQ criteria for turbidity, though General Water Quality Criteria (Title 25, Section 93.6) specifically prohibit substances attributable to any point or non-point source in concentrations inimical or harmful to aquatic life. Discharge of substances that produce turbidity are also specifically prohibited. As turbidity may vary considerably from stream to stream, the TTFIWMP uses a reference value of 8.05 NTU to define excess turbidity, based on an analysis of turbidity data from reference reaches in EPA Region IX, subregion 64. All sites in Tookany/Tacony-Frankford were determined to have excess turbidity in wet weather, and many sites were determined to potentially have problems with turbidity in dry weather as well (Table 5-7), though construction activities along SEPTA railroad tracks and within a restoration site in Cheltenham may have contributed excess turbidity in dry weather.

5.3.6.3 Conductivity and Total Dissolved Solids

Conductivity and Total Dissolved Solids (TDS) are measures of the concentration of ions and solids dissolved in water. TDS is an empirical laboratory procedure in which a water sample is filtered and dried to yield the mass of dissolved solids, while conductivity is a measure of the ability of water to conduct electricity over a given distance, expressed as microsiemens/cm (corrected to 25ºC, reported as Specific conductance) (Greenberg *et al.* 1993). With sufficient data, a good relationship between conductivity and TDS can be established. Waters containing large relative proportions of organic ions (*e.g.*, bog or wetland samples containing organic acids) generally have less conductivity for equivalent TDS concentration than waters containing primarily inorganic ions.

Dissolved ion content is perhaps most useful in determining the start of wet weather events at ungauged water quality monitoring stations. Conductivity probes are generally simple in design, robust, and very accurate. They are extremely sensitive to changes in flow, as stormwater (diluent) usually contains smaller concentrations of dissolved ions than stream baseflow. A notable exception to this rule concerns the application of ice melt chemicals to roads (primarily Sodium, Magnesium, and Potassium salts). When present in runoff or snowmelt, these substances can cause large increases in ionic strength of stream water. Though some formulations may increase levels of Chloride, PA DEP WQ criteria for Chloride (maximum 250mg/L) are intended to protect water supplies, and aquatic life effects have not been reliably demonstrated at moderate levels typically experienced in streams.

5.3.6.4 Hardness

Hardness is a calculated water quality parameter. Separate determinations of concentrations of Calcium (Ca) and Magnesium (Mg), which are the two primary cations in surface waters, are combined using the formula 2.497[Ca]+4.118[Mg], the result expressed as an equivalent concentration of $CaCO_3$ in mg/L. Waters of the Commonwealth of Pennsylvania must contain 20mg/L minimum $CaCO_3$ hardness concentration, except where natural conditions are less. No samples collected from Tookany/Tacony-Frankford had hardness concentration below this WQ criterion. Hardness is important in the calculation of WQ criteria for toxic metals (Commonwealth of Pennsylvania, 2001), as toxicity of most metals is inversely proportional to hardness concentration. Potential violations of water quality criteria for some toxic metals (*e.g.*, Cadmium) could not be determined, as hardness concentrations were small enough to decrease WQ criteria below reporting limits for the ICP-MS technique (*i.e.*, less than 1μg/L). These samples are discussed in greater detail in section 5.3.7.

5.3.6.5 Iron and Manganese

Iron (Fe) and Manganese (Mn) are generally not toxic in streams, but are regulated in waters of the Commonwealth of Pennsylvania for public water supply (PWS) protection (Commonwealth of Pennsylvania, 2001) because excess concentrations of these metals can cause color, taste, odor, and staining problems in drinking water and industrial applications. Both elements are essential nutrients for all life and relatively abundant in the soils and surface geology of the Tookany/Tacony-Frankford Watershed. Iron is particularly abundant (at approximately 5% of the Earth's crust it is second only to Aluminum in abundance among metals) and was detected in 746 of 761 samples collected from the Tookany/Tacony-Frankford Watershed. Manganese was less abundant but nevertheless detected in 745 of 762 samples. Presence of these metals in surface water samples may be natural- related to weathering of rock and soils- or due to stormwater runoff and ferrous materials in contact with the stream (*e.g.*, pipes and metal debris).

Violations of total recoverable Fe water quality criteria were frequent in wet weather and Mn criteria were exceeded in a small number (~2%) of samples (Table 5-5). However, neither Fe nor Mn is toxic to aquatic life at concentrations observed, and these constituents cannot be responsible for observed impairments in aquatic communities. Unlike toxic metals (*e.g.*, lead, cadmium and copper), Fe and Mn are not regulated by Pennsylvania Code Title 25, Chapter 16-Toxic Substances Criteria. Scientists from PWD's Bureau of Laboratory Services conducted a large scale case study of Fe and Mn concentrations in Tookany/Tacony-Frankford in 2000 and 2002, results of which are being prepared for publication.

5.3.7 Toxic Metals

Toxic metals have been recognized as having the potential to create serious environmental problems even in relatively small concentrations (Warnick and Bell 1969, LaPoint *et al*. 1984, Clements *et al*. 1988). As such, their presence in waters of the Commonwealth, treatment plant effluents, and other permitted discharges is specially regulated by Pennsylvania Code Title 25, Chapter 16-Toxic Substances Criteria. Considerable research over the past two decades has been directed at understanding the ecotoxicology of heavy metals (*e.g.*, biological pathways, physical and chemical mechanisms for aquatic toxicity, thresholds for safe exposure both acute and chronic, roles of other water quality constituents in bioavailability of toxic metals, etc.).

It is now widely accepted that dissolved metals best reflect the potential for toxicity to organisms in the water column, and many states, including PA, have adopted dissolved metals criteria (40 CFR 22227-22236). As many metals occur naturally in various rocks, minerals, and soils, storm events can expose and entrain soil and sediment particles that naturally contain metals. These inert particles are removed when samples are filtered for dissolved metals analysis (Greenberg *et al*. 1992). Total recoverable metals samples are digested and acidified to liberate organically-bound and complexed metals, but this process may also solubilize metals in inorganic and particulate states that are stable and inert under normal stream conditions, overestimating the potential for toxicity.

However, since it is not possible to filter samples collected with automatic sampling equipment immediately after collection, PWD has collected a greater number of total metals samples than dissolved metals samples. In order to ensure an adequate number of dissolved samples, particularly in wet weather, samples were collected from site TF280 during wet weather on two dates in summer 2004. Samples were collected manually by pumping through the automatic sampling tubing and apparatus and filtered immediately after collection. Site TF280 was sampled to conservatively direct sampling effort to the drainage that would be expected to contain the most potential sources of urban wet weather runoff pollution.

Analysis of paired dissolved/total metals concentration data suggests that most metals are generally found in considerably greater concentrations when total metals are measured, particularly in wet weather. Since dissolved metals concentrations are usually small or undetectable in both dry and wet weather, the potential for heavy metal toxicity in Tookany/Tacony-Frankford, at least for water column organisms, is believed to be low. Sediment and pore water conditions may result in greater concentrations or otherwise contribute to increased potential for toxicity to benthic organisms within stream sediment microhabitats, but these effects remain poorly defined and are difficult to measure. Total recoverable metals results and comparisons to discontinued total metals water quality criteria are included herein as a reference measure of the potential for sediment metal loading and metals loading to the Delaware estuary from Philadelphia's urban stormwater; though it is believed that, for at least some metals, samples more closely reflect natural soil and geologic features than water pollution.

With the exception of Aluminum and hexavalent Chromium, PA WQ criteria are based on hardness (as $CaCO_3$), to reflect inverse relationships between hardness and toxicity that exist for most metals (Figure 5-7). While these criteria are much improved over simple numeric criteria, they fail to describe the complex interactions between dissolved metals and other water constituents and physicochemical properties (*e.g.*, Dissolved Organic Carbon, pH, temperature, and ions other than Ca and Mg,). Hardness-based criteria may represent an intermediate step between simple numeric criteria and criteria based on more complex water quality models (*i.e.*, Biotic Ligand Model), drafts of which have been recently been presented by EPA.

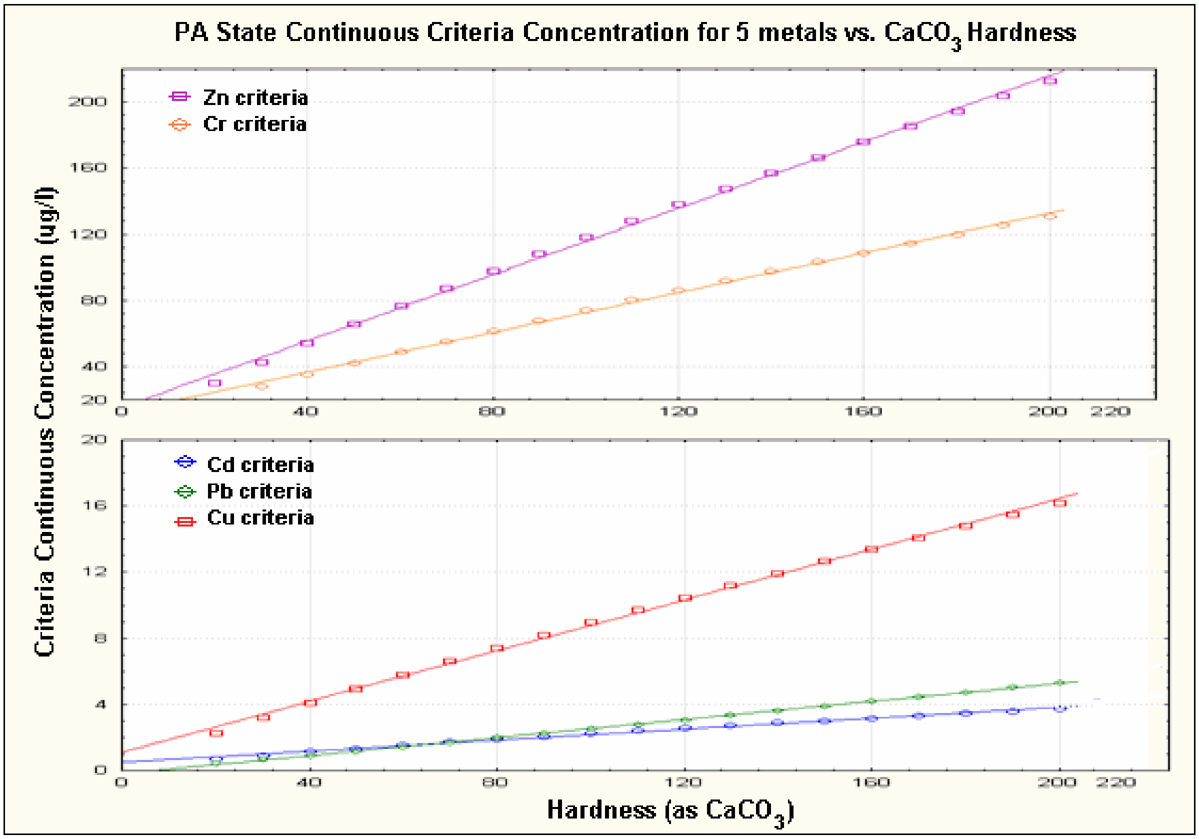

Figure 5-7 PA DEP Hardness-based Criteria Continuous Concentrations for 5 toxic metals.

5.3.7.1 Aluminum

Aluminum (Al) is the most abundant metal in the Earth's crust at approximately 8.1% by mass. As Al is a component of many rocks and minerals, particularly clays, weathering of rocks and soil erosion contribute Al to all natural waters. Water column Al concentrations were significantly higher in wet weather than in dry weather (Mann-Whitney test $Z_{2,699} = -13.28$, $p<.05$), which may be due to both natural and anthropogenic sources. Examination of paired dissolved and total recoverable Al concentrations from 45 samples collected from Tookany/Tacony-Frankford shows that while total recoverable Al concentrations may often exceed 100ug/L in wet weather, dissolved Al is rarely present in similar concentrations (Figure 5-8). This finding suggests that most Al is present in particulate form.

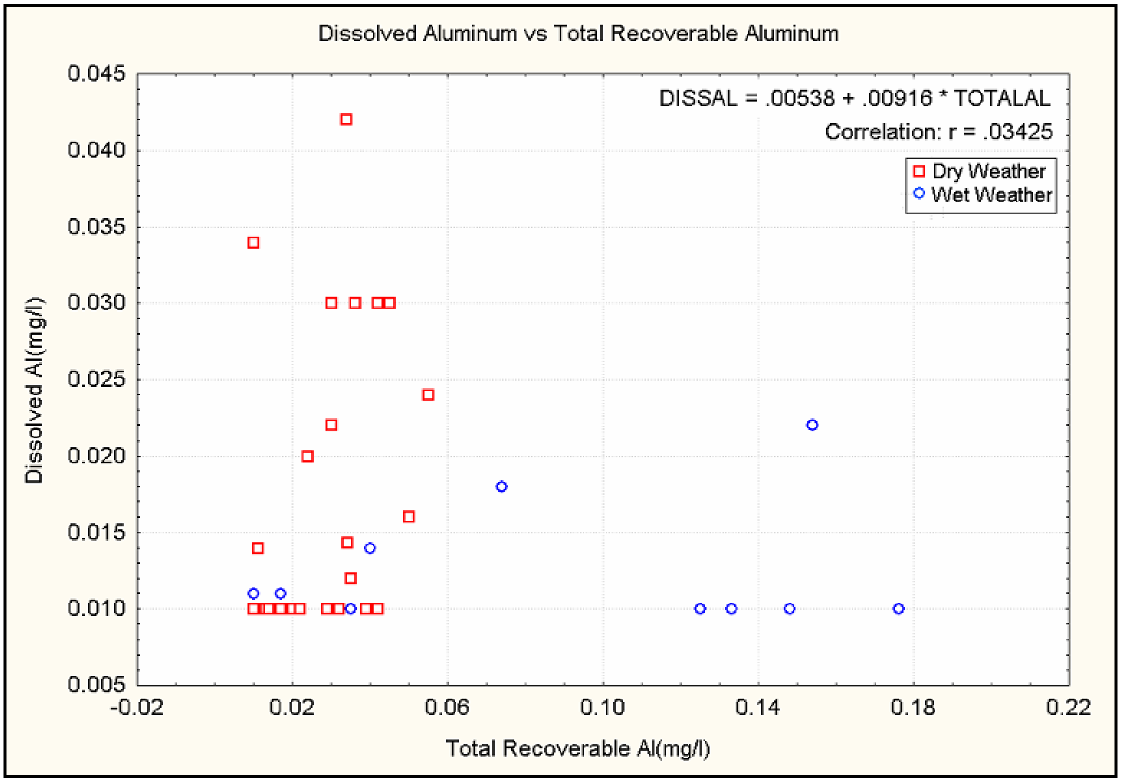

Figure 5-8 Scatterplot of Paired Dissolved Aluminum and Total Recoverable Aluminum Concentrations of Samples collected from 8 sites in Tookany/Tacony-Frankford Watershed, 2000-2004.

Al was detected in 643 of 701 samples from Tookany/Tacony-Frankford (Table 5-12). Though 120 of 135 samples found to be in violation of water quality criteria were collected in wet weather, violations occurred with similar relative frequency in dry and wet weather because wet weather samples were much more numerous overall and dry weather criteria are far more stringent than wet weather criteria (87µg/L and 750µg/L, respectively).

Table 5-12 Summary of Toxic Metals Samples Collected in Dry and Wet Weather and Corresponding Number of Samples Found to have Concentrations Below Reporting Limits

Parameter	Number of Dry Samples	Number of Dry Non-Detects	Number of Wet Samples	Number of wet Non-Detects
Total Aluminum	149	22	552	36
Dissolved Aluminum	55	26	12	7
Total Cadmium	129	129	605	560
Dissolved Cadmium	83	83	194	194
Total Chromium	102	82	548	267
Dissolved Chromium	46	45	76	76
Total Copper	154	0	609	0
Dissolved Copper	74	0	81	0
Total Lead	146	113	605	123
Dissolved Lead	65	65	76	59
Total Zinc	143	8	528	6
Dissolved Zinc	66	12	56	6

The strong correlation between Al and TSS (Figure 5-9) suggests that most of the Al present in wet weather water samples may be due to suspended particulate Al. However, wet weather suspended solids loads consist of a mixture of urban stormwater, eroded upland soils, and streambank particles. It is impossible to determine individual Al contributions of these sources. State water quality criteria for Al are based upon total recoverable fractions rather than dissolved, partially because under experimental conditions, Brook Trout (*Salvelinus fontinalis*) experienced greater mortality with increased total Al concentration despite constant levels of dissolved Al (the form of particulate Al present in this experiment was Aluminum hydroxide, and experimental pH was low). Furthermore, EPA has documented HQ waters that exceed WQ standards for Al (63FR 68353-68364). Al found in natural streams may be predominantly mica and clays, which are inert under normal stream conditions. As the Tookany/Tacony-Frankford Watershed is rich in both mica and clay soils, and rarely experiences pH < 6.0, other factors should probably be ruled out before attributing biological impairment to Al toxicity.

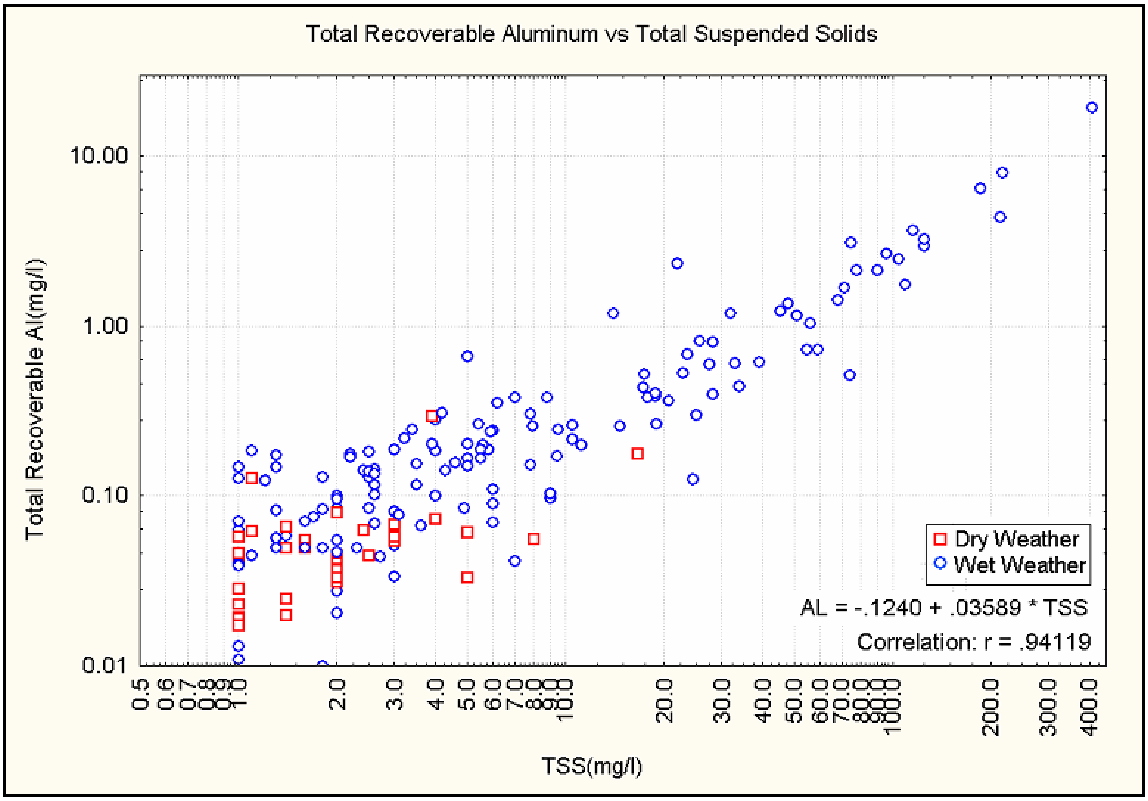

Figure 5-9 Scatterplot of Paired Total Recoverable Aluminum and Total Suspended Solids concentrations of samples collected from 8 sites in Tookany/Tacony-Frankford Watershed, 2000-2004.

5.3.7.2 Cadmium

Cadmium (Cd) is a heavy metal that is widely but sparsely distributed in the earth's crust. Cd is often associated with Zinc (Zn), but may also be found with other metals such as Copper (Cu) and Lead (Pb). For this reason, smelting and other industrial uses of nonferrous metals may be sources of Cd pollution. Other industrial sources include battery, pigment, and plastics manufacturing. Atmospheric deposition and some types of agricultural fertilizers may also contribute Cd to the environment. Cd has no known biological function, and may be toxic in very small concentrations. In aquatic environments, toxicity is assumed to be due to uptake of dissolved Cd, so PA DEP WQ criteria are based on dissolved concentrations.

Cd was rarely detected in water samples from Tookany/Tacony-Frankford Watershed. Though concentrations were nearly always below reporting limits, WQ criteria for Cd reflect the fact that this metal may be toxic in small concentrations. WQ criteria for Cd are calculated based on hardness and Cd concentrations less than 1ug/L may be a violation of water quality criteria in very soft water. Dissolved Cd was detected in only one of 277 samples (Table 5-12); there were no violations of state WQ criteria, but 4 of 276 samples in which Cd concentration was below reporting limits had sufficiently soft water (hardness < 34mg/L in dry weather or <26.5mg/L in wet weather) to lower the sample WQ criterion below the reporting limit.

Total recoverable Cd was only detected in 45 of 734 samples, and only in wet weather (Table 5-12). Of these samples, 15 would have exceeded the former total recoverable WQ criteria that were discontinued in 2001. An additional 14 samples would have had sufficiently soft water (hardness < 34mg/L in dry weather or <26.5mg/L in wet weather) to lower discontinued WQ criteria below the reporting limit. Although sediments and sediment pore water Cd concentrations may be a concern given observed increases in total recoverable Cd during wet weather, dissolved Cd concentrations were always small, and it is unlikely that Cd toxicity is responsible for observed biological impairment in Tookany/Tacony-Frankford.

5.3.7.3 Chromium

Chromium (Cr) is commonly used in alloys of stainless steel and, as Chromate salts, in other metallurgical and industrial applications. Of the two predominant naturally occurring forms, only hexavalent Chromium (Cr[VI]) is toxic, while trivalent Cr (Cr[III]) is an essential trace nutrient; Separate WQ standards exist for Cr[III] and Cr[VI]. Toxic Cr[VI] is much more soluble at normal stream pH than Cr[III] (Rai *et al*. 1989), so at the extremes, dry weather dissolved Cr samples probably more closely reflect actual water column concentrations of Cr[VI], while wet weather total recoverable Cr samples will contain a much greater proportion of insoluble, nontoxic Cr[III]. Despite the influence of other water quality constituents on the speciation and bioavailability of Cr, WQ criteria for Cr[VI] are absolute (CCC=10μg/L, CMC=16μg/L, dissolved fraction only).

Determinations of Cr described herein were obtained with ICP-MS equipment following acid digestion, a method that does not allow for speciation of Cr in either dissolved or total recoverable samples; concentrations were conservatively assumed to be Cr[VI], though the ratio of Cr[III] to Cr[VI] is very likely to be much greater in total recoverable samples as well as in wet weather samples. Dissolved Cr was detected in only one of 122 samples (Table 5-12), and there were no violations of WQ criteria (Table 5-5). Approximately 31 of 650 total recoverable Cr samples would have violated WQ criteria discontinued in 2001.

5.3.7.4 Copper

Copper (Cu) occurs naturally in numerous forms and is present to some degree in most soils and natural waters. Cu is also used industrially for electric wires and coils, as well as in building materials such as roofing and pressure-treated lumber. Cupric Ion (Cu^{2+}) is the bioavailable form of Cu in aquatic systems and its mode of toxicity involves ligand bonding with the gill surface of fish or similar structures of invertebrates. As such, WQ criteria are based on dissolved Cu concentration, which is a better predictor of Cu toxicity than total recoverable metal concentration. Dissolved concentrations are usually much smaller than total recoverable concentrations in natural waters, as Cu forms complexes and ligand bonds with other water column constituents (Morel & Hering, 1993). Cu can also be present in particulate form or be adsorbed to large particles that are trapped by filtering the sample.

Cu was always detectable in Tookany/Tacony-Frankford; all of the 763 samples collected had Cu concentration above reporting limits. Basic statistics for Total Cu and Dissolved Cu appear in (Table 5-12) and outliers excluded from subsequent analyses are tabulated in Appendix D (Contamination was suspected in two samples where the ratio of dissolved to total Cu exceeded 2:1, and also in a dry weather sample at site TF500 where Total Cu concentration was 102µg/L.). Some samples lacked hardness data, so conservative hardness values were substituted for the purpose of comparing observed dissolved Cu to WQ criteria. These substitute hardness values were mean hardness minus one standard deviation, calculated separately for dry and wet weather (hardness data aggregated for all sites and dates).

In 2004, PWD reinstated separate determinations of total and dissolved fractions on metals samples collected as part of the discrete interval sampling program. PWD also conducted two rounds of intensive metals sampling during wet weather at site TF280, which is believed to be the most chemically impaired non-tidal site in the watershed. As of May 2005, 152 paired dissolved and total copper results were available. The ratio of dissolved Cu to total recoverable Cu was significantly higher in dry weather samples than in wet weather samples (t-test, $F_{(2,148)}=2.809$, $p=.000039$). Furthermore, there was no strong relationship between dissolved and total recoverable Cu in wet weather samples (Figure 5-10). Despite total recoverable concentrations that ranged up to 200µg/L, maximum observed concentration of dissolved Cu was 22µg/L.

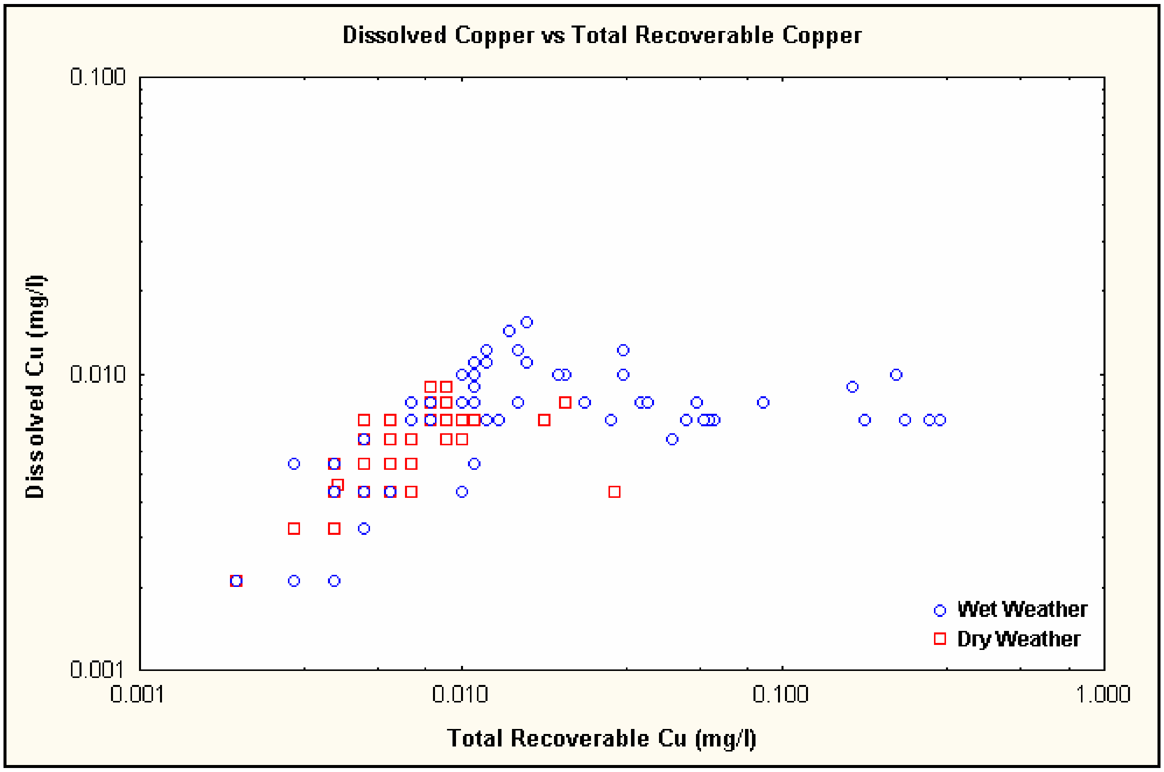

Figure 5-10 Paired Dissolved and Total Recoverable Copper Concentration of Samples Collected from 8 Sites in Tookany/Tacony-Frankford Watershed, 2000-2004.

As Cu strongly associates with sediment, pore water/sediment toxicity should not be ignored as a potential stressor to benthic invertebrates. The only sensitive taxa that were consistently collected throughout the watershed (though densities were low) were tipulid larvae; these relatively large larvae are shredders, and enshroud themselves in leaf packets. A diet and microhabitat rich in organic acids may confer resistance to heavy metal pollution. Mayflies, on the other hand, have been characterized as very sensitive to metals pollution (Clements *et al.* 1988, Clements *et al.* 1990) and the obvious disparity between Tookany/Tacony-Frankford sites and reference sites with respect to number and abundance of mayfly taxa may be attributable to heavy metal pollution. Sediment metals concentrations and reference site chemistry data are needed before any conclusions can be drawn.

Cu toxicity was also investigated using the Biotic Ligand Model (BLM) (DiToro *et al.* 2001). Data were lacking for some model input parameters, so conservative values were substituted. Many water chemistry parameters can affect Cu toxicity, particularly other ions and organic molecules that tend to compete with gill ligand bonding sites for available Cu. Figure 5-11 illustrates the effects of pH and temperature on Cu bioavailability and toxicity. BLM data were used only to determine whether Cu toxicity could affect the biology of Tookany/Tacony-Frankford Watershed, not to develop alternative water quality criteria. EPA is in the process of developing new WQ criteria for Cu incorporating the BLM with appropriate margins of safety for protecting aquatic life.

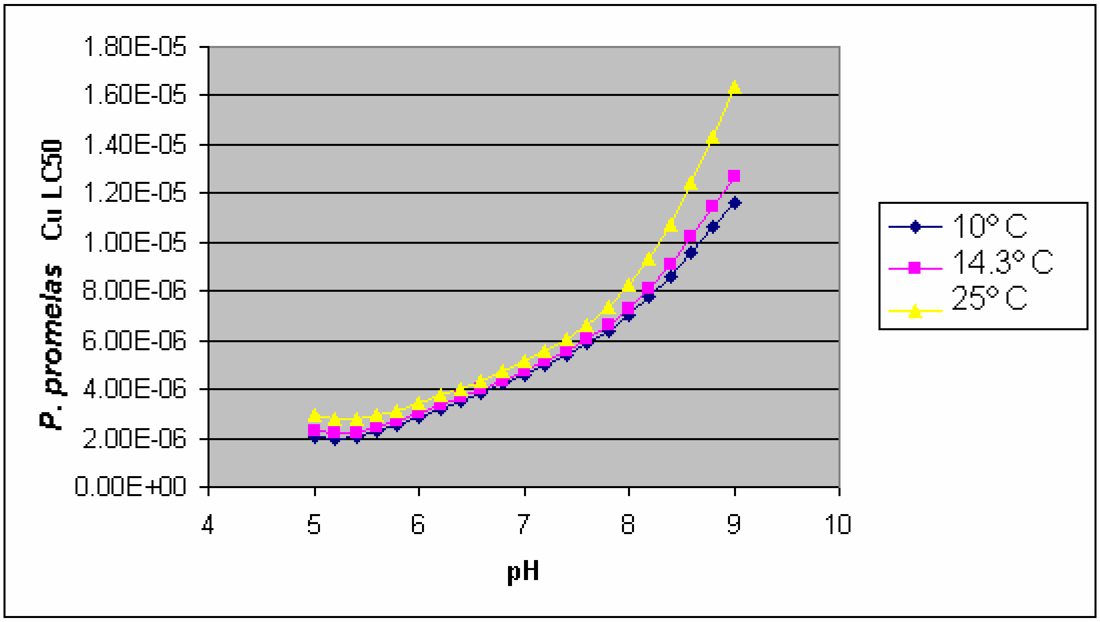

Figure 5-11 Effects of pH and Temperature on Copper Toxicity to Fathead Minnows.

The BLM was used to determine the LD50 of dissolved copper to Fathead Minnow (*Pimephales promelas*), and two cladoceran microcrustaceans (*Ceriodaphnia dubia*, and *Daphnia pulex*). For most parameters data entered into the model came from samples collected from Tookany/Tacony-Frankford Watershed. Data from each sample were entered into the model as a separate case and the LD50 of Cu was determined for each case. When data from Tookany/Tacony-Frankford Watershed were not available estimates from nearby streams were used. Parameters for which estimates were used included: DOC, Percent of DOC contributed by Humic Acids, Potassium, and Chloride. DOC competes for Cu with gill ligand sites and is positively correlated to the LD50 of Cu, therefore a conservative estimate of 2.9 mg/L from French Creek was used in place of 5.4 mg/L , an estimate given for PA streams (EPA document #822-B-98-005). Due to the lack of DOC characterization data, ten percent was used for the relative proportion of DOC made up by Humic acids as recommended by the model documentation (DiToro *et al.* 2001). Model input values for Potassium (K) were estimated by averaging potassium values from Pickering Creek, Trout Creek, and Wissahickon Creek, though K currently has no direct effect on metal toxicity in the BLM. Chloride model input values were calculated by averaging values from Pickering Creek and Trout Creek. When comparing dissolved Cu concentrations from Tookany/Tacony-Frankford Watershed to predicted LD50, the predicted LD50 concentration was reduced by an order of magnitude (margin of safety). Even with this margin of safety, no sample had dissolved Cu concentration above the LD50 for any of the target organisms

5.3.7.5 Lead

Lead (Pb) is a toxic heavy metal that was once commonly used in paints (as recently as 1978) and in automotive fuels (until being phased out in the 1980s). Pb is still used industrially in solder and batteries. Some areas have banned the use of lead in shotgun pellets and fishing weights, as chronic toxicity results when these items are ingested by waterfowl. Acute toxicity of Pb to aquatic life is considerably less than chronic toxicity, as evidenced by the large difference in CCC and CMC criteria (2.5 and 65µg/L, respectively, at 100mg/L $CaCO_3$ hardness). Dissolved Pb was only detected in 17 of 141 samples collected in Tookany/Tacony-Frankford; no violations of WQ criteria were found (Table 5-5). When compared to discontinued total recoverable metals criteria, 70 of 712 samples would have been violations.

5.3.7.6 Zinc

Zinc (Zn) is a common element present in many rocks and in small concentrations in soil. Zn is a micronutrient needed by plants and animals, but when present in greater concentrations in surface water, it is moderately toxic to fish and other aquatic life. Toxicity is most severe during certain sensitive (usually early) life stages. Zn is a component of common alloys such as brass and bronze and is used industrially for solders, galvanized coatings, and in roofing materials. Zn is usually present in surface waters of Tookany/Tacony-Frankford; only 14 of 671 individual total recoverable Zn samples and 18 of 122 dissolved Zn samples from Tookany/Tacony-Frankford had Zn below reporting limits (Table 5-5), though concentrations were relatively small.

Contamination was suspected in four sets of samples collected in 2004, where dissolved concentrations were consistently greater that total recoverable concentrations in 30 of 32 samples (Figure 5-12). Dates and sample information for these sample dates are summarized in Appendix D. Of 15 dissolved Zn samples exceeding WQ criteria, 14 are likely to have been affected by contamination. If these samples are ignored, dissolved Zn/total recoverable Zn ratios more closely mirror those of other metals (*i.e.*, higher in dry weather than in wet weather, Figure 5-12).

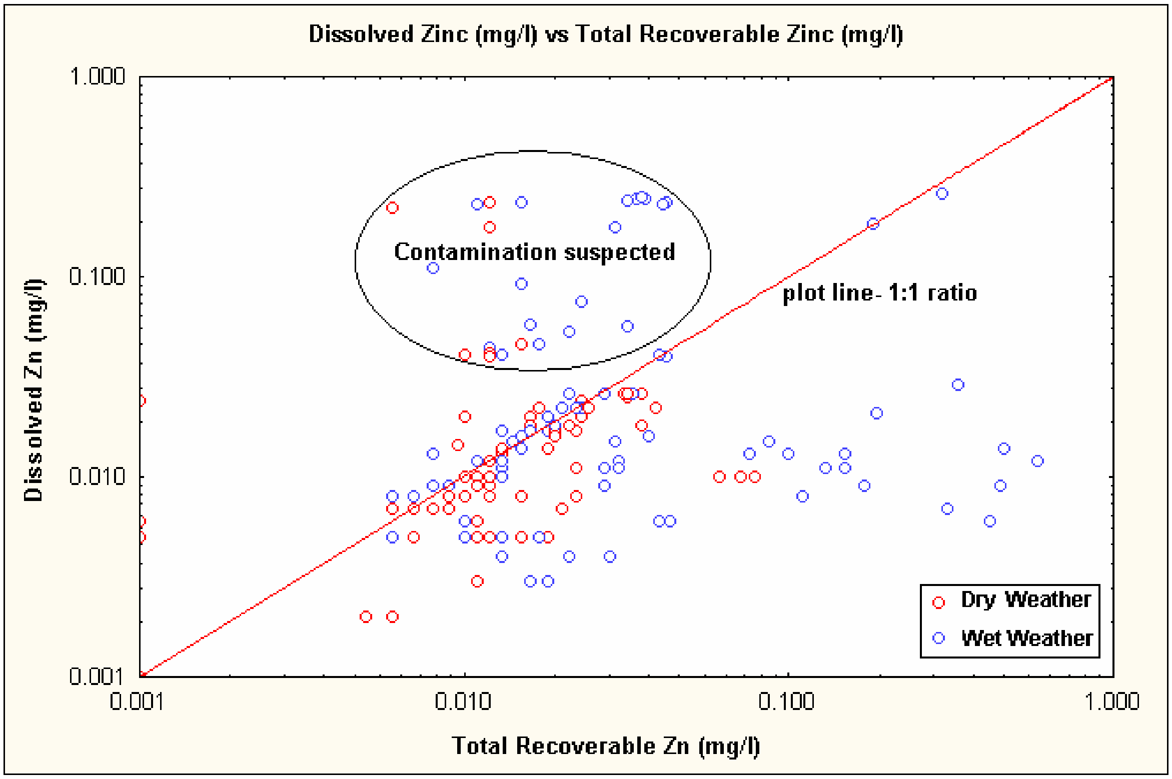

Figure5-12 Paired Total Recoverable and Dissolved Zinc Concentrations of Samples collected from 8 sites in Tookany/Tacony-Frankford Watershed, 2000-2004.

Discrepancies occurred with both dry and wet weather samples. Bench sheets did not indicate any problems with samples or the instrumentation, and all QC checks were passed. As samples were preserved and stored, the PWD Bureau of Laboratory Services (BLS) was able to re-analyze these samples, obtaining similar results. The analyst visually confirmed the presence of settled solids in sample containers used for total recoverable metal, while sample containers used for dissolved metals were visually clear. A series of subsequent filter blank trials showed filters used to prepare dissolved metals samples may have leached Zn, but the magnitude of the difference in total and dissolved concentrations was much too great to be explained by filter contamination. The source of contamination remains unknown.

The BLM was used to estimate the toxicity of dissolved Zn to fathead minnows (*Pimephales promelas*), rainbow trout (*Oncorhynchus mykiss*), and a cladoceran (*Daphnia magna)*. Input data were compiled or estimated in the same manner as dissolved copper model input data. An order of magnitude safety factor was applied to the LD_{50} concentrations generated by the model and the resulting concentration was compared with dissolved zinc data collected from the Tookany/Tacony-Frankford Watershed. Even with this safety margin, no observed dissolved zinc concentrations exceeded the calculated LD_{50} for the studied organisms.

5.3.8 Nutrients

5.3.8.1 Phosphorus

Phosphorus (P) concentrations are often correlated with algal density and are used as a primary indicator of cultural eutrophication of water bodies. N:P ratio analysis strongly suggests that P is the limiting macronutrient in the Tookany/Tacony-Frankford Watershed. Readily available dissolved orthophosphate (PO_4) was only detected in 5 of 129 total samples collected in dry weather, and in 55 of 584 wet weather samples, so nutrient analyses considered only total P concentrations (TP). TP includes some smaller fraction of P that is considered to be bioavailable, or readily usable by stream producers. Bioavailable P (BAP) includes soluble reactive P (SRP) and, depending on other factors, some portion of particulate inorganic P. Furthermore, some producer taxa can produce endogenous alkaline phosphatases and obtain P that is not normally available.

The Tookany/Tacony-Frankford Watershed has not been listed by PA DEP as impaired due to nutrients, and no WQ criteria exist for TP or OPO_4. For the TTFIWMP, TP concentrations were evaluated using a frequency distribution approach. Data were compiled for reference reaches in EPA Ecoregion IX, subregion 64 (median of 75th percentile value for each of four seasons=140µg/L) from EPA (822-B-00-019). This reference value is considerably greater than the mesotrophic/eutrophic boundary for TP suggested by Dodds *et al*. (1998) (*i.e.*, 75µg/L). Dry weather TP concentrations were usually below both reference values.

Total P concentration was below reporting limits in 58 of 135 samples collected in dry weather, but in only 87 of 555 wet weather samples. Elevated dry weather TP concentration was observed at sites TF280 and TFM006, probably due to dry weather sewage inputs. Log-transformed Mean TP concentration was significantly greater in wet weather than in dry weather ($F_{2,183}$=1.55, p=0.008), so stream producers in the Tookany/Tacony-Frankford Watershed are generally exposed to somewhat constant TP concentrations punctuated with episodic inputs of greater TP concentration due to runoff and erosion. Point sources of P include CSO and SSO discharges, contributing large amounts of phosphorus where and when they occur.

Phosphorus readily adsorbs to soil and sediment particles and is generally less mobile in soils than nitrogen compounds. Potential non-point sources of P are decomposing organic matter in or near the stream, runoff from industrial parks, golf courses, agriculture and residential areas, and inorganic P adsorbed to soil particles that are washed into the stream by erosive forces. In fact, soil erosion may be the greatest source of P in separate-sewered portions of Tookany/Tacony-Frankford. TP concentration was significantly positively correlated with TSS concentration, (Log transformed, $r_{(183)}$=0.60, p<0.001) (Figure 5-13). Wet weather phosphorus inputs, however, are coupled with physical disturbances (*e.g.*, hydraulic shear stress, other abrasive forces, reduced light availability). These stressors respond to changes in flow in a non-linear fashion. Some taxa have the ability to store intercellular reserves of inorganic nutrients ("luxury consumption") when concentrations exceed immediate demands. It is thus very difficult to estimate P concentrations available to stream producers and draw conclusions about stream trophic status. This topic is addressed in greater detail in Section 5.4.

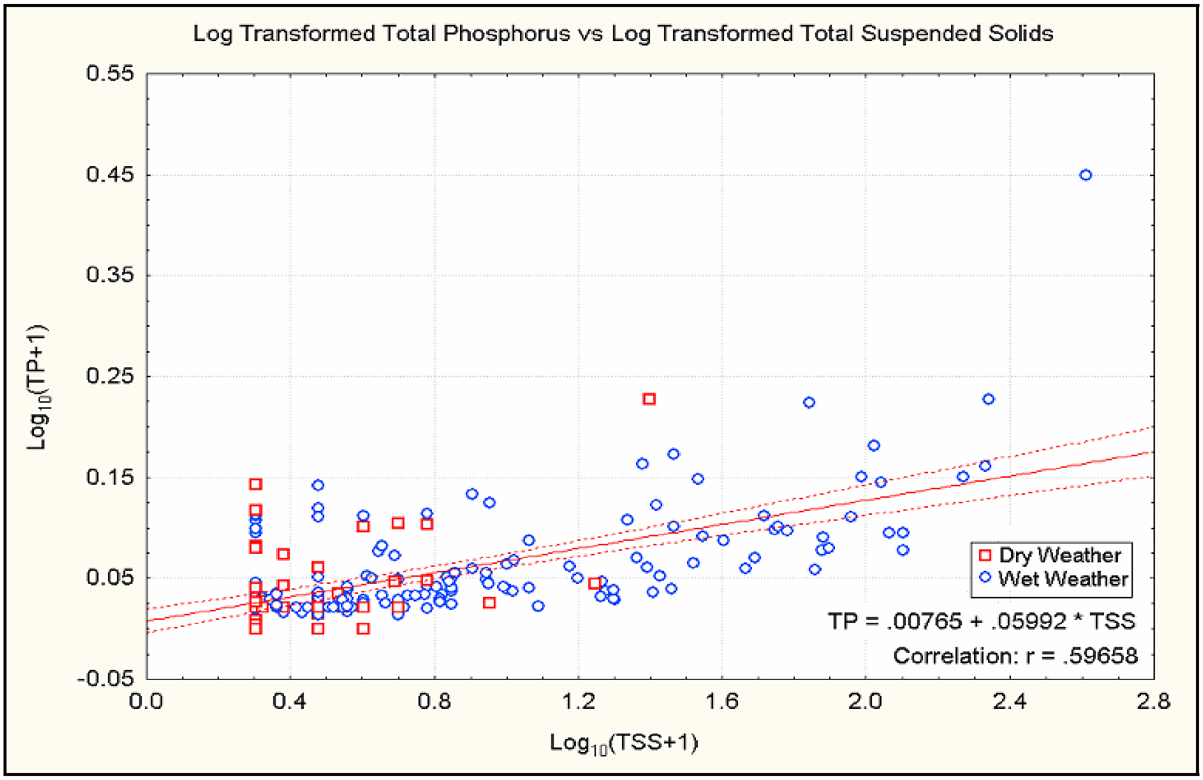

Figure 5-13 Scatterplot of Paired Total Phosphorus and Total Suspended Solids Concentrations of Samples Collected from 8 Sites in Tookany/Tacony-Frankford Watershed, 2000-2004.

5.3.8.2 Ammonia

Ammonia, present in surface waters as un-ionized ammonia gas (NH_3), or as ammonium ion (NH_4^+), is produced by deamination of organic nitrogen-containing compounds, such as proteins, and also by hydrolysis of urea. In the presence of oxygen, NH_3 is converted to nitrate (NO_3) by a pair of bacteria-mediated reactions, together known as the process of nitrification. Nitrification occurs quickly in oxygenated waters with sufficient densities of nitrifying bacteria, effectively reducing NH_3, although at the expense of increased NO_3 concentration. PA DEP WQ criteria for NH_3 reflect the relationship between stream pH, temperature, and ammonia speciation/dissociation. Ammonia toxicity is inversely related to hydrogen ion [H+] concentration; an increase in pH from 7 to 8 increases NH_3 toxicity by approximately an order of magnitude. At pH 9.5 and above, even background concentrations of NH_3 may be toxic.

Historic data comparisons show that, in the watershed overall, NH_3 concentrations have decreased significantly compared to samples collected from 1970 to 1980 ($F_{2,1001}=6.18$, $p<0.001$). Dry weather NH_3 concentrations, in particular, have improved dramatically. For example, in samples collected from 1970 to 1980, there was no significant difference in NH_3 concentrations between dry and wet weather samples at site TF280 ($F_{2,99}=1.19$, $p=0.77$), suggesting that sewage inputs or anoxic conditions were common at this site regardless of weather.

Though no dry weather samples collected from the Tookany/Tacony-Frankford Watershed from 2000-2004 contained NH_3 concentration in excess of 0.8mg/L and there were no violations of WQ criteria, 20 of 87 samples were above reporting limits, suggesting occasional inputs of untreated sewage, anoxic conditions, or the presence of other decomposing organic material. Site TF280 was responsible for most of these observations, and is believed to be the site most seriously affected by dry weather sewage inputs and anoxic conditions. Target A of the TTFIWMP is directed at further reducing dry weather sewage inputs through source track-down and infrastructure repair/improvements.

NH_3 concentration of sites within Tookany/Tacony-Frankford Watershed (log-transformed, all sites combined) was significantly higher in wet weather than in dry weather ($F_{2,710}=2.30$, $p=.0047$). NH_3 concentration was above detection limits in 211 of 436 total wet weather samples, though all samples with concentrations greater than 0.8mg/L were collected at site TF280.

There were no violations of WQ criteria due to the fact that pH remained near neutrality at the time samples were taken. Algal activity was observed to cause pH fluctuations, particularly at site TF620 in spring 2003. When severe, these fluctuations in pH caused NH_3 WQ criteria to decrease to within the range of values observed at other times. The NH_3 sampling regime was not ideal for identifying possible violations of WQ standards as discrete interval grab samples were collected in the morning, while daily pH maxima were typically reached in afternoon/early evening hours.

5.3.8.3 Nitrite

As an intermediate product in the oxidation of organic matter and ammonia to nitrate, nitrite (NO_2) is seldom found in unimpaired natural waters in great concentrations provided that oxygen and nitrifying bacteria are present. For this reason, NO_2 may indicate sewage leaks from illicit connections, defective laterals, or storm sewer overflows and/or anoxic conditions in natural waters. NO_2 was detected in only 14 dry weather samples collected from the Tookany/Tacony-Frankford Watershed; most of these observations were at site TF280 and most were collected prior to 2004. Comparison to data collected from 1970-1980 showed that the incidence of Nitrite detections in dry weather has been drastically reduced, suggesting fewer dry weather sources of sewage and/or reduced severity of anoxic conditions.

NO_2 concentrations were greater than reporting limits more frequently in wet weather (129 of 585 total samples) than in dry weather, but contribution of NO2 to total inorganic nitrogen was usually small and concentrations of many samples were estimated to be half the detection limit for the purpose of evaluating nutrient ratios. Large numbers of samples below detection limits prevented the use of parametric statistical methods to evaluate weather effects. Mann-Whitney U test analysis showed significantly greater NO2 concentration (log transformed, samples below MRL included as half the MRL) in wet weather than in dry weather ($Z_{2,717} = -2.75$, $p<0.005$).

5.3.8.4 Nitrate

Concentrations of nitrate (NO_3) are often greatest in watersheds impacted by (secondary) treated sewage and agricultural runoff, but elevated NO_3 concentrations in surface waters may also be attributed to runoff from residential and industrial land uses, atmospheric deposition and precipitation (*e.g.*, HNO_3 in acid rain) and decomposing organic material of natural or anthropogenic origin. Nitrate is a less toxic inorganic form of N than ammonia and serves as an essential nutrient for photosynthetic autotrophs. Availability of inorganic N can be a growth-limiting factor for producers, though usually only in oligotrophic (nutrient-poor) lakes and streams or acidic bogs.

PA DEP has established a limit of 10mg/L for oxidized inorganic nitrogen species (NO_3 + NO_2) (Commonwealth of Pennsylvania, 2001). This limit is based on public water supply use and intended to prevent methemoglobinemia, or "blue baby syndrome", not prevent eutrophication of natural water bodies. Waters of the Commonwealth that have been determined to be impaired due to excess nutrients have Waste Load Allocations (WLA) determined through the Total Maximum Daily Load (TMDL) process; Tookany/Tacony-Frankford Watershed has not been listed as impaired due to nutrient enrichment. For the TTFIWMP, NO_2 +NO_3 concentrations were evaluated using a frequency distribution approach. Data were compiled for reference reaches in EPA Ecoregion IX, subregion 64 (75th percentile of observed data=2.9mg/L). This reference value is considerably greater than the mesotrophic/eutrophic boundary for Total N suggested by Dodds *et al.* (1998) (*i.e.*, 1.5 mg/L TN).

Dry weather NO_3 concentrations in the Tookany/Tacony-Frankford Watershed are almost always found between the two aforementioned reference points (*i.e.*, between 1.5mg/L and 2.9mg/L). NO_3 concentrations typically decreased in wet weather. Mean NO_3 concentration (log transformed, all sites combined) was significantly lower in wet weather than in dry weather ($F_{2,180}$=1.70, p<0.001), and NO_3 was significantly negatively correlated with Log transformed TSS concentration (r(182)= -0.55, p<0.001, Figure 5-14). This relationship demonstrates dilution by stormwater and is the reverse of the phenomenon observed with P concentration. However, other forms of N (*i.e.*, TKN, NH_3, NO_2) tended to increase in concentration in wet weather. Nutrient dynamics and relationships to autotrophic community production are addressed in greater detail in section 5.4.

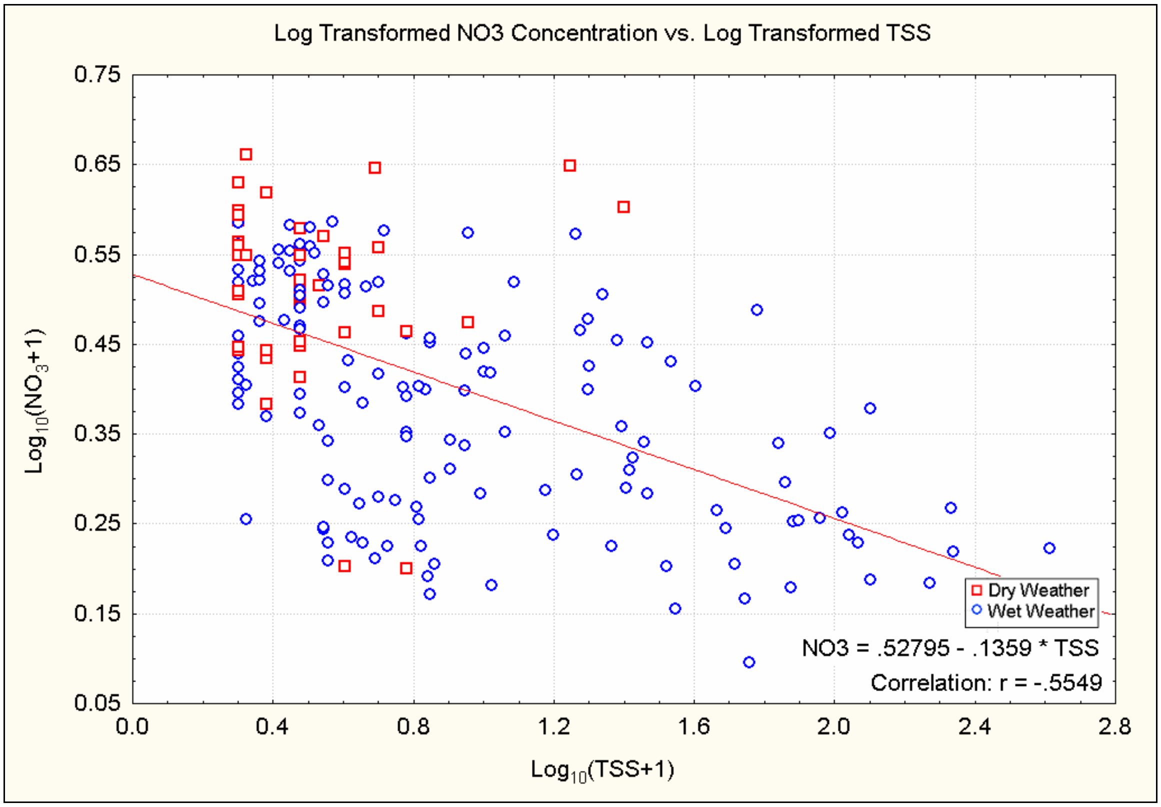

Figure 5-14 Scatterplot of Paired Nitrate and Total Suspended Solids Concentrations of Samples Collected from 8 sites in Tookany/Tacony-Frankford Watershed, 2000-2004.

Unusual dry weather samples were collected from site TF280 on July 7, 2004 and TFM006 on August 30, 2004 in which NO_3 concentration seemed diluted compared to most other dry weather baseflow samples. In the first case, accompanying data showed increases in TKN and NO_2, as would be expected with under anoxic conditions, but DO suppression could not be verified due to probe failure. In the second case, TKN was slightly elevated for a dry weather sample, but NO2 was below reporting limits and no DO data were available.

5.3.8.5 Total Kjeldahl Nitrogen

The Total Kjeldahl Nitrogen (TKN) test provides an estimate of the concentration of organically-bound N, but actually measures all N present in the trinegative oxidation state. Ammonia must be subtracted from TKN values to give the organically bound fraction. TKN analysis also does not account for several other N compounds (*e.g.*, azides, nitriles, hydrazone); these compounds are rarely present in significant concentrations in surface waters. Sampling results strongly suggest the most important source of organic N is sewage inputs from CSO and SSO discharge. Log-transformed Organic N concentration was significantly greater in wet weather than in dry weather ($F_{2,654}$=14.04, p<0.001). Organic N was also significantly positively correlated with fecal coliform bacteria concentration, r(647)=0.70, p<0.001 (Figure 5-15). As most organic N loadings to the watershed occur in wet weather, this N is probably transported out of the system and into the Delaware estuary before exerting nitrification DO demand or becoming available for uptake by algae.

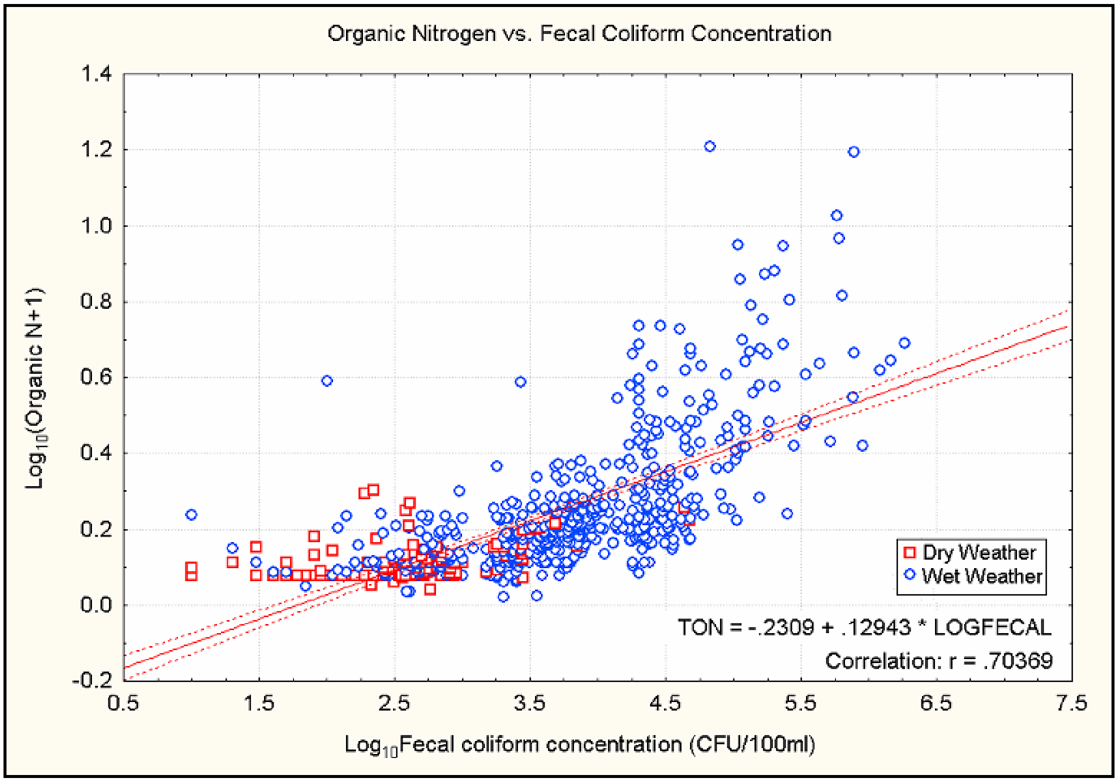

Figure 5-15 Scatterplot of Organic Nitrogen and Fecal Coliform Bacteria Concentrations of Samples Collected from 8 sites in Tookany/Tacony-Frankford Watershed, 2000-2004.

5.4 Stream Metabolism

Stream Metabolism is a measure of the basic ecosystem processes of primary productivity and community respiration. Primary productivity measures the total energy fixed by plants in a community by photosynthesis, and community respiration quantifies the use of reduced chemical energy by autotrophs as well as heterotrophs (Odum 1956). Benthic algae are important primary producers in aquatic systems and are often the greatest source of energy in mid-order streams with less than complete tree canopy. Where abundant, periphyton communities may strongly influence water column dissolved oxygen, pH and inorganic carbon speciation.

Continuous water quality data indicated that certain sites in Tookany/Tacony-Frankford experience pronounced diurnal fluctuations in DO and pH that can be reduced in magnitude following storm events (Figure 5-16). These fluctuations sometimes result in short-lived violations of state water quality standards, frequently so within 3 miles of the confluence with the Delaware River. As Tookany/Tacony-Frankford Watershed was not found to have large dry weather concentrations of chlorophyll in the water column that would be indicative of suspended phytoplankton, it was hypothesized that these pronounced fluctuations were due largely to periphytic algae.

Supporting this conclusion are observed reductions in the magnitude of fluctuations during and immediately after storm events (Figure 5-16) and increases in water column chlorophyll-a during storm events observed at some sites. The latter effect is difficult to characterize, as the degree to which chl-*a* increased in wet weather is believed to have been affected by algal density, predominant growth form, and stream velocity. To address these hypotheses, a study was carried out at sites TF280 and TF680 to determine the biomass of benthic algae in terms of chlorophyll-*a* (chl-*a*), spatial variation in biomass within and between sites, scouring effects of high flows, and algal accrual rates following a high flow event.

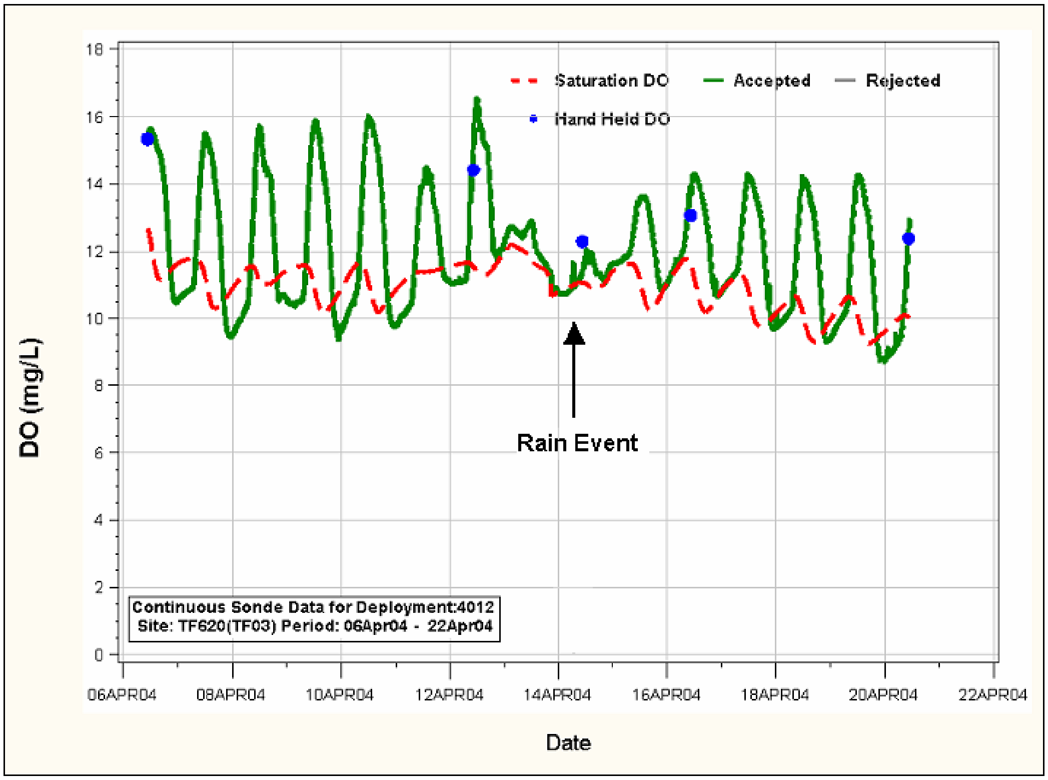

Figure 5-16 Continuous Plot of Water column Dissolved Oxygen Concentration at site TF620, April 2004.

Chlorophyll-*a* concentrations were consistently significantly greater at TF680 than at TF280 with mean concentrations ranging from 29.8 (±3.79) to 88.5 (±11.0) mg/m^2 at TF280, and from 108.5 (±14.8) to 127.9 (±12.8) mg/m^2 at TF680 (Figure 5-16). Mean chl-*a* at the TF680 site on 8 September 2004 was significantly lower (49.8 ± 6.5 mg/m^2) than on other sampling dates. This is possibly due to seasonal changeover in benthic algal community structure (summer die-off).

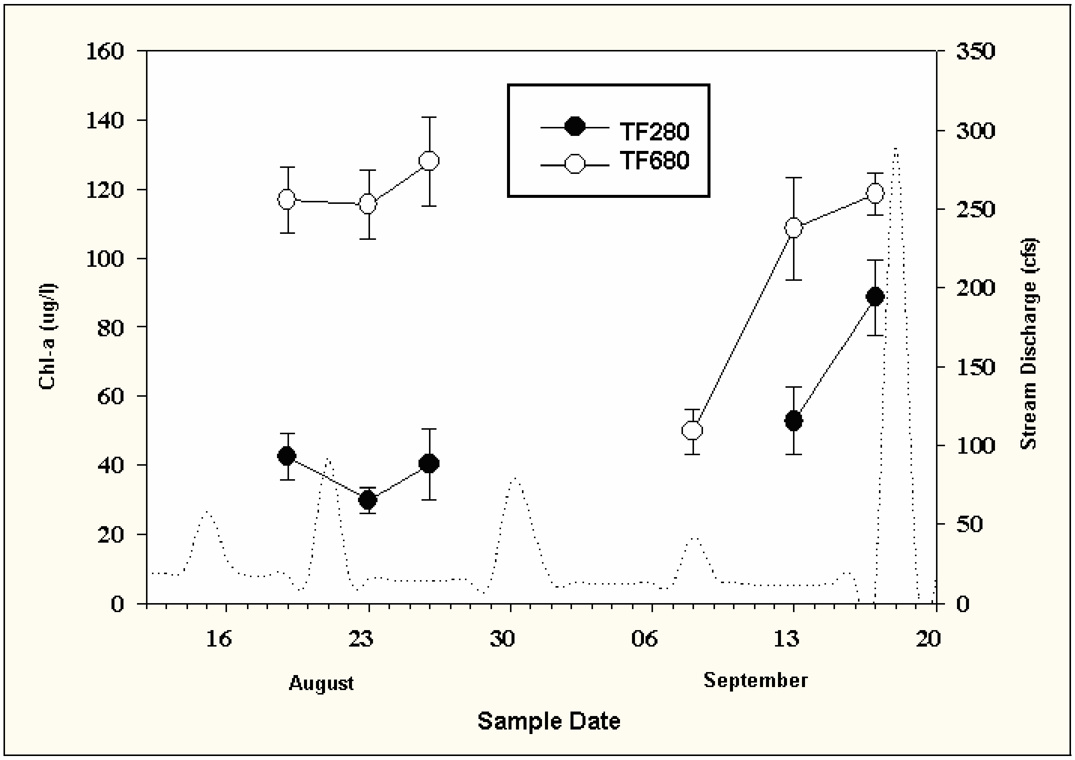

Figure 5-17 Chlorophyll-*a* Density on Natural and Artificially Scoured Substrates at sites TF 280 and TF620, September 2004

Algal accrual rates during the first 5 days following an artificial scouring experiment were similar to accrual rates on non-scoured rocks for each site (Figure 5-18). The average daily accrual rate for TF280 and TF620 was 8.36 ±1.30 mg/m^2 and 16.7 ± 4.34 mg/m^2, respectively. The accrual rate at TF03 of non-scoured rocks was 11.7 mg/m^2. During days 5-9 of the experiment, both sites lost biomass with an average daily loss rate of 1.73 (± 0.99) mg/m^2 at TF01 and 4.56 (± 1.31) mg/m^2 at TF620. The mean daily accrual rate of non-scoured rocks at TF01 during this time period was 8.96 mg/m^2 and 2.48 mg/m^2 at TF620.

Grazing, nutrients, current velocity, and scouring disturbances are likely the most important in driving algal communities in Tookany/Tacony-Frankford watershed. Differences in algal community structure between the two sites are likely the result of differential nutrient conditions, grazing pressures, and disturbance regimes. Light may also play a factor in explaining site differences (Triska *et al*. 1983, Hill and Knight 1988, Everett 1998).

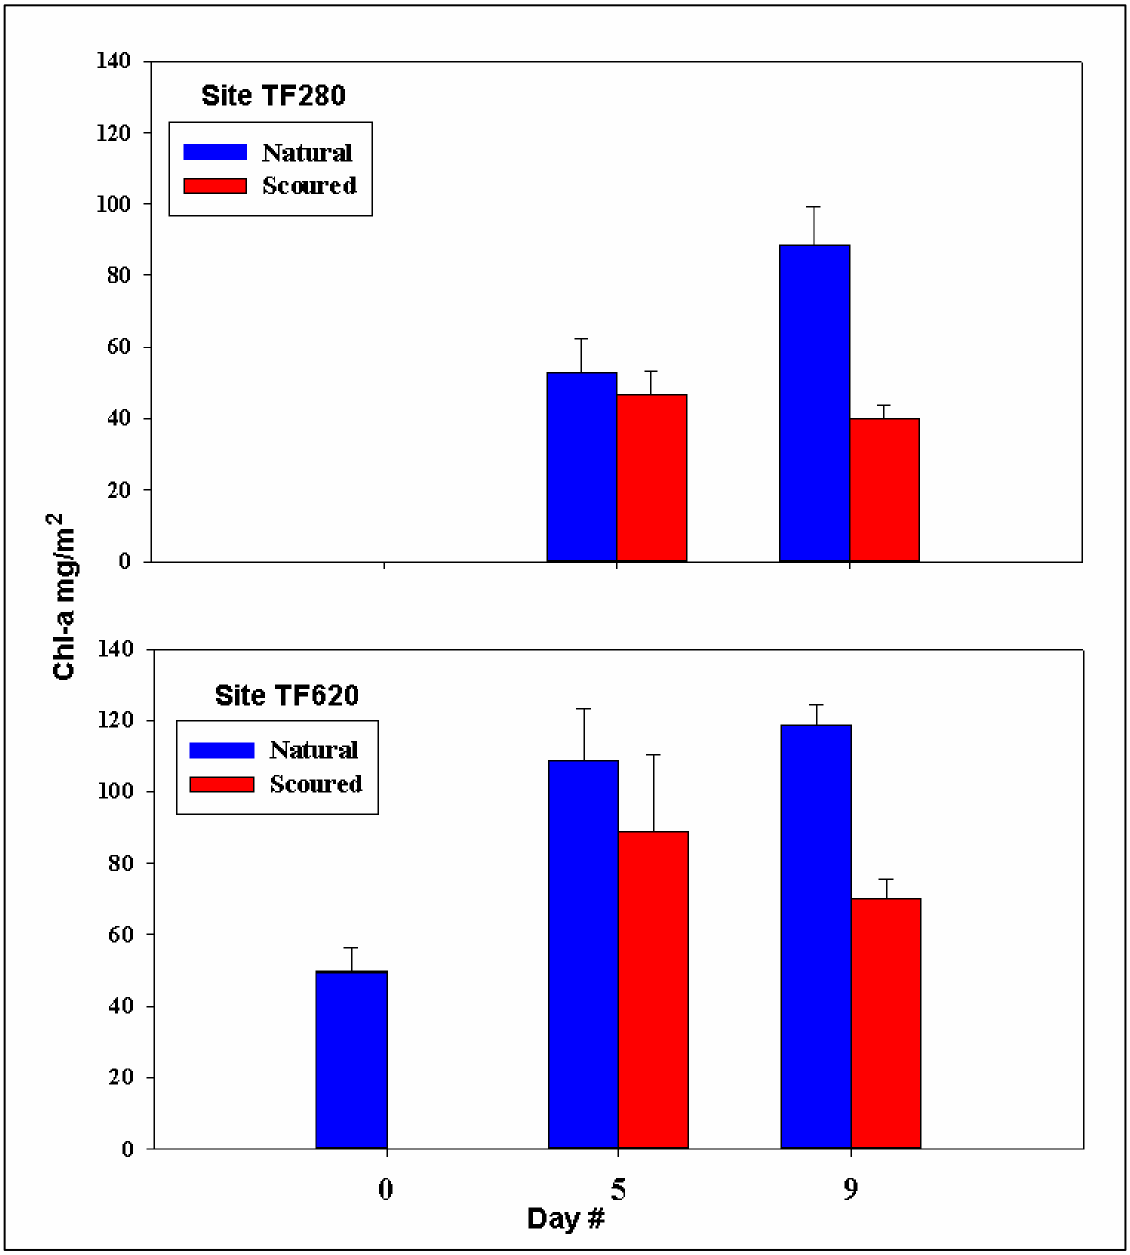

Figure 5-18 Chlorophyll-a Density on Natural and Artificially Scoured Substrates at sites TF280 and TF620, September 2004.

5.4.1 Relation of Algal Activity to Dissolved Oxygen Concentration

DO concentrations often strongly reflect autotrophic community metabolism and in turn, affect the heterotrophic community structure as a limiting factor for numerous organisms. Stream sites that support abundant algal growth often exhibit dramatic diurnal fluctuations in dissolved oxygen concentration. Algal photosynthesis infuses oxygen during the day (often to the point of supersaturation), while algae and heterotrophic organisms remove oxygen throughout the night. Diurnal fluctuations are more pronounced in the summer months than the autumn and winter months as colder water has a greater capacity for DO and biological metabolic activity is generally regulated by temperature.

Mainstem sites on Tookany/Tacony-Frankford Creek experience pronounced diurnal fluctuations in dissolved oxygen (DO) concentrations. When biological activity is high, DO concentrations may fall below the state-regulated limit of 4.0 mg/L. Violation of these standards is generally limited to the stretch of river within 6 miles of the confluence with the Delaware River and common within the lower three miles of the confluence (*i.e.*, downstream of site TF500). Dry weather dissolved oxygen suppression tends to occur at night and is likely caused by respiration of algae and microbial decomposition of algae and other organic constituents in the absence of additional photosynthetic oxygen production.

Following storm events, amplitude of daily DO fluctuations was reduced. DO concentrations may decrease sharply upon increase in stage, but it was difficult to determine how much of these instantaneous decreases were due to DO probe membrane fouling (Figure 5-19). It was hypothesized that anoxic effluent from storm sewers contributes to a sudden reduction in water column DO, but modeling of CSO discharge DO concentrations indicated that the discharge alone could not account for the observed DO reductions. BOD and SOD may have increased due to organic matter present in sewage. Mean BOD_5 was substantially higher at TF280 than at TF620 (Figure 5-2), although numerous samples were below reporting limits. Additionally, the scouring effect of high flows reduces algal biomass, and the oxygen produced through photosynthesis and consumed through respiration is reduced. As algal biomass accrues following scouring events, peak DO concentrations and range of diurnal fluctuations return to pre-flow conditions (Figure 5-20).

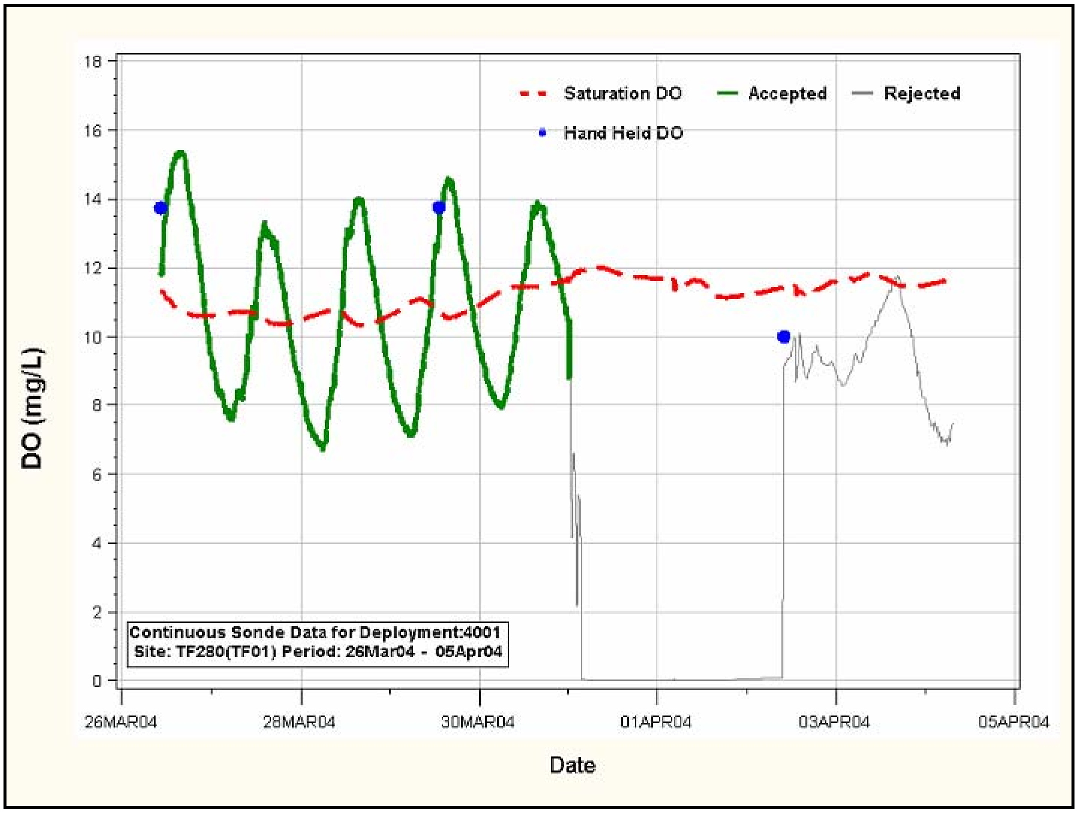

Figure 5-19 Continuous plot of Dissolved Oxygen Concentration at site TF280 Showing DO Probe Failure.

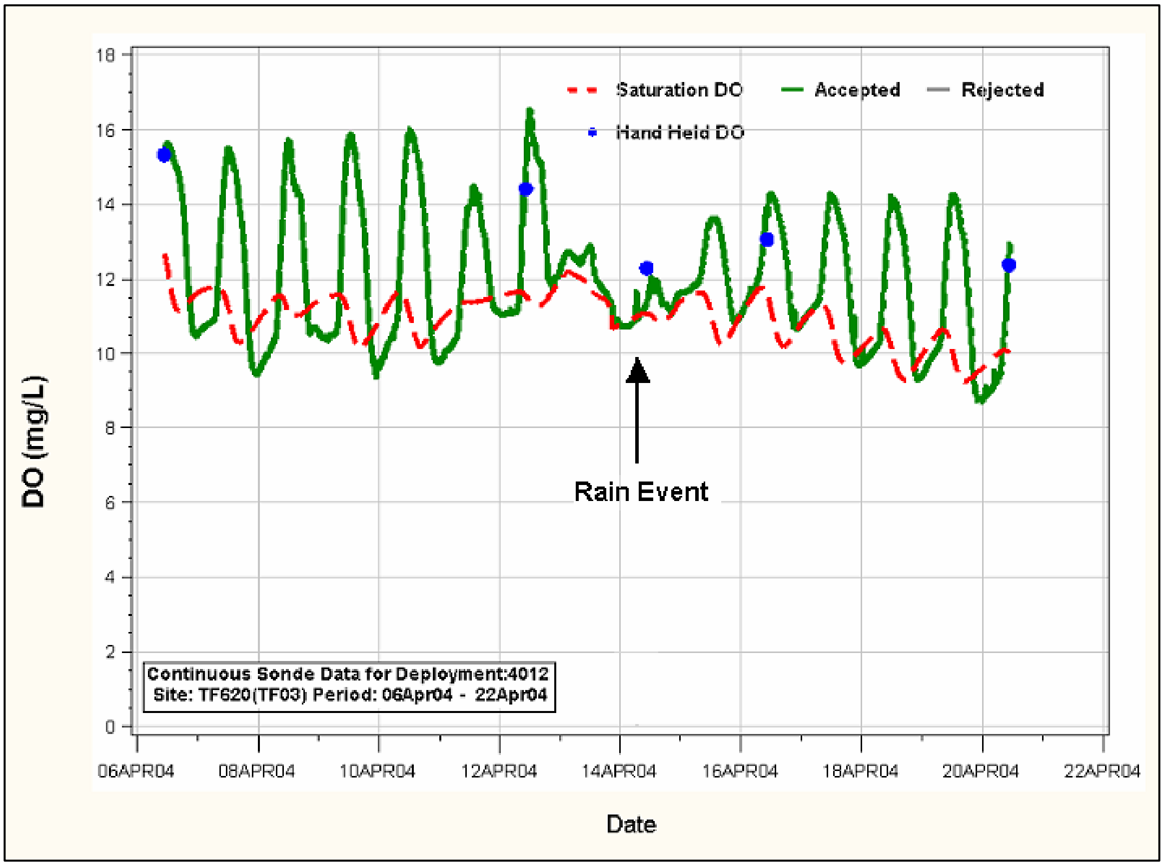

Figure 5-20 Continuous plot of Dissolved Oxygen Concentration at site TF280 returning to pre-flow conditions

Algal biomass at site TF280 was lower than at site TF620 further upstream. However, TF620 exhibits a higher mean DO and less pronounced diurnal fluctuations suggesting that the relationship between biomass and primary production is not straightforward. It is hypothesized that in dry weather the algae in combination with the residual effects of anoxic effluent, BOD and SOD accounts for the greater fluctuations in DO at site TF280. Further confounding the interpretation of this data is the fact that the sonde at site TF280 is located within a stagnant pool, the only location offering enough depth to allow the instrument to remain submerged at baseflow. Conversely, sonde locations at site TF620/680 are exposed to more streamflow, which replenishes the water surrounding the DO probe more frequently and helps keep the DO membrane itself from accumulating algae and debris. Microclimate conditions surrounding the DO probe membrane probably partially explain the difference in DO fluctuations observed between these two sites.

5.4.2 Relation of Algal Activity to stream pH

Fluctuations in pH can occur in freshwater systems as a result of natural and anthropogenic influences. Interplay between inorganic carbon species, known as the bicarbonate buffer system, generally maintains pH within a range suitable for aquatic life.

The bicarbonate buffer system describes the equilibrium relationship between carbon dioxide (CO_2) and carbonic acid (H_2CO_3), as well as bicarbonate (HCO_3^-) and carbonate (CO_3^{2-}) ions. In natural waters, the predominant source of hydrogen ions is carbonic acid. Biochemical metabolism of carbon throughout the day continually shifts the equilibrium equation, causing fluctuations in pH. As plants and algae consume carbon dioxide during photosynthesis, carbonic acid dissociates to replenish the CO_2 and maintain equilibrium. Decreasing carbonic acid concentrations cause elevated pH. As photosynthetic rates decline after peak sunlight hours, respiratory activities of aquatic biota replenish carbon dioxide to the system, decreasing pH. pH in Tookany/Tacony-Frankford Watershed is chiefly determined by this metabolic activity; the watershed is not heavily influenced by bedrock composition, groundwater sources or anthropogenic inputs, such as acid mine drainage.

Comparison of diurnal fluctuations of pH at sites TF280 and TF680 found that TF680 has greater variability between daytime and nighttime pH. This finding is attributed to the greater benthic algae biomass found at this site. pH affects aquatic biota directly, and also influences ionization of NH_3 and solubility/bioavailability of toxic metals. Severe fluctuations in pH driven by algal activity thus have the potential to exacerbate toxic conditions or even create toxic conditions where none previously existed.

5.4.2.1 Nutrient Limitation Effects on Primary Production

Nutrients are arguably the most important factor dictating algal standing crop, primary production, and community composition with examination of the nutrient-algae relationship requiring both an autecological and community-level approach (Borchardt 1996).

Nutrients can be a limiting factor to algal growth. In any given scenario, only one nutrient can limit algal growth for a given species at a time, although, at the community level, this rule does not apply where different species might be limited by different nutrients. Growth rates are not affected by nutrient concentrations alone. Light and temperature can affect nutrient uptake rates (*e.g.,*Falkner *et al*. 1980, Wynne and Rhee 1988), and more nutrients are often needed when light and temperature conditions are less than ideal (Goldman 1979, Rhee and Gotham 1981a,b, Wynne and Rhee 1986, van Donk and Kilham 1990). Additionally, nutrient uptake rates can vary depending on nutrient conditions. In steady-state growth conditions, the rate of nutrient uptake is equivalent to the rate at which nutrients are used in growth. However, cells may take up fewer or greater amounts of nutrients (for example, during nutrient pulses) and alter the nutrient ratios within the cell (Borchardt 1996).

The relationship between nutrients and algal biomass is complicated by numerous factors and findings are not consistent across ecoregions and water body types. Typically, nutrient enrichment stimulates periphyton growth in lotic systems and many studies have shown strong relationships between nutrient concentrations and algal biomass (*e.g.,* Jones *et al*. 1984, Welch *et al*. 1988, Kjeldsen 1994, Chetelat *et al*. 1999, Francouer 2001). However, other studies have shown no relationship between biomass and nutrient concentration (Biggs and Close 1989, Lohman *et al*. 1992). Periphyton standing crop can be highly variable (Morin and Cattaneo 1992) and other factors (described in subsequent sections) may override nutrient effects.

Of the necessary components for algal growth, nitrogen and phosphorus are likely to be growth-limiting in aquatic systems (Wetzel 2001) although carbon (Fairchild *et al.* 1989, Fairchild and Sherman 1993), trace metals (Winterbourn 1990), organic phosphorus (Pringle 1987) and silicates (Duncan and Blinn 1989) have also been implicated in limiting algal growth. Based on periphyton-nutrient studies, phosphorus is typically the limiting nutrient in the northern US (see Borchardt 1996 for review) while nitrogen has been shown to be limiting in the southwest (Grimm and Fisher 1986, Hill and Knight 1988a, Peterson and Grimm 1992) and Ozark (Lohman *et al.* 1991) regions.

In an effort to develop a practical system of stream classification based on nutrient concentrations similar to those used for lakes, Dodds *et al.* (1998) examined the relationship between chl-*a* (mean and maximum benthic chl-*a* and sestonic chl-*a*) and total nitrogen (TN) and total phosphorus (TP) in a large, global dataset. They defined the oligotrophic-mesotrohpic boundary by the lower third of the distribution of values with mean and maximum benthic chl-*a* concentrations of 20 mg/m^2 and 60 mg/m^2, respectively; and TN and TP concentrations of 700 µg/L and 25 µg/L, respectively. The mesotrophic-eutrophic boundary was represented by the upper third of the distribution of values with mean and maximum benthic chl-*a* concentrations of 70 mg/m^2 and 200 mg/m^2, respectively; and TN and TP concentrations of 1500 µg/L and 75 µg/L, respectively. Other recent studies examining specific chl-*a*-nutrient relationships include Dodds *et al.* (1997), Biggs (2000), Francouer (2001), Dodds *et al*. (2002a, b), Kemp and Dodds (2002).

N:P Ratio

Although nitrogen and phosphorus are the nutrients commonly limiting algal growth, the concentrations required to limit growth are less clear. Concentrations of phosphorus ranging 0.3-0.6 µg PO_4-P/L had been shown to maximize growth of benthic diatoms (Bothwell 1988) but higher concentrations have been needed in filamentous green algal communities (Rosemarin 1982), and even higher concentrations (25-50 µg PO_4-P/L) as algal mats develop (Horner *et al*. 1983, Bothwell 1989). Nitrogen has been shown to limit benthic algal growth at 55 µg NO_3-N/L (Grimm and Fisher 1986) and 100 µg NO_3-N/L (Lohman *et al.* 1991). In the past, the Redfield ratio (Redfield 1958) of cellular carbon, nitrogen, and phosphorus at 106:16:1 has been used to determine nutrient limitation. In benthic algae studies, ambient N:P ratios greater than 20:1 are considered phosphorus limited whereas those less than 10:1 are considered nitrogen limited. Nutrient limitation analysis was focused on steady state (*i.e.*, dry weather) conditions because these are the conditions under which limitation is most likely to affect periphyton communities.

Combining the above frameworks, most samples collected from sites in the Tookany/Tacony-Frankford Watershed in dry weather would be considered P-limited, mesotrophic with respect to TP, and eutrophic with respect to TN. A small number of samples would be considered not strongly limited by N or P and eutrophic with respect to both macronutrients. Sites TF500, TFJ110, and TF1120 were P-limited and never had TP concentrations exceeding the mesotrophic/eutrophic boundary of .075mg/L. TF620 was P-limited and not eutrophic for all but one sample which was considered co-limited and eutrophic. TF760 was always P-limited and did not have eutrophic concentrations of P in all but one sample. Two sites, TF280 and TFM006, were P-limited and had TP concentrations above the eutrophic boundary more often than not. The latter two sites also had other indicators of sewage (*e.g.*, fecal coliform bacteria) elevated in concentration in dry weather.

Sites TF280 and TF620 had similar mean TN values (2.59 ±0.49mg/L and 2.77± 0.45mg/L respectively), but mean dry weather TP concentration at site TF280 was significantly greater than at site TF620 ($F_{(47)}= 9.35$ $p=0.0002$). Given the greater TP concentration, one might expect greater algal biomass at site TF280. However, observed biomass was consistently smaller at site TF280 than at site TF620, which indicates that other parameters such as light, disturbance, grazing and scouring are controlling algal biomass.

5.4.2.2 Flow Effects on Stream Nutrient Concentrations

Stream nutrient concentrations in Tookany/Tacony-Frankford are dynamic. Macronutrients of greatest concern exhibited different responses to wet weather. NO_3 concentrations were relatively stable and adequate for abundant algal growth during dry weather and diluted in wet weather (mean NO_3 concentration 2.37mg/L ±0.65, and 1.49mg/L ±0.70, respectively). Conversely, other forms of N (*i.e.*, NH_3, NO_2, TKN) generally increased in concentration during wet weather, which is likely due to CSO and SSO discharge as well as presence of other organic constituents in stormwater runoff. Nitrate (NO_3) and ammonium ions NH_4^+ forms are generally bioavailable, but other forms are not available for algal growth. Total organic nitrogen concentration (TON; calculated as TKN minus NH_3) showed a significant positive correlation with fecal coliform concentration, suggesting that sewage is a primary source of organic loading to the watershed ($r_{(648)}=0.70$, $p<0.001$, Figure 5-15).

P concentration followed a pattern similar to NH_3 and TON, increasing in wet weather (Figure 5-13). This increase was likely due to CSO and SSO discharge, runoff, and soil erosion. Particle size mobilization and transport, traditionally related to flow by entrainment velocity curves (*i.e.* Shields curve), may determine the effective P loading for a given sediment load. Smaller particles, due to their greater relative surface area, can adsorb relatively more P than larger particles. Smaller particles are also generally more readily eroded and entrained in stormwater flow than larger particles.

Smaller storm events in Tookany/Tacony-Frankford thus probably contribute more to eutrophication than larger events. For example, if smaller sediment particles adsorb more P than larger particles as has been suggested, P loading becomes less efficient as larger particles are entrained in runoff. As shear stresses increase, streambank materials comprise a greater proportion of the sediment load. These particles are likely more similar to the soil parent material (*i.e.*, lower in P concentration) than more superficial soils layers that tend to incorporate more organic material. Furthermore, NH_3 showed a significant positive correlation with TSS ($r_{(380)}=0.46$, $p<0.001$), but the greatest concentrations of NH_3 were observed accompanying moderate TSS concentrations, suggesting that NH_3 concentration increases immediately due to sewage inputs but is diluted by stormwater in larger, more severe storm events (Figure 5-21).

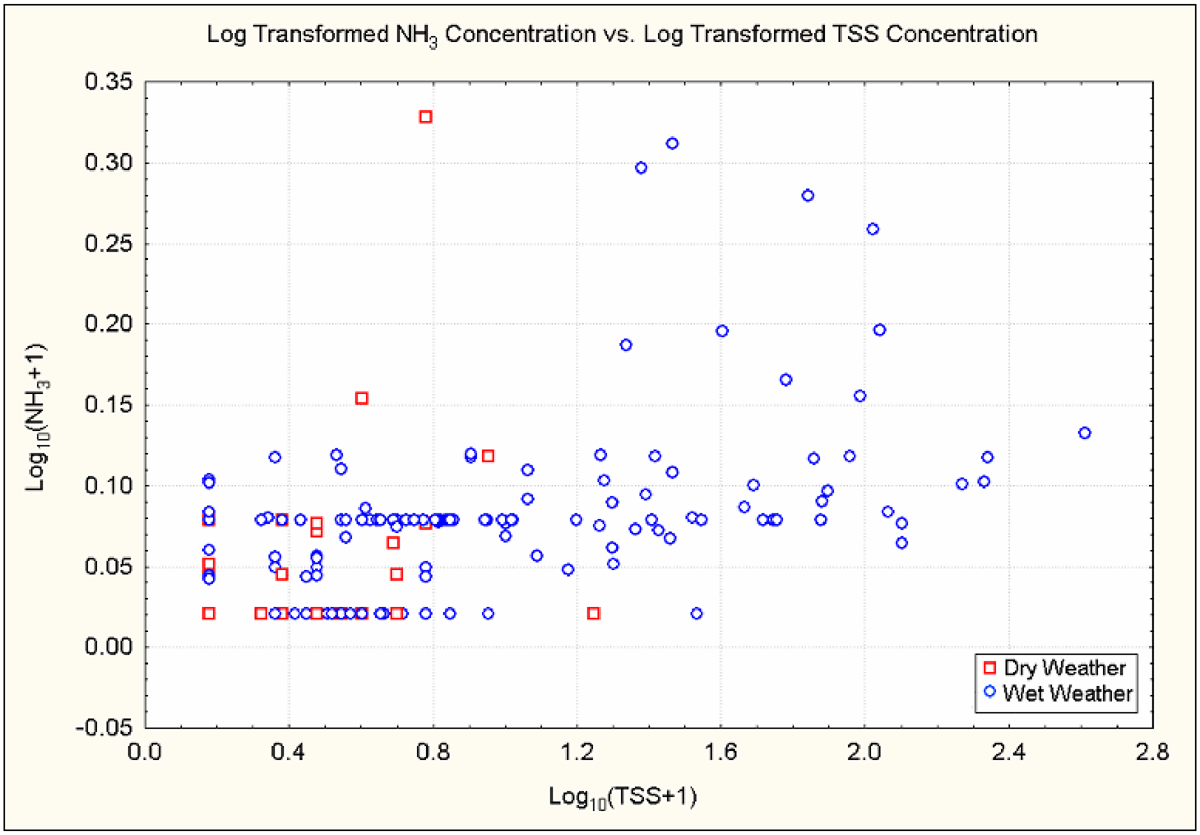

Figure 5-21 Scatterplot of log-transformed Ammonia and Total Suspended Solids Concentration of Samples Collected from 8 sites in Tookany/Tacony-Frankford Watershed, 2000-2004.

In addition to the decrease in relative bioavailability that accompanies high flows, physical stressors probably impose limits on the degree to which stream producers can take advantage of these increased concentrations. As flows increase, a greater proportion of the total nutrient load is transported out of the system, a greater proportion of the total load is inaccessible to producers, and much of the photosynthetic biomass (filamentous green algae and their associated epiphytes in particular) may be sloughed away and transported out of the system.

In areas served by combined sewers, the relative impact of small, intense storms is magnified. CSO discharge is minimally diluted by stormwater in the initial overflow phase, or "first flush". If nutrients present in these overflows can become deposited along with sediment or rapidly taken up by stream producers, discharges of short duration, particularly in which shear stresses do not result in major sloughing of algal communities, may have far-reaching consequences for stream nutrient dynamics and aquatic biota. A greater benefit may result from reducing frequency, number, and volume of small CSO discharges rather than attempting to capture releases from larger events.

Section 6
Biological Characterization

6.1 Historical and Existing Information

The Tookany/Tacony-Frankford Watershed was extensively developed as early as the 19th century. While under the control of the US Army Corps of Engineers from 1799 to 1940, the Tacony-Frankford creek channel was extensively modified, dammed, and channelized. Many businesses built mill races for hydropower and used the creek for waste disposal. With the exception of 302 acres acquired by Fairmount Park in 1915 and 1939, the remainder of the Philadelphia portion of the watershed was nearly built out in a construction boom that followed WWII. Major tributaries, including Little Tacony Creek, Wingohocking Creek, and Rock Run were buried in storm sewers both to protect people from what had essentially become open sewers, and to enable development consistent with the city's grid system. Likewise, suburban development consumed much of the Montgomery County portion of the watershed by the 1970s. Philadelphia Water Department Historian Adam Levine has amassed a collection of photographs, maps, and newspaper clippings documenting changes in Tookany/Tacony-Frankford Watershed brought about by urbanization. (More information is available on the internet at http://www.Phillyh2o.org/).

There is scant historical information about aquatic life in Tookany/Tacony-Frankford Watershed. In a 1998 report submitted to the Fairmount Park Commission (FPC), researchers from the Philadelphia Academy of Natural Sciences (ANS) reviewed existing information, citing macroinvertebrate surveys of Tookany and Baeder Creeks in Montgomery County by the Pennsylvania Department of Environmental Protection (PA DEP) in 1973, 1974, 1981, and 1998 (Fairmount Park Commission, 1999). According to ANS, most of these investigations were related to permits or spill responses, so results are probably not reflective of water quality throughout the basin.

A team of researchers from ANS conducted macroinvertebrate sampling at one site and collected fish at another site within Tacony Creek Park in 1998, documenting 8 benthic macroinvertebrate taxa and 9 species of fish. In 1999, PA DEP collected macroinvertebrates and surveyed habitats as part of the Unassessed Waters program, listing Tookany/Tacony-Frankford Watershed as impaired due to habitat alterations, flow variability and flow alterations (PA DEP, 2004 Integrated List of Waters). Philadelphia Water Department conducted a preliminary bioassessment of the watershed in 2000-2001, collecting macroinvertebrates and fish from 7 and 4 sites, respectively (Butler, *et al.* 2001). Sites sampled and collection methods were similar to the present study, allowing rough comparisons to be made.

Results of all historical studies have been consistent and unambiguous; impairment was evident in both macroinvertebrate and fish communities, whether measured as taxa richness, ecosystem function, or various numeric criteria used to evaluate aquatic communities (*e.g.*, Hilsenhoff Biotic Index, EPT index, Fish MIwb, etc.). The present study, however, is the first to integrate extensive physical habitat and chemical information.

When assessing an urban stream system that has been impaired for a long time, particularly one that lies at the center of a region of widespread impairment, it may be difficult to determine whether observed effects are the result of antecedent or ongoing impairments. There have been numerous improvements in water quality over the past 30 years, but the stream generally remains impaired.

6.2 Preliminary Documentation on the Biological Assessment of the Tookany/Tacony-Frankford Watershed

Though Tookany/Tacony-Frankford Watershed fish and benthic macroinvertebrate data suggest that many taxa have been extirpated or nearly extirpated in the past century, historical information to support these findings is generally lacking. There are simply no data to indicate what the biological communities of Tookany/Tacony-Frankford Watershed looked like prior to changes wrought by man. While some measures of community structure (*e.g.*, diversity indices) may provide meaningful information alone, conclusions of most analyses and metrics are enhanced by, or require, comparison to an unimpaired reference site. These unimpaired reference sites are often difficult to identify in southeast Pennsylvania due to extensive development and agricultural land uses. The most robust application of the reference site approach is a pair of sites located upstream and downstream of a suspected source of impairment. The downstream site in this scenario can be assumed to have a rather constant source of colonists, or "drift" from the upstream site, and all life stages of fish and macroinvertebrates are prone to displacement from the upstream site to the downstream site.

As applied to Tookany/Tacony-Frankford Watershed, reference site-based biological indexing methods assume that all similar habitats within a given ecoregion will have similar communities (absent major stressors) and that recovery of biological communities, particularly benthic macroinvertebrate communities, will occur quickly once stressors are removed. However, in regions where impairments occur watershed-wide and most first order streams have been eliminated, one cannot assume that study sites have a constant upstream source of colonists. Therefore, the most likely means of colonization of Tookany/Tacony-Frankford Watershed by rare or extirpated macroinvertebrate taxa is by winged adults, and the most likely means of re-colonization by rare or extirpated fish taxa is by passive dispersal (*i.e.*, purposeful or incidental inter-basin transfer by man).

Factors affecting re-colonization by macroinvertebrate taxa include:

1.) Geographic factors (*e.g.*, number and relative size of undisturbed first order tributaries within the watershed, distance to sources of colonists, predominant land cover and topological features separating target sites from sources of colonists, prevailing winds and climatic factors, natural and anthropogenic barriers to passive and active dispersal),
2.) Life history strategies (*e.g.*, propensity of the taxon to actively disperse, behaviors that increase the likelihood of passive dispersal, seasonal timing of oviposition and propensity to disperse prior to oviposition, duration of life cycle stages that are more prone to passive dispersal),

3.) Population factors (*e.g.*, stability of local populations representing potential colonists), and
4.) Miscellaneous factors, such as natural and anthropogenic mechanisms of passive dispersal.

Tookany/Tacony-Frankford Watershed is at the center of a region of widespread impairment due to urbanization (Figure 6-1). Some areas of the watershed may have water quality suitable for re-establishment of sensitive EPT taxa, but these taxa are generally much more abundant west of the Schuylkill River than in the Philadelphia region. PWD supports reintroduction of macroinvertebrates combined with stream restoration and stormwater BMPs for these areas.

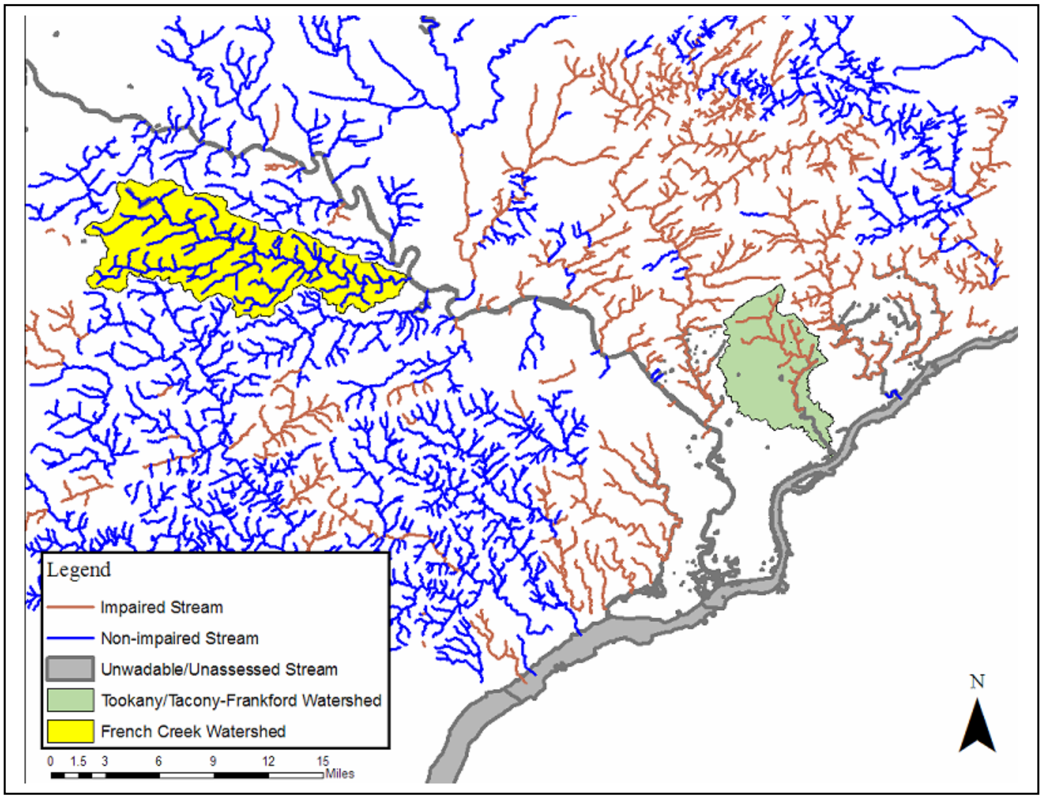

Figure 6-1 Southeastern PA stream segments in Tookany/Tacony-Frankford Watershed, French Creek watershed, and the surrounding region showing attainment status from PA DEP 2004 List of Waters (formerly 303d list).

The set of factors affecting recolonization by fish is simpler, as fish generally require water for all life stages and cannot disperse through the air. Poor water quality and physical impediments to upstream migration (*i.e.*, dams) probably prevent recolonization of non-tidal portions of Tookany/Tacony-Frankford Watershed via the Delaware River for most taxa, though American Eels are a noteworthy exception. The watershed is not actively stocked by the Pennsylvania Fish and Boat Commission (PAFBC), does not support game fish, and does not appear to be greatly affected by angling or similar activities that might result in releases of non-indigenous fish or aquatic life (*e.g.*, bait bucket release). Most of the common native fish species of southeast Pennsylvania are tolerant or moderately tolerant of water pollution.

Intolerant and non-game native fish species are unlikely to become established or re-established within the watershed other than by stocking, and PWD supports the efforts of ANS and FPC to reintroduce species such as tessellated darter and native minnows for which habitat in Tookany/Tacony-Frankford Watershed is appropriate. However, all restoration efforts should be well documented among watershed stakeholder communities so that progress can be tracked and results of subsequent ecological investigations are not jeopardized. Re-establishment of coastal plain wetlands and reintroduction of associated fish fauna (*e.g.*, Eastern mudminnow, sticklebacks, *Enneacanthus* spp.) is highly desirable, but probably not feasible in the watershed due to extensive development along the Delaware River.

Sites in Tookany/Tacony-Frankford Watershed were compared to reference sites on French Creek and Rock Run in Chester County, PA (Appendix F). Reference sites were chosen to represent a range of stream drainage areas, yet extensive impervious cover in portions of Tookany/Tacony-Frankford Watershed complicates these comparisons. Due to baseflow suppression, piping of tributaries, exaggerated storm flows and widespread erosion, sites in this urbanized watershed are difficult to categorize according to traditional frameworks (*e.g.*, stream order, link magnitude, drainage area, geomorphological attributes). These details are addressed in greater detail in Section 7.1 Habitat Assessment. Tookany/Tacony-Frankford Watershed is only linked to the tidal Delaware River and is considered a warmwater stream, while the reference sites have better connectivity and are classified as trout stocking fisheries or high quality trout stocking fisheries.

6.3 Fish

During the 2004 Tacony-Frankford Watershed fish assessment, PWD collected a total of 9774 individuals representing 17 species in 7 families (Table 6-1). Blacknose dace (*Rhinichthys atratulus)* and mummichog (*Fundulus heteroclitus),* two taxa extremely tolerant of poor stream conditions, were most abundant and comprised over half (56%) of all fish collected. Other common species included white sucker (*Catostomus commersoni*), satinfin shiner (*Cyprinella analostana*), banded killifish (*Fundulus diaphanus*), and swallowtail shiner (*Notropis procne*). Of 17 species collected in the watershed, four species comprised over 80% of the entire fish assemblage. Similarly, five species made up greater than 80% of the total fish biomass, with redbreast sunfish (*Lepomis auritus*) and American eel (*Anguilla rostrata*) contributing 42% of the biomass. American eel, blacknose dace, and satinfin shiner were found at all sites while bluegill sunfish (*Lepomis macrochirus*) and green sunfish (*L. cyanellus*) were each only found at one site and represented by a single individual. Two individual tessellated darters (*Etheostoma olmstedi*) were collected at two different sites (TF500, TF620) in the watershed; however, scientists from the Academy of Natural Sciences of Philadelphia likely stocked these fish as part of a reintroduction effort. The presence of only one tessellated darter at each site suggests that they have not become established and therefore were not included in the scoring criteria for the Index of Biotic Integrity. Overall, the non-tidal Tookany/Tacony-Frankford Watershed displayed the lowest fish diversity (*i.e.*, species richness) of all the watersheds in Philadelphia.

Table 6-1 Summary of Fish Species Collected at 7 Sites in Tookany/Tacony-Frankford Watershed, Summer 2004

Trophic composition evaluates quality of the energy base and foraging dynamics of a fish assemblage. This is a means to evaluate the shift towards more generalized foraging that typically occurs with increased degradation of the physicochemical habitat (Barbour, *et al.*, 1999). For example, the Tacony-Frankford fish assemblage was dominated by generalist feeders (69%) with insectivores composing 30% and top carnivores at less than 1% (Figure 6-2). Generalists become dominant and top carnivores become rare when certain components of the food base become less reliable (Halliwell *et al.*, 1999). Relative abundance of insectivores decreases with degradation in response to availability of the insect supply, which reflects alterations of water quality and instream habitat (Daniels, *et al.* 2002). The near absence of insectivores in the two upstream-most sites illustrates this point. Trophic composition was poor compared to reference sites. Though community composition varied between sites, the fish assemblage in Tookany/Tacony-Frankford Watershed was highly skewed towards a pollution tolerant, generalist feeding community.

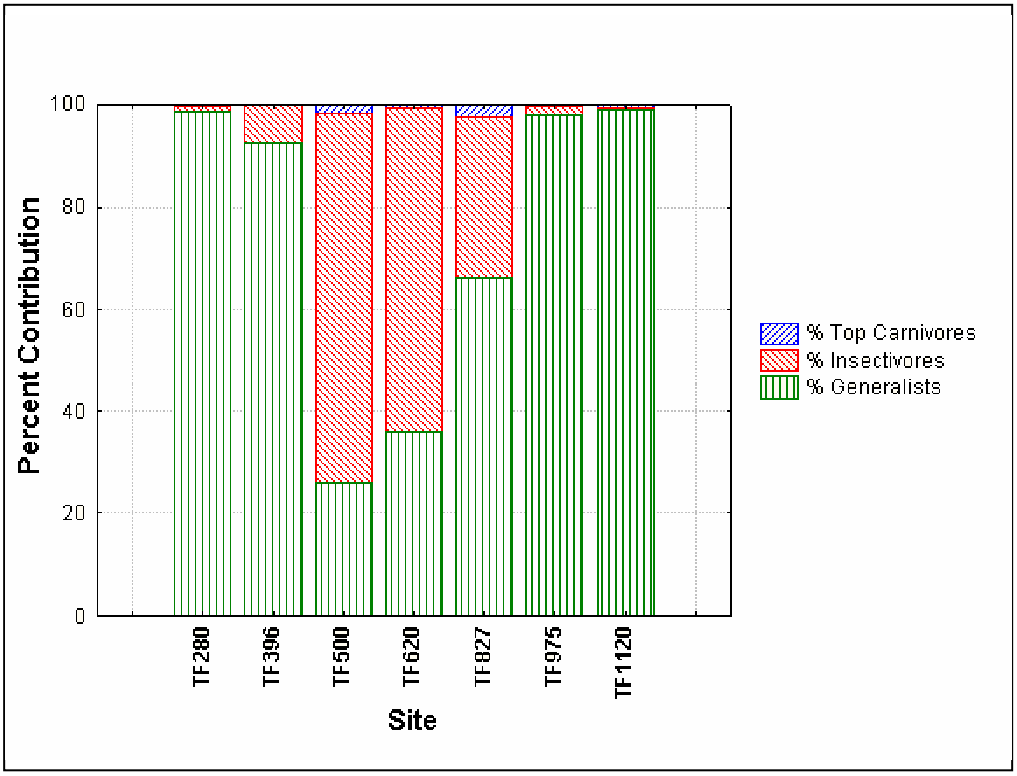

Figure 6-2 Fish Trophic Composition of the Tookany/Tacony-Frankford Watershed

Tolerance designations describe the susceptibility of a species to chemical and physical perturbations. Intolerant species are typically first to disappear following a disturbance (Barbour, *et al.*, 1999). For example, at least 70% of the fish collected at each monitoring station in Tookany/Tacony-Frankford Watershed were classified as "tolerant", and no "intolerant" species were collected (Figure 6-3). Moderately tolerant individuals were absent from the lowermost (TF280) and uppermost (TF1120) stations, and represented less than one percent (TF396) to 29% (TF500) of the assemblage at the remaining five sites. Furthermore, with approximately 91% of the fish assemblage composed of tolerant individuals, this watershed had the greatest percentage of fishes tolerant of poor stream conditions in all of Philadelphia's watersheds.

Figure 6-3 Fish Tolerance Composition of the Tookany/Tacony-Frankford Watershed

The Index of Biotic Integrity (IBI) is useful in determining long-term effects and coarse-scale habitat conditions because fish are relatively long-lived and mobile. A site with high integrity (*i.e.* high score) is associated with communities of native species that interact under natural ecosystem processes and functions (Karr, 1986). Since biological integrity is closely related to environmental quality, assessments of integrity can serve as a surrogate measurement of health (Daniels, *et al.* 2002). The mean IBI score for Tacony-Frankford Watershed was 21 (out of 50), placing it in the "poor" category for biotic integrity (Table 6-2). Low diversity, absence of benthic insectivorous species, absence of intolerant species, skewed trophic structure dominated by generalist feeders, high percentage of individuals with disease and anomalies, and high percentage of dominant species are characteristics of a fish community with "poor" biotic integrity. Spatial trends showed that only two sites received a "fair" IBI score, both centrally located within the watershed. Similar spatial trends were seen in Modified Index of Well-Being and Shannon Diversity Index values, which are measures of diversity and abundance. These indices were lowest in the lower and upper monitoring stations and highest in the middle of the watershed. This was to be expected because diversity is typically lower in upstream/smaller reaches of southeast Pennsylvania (Fairmount Park Commission 1999, W. Fairchild, personal communication). Overall, monitoring stations in the central portion of the watershed had higher biological integrity than downstream and upstream stations.

excluded from MIwb were brown bullhead, American eel, white sucker, satinfin shiner, spotfin shiner, green sunfish, bluegill sunfish, blacknose dace, banded killifish, mummichog, and common shiner.

Site TF324
A total of 813 individuals representing six species yielded a biomass of 5 kg during 77 minutes of electrofishing. This site had the lowest abundance (*i.e.* number of fish) and second lowest diversity in the watershed. Based on the site's estimated stream surface area of 1973 m^2, density and standing crop were estimated at 0.41 fish per m^2 and 2.5 grams per m^2 (g/m^2), respectively. This was the lowest density and second lowest standing crop in the watershed. Similarly, this site had the lowest catch per unit effort (CPUE) at 10.5 fish per minute of electrofishing (Table 6-2). Of the six species collected at site TF324, mummichog (*F. heteroclitus)*, a species extremely tolerant of high pollution levels and low dissolved oxygen, composed 98% of all fishes collected and 85% of the total biomass. There were neither intolerant or moderately tolerant taxa nor benthic insectivorous species collected at this location. Furthermore, the trophic structure of this assemblage was almost exclusively made up of generalist feeding taxa (98%).

Site TF324 received an Index of Biotic Integrity (IBI) score of 16 (out of 50), representing a "poor" quality fish assemblage and therefore, poor environmental health. To further support this characterization, the Modified Index of Well-Being (0.0) and Shannon Diversity Index (0.1) values, which are measures of diversity and abundance, were not only the worst in the watershed, but in all of Philadelphia's watersheds surveyed by PWD. These fish assemblage characteristics are symptomatic of a severely degraded stream system suffering from multiple chemical and physical stressors.

Site TF396
