In 1123 m^2 of stream surface area, a total of 1215 individuals representing nine species were collected during 62 minutes of electrofishing. This site had the smallest total biomass (1.2 kg) and standing crop (1.1 g/m^2) in the watershed, with a density of 1.1 fish/m^2 and catch per unit effort of 19.7 fish/minute (Table 6-2). Intolerant taxa, benthic insectivorous species, and white suckers (*C. commersoni*) were not collected. As observed at the previous site, mummichog (*F. heteroclitus)*, a species extremely tolerant of high pollution levels and low dissolved oxygen, accounted for 91% of all fishes collected and 78% of total biomass. Three of the nine species collected at this site were represented by a single individual. Pollution tolerant taxa accounted for greater than 99% of the fish assemblage and generalist feeders (93%) dominated the trophic structure. This highly unbalanced community structure of generalist feeding, tolerant taxa, dominated by a single species, exemplifies a stream with inadequate environmental quality.

The IBI score of 20 (out of 50) was typical of a fish assemblage with "poor" biotic integrity. Disease, tumors, fin damage, and other anomalies were prevalent at site TF396 (4.4% of fish affected). The Modified Index of Well-Being (2.71) and Shannon Diversity Index (0.44) values were second lowest in the watershed and corroborate the IBI designation. These values represent 22% and 18% comparability, respectively, to reference stream conditions. Principal causes of impairment are probably low dissolved oxygen concentration and habitat modification (instability promoted by urbanized hydrology).

Site TF500
TF500 contained the most diverse fish assemblage in the watershed with 1763 individuals representing 13 species. The single tessellated darter (*Etheostoma olmstedi*) specimen

collected at this site was assumed to have been recently stocked as part of a reintroduction program, and was thus excluded from calculations and metrics. The presence of only one individual tessellated darter suggests that the species has not, and may not, become established at this site and thus was not considered members of the fish assemblage. This site had the greatest number of water column species (n=6), which is directly comparable to reference conditions, however, there were no benthic insectivores or intolerant species. Satinfin shiner (*C. analostana*), swallowtail shiner (*N. procne*), and banded killifish (*F. diaphanus*), three pollution tolerant species, composed approximately 72% of all fishes collected (Table 6-1). Despite this, TF500 had the lowest percentage of tolerant individuals and the greatest percentage of moderately tolerant individuals (Table 6-2). TF500 had the most relatively balanced trophic structure in the watershed with 72% insectivores, 26% generalists, and almost 2% top carnivores; representing the greatest percentage of the fish assemblage as insectivores and smallest percentage of generalists. This was one of only two sites in which the percentage of insectivores was greater than the percentage of generalist feeders. This shift toward specialized feeding typically occurs in response to a stabilizing insect supply, which reflects possible improvements of water quality and instream habitat. However, benthic macroinvertebrate survey results were poor.

In addition to positive scores for abundance, diversity, and trophic structure indices, TF500 had the second lowest percentage of individuals with disease, tumors, fin damage, or other anomalies. As a result, this site received the highest IBI score in the watershed (34 out of 50), characteristic of a fish assemblage with "fair" biotic integrity. This was one of only two sites that obtained a "fair" IBI score, with the rest of the watershed scoring poor for biotic integrity. Similarly, the Modified Index of Well-Being (10.22) and Shannon Diversity Index (1.29) values were the second and third highest values, respectively, in the watershed and further support the IBI classification.

Site TF620

A total of 2050 fishes representing 12 species were collected in 1208 m^2 of stream surface area in 68 minutes of electrofishing. This site had the greatest total biomass (16 kg) and standing crop (13.2 g/m^2), as well as the second greatest number of individuals (n=2050), density (1.7 fish/m^2), and catch per unit effort (30.2 fish/minute) in the watershed (Table 6-2). These relatively high abundance and diversity values, indicative of the quality of the fish assemblage, produced the best Modified Index of Well-Being (10.58) and second-best Shannon Diversity Index (1.41) values in the watershed. This was the only site in the watershed where a green sunfish (*Lepomis cyanellus*) was collected. Though diverse and abundant, the fish assemblage at TF620 lacked pollution sensitive taxa and benthic insectivorous species. Also, of the 12 species collected, three pollution-tolerant species composed 75% of all individuals collected and four species contributed 79% of the biomass. This unbalanced assemblage is symptomatic of degraded stream conditions.

Trophic composition also displayed unbalanced characteristics with less than 1% top carnivores, 36% generalist feeders, and 63% percent insectivores. Furthermore, approximately 4.5% of all fishes had some type of disease, tumors, fin damage, or other anomalies. Regardless of this unevenness and prevalence of anomalies, TF620 was one of only two sites with more insectivores than generalists and at least 25% moderately tolerant individuals, which helped elevate the IBI score. With positive scores for abundance, diversity, and trophic structure, this monitoring location received the second highest IBI score (30 out of 50) in the watershed and was considered to have a "fair" quality fish assemblage.

Site TF827

As the first monitoring station upstream of the Philadelphia county line, TF827 marks a transition in the trophic structure from an insectivore-dominated community, to generalist feeders (66%), with insectivore abundance decreasing relative to generalist feeders (Table 6-2). Likewise, pollution tolerant individuals increased in abundance (88%) while moderately tolerant (12%) individuals decreased. Of 9 species collected at this site, blacknose dace, satinfin shiner, and white sucker composed approximately 84% of the assemblage. This was the only location where a hybrid sunfish (*L. cyanellus* x *L. gibbosus*) was identified. Redbreast sunfish (*Lepomis auritus*), American eel (*Anguilla rostrata*), and white sucker made up over 75% of total fish biomass (~10 kg) (Table 6-1). This site had the second smallest abundance (n=858), density (0.65 fish/m^2), and catch per unit effort (17 fish per minute) in the watershed.

The Modified Index of Well-Being (9.37) was above average and the Shannon Diversity Index (1.45) was best in Tookany/Tacony-Frankford Watershed. Since 9 species were collected at a site with low abundance, the Shannon Diversity Index is high. However, with over 5% of the fish assemblage affected by disease, tumors, fin damage, or other anomalies; numerous white suckers; and absence of intolerant species and benthic insectivores, this site received a "poor" IBI score of 22 out of 50. Habitat modification, particularly effects of infrastructure, may be responsible for observed poor qualities of the fish assemblage at this site.

Site TF975

This site contained the greatest number of fish (n=2095), density (1.8 fish/m^2), and catch per unit effort (34 fish /minute) in Tookany/Tacony-Frankford Watershed (Table 6-2). However, greater than 95% of all fish collected were blacknose dace (79%) and white sucker (16%), species highly tolerant of poor water quality and degraded habitat. These two species also accounted for 79% of fish biomass (11 kg) collected at site TF975. Of 10 species collected, there were no intolerant species, no benthic insectivores, three water column species, and five cyprinid species. This was the only site where a bluegill sunfish (*L. macrochirus*) was collected. Trophic structure of the fish assemblage at this site was dominated by generalist feeders (98%), with very few insectivores and top carnivores. Likewise, pollution tolerant taxa made up 98% of the fish assemblage.

The large percentage of white sucker (16%) may be indicative of degradation as this species typically shows increased distribution or abundance despite historical disturbances and they shift from incidental to dominant in disturbed sites (Barbour, *et al.*, 1999). This site had the second highest percentage (8.8%) of fishes with disease, tumors, fin damage, or other anomalies, which is symptomatic of an impacted assemblage downstream of point source pollution or in areas where toxic chemicals are concentrated (Barbour, *et al.*, 1999). Taking into account the aforementioned problems, TF975 received an IBI score of 14 (out of 50), placing it into the "poor" classification for biotic integrity. The IBI score for this site was tied for worst in the watershed. Modified Index of Well-Being (6.75) and Shannon

Diversity Index (0.70) values were low and represented 55% and 28% comparability, respectively, to reference conditions.

Site TF1120
The fish assemblage at TF1120 contained only five species, least for this watershed and all of Philadelphia's watersheds surveyed by PWD using RBPV protocols. Blacknose dace constituted 86% of all fish collected at this location and one species (*C. analostana*) was represented by a single individual (Table 6-1). This site was devoid of intolerant taxa and benthic insectivorous species, and only contained one water column species. With 99% generalist feeders, this was the most highly skewed trophic structure in all of Philadelphia's watersheds surveyed by PWD. This site contained only pollution tolerant species and had the highest percentage (9%) of individuals with disease, tumors, fin damage, or other anomalies in this watershed. These are excellent measures of the subacute effects of chemical pollution and aesthetic value of nongame fishes (Barbour, *et al.*, 1999). The Modified Index of Well-Being (0.0) and poor IBI score (14 out of 50) were tied for worst in Tookany/Tacony-Frankford Watershed (with TF324) and in all of Philadelphia's watersheds monitored by PWD. Low species richness and trophic composition metrics combined with poor abundance and condition metrics reflect severely degraded stream quality.

6.4 Benthic Macroinvertebrates

A total of 2,137 individuals from 19 taxa were identified during the 2004 benthic macroinvertebrate survey of Tookany/Tacony-Frankford Watershed (Table 6-3). The average taxa richness of the watershed was 7 (Figure 6-4). Overall, moderately tolerant (91%) and generalist feeding taxa (96%) dominated the watershed. The average Hilsenhoff Biotic Index (HBI) of all assessment sites was 6.16. Pollution sensitive Ephemeroptera, Plecoptera, and Trichoptera (EPT) taxa were absent throughout the watershed (Table 6-4). One site had one modified EPT taxon present. Modified EPT taxa are EPT taxa with Hilsenhoff Biotic Index score less than or equal to four. Seven of 12 sites included in the present study were sampled by PWD in November 2000 using the same protocols, allowing some rough comparisons to be made. Most sites had reduced taxa richness and metric scores compared to year 2000 samples.

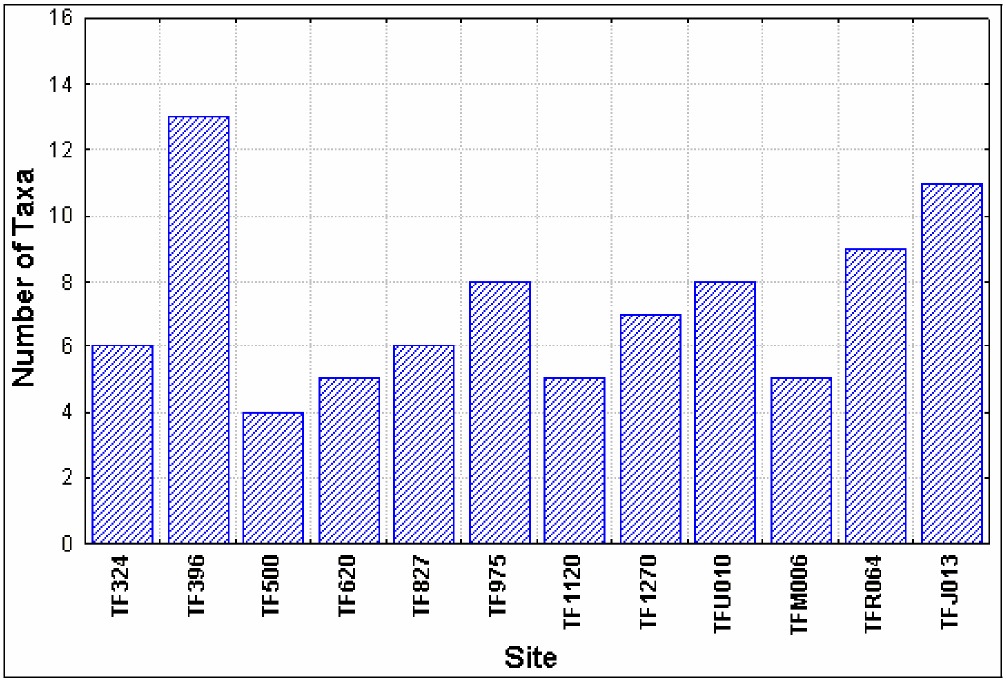

Figure 6-4 Benthic Macroinvertebrate Taxa Richness at 12 sites in Tookany/Tacony-Frankford Watershed, Spring 2004

Chironomidae (midges) dominated the benthic macroinvertebrate communities within the watershed (percent contribution ranged from 63% to 97%). Net-spinning caddisflies (Hydropsychidae), isopods, amphipods, tipulids, gastropods, and oligochaetes were also present throughout the watershed but in very low abundance (Table 6-3). Benthic macroinvertebrate communities of Tookany/Tacony-Frankford Watershed are thoroughly dominated by midges, suggesting stressors are affecting survival of more sensitive taxa.

Table 6-4 Summary of Benthic Macroinvertebrate Metric Scores from 12 sites in Tookany/Tacony-Frankford Watershed and Reference Sites in French Creek Watershed, Spring 2004

Site	Taxa Richness	Modified EPT Taxa	Hilsenhoff Biotic Index (modified)	Percent Dominant Taxon	Percent Modified Mayflies	Biological Quality (%)	Biological Assessment	Habitat Quality (%)	Habitat Assessment
TF324	6	0	8.92	72.15 (Tubificidae)	0.00	0.00	Severely Impaired	31.84	Non-Supporting

FC1310	21	9	3.69	21.60 (*Hydropsyche*)	13.59				

Feeding measures describe functional feeding groups and provide information on the balance of feeding strategies in the benthic macroinvertebrate community (Barbour *et al.* 1999). The trophic composition of the watershed was skewed toward generalist feeding gatherer collectors (greater than 90%) (Figure 6-5). Particularly notable was the general lack of moderately tolerant filterer collector taxa (*e.g.*, Hydropsychidae, Simuliidae) which are often abundant in organically enriched streams. These taxa were generally present in moderate numbers at all sites studied in 2000, so their reduced abundance is disturbing. This may reflect severe water quality and habitat degradation or perhaps a lack of fine particulate organic matter (FPOM). Food source limitation may also impair survivability of other specialized feeders, such as cranefly larvae that rely on accumulated leaf material. Other shredders, and sensitive taxa in general, were not encountered. Specialized taxa are generally more sensitive to perturbation than generalist feeders.

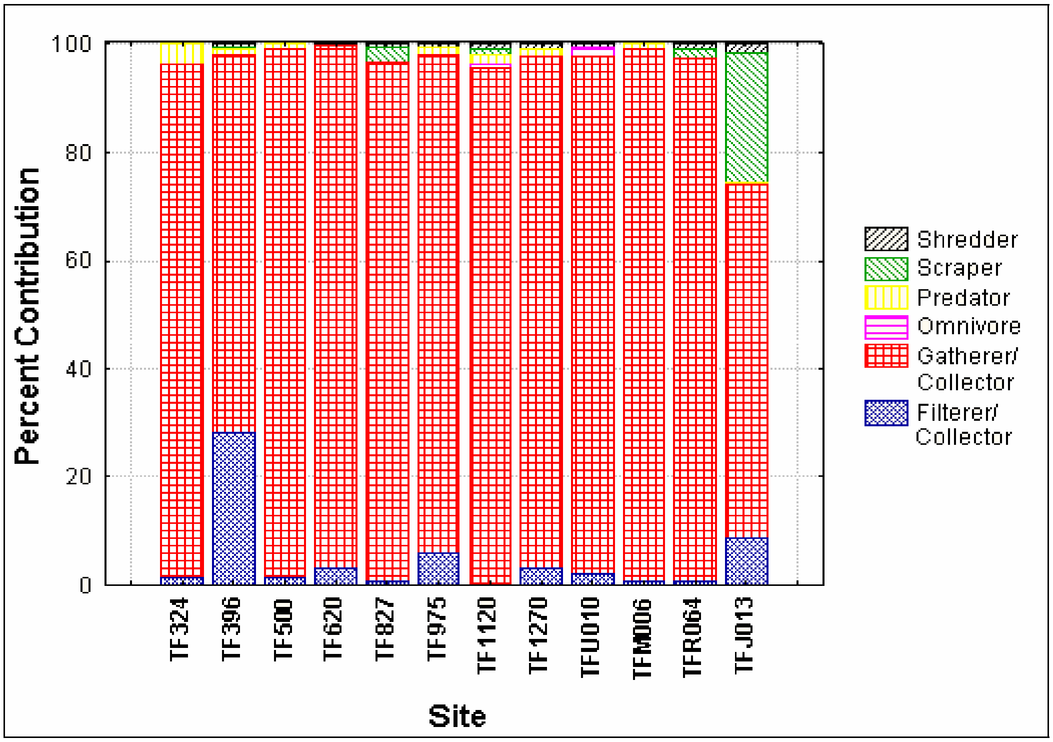

Figure 6-5 Benthic Macroinvertebrate Community Trophic Composition at 12 sites in Tookany/Tacony-Frankford Watershed, Spring 2004

Tolerance/intolerance measures are intended to be representative of relative sensitivity to perturbation and may include numbers of pollution tolerant and intolerant taxa or percent composition (Barbour *et al.* 1999). Moderately tolerant individuals (91%) dominated macroinvertebrates communities of Tookany/Tacony-Frankford Watershed. Sensitive taxa were poorly represented (2%), suggesting watershed-wide perturbation (Figure 6-6).

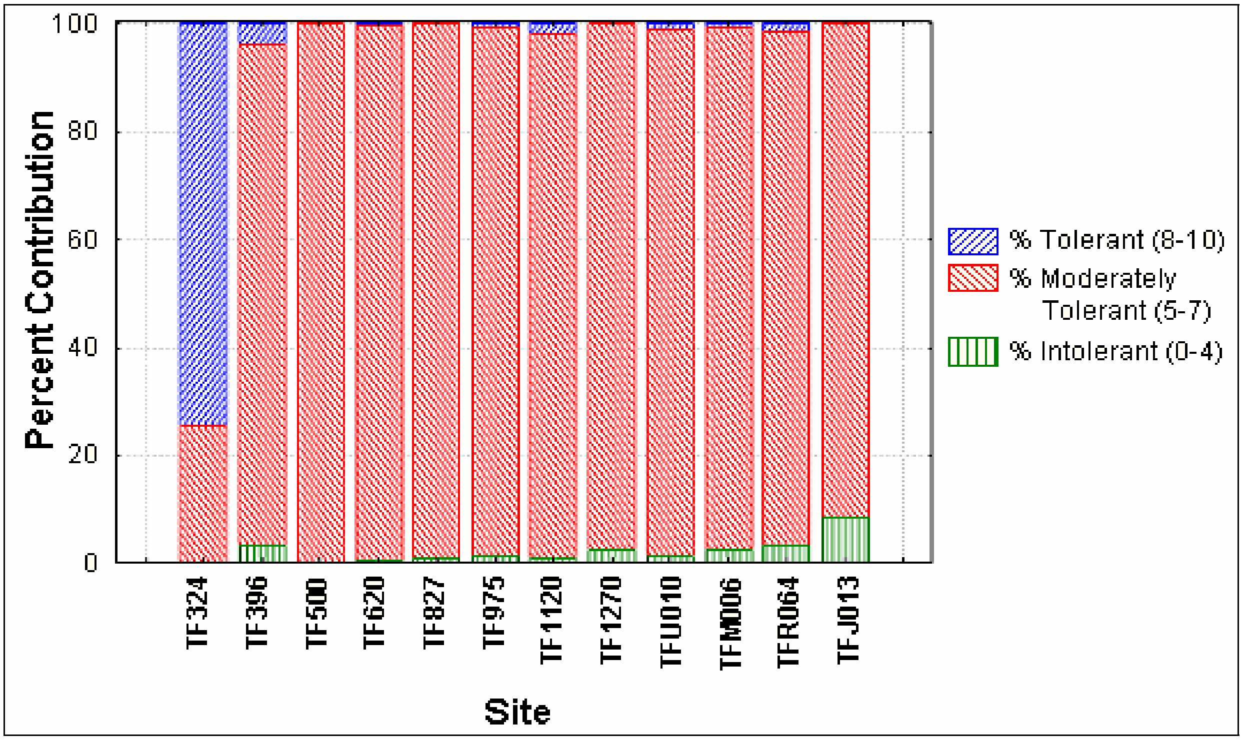

Figure 6-6 Tolerance Designations of Benthic Macroinvertebrate Communities at 12 sites in Tookany/Tacony-Frankford Watershed

The Hilsenhoff Biotic Index (HBI) is a metric used to determine the overall pollution tolerance of a site's benthic macroinvertebrate community. The HBI is oriented toward the detection of organic pollution. The HBI can range from zero (very sensitive) to ten (very tolerant). Differences in HBI score between reference and assessment sites greater than 0.71 indicate impairment. Mean HBI score of sites within Tookany/Tacony-Frankford Watershed was 6.16 (Figure 6-7). Dominance by moderately tolerant individuals and general lack of pollution-sensitive taxa contributed to the elevated HBI. In comparison, mean reference site HBI score was 4.08. When compared to reference conditions, Tookany/Tacony-Frankford Watershed mean HBI exceeded reference site mean HBI by 2.08, indicating severe impairment overall.

While HBI is very effective in determining whether a site is impaired relative to a reference site, HBI scores are not very useful in comparing impaired urban sites to one another, as these systems typically have one to three dominant taxa with similar HBI scores. For example, 90% of benthic macroinvertebrate samples collected by PWD in urban streams had HBI scores between 5 and 6. This lack of resolution is exacerbated when chironomids are not identified beyond the family level, as has been PWD practice.

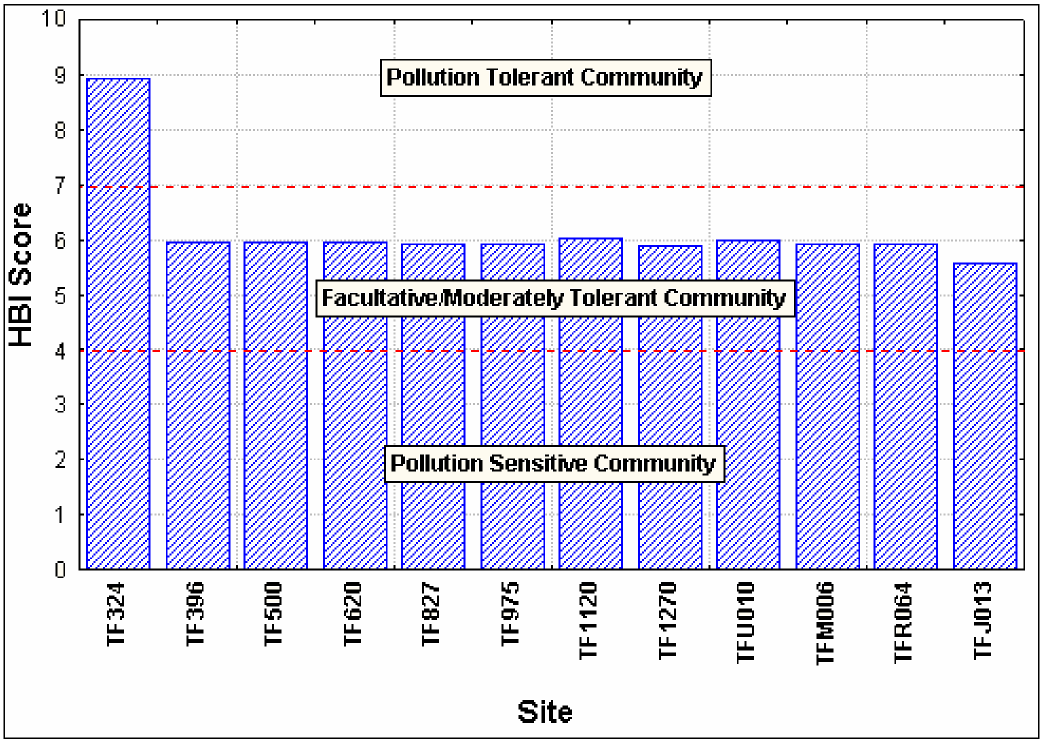

Figure 6-7 Hilsenhoff Biotic Index of Benthic Macroinvertebrate Communities at 12 sites in Tookany/Tacony-Frankford Watershed

Site TF324

Site TF324 received a total metric score of zero (0) out of a possible 30. The site was designated "severely impaired". Impairment is based primarily on low taxa richness (n=6) and the highest HBI score in the watershed (8.92) (Figures 6-4 and 6-7). This was the highest HBI score of any site assessed by PWD using RBPIII protocols. Despite a history of sampling sites below wastewater treatment plant discharge and in heavily urbanized stream systems, no other sites scored higher than 7. Tubificid worms dominated the benthic assemblage (72%) which accounts for the high HBI score. Tolerant individuals (75%) dominated the benthic assemblage at TF324 and there were no intolerant taxa collected. Generalist feeders (96%) also dominated the feeding structure of the site with predators being the only specialized feeders present (4%). The two specialized feeder taxa collected at TF324 were not pollution-sensitive.

Ten taxa were collected at this site during the 2000 survey, and tubificid worms were not collected. If the shift in benthic macroinvertebrate composition between these two subsamples reflects actual stream community changes, this site has become much more severely impaired over the past five years. Samples were collected in different seasons, and there were numerous natural disturbances (*e.g.*, floods and drought) over this period. It is assumed that water quality had been consistently poor at this site throughout the interval represented by these samples.

Site TF396

The assessment site at TF396 received a total metric score of zero (0) of 30 possible points. The site was designated "severely impaired". TF396 had the highest taxa richness (n=13) of all assessment sites and the lowest HBI (5.79) of mainstem assessment sites (Figures 6-4 and 6-7). Generalist feeders (98%) and moderately tolerant individuals (93%) dominated the site. TF396 scored substantially better in taxa richness, percent dominant taxon, and HBI than the other mainstem assessment sites. Site TF396 was the only mainstem site in which filterer collector taxa were well represented. A shift in community composition toward chironomid midges has been associated with water quality degradation, such as toxic metals contamination (Clements *et al.* 1988), but data from site TF396 are inconsistent with this explanation -- site TF396 had the best benthic macroinvertebrate community scores in mainstem Tacony-Frankford Creek despite frequent insults to water quality from CSO discharge and urban stormwater. Higher scores at this assessment location can probably be attributed to superior instream habitat and other site specific features that allow filterer collectors and other rare taxa to survive and/or recover from perturbations.

Site TF500
The total metric score at TF500 was zero (0) out of 30, which designated the site as "severely impaired". TF500 had the lowest taxa richness (n=4) of all assessment sites. TF500 also had an elevated HBI (5.98) and a very unbalanced trophic structure with 99% generalist feeders. Midge larvae (Chironomidae 97%) dominated the site. Like site TF324, 2004 metric scores and attributes of the benthic macroinvertebrate subsample were considerably worse than scores from 2000; relative abundance of filterer collector taxa decreased from 25% to <2%, and taxa richness decreased from 10 to 4. Researchers from ANS (Fairmount Park Commission, 1999) reported 63% chironomid relative abundance and 6% filterer-collector relative abundance in a quantitative benthic macroinvertebrate sample collected in winter 1998 near site TF500.

Site TF620
The total metric score at TF620 was zero (0) out of 30. The site was designated "severely impaired" when compared to the reference condition at FC1310. The site was dominated by Chironomidae (96%) and had a high HBI score (5.96). Generalist collector-gatherers (97%) dominated the feeding structure of the assemblage. When the 2000 subsample was compared to the 2004 subsample, relative abundance of filterer collector taxa decreased from 34% to 3%, and taxa richness decreased from 11 to 6. Again, if comparisons between single subsamples are representative of actual changes in benthic macroinvertebrate community structure, this site has become more severely impaired.

Site TF827
TF827 received a total metric score of zero (0) out of a possible 30. The site was designated as "severely impaired". The macroinvertebrate sample was dominated by chironomids (95%) and had low taxa richness (n=6) and an HBI score of 5.94. Generalist feeders (97%) and moderately tolerant individuals (99%) dominated the assemblage.

Site TF975
The assessment site at TF975 received a total metric score of zero (0) out of 30. The site was designated "severely impaired". Impairment was based primarily on low taxa richness (n=8) and an elevated HBI (5.94). Similar to other assessment sites, generalist feeders (98%) and moderately tolerant individuals (98%) dominated the assemblage. Chironomids composed 89% of the sub-sampled sorted for identification.

Site TF1120
The macroinvertebrate assemblage at TF1120 scored zero (0) out of 30. The site was deemed "severely impaired" when compared to the reference condition at FC1310. TF1120 had an elevated HBI score (6.04) and very low taxa richness (n=5). TF1120 was the only site surveyed where net-spinning caddisflies (Hydropsychidae) were not identified. Chironomids (96%) dominated the assemblage. When this site was sampled in 2000, filterer collectors were much more abundant, trophic and overall community composition was more even compared to results from the present study.

Site TF1270
The total biological score at TF1270 was zero (0), which designated the site as "severely impaired". TF1270 was the most upstream mainstem assessment site sampled during the 2004 survey. Similar to other assessment sites, there was an elevated HBI (5.93), low taxa richness (n=7) and abundance of chironomids (92%). Moderately tolerant individuals (98%) dominated the assemblage.

Site TFU010
TFU010 received a total metric score of zero (0) out of a possible 30. The site was designated as "severely impaired". TFU010 had an elevated HBI (5.99) and low taxa richness (n=8). The assemblage consisted mostly of chironomids (93%) and moderately tolerant individuals (98%). Although most feeding groups were represented, generalist feeders (98%) dominated the assemblage.

Site TFM006
The assessment site at TFM006 received a total metric score of zero (0) out of 30. The site was designated "severely impaired". The site had very low taxa richness (n=5) and a high HBI score (5.94). Similar to other assessment sites, generalist feeders (99%) and moderately tolerant individuals (97%) dominated the assemblage. Chironomidae (96%) dominated the benthic community and all metrics were scored as zero. Water quality in Mill Run was generally poor, with indicators of sewage present in dry and wet weather.

Site TFR064
The total metric score at TFR064 was (0) out of 30. The site was designated "severely impaired" when compared to the reference condition at FCR025. Resembling the rest of the watershed, TFR064 had an elevated HBI (5.93) and low taxa richness (n=9). Midge larvae composed 89% of the sub-sampled sorted for identification. Generalist feeders (97%) and moderately tolerant individuals (95%) dominated the assemblage.

Site TFJ013
The total biological score at TFJ013 was six (6) out of a possible 30. The site was designated as "moderately impaired". The metric score for TFJ013 was between two condition categories. The site was listed as "moderately impaired" because TFJ013 was the only site with a modified EPT taxon (*Chimarra*) present. The site was impaired primarily for low taxa richness (n=11) and an elevated HBI (5.57) score. Similar to other assessment sites, generalist feeders (74%) and moderately tolerant individuals (92%) dominated the assemblage. Compared to the rest of the watershed, the site had the smallest relative

proportion of the dominant taxon (Chironomidae, at 63%). PWD 2000 survey data suggest that sensitive *Chimarra* caddisflies may have been more abundant at this site than presently. Furthermore, two additional sensitive caddisfly taxa (*i.e.*, *Glossosoma*, *Dolophilodes*) were collected in 2000 but not in 2004.

6.5 Periphyton

Periphyton communities were sampled from a limited number of sites, chiefly to assess the role of periphyton regulating stream metabolism (Section 5.4). Several samples were preserved for taxonomic identification, but these analyses have not been completed. As most water chemistry parameters (*e.g.*, nutrients, BOD, etc.) have been fully characterized through extensive sampling, there is little need to use periphyton communities to infer an ecological condition. The ratio of water column chlorophyll-*a* to periphyton chlorophyll-*a* in dry weather and observed increases in concentrations of water column chlorophyll-*a* in wet weather suggest that attached algal communities are the dominant primary producers in Tookany/Tacony-Frankford Watershed and that storm events tend to scour and remove algal biomass.

Chlorophyll-*a* concentrations (± Standard Error (SE)) at sites TF324 and TF680 are shown in Section 5.4, (Figure 5-16). Although temporal patterns of chl-*a* were similar at both sites, chl-*a* concentrations were consistently significantly greater at site TF680 than at site TF324 ($F_{5,50}$= 14.27, p<0.05). Mean chl-*a* at site TF680 was significantly lower (49.8 ± 6.5 mg/m^2) on 9/08/2004 than on other sampling dates ($F_{4,50}$= 2.66, p= 0.043). Mean chl-*a* concentration at the TF02 site sampled 19 August 2004 (not shown in Figure) was 34.9 (± 6.9) mg/m^2.

An artificial scouring experiment was conducted to examine differences in accrual rates with respect to site and non-scoured substrates. As with the monitoring program, there were significant site differences in algal biomass with TF680 having greater chl-*a* concentrations than TF324 ($F_{2,32}$= 14.96, p <0.05). Algal accrual rates for each site were positive for the first 5 days of the study period with TF324 having an average daily accrual rate (8.36 ±1.30 mg/m^2) approximately half that of TF680 (16.7 ± 4.34 mg/m^2). During days 5-9 of the experiment, both sites lost biomass with an average daily loss rate of 1.73 (± 0.99) mg/m^2 at TF324 and 4.56 (± 1.31) mg/m^2 at TF680. The mean daily accrual rate of non-scoured rocks at TF324 during days 5-9 was 8.96 mg/m^2 (accrual rates could not be calculated for the first 5 days because of insufficient data). At TF680, the mean daily accrual rate of non-scoured rocks was 11.7 mg/m^2 and 1.98 mg/m^2 during days 0-5 and 5-9, respectively.

Algal samples for water column chl-*a* analyses were collected from sites on mainstem Tookany/Tacony-Frankford Creek during 2000-2002, and for benthic chl-*a* analyses during 2003. These data are presented in Appendix I to amalgamate all available chl-*a* data for the Tookany/Tacony-Frankford Watershed into a single document. Suspended water column samples were collected as grab samples at all Tookany/Tacony-Frankford Watershed sites on multiple occasions. In 2003, algal samples were collected from TF324, TF500, TF680, and TF760 on 16 October. Algal samples were processed and analyzed in the same manner as samples collected for the present study.

Water column (*i.e.*, suspended) chl-*a* concentrations are typically below 5 mg/L at all sites although concentrations at TF324 tend to be more variable (Table 5-7). The large spikes in chl-*a* concentrations are likely the result of scouring and suspension of benthic algae due to high flow events. Large river phytoplankton communities (potamoplankton) are typically prolific and can reach concentrations of 250 µg/L (Reynolds 1988), but Tookany/Tacony-Frankford Watershed is a relatively small, shallow stream. Given the baseflow concentrations observed, it is likely that the source of water column chl-*a* is suspended benthic algal material.

Benthic chl-*a* collected during 2003 showed a similar spatial pattern to that of this study. Chlorophyll-*a* concentrations at TF324, TF500, TF680, and TF760 were 114 mg/m^2, 222 mg/m^2, 167 mg/m^2, and 116 mg/m^2, respectively. As with the current study, it would be expected that chl-*a* concentrations would be greater at TF324 than at upstream sites because of the observed diurnal DO fluctuations. It appears that other factors such as disturbance, light, or grazing may be limiting accrual at TF324 and that the relationship between biomass and production is not as clear-cut as expected.

6.6 Summary of Biology by Reach

Site TF280/324

Site TF 324 is one of the most severely degraded aquatic habitats in the City of Philadelphia. Approximately one third of the watershed land area, roughly representing the drainage area of the former Wingohocking Creek, drains directly to the combined sewer outfall located just upstream of this site (Figure 7-1). This outfall is responsible for combined sewer overflows of 2 billion gallons per year on average. Due to stormwater collection system efficiency and the sheer size and imperviousness of its drainage area, it is assumed that even small storm events may cause discharge of combined sewage from this outfall. Sewage that is constantly present in the system is minimally diluted by stormwater in these small events, and the large scour pool downstream of this outfall is capable of storing many gallons of mixed discharge. One component of PWD's CSO long term control plan is construction of a Pelican gate within this outfall that will allow for storage and capture of combined sewer flows; this project is in the conceptual design stage. It is estimated that once completed, this gate will reduce the number of overflows from 69 to 51 per year on average at this site. It is hoped that this gate will capture small rain events and provide many benefits to dry weather water quality.

As evidenced by comparison to water quality data from the 1970s in which fecal coliform concentration was elevated in both wet and dry weather at this site (Appendix A), much improvement has been made with regard to controlling and managing this combined sewer, but tracking down and fixing sources of dry weather discharge is still a high priority. This site had the most severe wet weather loading of organic material (mean BOD_5 and TKN) in Tookany/Tacony-Frankford Watershed. Dissolved oxygen suppression due to the breakdown of organic matter is probably limiting the success of most taxa at this site. Saprobic conditions are further indicated by the dominance of tubificid worms and mummichogs, two taxa known to be tolerant of anoxia; the presence of black, reduced sediments and hydrogen sulfide odors which were commonly encountered here; and the fact that periphyton biomass was smaller at TF280 than upstream sites that do not typically experience frequent DO suppression.

Site TF396

Site TF396 is located only 0.7 mi upstream of site TF324, and was chosen to enable an assessment of effects from the large CSO outfall at site TF324. While nearly all attributes of this site were much improved over site TF324, this site is still considered severely impaired. Water quality and hydrologic impairment are assumed to be co-limiting factors. This site had excellent habitat relative to other sites in the watershed, and without the influence of combined sewer overflows and untreated stormwater it might be expected to have much better biological communities. While upstream of the former Wingohocking Creek, based on computer simulation this site is still subject to the effects of over 1 billion gallons per year of combined sewer overflows.

Dominance of the fish community by *H. heteroclitus* shows that these fish will ascend into non-tidal waters to exploit suitable habitats and further suggests that anoxic conditions at this site may limit the success of less tolerant fish taxa. Conversely, the macroinvertebrate community at site TF396 showed significant improvement over that of TF324, with the highest taxa richness and lowest HBI score on mainstem Tacony Creek. This finding suggests that long, extensive riffles with large, relatively stable, non-embedded substrate can partially offset effects of stormwater on a local scale. However, few of the macroinvertebrate taxa present at this site are considered sensitive to organic pollution, and sensitive taxa that were present (*i.e.*, tipulids) were found in small numbers.

Extensive riparian buffers on both banks fail to ameliorate the hydrologic effects of a 22mi^2 drainage area with 60% impervious surface, and stream segments just upstream and downstream of this site have severe habitat impairments as well. This site is exceptional and not representative of habitat south of Roosevelt Blvd. Surface geology and the sharp bend at the upstream limit of the sampling site allow for more stormwater flow energy dissipation and the left bank of this site (outside meander) has been protected by extensive large boulder rip rap revetments. A large stand of Japanese knotweed was the only vegetation present along this bank.

Site TF500

With drainage area of approximately 17 mi^2, site TF500 should be large and stable enough to support complex native fish and macroinvertebrate communities. Water quality, and to a more limited extent, habitat stability tend to generally improve from downstream to upstream within the City of Philadelphia. While fecal coliform counts were elevated at all city sites downstream of CSO outfalls, Site TF500 had smaller dry weather concentrations of NO_2, BOD_5, TKN and NH_3 than site TF280 (Appendix A). Continuous water chemistry results indicated that anoxic conditions were also less frequent than at site TF280 (Table 5.6); these findings correlate well with an increase in fish species richness, though not with macroinvertebrate taxa richness, which was lowest in the watershed.

North of site TF396, riparian zones of Tacony Creek Park are consistently wider and more densely forested than downstream portions that are narrower or have more mown lawn and golf course area. The mainstem of Tacony Creek North of Whitaker Avenue is a nearly continuous band of forested parkland (Figure 6-8). However, riparian buffers do not protect the stream from stormwater erosion effects, as only a small portion of stormwater flow reaches the stream as surface runoff. Effects of erosion and destabilization were very apparent – Site TF500 and other stream segments in its vicinity have been severely overwidened and straightened by exaggerated storm flows (Appendix F in preparation). The fish assessment site was bisected at its upstream limit by a large channel bar, and the downstream left bank had extensive deposits of fine sediment that were black in color and odorous.

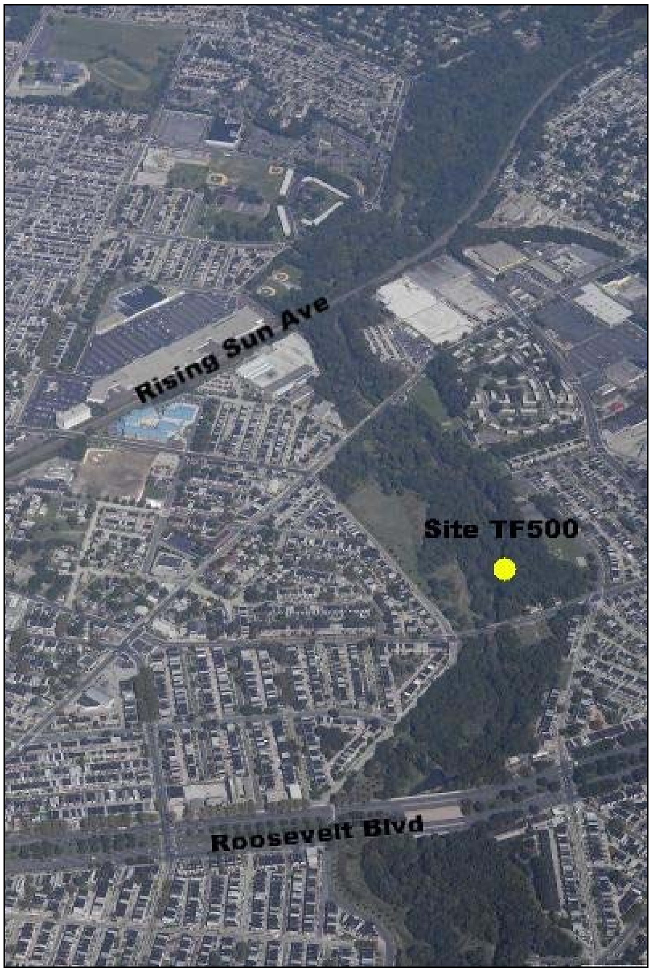

Figure 6-8 Oblique Aerial Photograph of site TF500 and Vicinity

Though mainstem Tacony Creek in Tacony Creek Park is disconnected from its floodplain, abandoned floodplains are generally wide and undeveloped, offering many opportunities for stormwater wetland creation. In a 1998 report to the Fairmount Park Commission, scientists from the Philadelphia Academy of Natural Sciences (ANS) recommended the creation of a wetland just downstream from site TF500 in a ballfield that has been largely abandoned due to frequent inundation. This site was also identified as having wetland creation potential in a wetland inventory performed by PWD in 2001. Another important task is maintenance of the steep slopes that drain directly to the stream at this point.

Erosion in gullies and along trails may introduce sediment to the stream. ATV use has been reduced since metal gates were installed in 2003.

Despite obvious habitat impairments, fish community metrics at site TF500 were substantially improved over site TF396, especially species richness and evenness. These improvements can be largely attributed to an increase in the number and relative abundance of insectivorous minnow taxa that feed in the water column (*i.e.*, *Cyprinella* and *Notropis* spp.). As these fish feed opportunistically on drifting food items, including terrestrial insects, increased abundance may be partially due to an increase in the availability of terrestrial insects which might be expected to accompany increased canopy cover and riparian zone vegetation. Substrates at site TF500 were typically much smaller than at sites TF396 and TF324, perhaps an important factor for species that spawn over sand and gravel substrates. Many species classified as pollution tolerant were present at site TF500 but not downstream, which corroborates the findings of water quality data (*i.e.*, poorer water quality downstream).

Site TF500 was located approximately 0.5mi downstream of the site where ANS collected fish in a 1998 survey of fish in Philadelphia Parks (Fairmount Park Commission, 1999 Volume III). While the fish community in the 1998 sample was generally similar to the 2004 sample, certain changes were noted. For example, ANS scientists collected 118 Spotfin shiners (*C. spiloptera*), but did not collect Satinfin shiners (*C. analostana*). The investigators concluded that *C. analostana* was not present in the basin, possibly due to interspecific competition, and recommended against its introduction. However, PWD did not record *C. spiloptera* from the basin in a 2000 assessment. In 2004, *C. analostana* was found at each assessment site, greatly outnumbering its congener. Though these results come from a small number of sites only, it appears that either a major shift in relative abundance has occurred since 1998, or the 1998 record is in error. The relative abundance of *Notropis* spp. was also interesting, with ANS collecting 183 *N. procne* and 117 *N. hudsonius*. In 2004, *N. procne* still appeared to be abundant in the basin, but *N. hudsonius* was rarely caught (12 individuals). In this case, however, intermediate (2000) sample data seem to support the hypothesis that a change in relative abundance has taken place (91*N. procne* and 57 *N. hudsonius* individuals collected in 2000). No specific explanation is offered for the observed change in relative abundance, but water quality and habitat modification, along with biotic interactions (*e.g.*, predation, competition) are possible factors.

Site TF620/680

Much like site TF500, site TF620 lies in a continuous belt of riparian forested parkland in Tacony Creek Park where canopy cover and width of riparian vegetated zone were considered good. Like all sites in Philadelphia served by combined sewer systems, this site shows elevated dry weather fecal coliform concentration (Tables 5-4 and 5-5), but most other dry weather water quality constituents were similar to site TF500 or improved slightly at site TF620 compared to downstream sites. Dissolved oxygen concentration, in particular, seems to be much improved over downstream locations, as site TF620 marks the upstream-most limit of the area in which DO concentration is considered to be a problem (Table 5-6). Sites for water chemistry monitoring and biological monitoring were not identical, and the water chemistry monitoring site was moved 0.5mi upstream in 2003 due to recurrent vandalism at the site 200m upstream of Adams Avenue.

Two dams separate site TF620 from site TF500. The first dam, located upstream of Rising Sun Avenue, is only about 3ft high, and creates a total water surface drop of approximately 1ft. The dam at Adams Avenue, however, is much larger and creates an impoundment of slower, deeper water where sediment deposition is high. Furthermore, site TF620 had the smallest percentage of boulder substrate in Tookany/Tacony-Frankford Watershed. Like most other sites, TF620 is in a region where most stream segments are extensively destabilized due to stormwater and urbanized hydrology. Because PWD protocols result in direct sampling of the richest habitat in an area, fish and macroinvertebrate sites probably score much higher for habitat metrics than would more typical stream segments upstream and downstream. The 100m segment chosen for fish sampling at TF620 was the only segment in this area where adequate pool and riffle habitats could be found.

The dam at Adams Avenue probably has other effects on aquatic biota other than increased sediment deposition and habitat homogeneity upstream. Over five feet in height, this dam is assumed to be an impediment to upstream migration of most fishes other than eels (*A. rostrata*), though eel abundance and biomass decreased from site TF500 to site TF620. Though stream size and drainage area no doubt are influential, and species richness is expected to be greatest in medium-sized streams, dams may be partially responsible for the absence or decreased abundance of certain species from downstream to upstream (*e.g.*, *A. nebulosus*). Furthermore, habitat between the sampling reach and the dam at Adams Avenue is a homogeneous run with sand and gravel substrates due to deposition caused by the dam. Sand and gravel are needed by many native species for spawning, a factor that may partially explain the increased number of native minnow species at sites TF620 and TF500 relative to sites with coarser substrates. The natural forested floodplain also probably provides more roots, coarse woody debris and snags of the type used by crevice spawners (*e.g.*, *Cyprinella* spp.).

Site TF760/827

Site TF 760 is the first assessment site within Montgomery County and this area marks numerous changes that have implications for water quality and biological communities. Most importantly, stormwater is collected in a separate sewer system which discharges directly to the stream, unlike downstream reaches which are served by combined sewers that discharge to the stream only when the receiving capacity is exceeded. Along mainstem Tookany Creek in Montgomery County, riparian buffer zone width becomes more variable and riparian zones are increasingly maintained as lawn. Predominant land use drastically changes from multi-family residential to single-family residential housing (Figure 2-7). The frequency and amount of stream area impacted by bridges, culverts, and channelized sections increases compared to the non-tidal portions of Tookany/Tacony-Frankford Watershed (especially within Tacony Creek Park upstream of Whitaker Avenue). Much of the land abutting streams is privately owned and maintained as lawn. Erosion control structures are often built by private landowners, and these structures vary widely in design, effectiveness and impacts to stream stability.

Site TF760 is another example of a site where the biological assessment points were shifted upstream from the location where water chemistry samples were taken. This change was necessary to find adequate habitat, as the chemical sampling point was located within a channelized section. The confluence of an unnamed tributary with a drainage area of 0.6 mi^2 was located between the biological assessment sites and the chemical monitoring site. Nearly 3000 ft of streambank restoration have been completed in Tookany Creek along Tookany Creek Parkway in Cheltenham Township as of May 2005. Restoration techniques used at this site followed a semi- naturalized revetment approach, incorporating live willow stakes and branch bundles. Telephone poles were trenched and pinned to the streambank and the toe of slope was reinforced with boulders. Construction activities at this restoration site and along railroad tracks in the vicinity of site TF1120 may have impacted the results of chemical samples and biological assessments. For example, continuous water quality monitoring probes recorded turbidity >8NTU during 20% of all dry weather observations (373 days of combined dry weather monitoring from 2000-2004, (Table 5-7).

Substrate at this site was much coarser than at site TF620, and the site was lacking pools, factors that contribute to decreased HSI scores for some species. Lack of pool habitat may partially explain the low abundance of Swallowtail Shiners and absence of Creek Chubs at this site. These fish are regarded as pool species and were found to be more numerous in sites with greater pool volume downstream and upstream of site TF760, respectively. This site also had many Redbreast sunfish, a species that was not found again in any upstream Tookany Creek sites. Decreased species richness at this site relative to site TF620 may be partially due to construction disturbances within the stream restoration area upstream of the assessment site. There are also 2 dams between site TF620 and TF760 which may impair upstream migration of fish.

Many fish require sand and gravel substrates for spawning, and fish assessments were conducted during the spawning season for many native species. The paucity of appropriate spawning substrates at sites TF760 and TF975 relative to site TF620 may help explain the decreased abundance of these species. Urbanized stormwater flows are exacerbated by extensive channelization and scour the streambed of sand and gravel substrates. A decrease in the proportion of sand and gravel substrates might be expected to correlate with an increase in overall health of the benthic macroinvertebrate community, as cobbles and larger substrates are more stable, but this site had one of the worst assemblages in Tookany/Tacony-Frankford Watershed. Again, construction disturbances may be partially to blame. While crayfish were not collected or enumerated, biologists observed them to be very abundant at this site while electrofishing. Increased crayfish abundance is probably also related to the increased substrate size.

Site TFJ013

Though impaired compared to reference sites on French Creek, site TFJ013 exemplifies some of the best conditions within Tookany/Tacony-Frankford Watershed. This sub-watershed was among the lowest in impervious cover (28%), and fewer Jenkintown Creek stream segments were channelized and culverted compared to many other tributaries in Montgomery County (Appendix F in preparation). Decreased impervious surface, combined with fewer infrastructure impacts, probably helps ameliorate the effects of urbanized hydrology. Jenkintown Creek has the best Baseflow characteristics in the watershed, as evidenced by USGS gauge data analysis (Table 4-6), so drought effects may be lessened compared to tributaries with smaller drainage area. Jenkintown Creek may serve as an example of changes one would hope to find once more severely degraded reaches in the watershed are restored.

Substrates in Jenkintown creek were generally coarser than in mainstem sites (Appendix F to be added at a later date), and most habitat attributes related to substrate and riffle stability for macroinvertebrates were rated suboptimal. Site TFJ013 had the best benthic macroinvertebrate community of all Tookany/Tacony-Frankford Watershed sites. Certain sensitive EPT taxa appear to have become less numerous or extirpated completely, based on comparison to 2000 PWD survey data, but there appears to be a population of *Chimarra* remaining. Repeated sampling or sampling at additional locations would enable us to draw stronger conclusions about whether this site has become more severely impaired since 2000. Water quality data do not indicate serious physicochemical stressors, so hydrologic modification is the most likely explanation for increased degradation, if the site is indeed continuing to degrade.

Jenkintown Creek is shallow and was not selected for fish sampling, but it is likely that Jenkintown Creek has many of the same species of fish as site TF1120 (*i.e.*, Blacknose Dace and Creek Chubs). A northern water snake was observed eating a small sunfish in Jenkintown Creek. A small instream pond located north of Indian Creek Road may support greater diversity of fish life.

Site TF975

Biological communities at site TF 975 showed signs of severe impairment, as benthic macroinvertebrate and fish species known to be tolerant of poor water quality were nearly completely dominant. This site had the greatest proportion of white suckers within the watershed and the second greatest proportion of blacknose dace and fish with deformities, lesions and tumors in the watershed. This site experienced water quality criteria exceedances frequently in both dry and wet weather. Indicators of dry weather sewage inputs (*e.g.*, fecal coliform bacteria concentration, *E.coli*) were highest among sites upstream of combined sewer outfalls (Appendix A). However, site TF975 is located within a small park in Cheltenham Township, so dog feces must be considered a potential source of indicator bacteria.

Numerous infrastructure impacts are present in the vicinity of this site. Bridge culverts and a dam located at High School Road promote instability and the semi-natural revetments installed along the right bank to curb erosion are beginning to deteriorate. Dams located downstream of the site (n=3) may partially explain the decreased fish species evenness relative to downstream sites. Upstream of High School Road, the stream has been extensively channelized, particularly along the left bank (20% of the left bank of Tookany Creek is channelized between site TF1120 and TF975). Stormwater outfalls (n=20) with combined cross sectional area 180ft^2 discharge to the stream between site TF1120 and site TF975, the greatest relative impact of stormwater outfall density outside the City of Philadelphia's Combined sewer system (Appendix F, in preparation). Like site TF827, habitat attributes associated with streambanks and riparian zone management scored poorly, despite the fact that these sites are located within parkland (Table 7-2).

Site TF1120

Site TF1120 is located just downstream of a straightened and recently channelized portion of Tookany Creek that runs parallel to SEPTA Railroad tracks. Gabion baskets were installed in 2004 to reinforce the railroad bed. Cheltenham Township also replaced many water mains in the vicinity of this site. Though sediment bags were used in combination with coffer dams and trash pumps, construction disturbance often caused the Creek to appear turbid throughout the course of work. Signs of hydrologic instability were very evident at this site, especially within the fish assessment site located immediately downstream of Washington Lane Bridge. Bedrock outcrops have been scoured of smaller substrates and the inside meander bar was observed to increase in size dramatically since 2000. Near the lower end of the fish assessment site, the stream is channelized along the right bank where the creek adjoins Chelten Hills Drive. The portion of Tookany Creek between site TF1270 and TF1120 has 24 stormwater outfalls with combined cross sectional area greater than 185ft^2.

Tree canopy was nearly complete throughout most of the site and algae were not observed to grow to nuisance densities. Continuous water quality data do not indicate DO stress at this site (Table 5-7) and there were few violations of WQ criteria at this site overall (Tables 5-4 and 5-5). It is believed that hydrologic modification and construction disturbances are responsible for the poor benthic macroinvertebrate and fish communities observed at this site. In addition to channelization and peak flow modification, four dams separate site 1120 from site TF975, probably limiting upstream migration of fish species, other than minnows that are known to have an affinity for smaller streams (*i.e.*, blacknose dace, creek chubs)

Section 7
Physical Habitat Characterization

7.1 Habitat Assessment

Tookany/Tacony-Frankford is an urban stream system that has been adversely affected by development and land use practices over the past century. Impervious cover is estimated at 40.9% of the watershed in total and 53.6% within the city of Philadelphia. More than 55% of the watershed, particularly the portion representing the former Wingohocking Creek, has been encapsulated and does not flow to natural surface waters, but to a combined sewer system. (Figure 7-1) Impervious cover, especially directly connected impervious cover, decreases groundwater recharge and the percent of annual streamflow represented by baseflow. Tookany/Tacony-Frankford streams are extremely "flashy"- increases in streamflow and erosive forces occur almost immediately following the onset of storm events. Both maximum discharge and total runoff volume are increased compared to an undeveloped watershed (Figure 7-2).

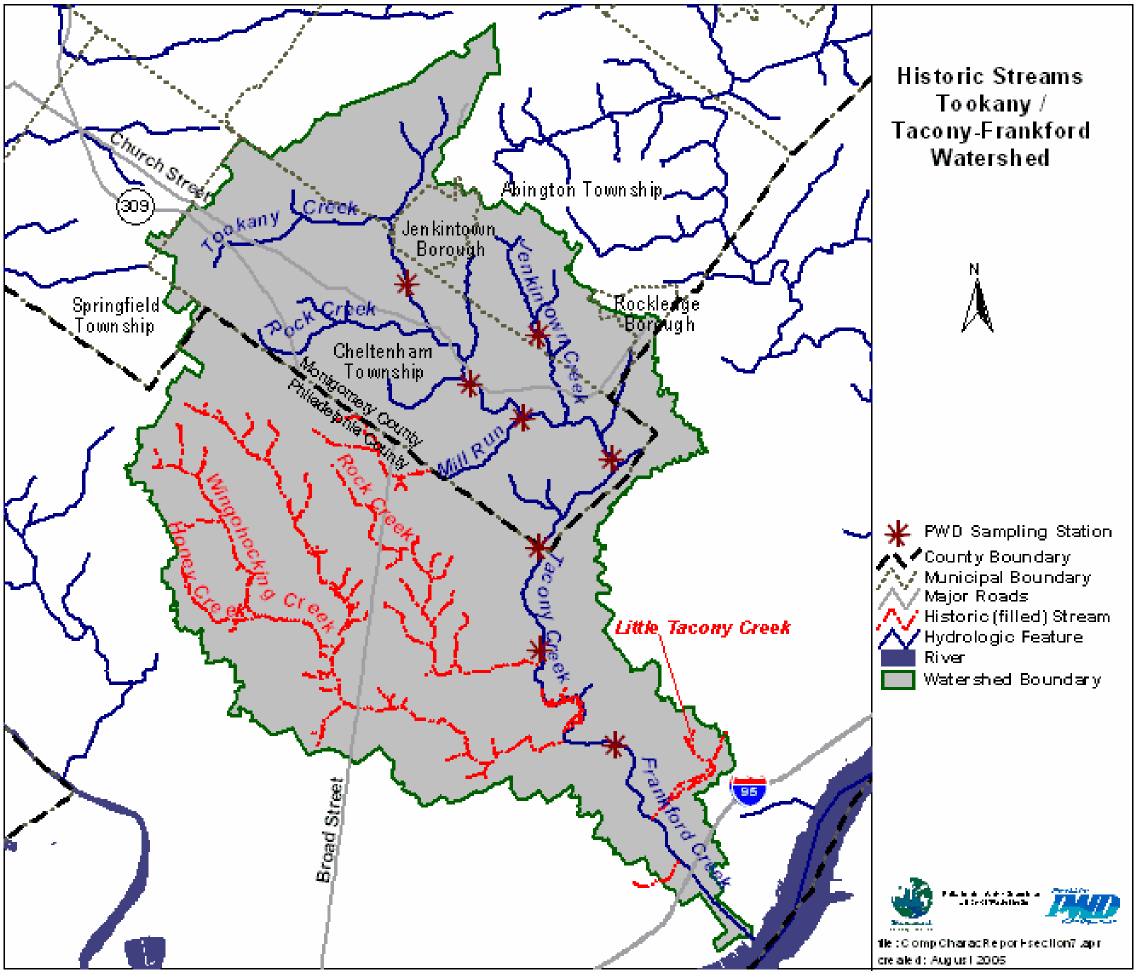

Figure 7-1 Historic and present day streams of the Tookany/Tacony-Frankford Watershed

Changes in hydrology have resulted in de-stabilization of much of the watershed. Urbanization promotes a cumulative, self-reinforcing pattern of streambank erosion. As stream channels become physically larger and further disconnected from their historic floodplains, more stormwater forces are restricted to the stream channel, where compromised, heavily eroded banks are least suited to dissipate them. These overwidened stream segments deficient in baseflow make very poor habitats for all but the most tolerant generalist species. Signs of habitat impairment were present in the watershed's biological communities; Tookany/Tacony-Frankford Watershed is nearly devoid of sensitive macroinvertebrates and fish taxa, while unstable stream banks have been extensively colonized by invasive species, especially Japanese knotweed (*Polygonum cuspidatum*).

Other habitat effects include widespread sedimentation in runs and pools as well as along channel and lateral bars. With few exceptions, historic first order tributaries and wetlands within the watershed have been filled in and/or piped into storm sewers. Erosion has exposed, threatened, and in some cases, destroyed valuable infrastructure and private property. Unfortunately, traditional solutions for addressing erosion and flooding problems may increase instability overall, exacerbating problems they are intended to solve. The Tookany/Tacony-Frankford Watershed Management Plan (TTFIWMP) outlines several options for detaining, infiltrating, and treating stormwater to reduce stream channel impacts. Healthy ecosystems require healthy habitats, and healthy habitats cannot be restored without addressing stormwater impacts.

7.2 EPA Habitat Assessment Results

Comparison to Reference Sites

Habitat features at twelve Tookany/Tacony-Frankford Watershed sites were compared to those of the reference sites located in nearby Chester County. Mainstem and third order tributary sites were compared to French Creek reference sites, located in Coventry Township, Chester County, PA. Tributary sites, second order or less, were compared to Rock Run, a tributary to French Creek located in Coventry Township, Chester County, PA (Appendix F). In general, habitat was determined to be very poor, with seven of twelve sites designated "non-supporting" of the watershed's designated uses (Figure 7-3). Five sites, including three in Tacony Creek Park in the City of Philadelphia, had slightly better scores and were designated "partially supporting". Habitat degradation was considered to be the most important impairment in Tookany/Tacony-Frankford Watershed, corroborating the results of biotic indexing. Table 7-1 summarizes the results of habitat assessment using EPA habitat assessment protocols.

TF324

The mean habitat score at TF324 was 67.5, and the habitat was designated as "non-supporting" (31.84% comparison). All condition categories were scored as "marginal" or "poor" except sediment deposition (Table 7-1). Sediment deposition was scored as "suboptimal" because of a large CSO outfall upstream of the assessment site that routinely scours the area. The channel of the creek is relatively straight and there is extensive alteration of both banks. Pools were almost absent and epifaunal substrate was very inadequate. The riparian zone on both banks was reduced and both banks were unstable with poor vegetative protection. Both stream banks were highly eroded.

TF396

TF396 received a mean habitat score of 158.0. The site had a 74.53% comparison to the reference condition and was designated as "supporting" (Table 7-1). TF396 is located in an undisturbed area behind Friends Hospital, and the site had the highest mean habitat score of all assessment sites. The site had an even distribution of morphology types and substrate components. Most condition categories were scored as "suboptimal" or high "marginal". Highest scores were for channel alteration and riparian vegetative zone width on the right bank. The assessment site is one of the few areas within the watershed that has not had the surrounding land impacted by urbanization.

TF500

Site TF500 received a mean habitat score of 131.5 and was deemed "partially supporting" (62.03% comparison, Table 7-1). The site had an even distribution of morphology types and substrate components. Most habitat attributes were scored as "marginal". Most notable at the site was a large mid-channel bar at the upstream limit of the assessment site. The riparian zone on both banks was reduced and both banks were moderately stable with poor vegetative protection. Field observations included heavy erosion on both banks.

TF620

The mean habitat score at TF620 was 153.5 and the habitat was designated as "partially supporting" (72.41% comparison) (Table 7-1). The substrate of the assessment site was dominated by sand (40%) and run dominated the stream morphology (45%). Riffles composed 20% of the stream reach. The channel had a normal pattern and alteration was absent. TF620 is located in Tacony Park and the riparian zone at the assessment location was well preserved. Although sand was the dominant substrate, embeddedness was scored as suboptimal. The higher scores for embeddedness were most likely due to periodic surges of storm water that scour and redeposit sediment through out the assessment site.

TF827

TF827 had a mean habitat score of 123.5, which was 58.25% comparison to the reference site ("non-supporting" designation) (Table 7-1). Overall the habitat scored mostly as "marginal" and "poor". In particular, the right bank was very unstable with long stretches that were highly eroded. The right bank also had very poor vegetative protection. The instream morphology and substrate was evenly distributed, but the stream was channelized both upstream and downstream of the assessment site.

TF975

Site TF975 received a mean habitat score of 116.5 and was deemed "non-supporting" (54.95% comparison) (Table 7-1). The substrate of the stream reach was well distributed, but the morphology type of the stream was dominated by run (50%). Most condition categories were scored as "marginal". A dam is present upstream of the assessment site, and the stream is channelized downstream of the assessment location. The riparian zone at the site is highly reduced. The surrounding land use is residential with maintained lawns dominating the riparian vegetation.

TF1120

The mean habitat score at TF1120 was 123.0, which was a 58.02% comparison to the reference condition at FC1310 ("non-supporting" designation) (Table 7-1). Most habitat attributes were scored as "marginal". The substrate of the site was well distributed with a large portion of bedrock (15%) and a sizeable portion of sand (30%). A large bedrock outcropping comprised a substantial portion of the left bank of the assessment site. The riparian vegetative zone width of the right bank scored low because of an electrical/railroad access road and vehicle roadway.

TF1270

TF1270 had a mean habitat score of 109.5, which was 48.03% comparison to the reference site ("non-supporting" designation) (Table 7-1). The inorganic substrate of the site was dominated by sand (40%), and the morphology of the assessment reach was predominantly run (60%). A majority of the condition categories were scored as "marginal". Pool variability was scored low with pools comprising 10% of the stream morphology. The riparian zone on both banks was reduced and both banks had decreased vegetative protection.

TFU010

Site TFU010 received a mean habitat score of 110.5 and was deemed "non-supporting" (48.46% comparison) (Table 7-1). Most habitat attributes were scored as "marginal". The site had a disproportionate percentage of riffles (75%) and sand and gravel (35% each) dominated the substrate. Pools were almost absent and epifaunal substrate was less than desirable. TFU010 is located in a residential neighborhood with moderate erosion. The right bank was moderately unstable with a reduced riparian zone.

TFM006

The mean habitat score at TFM006 was 88.0, which was a 38.60% comparison to the reference condition at FCR025 ("non-supporting" designation) (Table 7-1). Most habitat attributes were scored as "marginal" or "poor". The site is located within a golf course and the riparian zone and vegetative protection were both poor. The channel is extensively armored or channeled and is relatively straight. Sand and gravel (35% each) dominated the substrate and pools were almost absent (5%). There were also large, thick mats of filamentous algae at the time of macroinvertebrate sampling/habitat assessment.

TFR064
TFR064 had a mean habitat score of 147.5, which was 64.69% comparison to the reference site ("partially-supporting" designation) (Table 7-1). The inorganic substrate of the site was predominately boulder and cobble (35% each). Riffle (40%) and run (50%) dominated the morphology of the stream reach. Pools were either shallow or absent throughout the site. Most condition categories were scored as "suboptimal" or "marginal". The higher gradient and number of riffles at the site increased scores for sediment deposition, embeddedness, and frequency of riffles.

TFJ013
Site TFJ013 received a mean habitat score of 138.0, and was designated as "partially-supporting" (60.53% comparison) (Table 7-1). The site had an even distribution of morphology types and substrate components. All habitat attributes were scored as either "suboptimal" or "marginal". The surrounding land use at TFJ013 is residential and there is heavy erosion throughout the assessment reach. Both banks were moderately unstable and the riparian zone on both banks was reduced. Rip-rap has been used on both banks in an attempt to reduce erosion.

7.3 Fish Habitat Suitability Indices (HSI)

7.3.1 HSI Model Selection

HSI models for seven species were selected for Tookany/Tacony-Frankford Watershed. Models were chosen to reflect the range of habitat types and attributes needed to support healthy, naturally-reproducing native fish communities and provide recreational angling opportunities in non-tidal portions of the watershed (Table 7-2). Two centrarchid fish, redbreast sunfish (*Lepomis auritus*), and smallmouth bass (*Micropterus dolomieu*), were included in the analysis. These species are tolerant of warmer water temperatures and require extensive slow, relatively deep water (*i.e.*, pool) habitats with appropriate cover or structure to achieve maximum biomass.

While black basses (*M. dolomieu* and its congener *M. salmoides*) are not native to Southeast Pennsylvania, they occupy the top carnivore niche and are among the most sought-after freshwater game fish in water bodies where they occur. Moreover, the only other large bodied piscivores known to occur in non-tidal portions of Tookany/Tacony-Frankford Watershed are American eels, native catadromous fish for which no HSI have been developed. Salmonid HSI models were available but inappropriate because coldwater fish generally cannot establish and maintain reproducing populations in warmwater streams, and PFBC does not stock salmonids in Tookany/Tacony-Frankford Watershed.

Five native minnow species were selected for HSI analysis: blacknose dace (*Rhinichthys atratulus*), common shiner (*Luxilis cornutus*), creek chub (*Semotilus atromaculatus*), fallfish (*Semotilus corporalis*), and longnose dace (*Rhinichthys cataractae*). Of these, *R. cataractae* and *S. corporalis* are not known to occur in Tookany/Tacony-Frankford Watershed. However, the former species' known affinity for stable, high quality riffle habitats and the substrate requirements of the latter species are reflected in HSI models, prompting inclusion in the analysis as indicators of riffle habitats and stream stability. The longnose dace HSI may be considered a surrogate indicator of habitat suitability for other native riffle species (*e.g.*, margined madtom) for which no HSI are available.

Table 7-2 HSI Data Summary

HSI Model Variable Matrix	Variable Type	Blacknose Dace	Common shiner	Creek Chub	Fallfish	Longnose Dace	Redbreast Sunfish	Smallmouth Bass
Total number of HSI variables		16*	9	20	6	6	10	13*
Avg. Temperature during growing season (May-Oct.)	temperature	X						X
Average Temperature in spawning season**		X	X		X		X	X
Maximum temperature sustained for 1 week			X			X	X	
Average Summer Temperature (Jul-Sep)				X	X			
Average temperature during spring (May-Jun)				X				
Average Turbidity (JTU)***	water quality	X	X	X	X		X	X
Average yearly pH value			X					X
Least suitable pH value (instantaneous)							X	
pH fluctuation classification				X				
Minimum dissolved oxygen concentration				X			X	X
Minimum dissolved oxygen conc. during spring				X				
Percent instream cover during average summer flow	general stream characteristics			X		X	X	X
Instream cover classification					X			
Percent shading of stream between 1000 and 1500 hrs.		X		X				
Percent vegetative cover							X	
Availability of thermal refugia (winter) (Y/N)				X				
Stream gradient (m/km)		X		X				X
Average stream velocity during average summer flow				X		X		
Dominant substrate characterization					X		X	
Stream width		X		X			X	
Mode of stream depth during average summer flow					X			
Water level fluctuations								X
Stream margin substrate characterization (Y/N)		X						
Average velocity along stream margins		X		X				
Stream margin vegetation characterization				X				
Substrate food production potential				X				
Percent riffles	riffles					X		
Riffle substrate characterization		X	X	X		X		
Average velocity in riffles		X	X	X				
Average depth of riffles		X						
Average maximum depth of riffles						X		
Percent pools	pools	X	X	X			X	X

7.3.2 Smallmouth Bass HSI Model

Smallmouth bass were not collected from Tookany/Tacony-Frankford Watershed in 2004, and there is insufficient data to determine whether black basses (*Micropterus* spp.) ever established reproducing populations in non-tidal portions of the watershed. The smallmouth bass HSI model identified several habitat attributes that would be detrimental to bass. Like most centrarchids, smallmouth and largemouth basses are able to acclimate to brief periods of suboptimal dissolved oxygen concentration. However, continuous water chemistry analysis indicated DO concentrations at sites TF324, TF396, and TF620 may drop below 3mg/l for extended periods, yielding HSI scores of zero (Table 7-3). DO suppression at these sites is likely due to sewage inputs.

Site TF1120 had HSI score 0.90, and may have good habitat for smallmouth bass, but one might not expect bass to occur in large numbers at a site so near the headwaters (Drainage area ca. 5sq mi), especially considering the baseflow reduction that often accompanies increased impervious cover. It may be more feasible to establish/restore populations of other native centrarchids (e.g. redbreast sunfish and rock bass) in upper watershed sites. All other sites appear to be limited by the size and frequency of pools with appropriate cover, especially site TF760, which lacked pool habitats and received an HSI score of zero (Table 7-3).

Stream restoration activities that increase the amount of instream and overhanging cover, or activities that create, expand or improve pool habitats probably will result in increased habitat suitability for smallmouth bass. Re-meandering of the stream channel, installation of flow diverters such as rock vanes and J-hooks, as well as the creation of bank habitat through log sill cribbing and cantilevered banks should also enhance habitat for smallmouth bass, and other centrarchids, and forage fish. Infrastructure assessments, inspections, and dry weather pollution source trackdown activities will likely reduce the severity and frequency of water quality (*i.e.*, DO and pH related) impacts at some sites, particularly downstream of TF620. It is unlikely that habitat impairment due to frequent water level fluctuations and effects of erosion and sedimentation will be ameliorated in the near future without significant investments in streambank restoration and basin-wide implementation of stormwater BMPs.

7.3.3 Redbreast Sunfish HSI Model

As a generalist species, redbreast sunfish (*Lepomis auritus*) are adaptable to a range of habitat attributes and may feed opportunistically upon a variety of prey types. Most suitability index (SI) variable expressions in this species' HSI include a large range of highly suitable values (or large area "under the curve"). HSI scores (Table 7-4) did not correlate well with observed *L. auritus* abundance or biomass (the correlation was, in fact, negative). Limiting factors included vegetative cover, temperature, and substrate-related variables, but the discriminatory power of the HSI was probably limited by lack of variability and marginal habitat available at all sites. pH limitation was difficult to identify due to differences in data collection methods between sites. Though pH fluctuations due to algal activity occasionally result in pH >9.0, the Redbreast sunfish HSI model was not designed to be used with the least suitable value picked from a continuous database. Because fish can avoid areas of unsuitable pH when they occur infrequently, model input was modified to exclude the worst 5% of pH values.

Table 7-4 Redbreast HSI Data

HSI Variable	TF324	SI	TF396	SI	TF500	SI	TF620	SI	TF760	SI	TF975	SI	TF1120	SI

correlations	r^2 value
HSI: biomass/unit vol	**-0.21562**
HSI :abundance/unit vol	**-0.23605**

Likewise, summer temperature during spawning may poorly reflect habitat suitability for this species. The HSI was designed to be used throughout the species' range; temperature parameters should not be expected to be "optimal" in the temperate northeast. Fish may spawn at warmer downstream locations or in sunnier, sandy backwaters that are not accounted for in HSI model input. Observations made during electrofishing surveys suggested that Redbreast sunfish (and congeneric sunfishes) are most frequently found associated with cover, which can be difficult to measure quantitatively.

For example, site TF760 scored well for percent cover, due to the presence of many large boulders that were not exposed (Figure 7-4). Though this site was limited by a lack of pools and received a final HSI score of 0.2, it had the second greatest Redbreast sunfish abundance in Tookany/Tacony-Frankford Watershed. Fish collected were generally small (mean TL= 10.3 ±2.4; only four of 99 total individuals were >15cm). These findings reflect the fact that habitat requirements for a given species change over an individual's lifetime (as fish age they may require larger habitats for foraging) or even seasonally (such as specific substrate types and/or flow scenarios required during spawning). With more large, deep pool habitats, site TF 760 might support larger fish.

Figure 7-4 Instream Habitat at Cheltenham Restoration Site.

7.3.4 Longnose Dace

The longnose dace HSI model was applied to Tookany/Tacony-Frankford Watershed despite the fact that this species was not collected from the watershed in the 2004 fish survey. Longnose dace are, however, present in the nearby Pennypack and Wissahickon watersheds. This species is considered a riffle specialist, feeding and spawning in fast water in higher gradient, clear and cool streams. This species has good indicator potential, as hydrologic effects of urbanization tend to cause over-widening of stream channels, reduce baseflow and baseflow velocities, increase stream temperature, and generally make habitat unsuitable for this species.

High longnose dace HSI scores indicate favorable riffle conditions, not only for this species, but for a variety of other riffle dwellers such as margined madtoms and sensitive macroinvertebrate bioindicator taxa. High longnose dace scores might suggest that a site is appropriate for re-introduction, but scores in Tookany/Tacony-Frankford Watershed were marginal, reflecting general habitat unsuitability and stream instability caused by urbanized hydrology (Table 7-5). Stream restoration projects that are based in fluvial geomorphological (FGM) principles should help correct the problem of riffle substrate exposure due to overwidening (a universal problem in urbanized watersheds), while stormwater BMPs and infiltration projects could eventually begin to restore historic baseflow levels and mitigate the effects of scouring and sedimentation exhibited by streams with extensive impervious cover.

Table 7-5 Longnose Dace HSI Data

HSI Variable	TF324	SI	TF396	SI	TF500	SI	TF620	SI	TF760	SI	TF975	SI	TF1120	SI

7.3.5 Fallfish

Fallfish was the third species for which an HSI model was applied despite an apparent absence of the species within the watershed. Fallfish have many attributes that make them suitable as indicator species. They are long-lived, and the largest native minnow that occurs in Southeast PA, capable of attaining lengths over 30 cm (1ft.). Fallfish also build large gravel mounds over which to spawn, and bury their eggs within for protection. Changes in several factors that typically accompany increased urbanization may be implicated in fallfish habitat loss or decreased suitability (*e.g.*, range of substrate materials available for use in constructing spawning mounds, stability and sufficiency of baseflow depth, sediment oxygen state, and frequency of hydrologic disturbance).

The fallfish HSI model was too simplistic, incorporating only four variables as modified for Tookany/Tacony-Frankford Watershed, and final scores did not reflect decreased habitat suitability caused by urbanization (Table 7-6). For example, nearly all mainstem stream reaches are overwidened, riffles substrates are coarsened, and dry weather (*i.e.*, baseflow) flow characteristics (particularly depth) are poor. Pools and runs generally are affected by sedimentation and may not have stable substrate of appropriate size for fallfish nest building in combination with the appropriate flow regime. Sediments may be poorly oxygenated or even anoxic, especially in lower reaches of the watershed. This is an unsuitable condition for not only fallfish, but other egg-burying cyprinid species (*e.g.*, cutlips minnow, creek chub) and benthic macroinvertebrates. Frequent severe scouring flows may also scour away or bury and stifle eggs and various aquatic macroinvertebrate life stages. To be useful in an urban setting, the fallfish HSI model would have to be modified to account for some of these effects.

Table 7-6 Fallfish HSI Data

7.3.6 Blacknose Dace HSI Model

The blacknose dace HSI model was modified to suppress the influence of two limiting variables (gradient and stream margin substrate) because limitation by these factors is not evident in fish collections from Philadelphia area streams. Geography and topographic features undoubtedly influenced blacknose dace distribution, but the relationship between stream gradient SI scores and blacknose dace abundance was weak. Similarly, there was no strong relationship between stream margin substrate SI scores and blacknose dace abundance. While most sites generally had coarser margin substrates than would be desirable, shallow low velocity habitats that could be used as "nursery habitat" by immature fish were present at all sites but TF324.

Once modified, the HSI model was a fair predictor of blacknose dace abundance and biomass (Table 7-7). SLR analysis of HSI score with observed abundance and biomass yielded r^2 values of 0.62 and 0.67, respectively. The blacknose dace is classified as a "tolerant" fish. In fact, along with *C. commersoni*, *A. rostrata*, and *Fundulus* spp., blacknose dace is one of the most common fish in degraded streams in southeast PA. Blacknose dace appears to be an "upstream" species, abundance and biomass increased in an upstream direction. The stream gradient factor in the HSI model probably addresses this aspect of the species' ecology. Life history strategies and morphological features that allow blacknose dace to exploit upstream reaches of natural streams may partially explain its dominance of streams that are hydrologically impaired due to urbanization.

Blacknose dace is a stocky fish, moderate in body form and somewhat rounded (dorsoventrally flattened) in comparison to vertically compressed minnows. Hydrodynamics may contribute adaptability to a variety of flow conditions and, in part, explain its abundance at degraded sites that are periodically exposed to intense scouring flows. Over-widening of channels and coarsening of stream substrate are typical of streams that are exposed to extremes in hydrology. Blacknose dace appear resilient to these factors. Other minnow species may not be as well adapted for these effects.

7.3.7 Creek Chub HSI Model

The creek chub HSI model produced good results overall. HSI score was correlated with creek chub abundance and biomass (SLR, r^2= 0.78 and 0.72, respectively). Furthermore, sites where no fish were collected had the lowest HSI scores in the watershed and the site with the highest HSI score had the greatest abundance and biomass in the watershed (Table 7-8). The HSI model scale of resolution was greatly compacted. Only two creek chubs were collected from four sites that were deemed unsuitable (HSI=0). The limiting factor in these cases was identified as low dissolved oxygen, which corroborates results of continuous water quality monitoring (Table 5-6). However, USFW scientists did not have access to continuous water quality data when building the model so it may be inappropriate to choose the lowest value from a continuous database.

Though creek chubs and blacknose dace share some habitat associations and both tended to be more numerous in upstream reaches, creek chubs generally showed a stronger affinity for narrower streams with abundant pools and overhead cover. For example, creek chub biomass increased almost tenfold from site TF975 to TF1120, while blacknose dace biomass decreased between these sites which differ greatly in width, percent pools, and surface to volume ratio. Blacknose dace biomass seemed more closely tied to stream surface area, while creek chub biomass seemed more attuned to volume, which may reflect the latter species' stronger association with pool habitats (Jenkins and Burkhead, 1993).

A similar effect was noted at site TF760, which was wide and lacked pool habitats. While blacknose dace biomass was reduced at site TF760 relative to the two upstream sites, creek chubs were nearly absent. Unlike creek chubs, blacknose dace did not show a strong association with pools. This site also had the most violations of daily minimum DO of all Montgomery County sites, which reinforces the view that blacknose dace are more tolerant of low DO than creek chubs.

With 20 habitat and water quality variables and 5 life requisite components, the creek chub HSI model was most complex of the models used (Table 7-2). As many water quality variables returned optimum suitability values (*i.e.*, SI= 1.0, Table 7-8), and most had limited discriminatory power, the model could be made simpler without sacrificing predictability. It is likely that if a smaller number of critical habitat variables were focused on, the model could have better resolution over a larger scale of final HSI scores.

7.3.8 Common Shiner HSI Model

Common shiner HSI model results were fair. The model performed well in identifying unsuitable conditions in the lower watershed, but did not help explain the absence of common shiners from site TF1120, which had the highest HSI score in the watershed (Table 7-9). Due almost entirely to this site, SLR coefficients between HSI score and common shiner abundance and biomass were lowered: r^2= 0.45 and 0.48, respectively (However, if site TF1120 were ignored, r^2 values increased to 0.92 and 0.93, respectively). The HSI score at site TF760 was zero, due to a lack of pools, and though the species was collected at site TF760, abundance and biomass were reduced compared to mid-watershed sites with more pool habitat available.

Common shiners were most abundant in Tacony Creek in the City of Philadelphia at sites TF500 and TF620. These sites had the best diversity, fish index of biological integrity (IBI), and modified index of well-being (MIWB) scores in the watershed Table 7-9. Much like the redbreast sunfish model, SI variables used are general in nature, and contain a large range of suitable values (redbreast sunfish and common shiners are both considered generalist species). Interspecific competition, low productivity, water quality and hydrologic perturbations are among the possible explanations for low common shiner abundance in upstream segments of Tookany/Tacony-Frankford Watershed.

7.4 Sensitivity Analysis

A pseudo-Monte Carlo approach was used with all HSI models to determine which habitat attributes were most sensitive, and thus influential in the final HSI score. Data for all variables was compiled and basic statistics (*i.e.*, mean, standard deviation, range) were computed. Most physicochemical variables were found to most closely fit a normal (Gaussian) distribution, while other parameters (*e.g.*, stream width, percent shade) best fit an even distribution, so two separate random number generators (Microsoft Excel and Statistica) were used to obtain an array of values for model input. Each case in the array was a combination of random values within the range of values that might have come from a stream in Tookany/Tacony-Frankford Watershed. In combining the randomly generated results, variables were considered completely independent, so some combinations of random input values were less realistic than others (*e.g.*, very low average yearly temperature and very high growing season temperature; very wide stream with 100% shade; severe DO fluctuations and stable pH). To be sure, Interdependencies exist between some variables, but these relationships were difficult to quantify and build into the Monte Carlo procedure. It was assumed that the influence of these unlikely combinations would be suppressed by using a large number of iterations.

The habitat attribute input array for each HSI model was used with the model to compute the final HSI score for each case in ten trials of 1000 iterations each, for a total of 100,000 iterations in total for each model. Values for the input array were re-computed between trials, and the correlation of each variable with final HSI score was computed after each trial. After ten trials were completed, habitat attributes were ranked according to the mean of their correlation scores. In interpreting sensitivity analysis results, it should be noted that many variables were almost always completely suitable (*i.e.*, SI=1) and not found to be important in determining the HSI score for a given species. Those variables that have a limiting effect are thus more likely to influence the score than variables that tend to maintain the total score at or near complete suitability (*i.e.*, HSI=1). If the situation was reversed and many habitat variables were influential and less suitable, a variable or variables that tended to increase scores would be more influential.

Blacknose Dace

Sensitivity analysis showed that stream width was the most important attribute in determining habitat suitability for blacknose dace (Table 7-10). This corroborates results of the 2004 fish assessment, and other records in the PWD bioassessment database which have shown the species to be more abundant in upstream reaches. Stream gradient would likely have ranked high in HSI influence, had the model been adequately calibrated to the range of stream gradient values present in Tookany/Tacony-Frankford Watershed, as mainstem sites were generally found to have milder slopes than upstream and tributary sites. During the infrastructure assessment procedure in which PWD biologists walked entire segments of the stream, blacknose dace were observed in very small tributaries that originate in stormwater pipes, in some cases even in small disconnected pools left by intermittent streams. Blacknose dace is assumed to be a fast colonizer of these small tributaries, feeding primarily on dipteran larvae (*e.g.*, chironomids, mosquitoes).

Table 7-10 Blacknose Dace HSI Model Sensitivity Analysis

HSI Variable	*r* value	*r*²	rank
Stream Width	0.60	0.36	1

Velocity in Riffles (juvenile)	0.04	0.00	
Temperature (growing season)	0.03	0.00	
Percent pools	0.02	0.00	
Percent shaded	0.01	0.00	
Velocity in Riffles	0.01	0.00	

Common Shiner

Common shiner is described as primarily a pool shiner (Jenkins and Burkhead 1993, Trial and Nelson 1983), and "percent pools" was found to be the second most influential variable in final HSI score (Table 7-11). It was unusual, however, that riffle attributes were found to be so influential in final HSI score. Exceptional sites such as TF396 that were steep in gradient and not overwidened tended to have greater velocity in riffles. Habitat at sites such as TF396, while highly desirable overall and good for a majority of indicator species, is actually not as suitable for common shiners as more degraded sites. So, in this case, riffle velocity and substrate had an important influence on total HSI score. Common shiners do not appear to exploit small streams and upstream reaches, as do blacknose dace and creek chubs; rather they show a preference for larger, mid-watershed stream segments with a mix of pool habitats, especially if large, slow pools are present.

Table 7-11 Common Shiner HSI Model Sensitivity Analysis

HSI Variable	r value	r²	rank

Percent pools	0.37	0.14	2
Riffle Substrate Category	0.19	0.04	3
Pool Class	0.08	0.01	
Max. Summer Temperature	0.07	0.01	
Velocity in Pools	0.02	0.00	

Creek Chub

As mentioned previously, the creek chub HSI model includes a large number of habitat attribute input variables (n=20), many of which nearly always scored perfect suitability (SI=1). A small number of variables were very powerful in the analysis, and seemed to perform well in estimating habitat suitability (Table 7.8). In the original HSI analysis of Tookany/Tacony-Frankford Watershed data, minimum oxygen concentration in spring and summer limited suitability at all sites in Philadelphia and site TF760.

When the sensitivity analysis was initially run using a simple random number generator that limited the output values to a range with even distribution, DO variables were very important, accounting for a majority of the variance in HSI total score (Table 7.12). However, when the sensitivity analysis was performed using randomly generated, normally distributed minimum oxygen values, the influence of spring DO concentration was reduced and summer DO concentration was almost negligible (Table 7.12). The pH habitat suitability factor was an ordinal variable (only three categories were valid input values as applied to the Tookany/Tacony-Frankford Watershed) and thus very influential on the total HSI score once DO input variables were converted to an array of values fitting the normal distribution. As pH and oxygen fluctuations are inter-related, it may be sufficient to say that downstream sites that exhibit problems with either variable will be generally unsuitable for creek chubs.

Fallfish

Sensitivity analysis performed with the fallfish HSI model suggested that substrate and temperature variables had the most influence on total HSI score (Table 7-14). The model was very simple, and since the species was not collected from Tookany/Tacony-Frankford Watershed, there was no opportunity to compare model output with observed fish data.

Table 7-14 Fallfish HSI Model Sensitivity Analysis

Longnose Dace

The longnose dace HSI model was similar to the fallfish model in that it did not appear to have a sufficient number of input variables to estimate habitat suitability for the species. Results of sensitivity analysis suggested that the longnose dace model was very sensitive to stream velocity (Table 7-15). Many sites in Tookany/Tacony-Frankford Watershed probably do not have the swift flowing riffles with moderate depth during baseflow that this species needs in order to thrive. Unfortunately, the one site that appeared to have adequate physical habitat, TF396, probably could not support a population of longnose dace due to water quality problems.

Table 7-15 Longnose Dace HSI Model Sensitivity Analysis

Percent Riffles	0.011341	0.000912	

Redbreast Sunfish

The redbreast sunfish HSI model used an ordinal (*i.e.*, categorical) variable for minimum dissolved oxygen concentration, and suggested that habitat suitability for this species is not adversely affected at 5.0 mg/l and is still moderately suitable (SI=0.70) at 3.0mg/l (Aho, *et al*. 1986). Results were very similar to the creek chub model. In the absence of influence from DO concentration, pH was very influential, overshadowing the other variables (Table 7-16). As mentioned previously, pH and DO fluctuations are interrelated, and sites that exhibit severe fluctuations in either DO or pH will be less suitable habitat for redbreast sunfish and fish in general.

Table 7-16 Redbreast Sunfish HSI Model Sensitivity Analysis

HSI Variable	r value	r^2	rank
Least suitable pH observed	0.830002	0.68896	1

Max temp growing season	0.00385	0.000558	

Smallmouth Bass

The smallmouth bass HSI model was considered to be the most comprehensive and refined of all HSI models used. One explanation for this is the fact that Smallmouth bass are large predators and economically important. All factors appear to have been considered and included in the model, yet there are few extraneous factors. The only shortcoming was the number of variables defined by ordinal data.

When minimum DO concentration values were generated for sensitivity analysis input as a range of values with an even distribution, low DO values appeared frequently in the input array and the influence of DO concentration on final HSI score was the most important factor (Table 7-17). When minimum DO input values were fitted to a normal distribution, the incidence of low DO concentrations was much less and the overall influence of DO on the final HSI score decreased and physical habitat features became much more influential. Unfortunately, no smallmouth bass were collected from Tookany/Tacony-Frankford Watershed, so further interpretation of the model output was not possible. Factors the model suggested were influencing habitat suitability (*i.e.*, substrate type, percent pools and DO) were considered to be limiting for other indicator species as well.

Section 8
Indicator Status Update

Overview

An important component of the Comprehensive Characterization Report is a concise update on the biological, chemical and physical conditions within the Tookany/Tacony-Frankford Watershed. Indicator status updates derived within this report will be used as a tool for identifying spatial and temporal trends of a particular stream reach or for the entire watershed. Moreover, indicators defined in the Tookany/Tacony-Frankford Integrated Watershed Management Plan (TTFIWMP) will serve as benchmarks for future restoration projects. The indicators addressed in this section are:

- Indicator 3: Stream Channels and Aquatic Habitat
- Indicator 5: Fish
- Indicator 6: Benthos
- Indicator 7: Effects on Public Health (Bacteria)
- Indicator 8: Effects on Public Health (Metals and Fish Consumption)
- Indicator 9: Effects on Aquatic Life (Dissolved Oxygen)

8.1 Indicator 3: Stream Channels and Aquatic Habitat

Indicator 3 of the TTFIWMP stresses the importance of physical habitat features that will support healthy fish and benthic communities. As described in Section 3.8.1, thirteen habitat variables, ranging from instream parameters to riparian zone width and quality were compared against reference conditions to obtain an overall habitat integrity score.

In 2004, PWD staff biologists surveyed habitat at 12 sites throughout the Tookany/Tacony-Frankford Watershed. Monitoring locations along the mainstem of Tookany Creek (Montgomery County) received uniform scores of “Non-Supporting”, indicating a region of severe habitat degradation (Figure 8-1). In general, upstream reaches in Tookany Creek lacked habitat heterogeneity, possessed poor riparian zones, and experienced high levels of channelization. Moreover, poor bank stability and exaggerated levels of sediment deposition also contributed to the poor aquatic habitat in the upper portions of the watershed.

Habitat values in the middle portion of Tacony Creek varied among sites, ranging from “Non-Supporting” to “Supporting” (*i.e.*, good). With the exception of site TF 396, a site with exceptional habitat for an urbanized stream, assessment sites in Tacony Creek possessed the same attributes as the upstream reaches (erosion, poor bank stability, reduced riparian zones and heavy sediment deposition).

Rock Creek and Jenkintown Creek sites, the two surveyed upstream tributaries, both were rated as partially supporting, indicating slightly better habitat conditions relative to the mainstem.

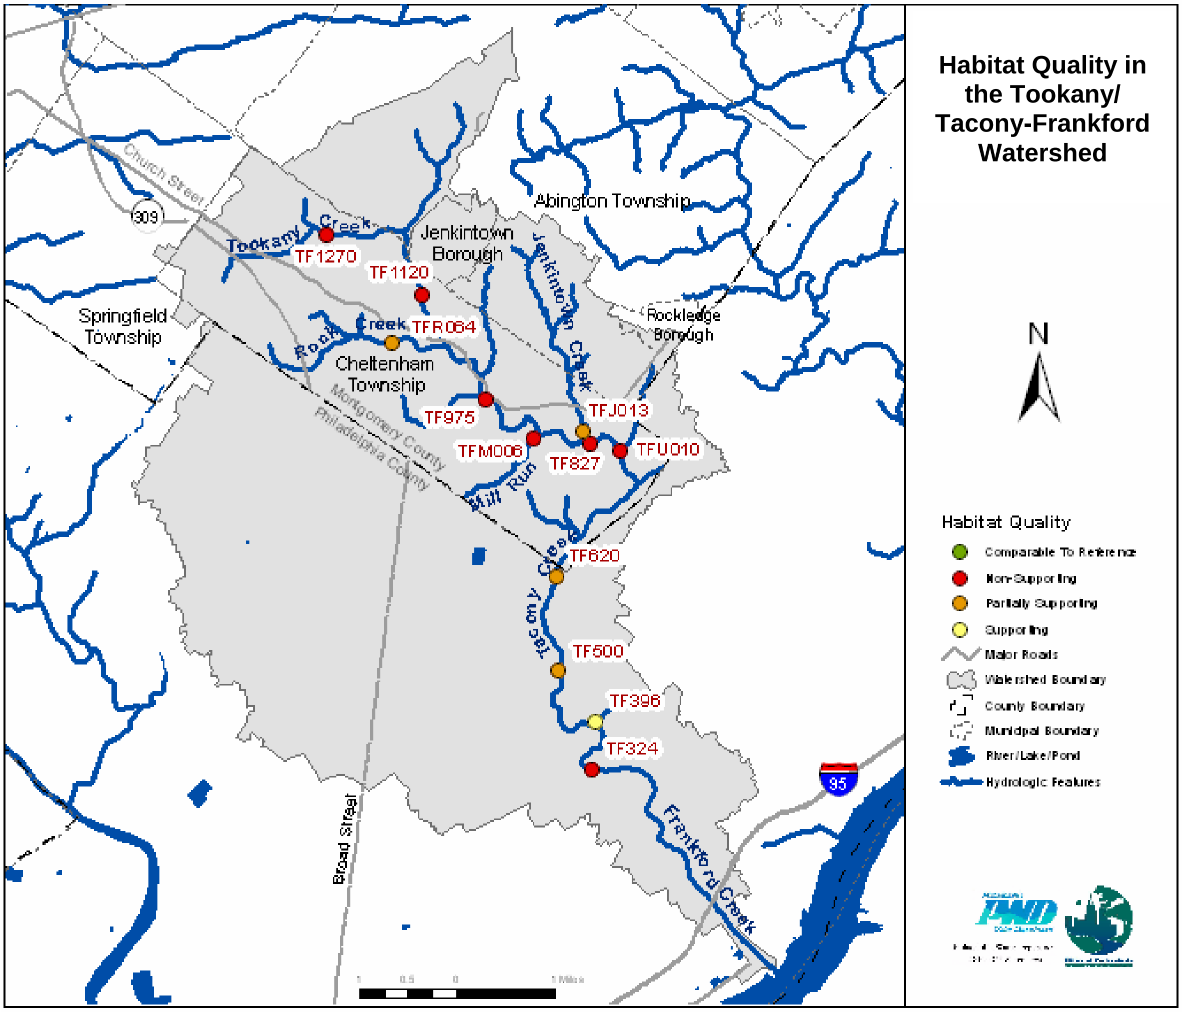

Figure 8-1 Tookany/Tacony-Frankford Watershed Habitat Quality Indicator Status Update.

8.2 Indicator 5: Fish

During 2000, three surrogate indicators were used to define the integrity of fish communities in the Tookany/Tacony-Frankford Basin. Relative abundance (*i.e.*, density), pollution tolerance, and number of native species provided a semi-quantitative measurement of fish assemblage health. With the development of ecoregion-specific metrics, PWD replaced these early indicators in 2004 with the Index of Biological Integrity (IBI), a multi-metric approach that characterizes fish community health at a particular stream reach or at the watershed scale (Section 3.6).

Fisheries data revealed a mean IBI score of 21 (out of 50), placing the Tookany/Tacony-Frankford Watershed in the “poor” category for fish community health (Figure 8-2). Low diversity, absence of benthic insectivorous species, absence of intolerant species, skewed trophic structure dominated by generalist feeders, high percentage of individuals with disease and anomalies, and high percentage of dominant species are characteristics of a fish community with "poor" biotic integrity. Spatial trends showed that only two sites received a "fair" IBI score, both located in Tacony Creek Park in the City of Philadelphia. Similar spatial trends revealed that Modified Index of Well-Being (MIWB) and Shannon Diversity Index values, which are measures of diversity and abundance, were lowest in the lower and upper monitoring stations and highest in the middle of the watershed, mirroring the habitat indicator results. Overall, monitoring stations in the central portion of the watershed had higher biological integrity and thus environmental quality, than either downstream or upstream stations.

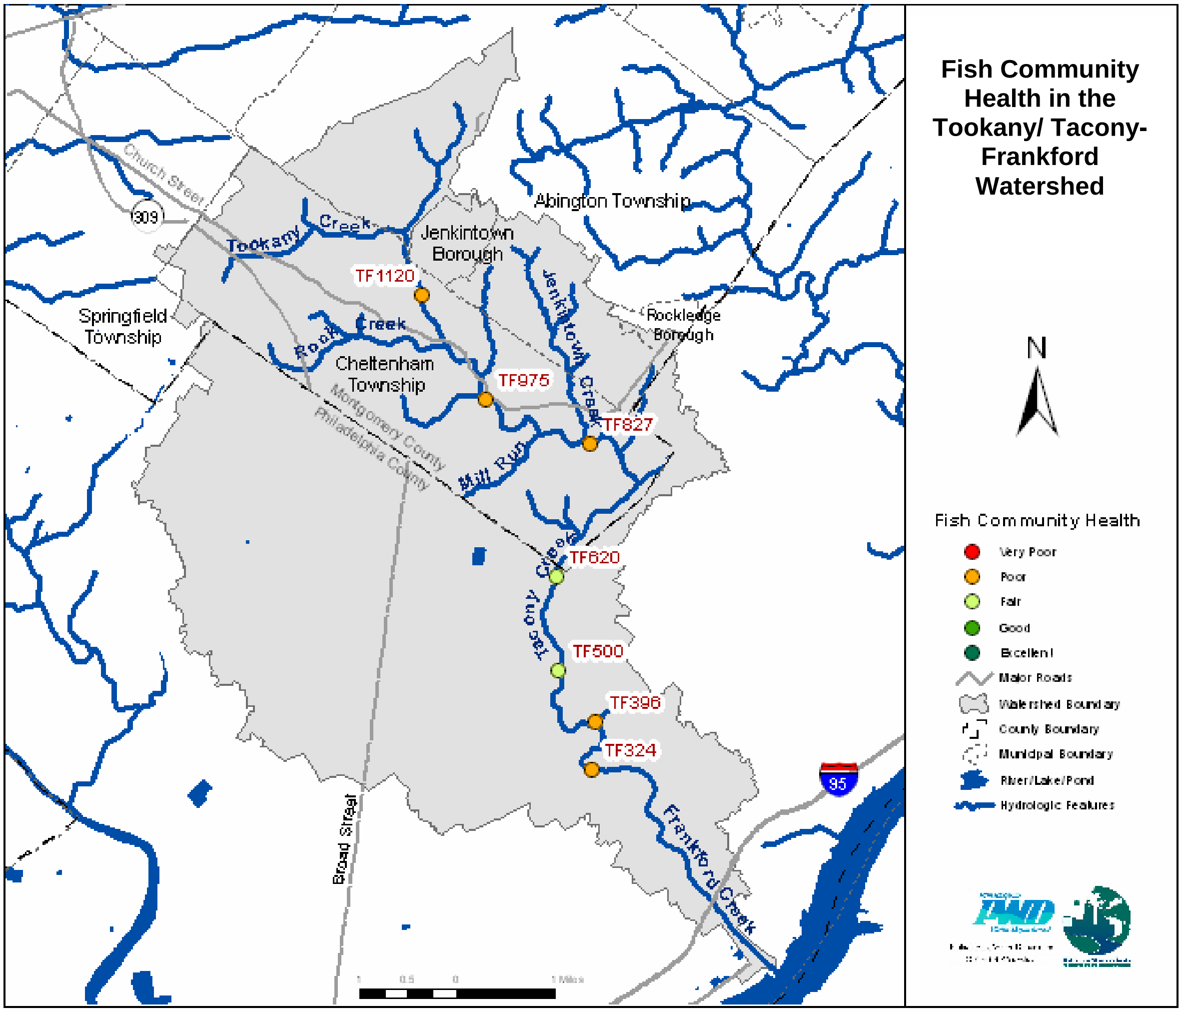

Figure 8-2 Tookany/Tacony-Frankford Watershed Fish Indicator Status Update

8.3 Indicator 6: Benthos

Benthic macroinvertebrate monitoring occurred at 12 sites in Tookany/Tacony-Frankford Watershed during 2004. Similar to the 2000 sampling effort, Rapid Bioassessment Protocol III (RBP III) was chosen as the approved method for assessing the condition of the macroinvertebrate community in Tookany/Tacony-Frankford Watershed.

The assessment conducted in 2004 reconfirmed earlier findings of the Pennsylvania Department of Environmental Protection (PA DEP) and Philadelphia Water Department (PWD). Benthic impairment in Tookany/Tacony-Frankford Watershed was omnipresent;

with the exception of Jenkintown Creek, all stream segments were designated "severely impaired" (Figure 8-3).

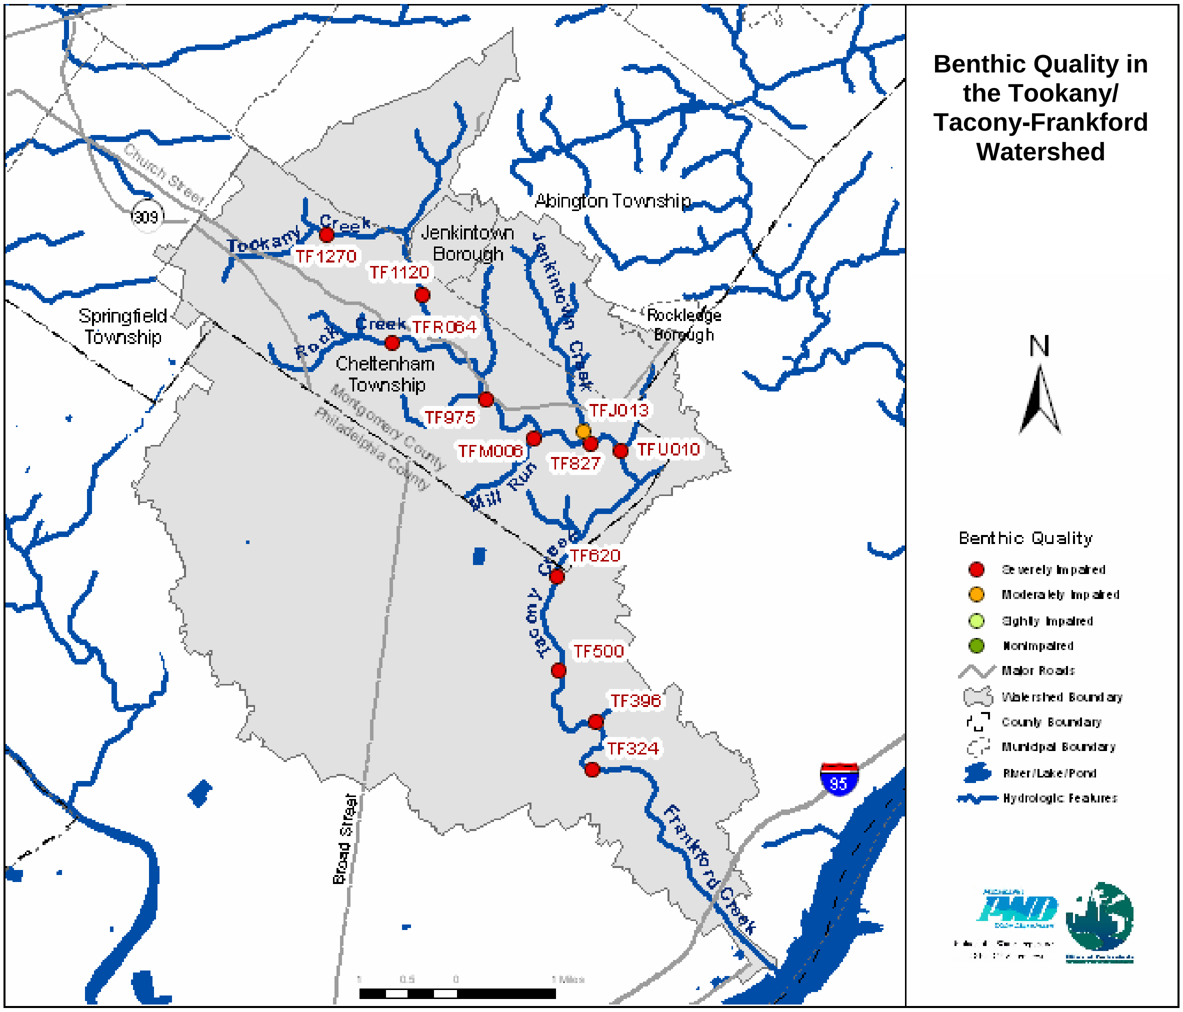

Figure 8-3 Tookany/Tacony-Frankford Watershed Benthic Indicator Status Update.

The severity of impairment throughout Tookany/Tacony-Frankford Watershed suggests that attaining healthy benthic communities in mainstem localities and associated tributaries is not a feasible option at this time. Habitat restoration, flow attenuation and possibly, active re-introduction (*i.e.*, "invertebrate seeding") may be the only solutions to ensure a viable benthic community within this watershed.

8.4 Indicator 7: Public Health Effects (Bacteria)

Based on Pennsylvania's water quality criteria, the maximum fecal coliform concentration during the swimming season (*i.e.*, May 1 through September 30) shall not exceed a geometric mean of 200 colony forming units (CFU) per 100 ml for five non-consecutive samples. During the remainder of the year, the maximum fecal coliform concentration should be equal to or less than a geometric mean of 2000 CFU per 100 ml based on five samples collected on different days.

Discrete chemical samples taken at ten sites (n=10) in Tookany/Tacony-Frankford Watershed between 2000 and 2004 were used to calculate the percentage of samples meeting the appropriate standard (*i.e.*, swimming vs. non-swimming seasons) during wet and dry periods.

During dry weather, fecal coliform concentrations from May 1st through September 30th were placed in the “red” category (met standards less than ninety percent of the time) at all sites in Tookany/Tacony-Frankford Watershed (Figure 8-4). Between 91.1% - 100% of samples at all sites along Tookany-Tacony/Frankford mainstem did not meet the water quality standard of 200 CFU/100 ml during dry weather. Conversely, all sites with the exception of TF 280 met the non-swimming standard (2000 CFU/100 ml) greater than ninety-eight percent of the time during dry periods (Figure 8-4).

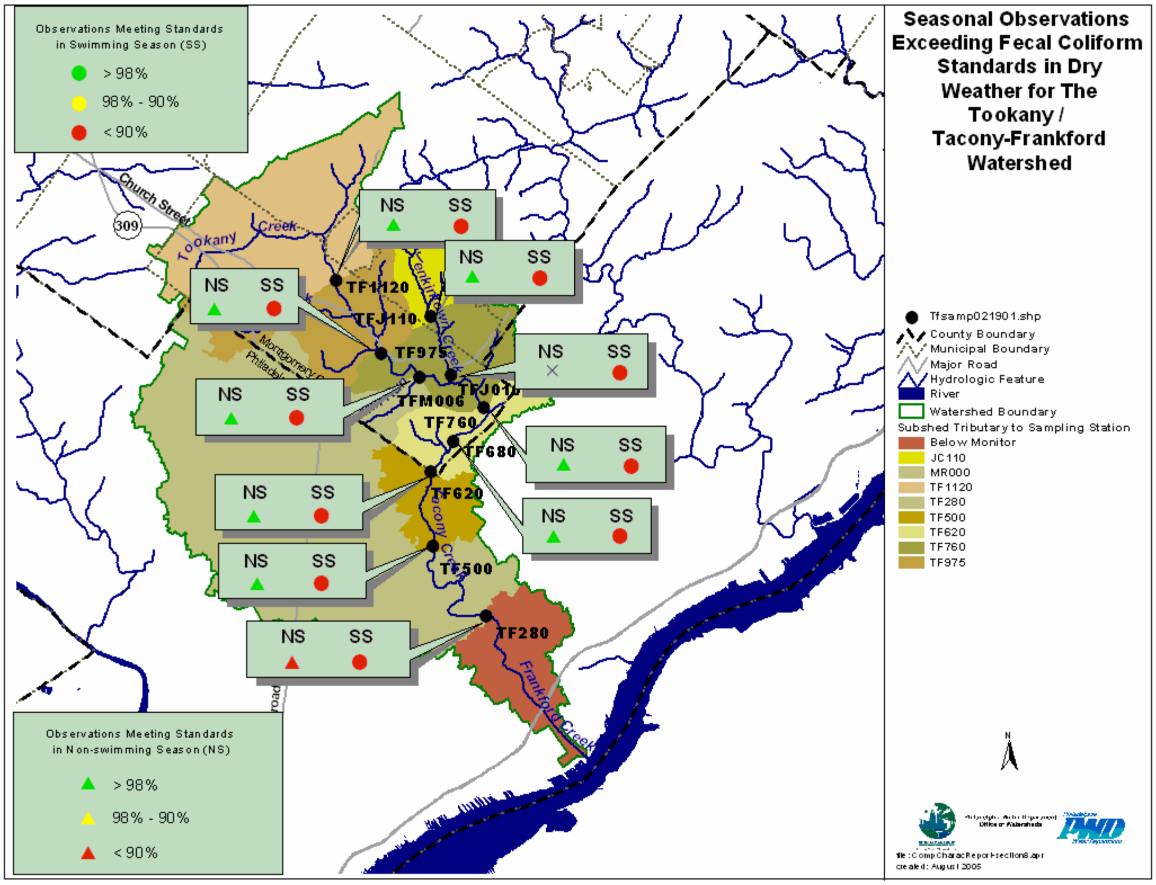

Figure 8-4 Fecal Coliform Samples Meeting Standards in Dry Weather during the Swimming and Non-Swimming Seasons.

Wet weather sampling results showed concentrations of fecal coliform exceeding water quality standards at all mainstem sites in Tookany/Tacony-Frankford Watershed during swimming and non-swimming seasons (Figure 8-5). Approximately 87.5% to 100 % of samples taken during the swimming season at the mainstem sites exceeded standards. Samples taken during the non-swimming period showed similar results with exception of the two major tributaries, Mill Run and Jenkintown Creek. Samples taken at these localities met the water quality standards greater than 98% of the time (Figure 8-5).

Figure 8-6 depicts the relationship (*i.e.*, magnitude of departure) between the geometric mean of fecal coliform concentrations and the appropriate standard at each site during dry and wet weather conditions. During the swimming season, concentrations of fecal coliform exceeded the standard at all locations along mainstem Tookany and Tacony Creeks in dry and wet weather. Most pronounced were sites TF500 and TF975, with fecal coliform levels exceeding the standard by a factor of 5 (*i.e.*, >1000 CFU/100 ml) during dry periods. Other sites along the continuum ranged between 1 to 4 times the standard during dry weather. All sites, with the exception of TFJ110, showed concentrations greater than five times the standard during wet weather.

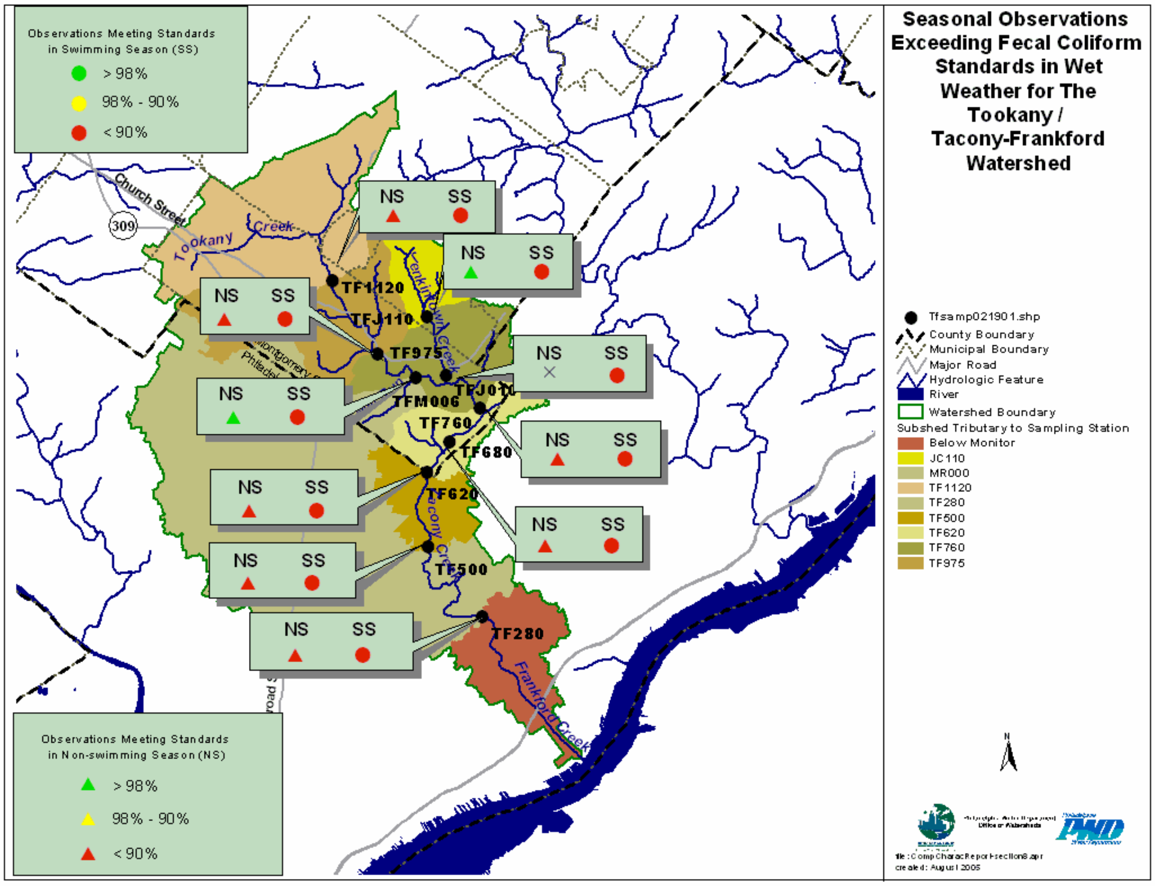

Figure 8-5 Fecal Coliform Samples Meeting Standards in Wet Weather during the Swimming and Non-Swimming Seasons.

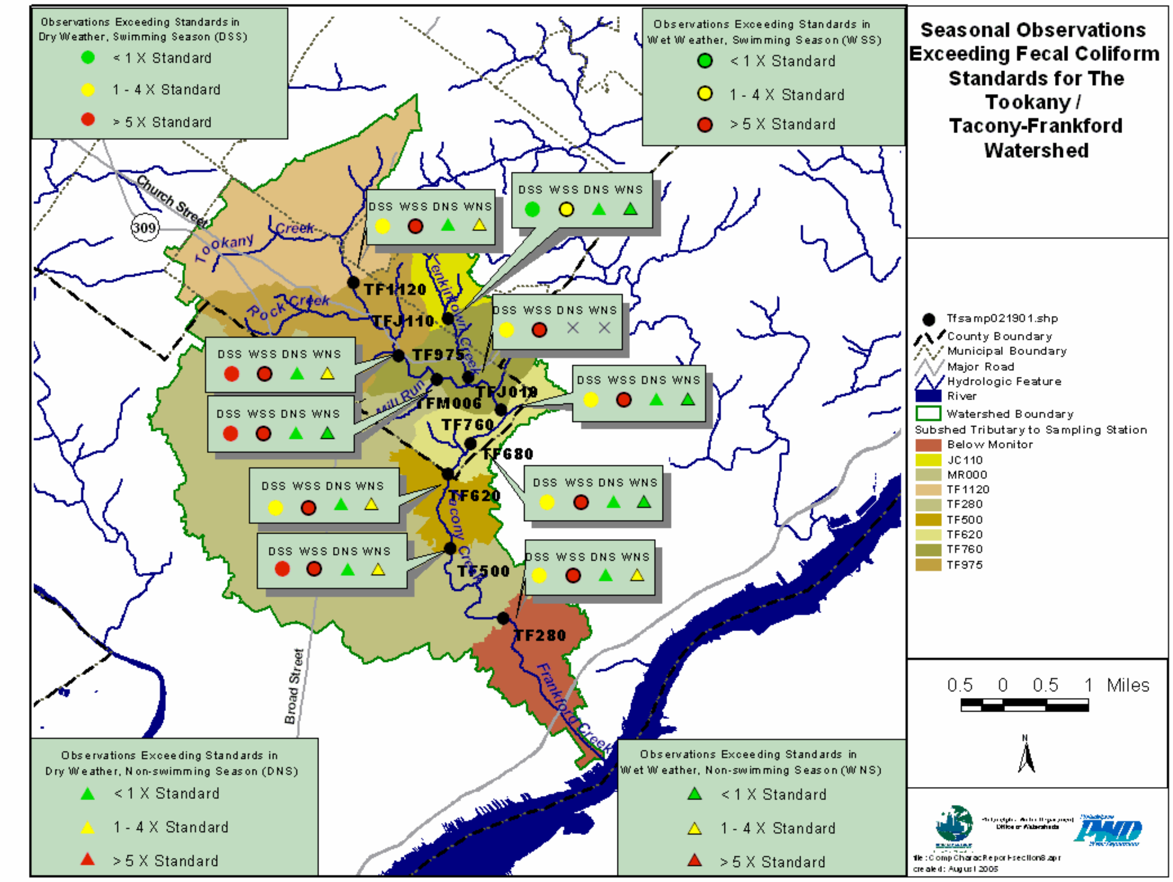

Figure 8-6 Seasonal Observations Exceeding Fecal Coliform Standards during Dry and Wet Weather

8.5. Indicator 8: Public Health Effects (Metals and Fish Consumption)

Relatively small amounts of certain toxic compounds can kill aquatic life through acute poisoning, while chronic levels may be harmful to developmental stages of fish and macroinvertebrates. For example, bioaccumulation of toxins in fish may have a profound effect on fecundity and may also pose a threat to humans who regularly consume fish. The established indicator measures the percent of aluminum, cadmium, chromium, copper, lead and zinc samples meeting state standards at various sites in Tookany/Tacony-Frankford Watershed.

Results suggest acute standards intended to protect aquatic life were met at all locations during dry-weather, while concentrations for aluminum exceeded chronic standards at most localities (Figures 8-7 and 8-8, respectively). Similarly, concentrations of aluminum exceeded acute standards regularly during wet conditions (Figure 8-7). In addition, copper generally exceeded acute standards during wet weather more than 10 % of the time at sites TFM006, TF620 and TF280.

Figure 8-9 represents observations of samples exceeding human health standards for toxic metals. As shown, all sites met standards greater than 98% of the time during dry and wet conditions.

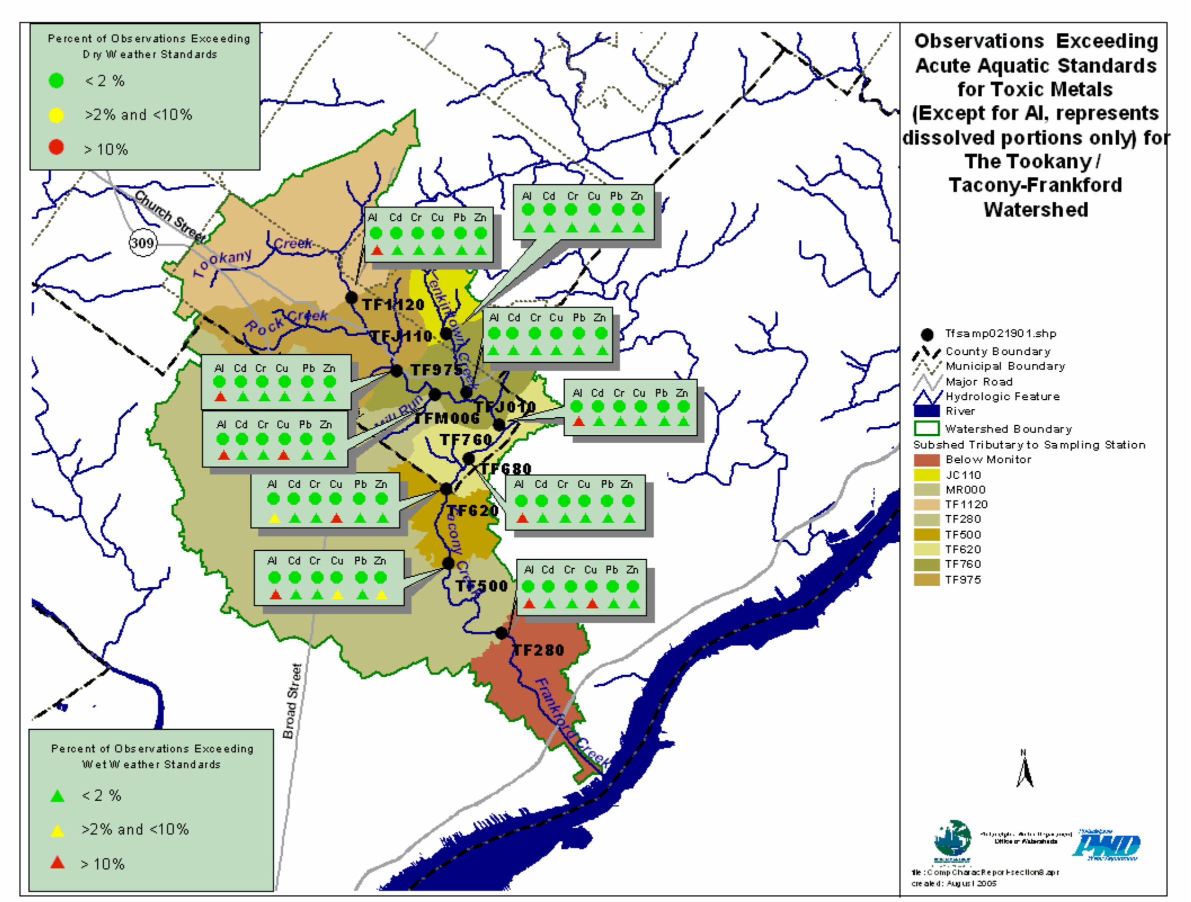

Figure 8-7 Acute Aquatic Standards for Toxic Metals during Wet and Dry Conditions.

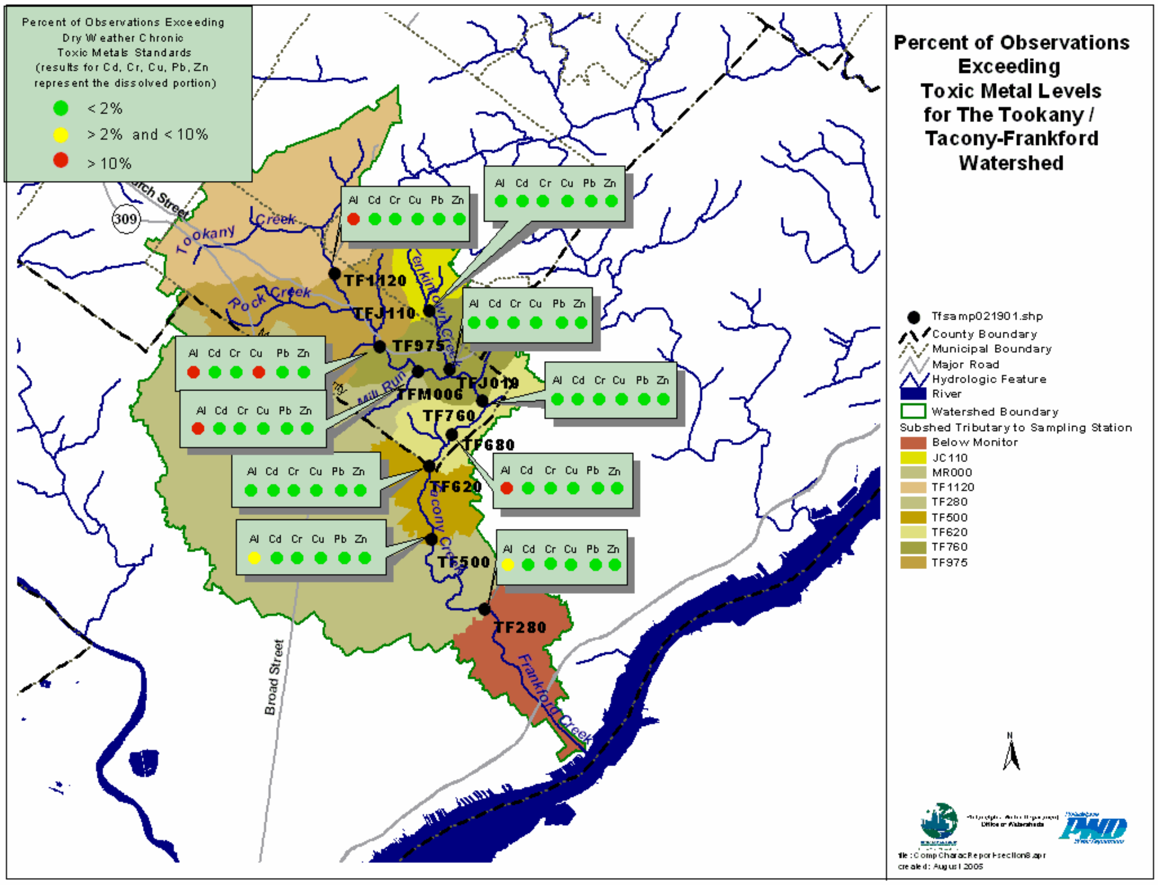

Figure 8-8 Percent Exceedance of Dry Weather Chronic Toxic Metals Standards.

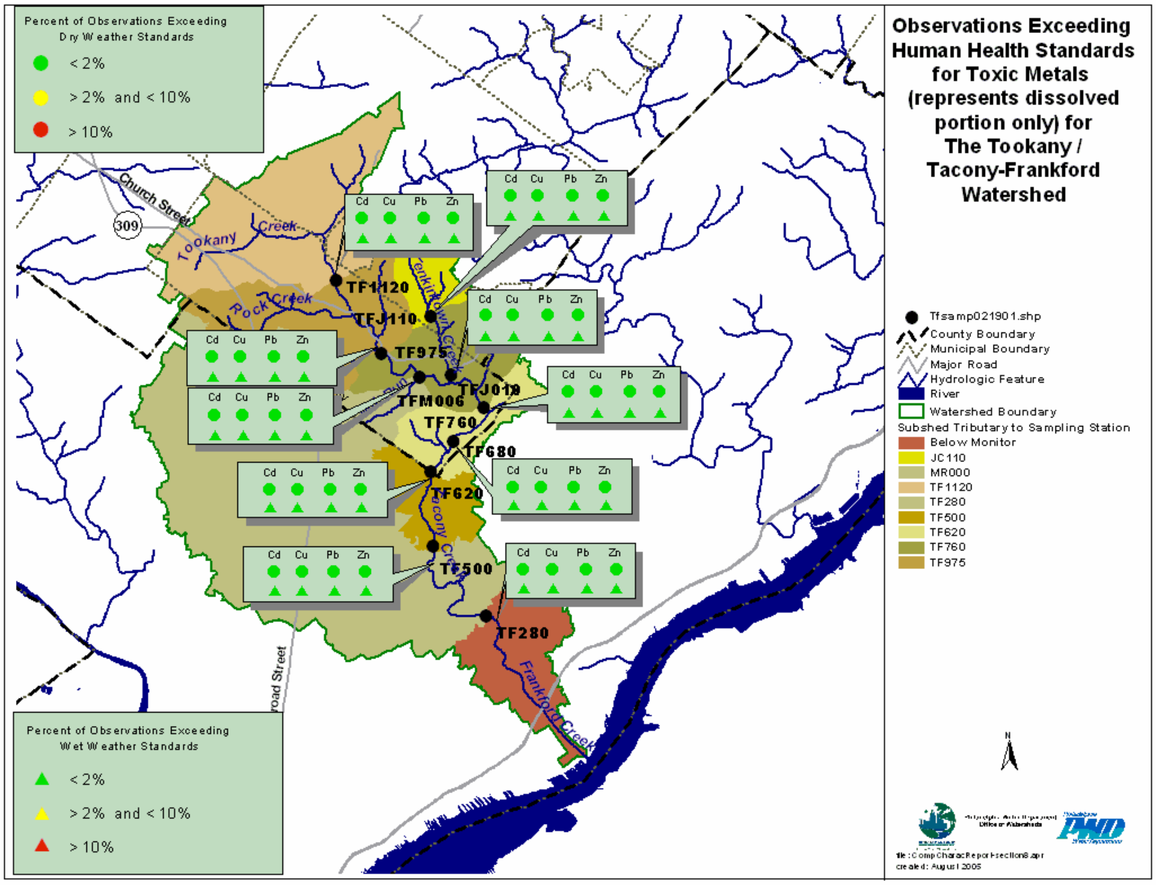

Figure 8-9 Observations Exceeding Human Health Standards for Toxic Metals in Wet and Dry Weather.

8.6. Indicator 9: Aquatic Life Effects (Dissolved Oxygen)

Automated water quality monitors (*i.e.*, Sondes) were deployed in Tookany/Tacony-Frankford Watershed at seven locations along the mainstem and three locations in major tributaries between 2000 and 2004. Sondes were deployed for approximately two-week periods, recording dissolved oxygen concentrations (mg/L) every 15 minutes. Upon completion of a cycle, Sondes were retrieved from the stream and exchanged for a reconditioned unit.

Continuous data from the mainstem sites indicated that daily average DO concentrations met minimum standards (daily average >5 mg/L of O_2,) greater than 90% of the time (Figure 8-10), with some locations meeting standards greater than 98% of the sampling period. Similar results were observed in Mill Run and Jenkintown Creek. Daily minimum standards for dissolved oxygen (instantaneous minimum 4 mg/L of O_2), however, indicate a potential problem in the downstream portion of the watershed. Site TF280 met minimum daily standards less than 90% of the sampling period while all other locations met the daily minimum standard between 90% and 100 % of the time.

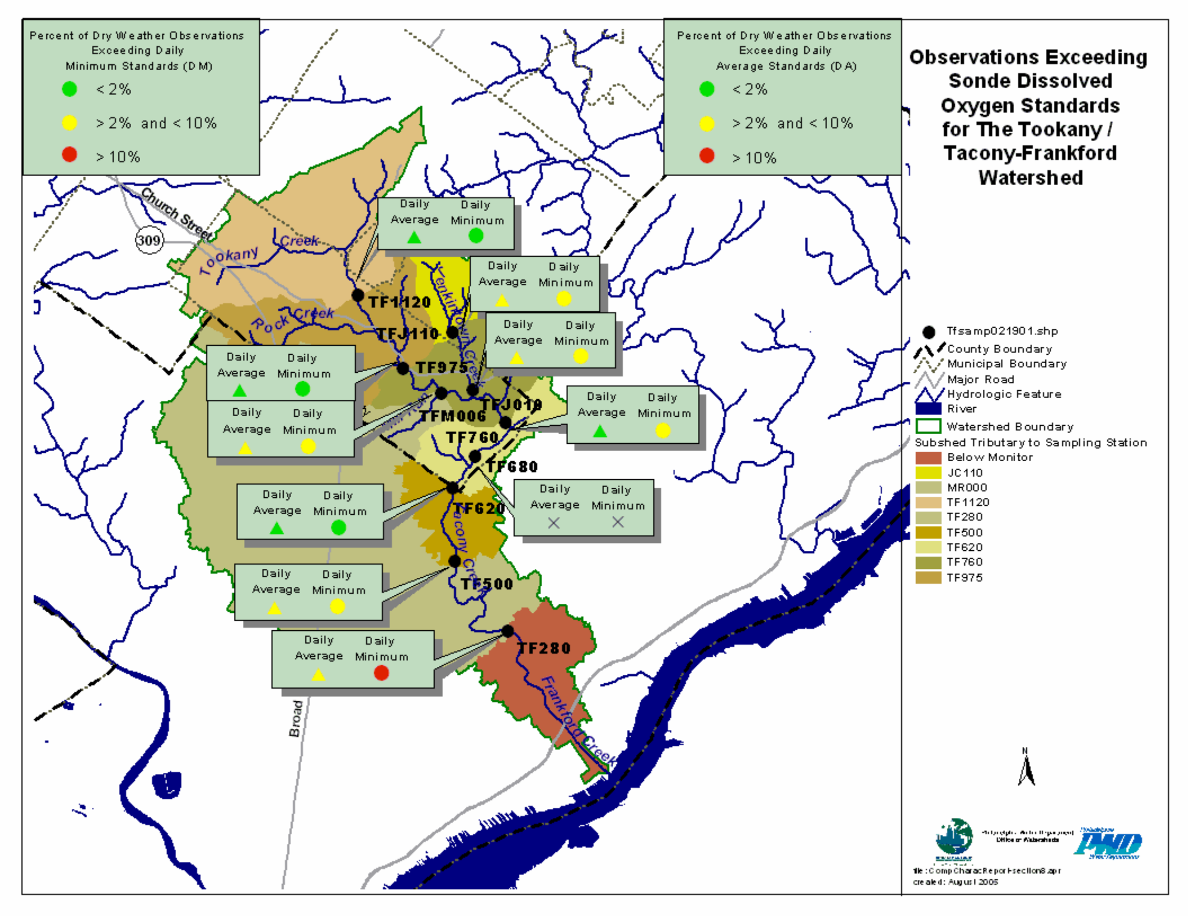

Figure 8-10 Observations Exceeding Dissolved Oxygen Standards.

Section 9
Active and Potential Sources of Water Quality Constituents

9.1 Model Description and Data Sources

9.1.1 Introduction

This subsection summarizes the results of a preliminary estimate of loading rates of various pollutants to Tookany/Tacony-Frankford Creek and tributaries. The waters in the drainage area receive point source discharges including CSO and other urban and suburban stormwater, sanitary sewer overflows, and limited industrial storm, process, and cooling waters. Combined sewers service approximately 47% of the watershed. Nonpoint sources in the basin include atmospheric deposition, limited direct overland runoff from urban and suburban areas, and limited individual on-lot domestic sewage systems discharging through shallow groundwater. Results for the Tookany/Tacony-Frankford Watershed were obtained using the detailed Storm Water Management Model (SWMM).

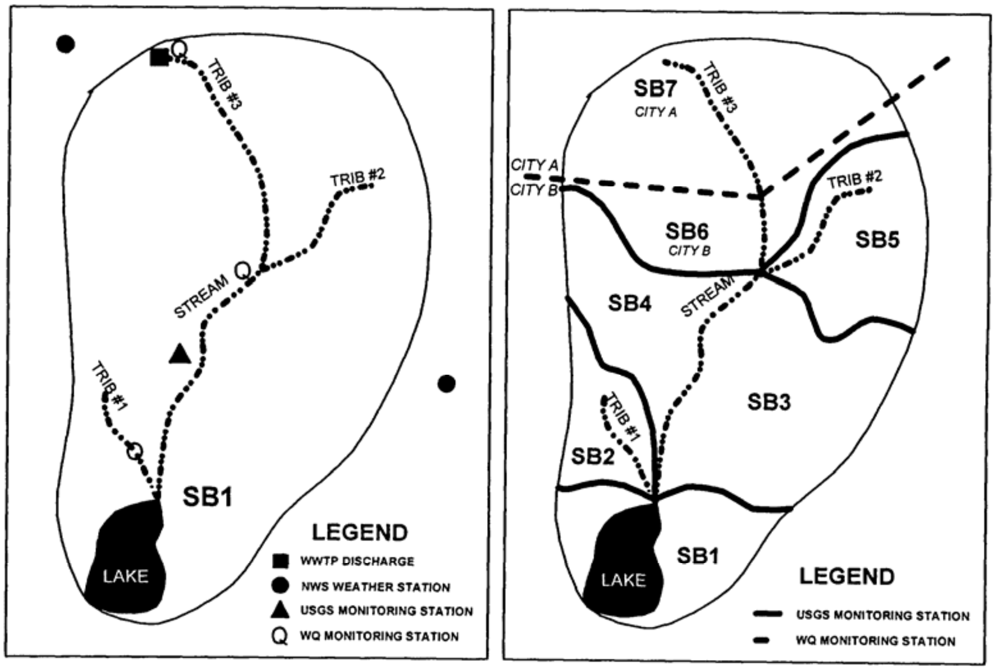
9.1.2 The Storm Water Management Model (SWMM)

The U.S. EPA's Storm Water Management Model (SWMM) was used to develop the watershed-scale model for the Tookany/Tacony-Frankford Watershed. The major components of the SWMM model used in the development of the Tookany/Tacony-Frankford Watershed model were the RUNOFF and EXTRAN modules.

The RUNOFF module was developed to simulate both the quantity and quality of runoff in a drainage basin and the routing of flows and contaminants to sewers or receiving body. The program can accept an arbitrary precipitation (rainfall or snowfall) hyetograph and performs a step by step accounting of snowmelt, evapo-transpiration losses, infiltration losses in pervious areas, surface detention, overland flow, channel flow, and water quality constituents leading to the calculation of one or more hydrographs and/or pollutographs at a certain geographic point such as a sewer inlet. The driving force of the RUNOFF module is precipitation, which may be a continuous record, single measured event, or artificial design event.

The EXTRAN module was developed to simulate hydraulic flow routing for open channel and/or closed conduit systems. The EXTRAN module receives hydrograph inputs at specific nodal locations by interface file transfer from an upstream module (*e.g.* the RUNOFF module) and/or by direct user input. The module performs dynamic routing of stormwater flows through storm drainage systems and receiving streams.

9.1.3 Planning Areas/Units (Subsheds)



A. Map of Watershed and Location of Potential Data Sources B. Delineation of Subbasins by Drainage and Jurisdiction

Figure 9-1 Conceptual Framework for Delineation of Model Units

Model subsheds were delineated differently in areas with separate storm sewers and areas with combined sewers. In areas with separate storm sewers, a digital elevation model was used to delineate topographic drainage areas to points along the stream. Figure 9-1 illustrates this delineation conceptually. The points chosen were locations where a fluvial geomorphological analysis of the stream was conducted as part of a related study. In areas with combined sewers, model subsheds coincided with sewersheds, or topographic areas draining to individual regulator structures. Model subsheds were further refined in two ways. First, subsheds extending across the county boundary were separated into two areas to allow pollutant loads to be summed individually. Second, subsheds were delineated at a finer scale in some areas with known flooding problems, such as the Wingohocking area in the northwest portion of the drainage area within Philadelphia. The model was not optimized for the loading analysis; rather, a model was created to adequately serve multiple purposes such as pollutant loading analyses, combined sewer infrastructure studies, flood management studies, and water quality studies.

The planning areas or jurisdictional sub-watersheds range in size from less than 1 acre to greater than 1400 acres. The mean size of the planning areas is about 430 acres with a median size of about 71 acres. The largest planning area is located in the City, and drains to CSO regulator T14. The smallest basin also is located in the City and contributes to CSO regulator T14. Eighty percent of the planning areas are between 5 and 1000 acres.

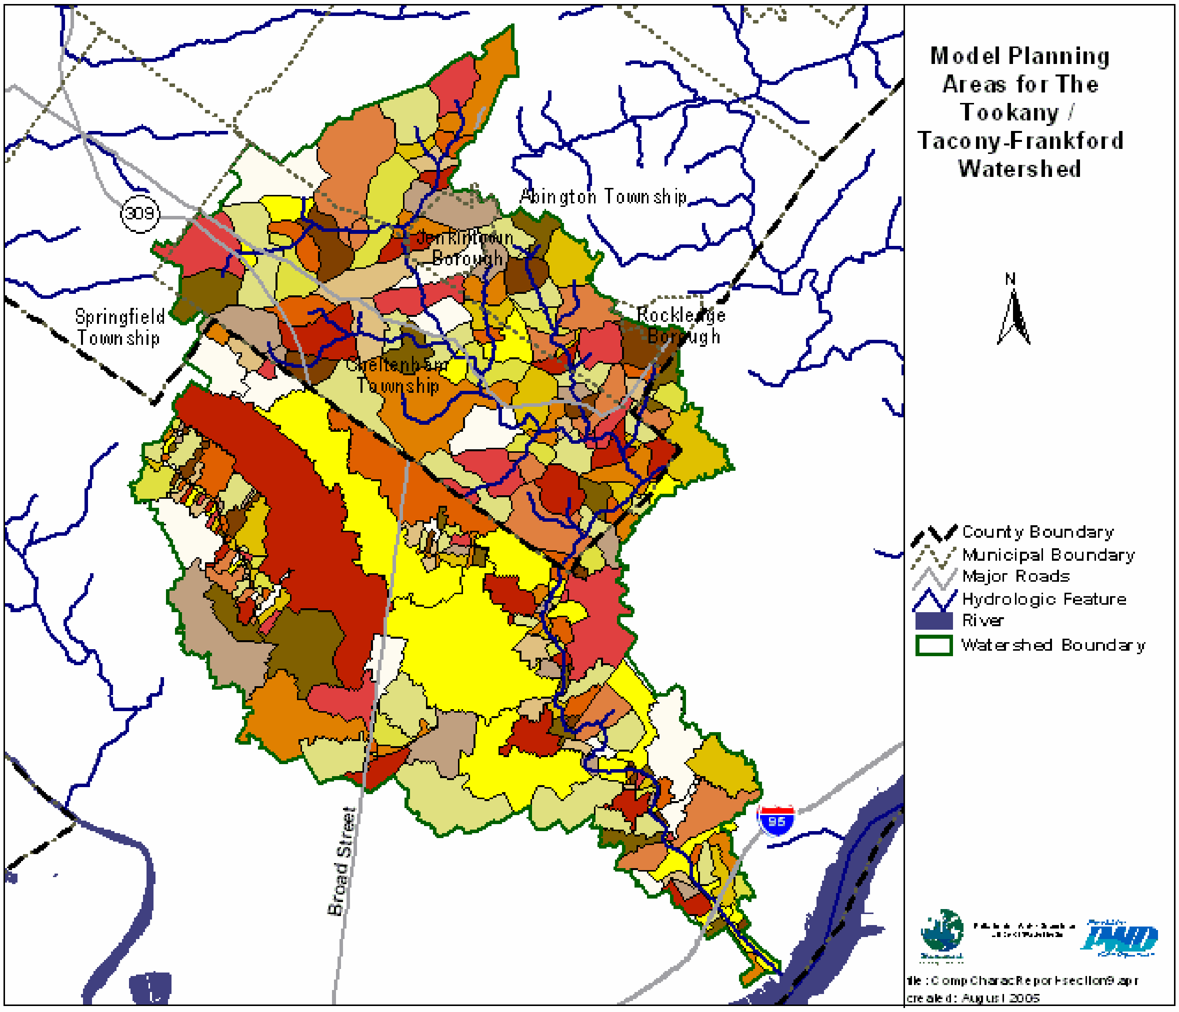


Figure 9-2 Planning Areas or Model Units in the Tookany/Tacony-Frankford Watershed

9.1.4 Land Use

Data used to define the land uses by planning area were compiled by the Delaware Valley Regional Planning Commission (DVRPC) and are shown in Figure 2-6.

9.1.5 Event Mean Concentrations (EMCs)

Event Mean Concentrations (EMCs) are defined as the total mass load of a chemical parameter yielded from a site during a storm divided by the total runoff water volume discharged from the site during the storm. The EMC is widely used as the primary statistic for evaluations of stormwater quality data and as the stormwater pollutant loading factor in analyses of pollutant loads to receiving waters.

Use of EMCs in Loading Analyses: Nonpoint source pollution loading analyses typically consist of applying land use- specific stormwater pollution loading factors to land use scenarios in the watershed under study. Loading rates of urban stormwater pollution (nutrients, metals, BOD, fecal coliform) are determined by the quantity of runoff from the land surface. Thus, they are closely related to the imperviousness of the land use type.

Runoff volumes are computed for each land use category based on percent imperviousness of the land use and annual rainfall. These runoff volumes are multiplied by the land use specific EMC load factor (mg/L) to obtain nonpoint source pollutant loads by land use category. This analysis can be performed on a subarea or watershed-wide basis, and the results can be used to perform load allocation studies, to evaluate pollution control alternatives, or as input into a riverine water quality model.

The model calculates pollutant loads based upon nonpoint source pollution loading factors (expressed as lb/acre/year) that vary by land use and the percent imperviousness associated with each land use. The pollution loading factor M_L is computed for each land use L by the following equation:

$$M_L = EMC_L * R_L * K$$

where:

M_L = loading factor for land use L (lb/acre/year)
EMC_L = event mean concentration of runoff from land use L (mg/L); EMCs may vary by land use and pollutant
R_L = total average annual surface runoff from land use L (in/yr); and
K = 0.2266, a unit conversion constant.

By multiplying the pollutant loading factor by the acreage per land use and summing for all land uses, the total annual pollution load from a sub-basin can be computed. The EMC coverage is typically not changed for various land use scenarios within a given study watershed.

In areas drained by separate storm sewers, applying EMCs to calculated runoff volumes provides reasonable estimates of stormwater pollutant loadings to surface water. In areas drained by combined sewers, this approach estimates the pollutant load entering the sewer system; additional analysis is required to estimate the pollutant load to the receiving water.

History and Sources of EMCs: Once point source discharges from treatment plants and industrial facilities were addressed in the 1970s and 1980s, more attention was focused on stormwater runoff from urban areas as a source of water quality degradation. As pollution from stormwater and urban drainage began to be investigated, studies focused on the types of pollution and methods to reduce the loads. However, these investigations did not consider the achievable level of improvement of receiving water bodies with the mitigation of stormwater pollution. In addition, many research studies concluded that additional and more comprehensive information was needed to make such assessments. This need led to the development of the Nationwide Urban Runoff Program, also known as NURP.

The goals of NURP were to develop and provide information to local decision makers, the States, EPA, and other parties for use in assessing the impacts of stormwater and urban runoff on water quality. The information collected also was intended to aid in the development of water quality management plans and provide a foundation for local, State and Federal policy decision making about water quality issues.

The NURP studies investigated 10 standard water quality constituents to characterize urban runoff. As a result of data collected through the NURP program, EMCs for these and other pollutants were developed from over 2,300 station-storms at more than 81 urban sites located in 28 different metropolitan areas. These studies greatly increased the knowledge of the characteristics of urban runoff, its effects upon the designated uses of receiving water bodies, and the performance efficiencies of various control measures. Pertinent conclusions from the NURP Program include:

- The variance of the EMCs, when data from sites are grouped by land use type or geographic region, is so great that differences in measures of central tendency among groups are not statistically significant.

- Statistically, the entire sample of EMCs and the medians of all EMCs among sites are log-normally distributed.

EMCs often are used in screening-level models. The pollutant loads (L_i) are estimated as the product of the area of urban land (A_U), the rainfall-runoff depth as estimated by a modified rational formula approach (d_r), and a constant pollutant concentration (C_i), usually estimated from the EMCs reported by NURP (i.e., $L_i = C_i A_u d_r$).

Since the conclusion of the NURP Program in the 1980's, additional urban runoff quality monitoring data has been collected. One large effort conducted by the United States Geological Survey resulted in the collection of urban runoff data for over 1,100 station-storms at 97 urban sites in 21 metropolitan areas. Additionally, EPA required many major cities to collect urban runoff quality data as part of the application requirements for stormwater discharge permits under the National Pollutant Discharge Elimination System (NPDES). Data from 800 station-storms from 30 cities was gathered and incorporated into a database by CDM. CDM analyzed the data collected from NURP, USGS, and NPDES to assess if additional EMC observations (more degrees of freedom) would uncover statistically significant differences in EMCs among various land uses. While the resulting EMCs from the combined data sets did not indicate statistical differences in water quality among land uses, the pooled EMCs were significantly different than the NURP EMCs for several parameters (*e.g.*, TSS, Cu, and Pb) and would produce different loading rates for urban areas. Table 9-1 illustrates the EMCs used in the Tookany/Tacony-Frankford Watershed Study and the source of each EMC value.

Note: All metals data are from Smullen (1999), except Highway. Atmospheric contributions are included in these values. The EMC for fecal coliform is based on NURP data as reported in NOAA (1987).

9.1.6 Baseflows

Most streams exhibit dry weather flow due to groundwater infiltration. As discussed in Section 4, baseflows for the individual planning areas were determined using USGS streamflow gauging data.

Baseflow due to groundwater inflow is the main component of most streams in dry weather. Baseflow slowly increases and decreases with the elevation of the shallow aquifer water table. In wet weather, a stormwater runoff component is added to the baseflow. Estimation and comparison of these two components can provide insights into the relationship between land use and hydrology in urbanized and more natural systems. For a more detailed explanation of the baseflow separation techniques used, see Section 4.3.

9.1.7 Constituent Source Types

For a watershed or TMDL study, an inventory of pollutant sources to the receiving water bodies must be compiled. The various types of sources usually considered are listed below. Note that urban stormwater runoff has some attributes of both point and nonpoint sources.

- Point (industrial and municipal dischargers, CSOs, SSOs);
- Nonpoint (stormwater, urban drainage, leaking septic systems);
- Background (instream, baseflow); and
- Atmospheric.

Stormwater and Urban Drainage: Stormwater from areas with separate storm sewers contributes to water body impairment in highly urbanized, impervious catchments. Pollutants most frequently associated with stormwater include sediment, nutrients, bacteria, oxygen demanding substances, oil and grease, heavy metals, other toxic chemicals, and floatables. The primary sources of these pollutants include automobiles, roadways (pavement, bridges), housekeeping and landscaping practices, industrial activities, construction, non-storm connections to drainage systems, accidental spills and illegal dumping. Calculations used to estimate pollutant loads in stormwater are described in Section 9.1.5.

Combined Sewer Overflows (CSOs): In many cities throughout the United States, stormwater runoff and sanitary wastewater are collected in the same sewer (a combined sewer). In dry-weather conditions, all flows are conveyed to and treated at a local or regional wastewater treatment plant. In wet-weather conditions, the capacity of the combined sewer system can be exceeded and discharges of mixed sanitary and stormwater then occur to receiving waters. The fraction of sanitary sewage in discharges varies from storm to storm, but is typically on the order of 10% over the long term, while the remaining 90% is untreated stormwater. For constituents where sanitary sewage and untreated stormwater concentrations are the same order of magnitude (*e.g.*, TSS, nutrients), concentrations in CSO are similar or slightly higher than when compared to stormwater. For constituents where sanitary concentrations are typically lower (*e.g.*, metals such as Pb, Cu, Zn), concentrations in CSO are slightly lower than in untreated stormwater. For bacteria and other pathogens, concentrations in CSO are one or more orders of magnitude higher than those found in stormwater.

Estimating loads to surface waters from an area served by a combined sewer requires three steps.

1. Stormwater flow and load entering the sewer system are estimated by the methods described in Section 9.1.5.

2. A hydraulic simulation of the sewer system predicts the portion of flow that is captured and sent to a wastewater treatment plant, the portion of flow that overflows to the receiving water (CSO), and the fractions of CSO made up of sanitary sewage and stormwater.

3. Using known volumes and pollutant concentrations of sanitary sewage and stormwater reaching the receiving water (step 2), the total pollutant load reaching the receiving water is estimated.

Municipal and Industrial Process Water Discharges: A search of federal and state NPDES permit databases was performed to identify permitted dischargers within the Tookany/Tacony-Frankford Watershed. Table 9-2 presents the list of dischargers and the information found for each point source.

Sanitary Sewer Overflows (SSOs): SSOs result in discharges of untreated wastewater that can affect stream quality and occasionally back up into basements and city streets. The USEPA has found that SSOs represent a significant threat to health and the environment in areas where they occur frequently. Frequent SSOs may indicate that the capacity of the collection system is insufficient to convey the flows introduced or that the system is in need of maintenance or repair. Potential causes of excess flow include infiltration and inflow, illegal connections, population growth, and under-design. Problems requiring maintenance or repair may include broken or cracked pipes, tree roots, poor connections, and settling. Proper maintenance can help prevent problems or identify them before they become extremely costly to repair (USEPA, 2000).

Sanitary Sewer Overflows (SSOs) are a known source of bacterial and other pollution to the Tookany/Tacony-Frankford Watershed. Currently, no inventory of SSOs exists for the area within the two counties that contain the Tookany/Tacony-Frankford Watershed. Since the data collection effort required to obtain SSO load information was beyond the scope of this screening-level study, SSO loads were not considered part of this study. An SSO assessment methodology will be implemented as part of the Phase II efforts.

Septic Tanks: Although there are septic systems in the watershed, most of the population is served by sanitary sewers. The number of septic tanks within the watershed is difficult to accurately quantify; according to 1990 census data there are estimated to be about 1,075 septic tanks present in the watershed, 706 of which are located within the city of Philadelphia. This number is believed to be a high estimate of the actual number.

Compilations of septic tank and on-lot sewer systems have not been completed to date. Detailed assessment of individual municipalities for septic tank and on-lot sewage disposal inventories and/or permits was beyond the scope of the current phase of this study.

Atmospheric Sources: Pollutants from atmospheric deposition on land surfaces are considered to be included in the calculations of stormwater runoff. Direct deposition on water surfaces also is included in these calculations by the use of a water surface land use type. Specifically, precipitation falling on the water surface land use was assigned EMCs of nutrients and metals derived from rainfall data. For this study, the water surface EMCs were taken from the Chesapeake Bay Program literature (EPA, 1982).

9.2 Results: Estimated Annual Constituent Loads

Figures 9-3 through 9-11 show estimated loading rates for stormwater runoff and CSO. Table 9-3 breaks load estimates into two geographic regions, the upper and lower Tookany/Tacony-Frankford. The loads are estimates of the total input to the stream system. For example, the surface runoff listed for lower Tookany/Tacony-Frankford (an area serviced by combined sewers) is relatively low because it does not include the volume that is captured, treated, and discharged outside the system. With some exceptions, higher pollutant loading rates are found in the lower Tookany/Tacony-Frankford Watershed, in and near the densely populated areas of Philadelphia. Loads from areas with combined sewers are higher for some constituents because a portion of the discharge is made up of sanitary sewage. In these areas, the pollutant load is a function both of pollutants washed from the land surface and pollutants added to the sewer system directly by residences and businesses. Thus, areas of higher loading shown in the figures do not necessarily indicate that stormwater from those areas is more polluted.

9.2.1 Relative Contribution of Source Types

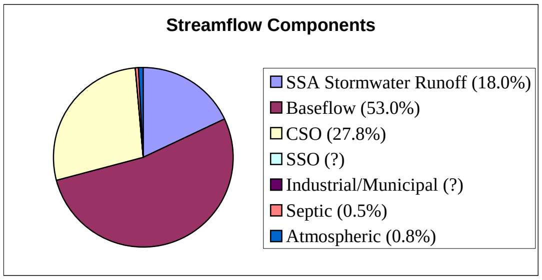
Figure 9-12 presents the approximate relative contribution each source (stormwater runoff from separate sanitary areas, baseflow, CSOs, industrial and municipal point sources, septic tanks, and atmospheric sources) contributes to the total potential load to the Delaware River from the Tookany/Tacony-Frankford Watershed area. As expected in highly urbanized settings, runoff from separate sanitary areas is a significant (over 10%) source of water pollution for most pollutant types except fecal coliform. Baseflow contributes a significant amount of total nitrogen. Separate sanitary overflows (SSOs) may be a significant source of pollutants, but information concerning these sources was insufficient to include in the current analysis. The results indicate that CSOs are a dominant source of the total load for all parameters. The model indicates that almost 90% of the fecal coliform introduced to the system is the result of CSOs; however, this portion may change when future work accounts for the contribution of SSOs. Industrial and municipal point sources are a relatively small source of pollutants. Septic tank loads are significant only for phosphorus and nitrogen. However, the reliability of the data available on septic tanks in the watershed is questionable. Atmospheric inputs, based on wetfall or concentrations within rainfall, are included in the EMCs for all land use types except for wetlands and open water. Atmospheric loads to wetlands and water were small (1% or less) but measurable.

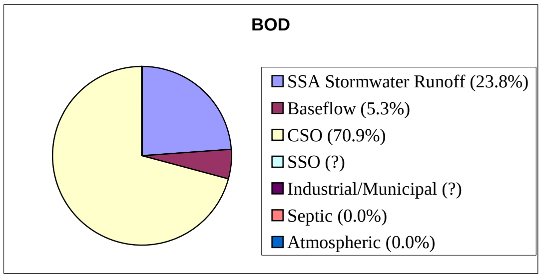
Table 9-4 presents the average areal loads contributed by runoff from separate and combined sewer areas. Areal loads show the intensity of loading rather than total loads. The areal loadings for most parameters are similar for the two sources, but the fecal coliform loads introduced by combined sewer areas are approximately 100 times greater per acre than those introduced by runoff from separate sewer areas. For comparison, the table includes loads for the other sources.

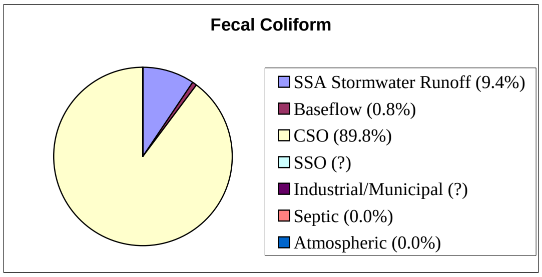
Table 9-4 Estimated Annual Area Loads by Source (lb/ac except as noted)

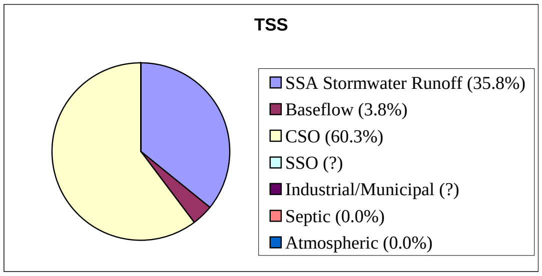
Parameter	SSA Stormwater Runoff (lb/ac)	Baseflow	CSO	Industrial/ Municipal	Septic	Atmospheric
BOD	22.4	2.5	73	0	0	0
TSS	127	6.8	235	0	0	0
Fecal Coliform (col/ac)	2.2E+11	9.8E+9	2.3E+12	0	0	0
Total Nitrogen	3.90	5.9	12.3	0	0.072	0.062
Total Phosphorus	0.50	0.34	1.74	0	0.027	0.002
Copper	0.02	0.015	0.06	0	0	8.5E-05
Lead	0.12	0.002	0.19	0	0	1.0E-04
Zinc	0.27	0.041	0.50	0	0	2.5E-03

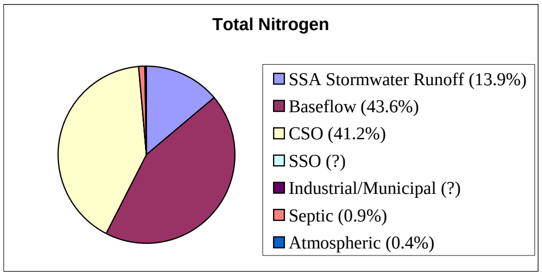
Figure 9-12 –Estimated Annual Relative Contribution of Constituent Sources

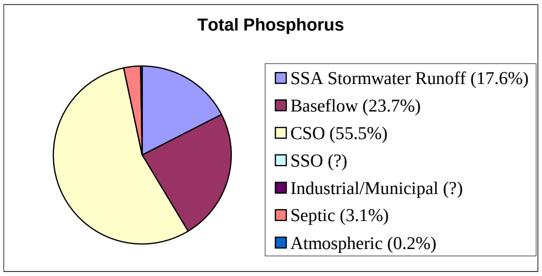


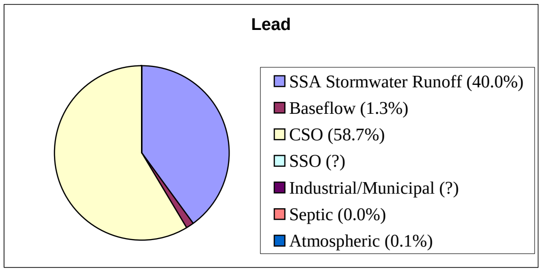


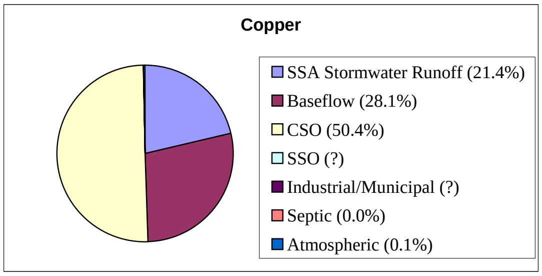


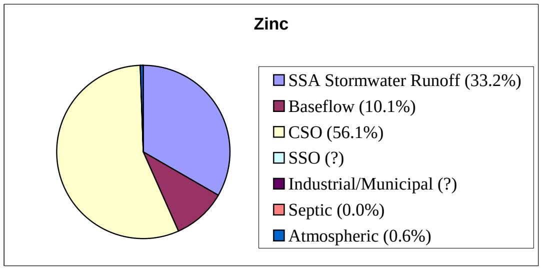












Notes:

- SSA = separate sanitary area runoff
- CSO = combined sewer overflow
- Sanitary sewer overflows (SSOs) were not explicitly included in this analysis.
- The model indicates that direct atmospheric loads to surface water were found to contribute less than 0.4% of the load for any parameter studied. This result is due mainly to the fact that very little area is classified as water or wetlands.

9.2.2 Sources of Uncertainty

Baseflow water quality information is based upon water quality sampling data obtained between 1999 and 2000. The data represents background conditions; if significant dry weather pollutant inputs are present, these will be reflected in the baseflow concentrations.

EMCs are based on literature values. The EMCs used for this study for urban land uses are from Smullen, Shallcross, and Cave (1999). These values represent a compilation of stormwater monitoring data from NURP, the USGS, and NPDES Phase I Municipal Stormwater Monitoring Requirements.

Sanitary sewer overflows (SSOs) are believed to be a significant potential source of bacterial and other pollution in the watershed. For the watershed study, estimates of SSO flows and pollutant loads were not calculated due to lack of readily available information on municipal sewer systems. Future studies may include a more thorough investigation of these sources.

Failures of septic tanks can contribute nutrient and bacterial loads to receiving waters. For this screening level study, the 1990 census data for on-lot septic systems was used to determine the number of septic systems in each drainage area. Although of limited accuracy, the census data indicated that over 1075 septic systems were located within the watershed. Since extensive research into on-lot systems and Act 537 plans for Montgomery Counties will be required, the 1990 census counts of septic systems were used for all portions of the Tookany/Tacony-Frankford Watershed study except Philadelphia.

9.3 Comparison of Load Estimates

Table 9-5 compares several loading rate estimates for Tookany/Tacony-Frankford Creek. These estimates are based on historical water quality monitoring, 2000-2004 water quality monitoring, and SWMM model estimates. The loads from the monitoring data were calculated by applying wet weather and dry weather pollutant concentrations to USGS historical flow data. The resultant loads were averaged over the period of record to determine the average daily load.

Table 9-5 compares the loads of some conventional water quality parameters calculated from the results of the first 50 months of sampling of the PWD/USGS Cooperative Program. Ammonia and nitrate loads were not calculated for the estimate. The loading rates estimated by SWMM are much larger than the instream mass load estimated from the current monitoring data. This difference is not a mistake but a result of the modeling philosophy:

- SWMM loads represent the total potential load to be delivered downstream and do not specifically account for the instream processes that reduce the total load.
- For the screening level study, the loads were used to estimate an overall delivery ratio for each pollutant, rather than estimate delivery ratios for various land uses by pollutant.

- The instream mass loads were based on limited, discrete, wet and dry weather monitoring data in addition to streamflow data from the 1970s.

- Loading is based on national EMCs which are measures of central tendency with significant variance. Local conditions may not be reflected by the national EMCs.

9.4 Delivery Ratios

The delivery ratio represents the fraction of the original pollutant load remaining after a particular pollutant travels downstream and is affected by instream processes. Data available in the literature indicate that the delivery ratio varies with drainage-area size. Some representative values calculated by the USDA for sediment are:

Drainage Area (sq. miles)	Delivery Ratio
0.5	0.33
10	0.18
100	0.10

However, the delivery ratios may vary substantially for any given size of drainage area. Other important factors affecting pollutant delivery include soil texture, relief (slope), types of erosion, sediment transport system, and deposition areas. For instance, a watershed with fine soil texture, high channel density, and high stream gradients would generally have a higher than average delivery ratio for watersheds of similar drainage area. Also, edge-of-field delivery ratios can approach 1.0 while delivery ratios for larger study areas can be less than 0.05. Instream processes also affect the delivery ratio. Such processes include deposition, sediment and water column diagenesis, remineralization, and volatilization. These processes are discussed in the next section.

The delivery ratios were calculated by dividing the runoff loads by the 2000-2004 sampling means, if available. Table 9-5 presents the calculated delivery ratios for two sites along Tookany/Tacony-Frankford Creek (TF620 and TF680). Although delivery ratios might be expected to decrease with distance downstream, the data do not display such behavior. The delivery ratio for most pollutants increases from the upstream to the downstream cross-sections; the delivery ratios for total suspended solids stay about the same. This trend may be largely explained by greater urbanization in the downstream reaches of Tacony-Frankford Creek; much of the loading occurs downstream where less time and distance are available for degradation processes to take place.

Table 9-5 Comparisons of Load Estimates for Tookany/Tacony-Frankford Creek

	Historic Data		2000-2004 Monitoring Data		2000-2004 vs. Historical		SWMM Estimate		Calculated Delivery Ratio	
	Upstr.	Downstr	Upstr.	Downstr	Upstr.	Downstr	Upstr.	Downstr	Upstr.	Downstr

Note: “Upstream” corresponds to station 8 for the historical and Radzuil data, station TF620 for the 2000-04 monitoring data and USGS station 01467086 (Tacony Creek at County Line). “Downstream” corresponds to station 9 for the Historical, station TF280 for the 2000-04 monitoring data, and USGS station 01467089 (Frankford Creek at Torresdale Ave).

* The difference in drainage area at the downstream end is because the recorded drainage area for the USGS station includes the Old Frankford Creek.

Appendix A: Temporal Changes in Water Quality

Tukey plots were used to characterize water quality parameters by comparing load changes as Tookany/Tacony-Frankford Creek passes through Montgomery County and the City. Using the wet/dry flow designations, box plots compared current water quality data with historical (PWD/USGS Cooperative Program 1970-1980) water quality data. Ammonia, total phosphate, and fecal coliform are shown in this section of the report. Figure A-1 shows the schematic of the modified Tukey plots.

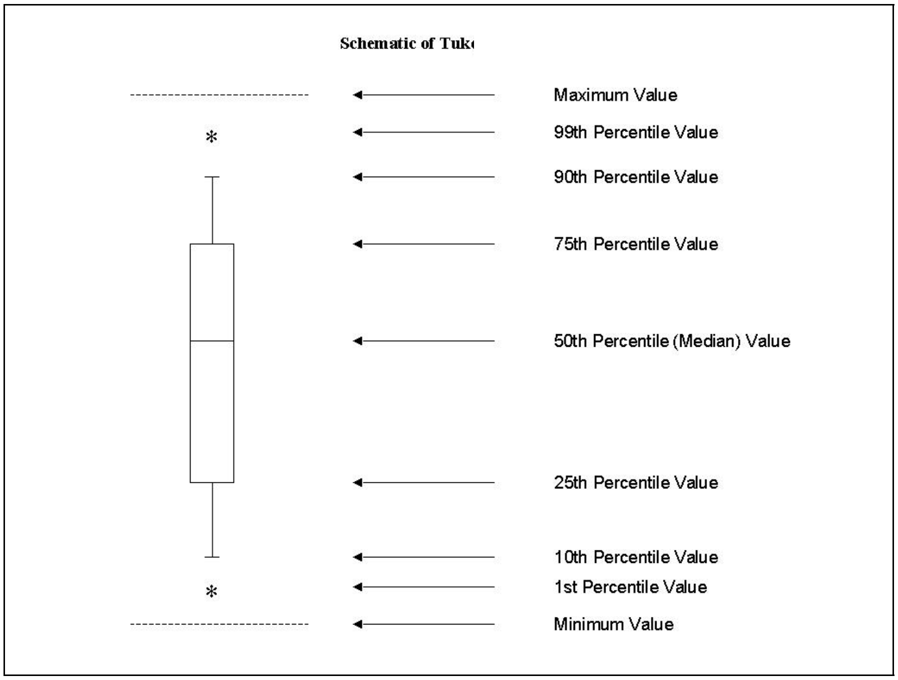

Figure A-1 Schematic Diagram of the Modified Tukey Box Plot

The ammonia, total phosphate, and fecal coliform plots, Figures A-2 through A-23, display an increased concentration from the upstream location at the County Line (TF620, or Site 8) to the downstream location at Castor Avenue (TF280, or Site 9). Malfunctioning regulators and higher loading rates during storm events are the most likely cause. However, other sources of fecal coliform bacteria not previously considered include urban runoff, broken or leaking sewers, failing septic systems, and unanticipated pump station discharges from non-gravity separate sewer systems. For these three constituents, the concentrations have decreased since the historical data collection.

Appendix B: Sonde Data Protocol for the Tookany/Tacony-Frankford Creek

DO Acceptance:
The large number of measurements made by the continuous sampling equipment serves to characterize DO throughout the diurnal cycle under a range of flow conditions. The equipment produces 96 observations of DO every 24 hours, but cost and quality control are more challenging compared to discrete sampling. A variety of procedures are followed before, during, and immediately after deployment to help insure quality and identify problems that may affect DO data quality. These procedures are outlined in detail in the main body of "YSI 6600 Sondes to Monitor Water Quality in Streams" and are summarized below.

- Pre-deployment and post-deployment laboratory validation checks are performed on all parameters. The probes are tested in solutions of known concentrations as established by standard laboratory testing procedures. Instruments are deployed and data is initially accepted if probe measurements are within a certain tolerance of the standards.

- Field personnel fill out standardized forms to note conditions and events that may have an effect on data quality. Examples include debris or sediment obstructing the probe, debris obstructing free flow of water around the instrument, or instrument failure such as a battery failure.

- Beginning in the fall of 2001, field measurements are taken of DO, pH, and specific conductance at deployment and retrieval. Measurements are taken as close to the probe locations as possible, and the data is added to the pre- and post-deployment validation checks when determining whether data is initially accepted.

- BLS personnel prepare time series plots and make preliminary determinations of whether data fall within reasonable ranges and patterns. BLS staff recommends acceptance of data at this point provided they pass the criteria discussed above.

These four items represent initial screens for poor quality data; they identify instances where probes do not accurately measure conditions in the immediate vicinity of the instrument. However, suspended sediment, debris, and biofouling can all affect the microenvironment in the immediate vicinity of the instrument, causing data to be collected that does not represent overall conditions in the water column. For this reason, additional procedures are needed to distinguish data that is sufficiently representative to be included in analyses from data that is not representative.

Table B-1 summarizes a system that assigns points to data based on the presence of characteristics that are indicative of reliable data. Data analysis suggests that conditions that lead to unreliable data are present primarily during and after wet weather and depend on the intensity of the runoff event. For this reason, the continuous data is biased toward dry weather conditions although they do represent some wet weather events.

Table B-1 Criteria Applied to Determine Sonde DO Data Reliability

CRITERIA (Accept data with 5 or more points.)	**CHARACTERISTICS OF Chapter 1 HIGHER RELIABILITY DATA**	⟷	**CHARACTERISTICS OF LOWER RELIABILITY DATA**
VALIDATION CHECKS	The data pass all field and laboratory validation checks within 1.0 mg/L. PROCEED TO NEXT STEP.	Does not apply.	The data do not pass one or more validation checks. REJECT THE DATA.
PROBE FAILURE	The data never drop to zero for two or more days. PROCEED TO NEXT STEP.	The data drop to zero for two days or more, but recover later in the deployment. PROCEED TO NEXT STEP.	The data drop abruptly to zero and remain there for the duration of the deployment. REJECT THE DATA.
SITE CONDITIONS	Field notes do not document any conditions that may cause instrument failure. (+2 POINTS)	Field notes indicate light to moderate obstruction by debris, sediment, and/or biofouling. (+1 POINT)	Field notes indicate moderate to extensive obstruction by debris, sediment, and/or biofouling. (+0 POINTS)
NOISE	The data pattern is smooth, without sudden and erratic changes. (+2 POINTS)	Data are slightly to moderately noisy, but the underlying pattern is readily apparent. (+1 POINT)	The data are extremely noisy. (+0 POINTS)
IF diurnal pattern is evident…	The diurnal pattern is relatively constant in dry weather and has an amplitude of less than 4 mg/L. (+2 POINTS)	The diurnal amplitude is less than 4 mg/L, but it changes over the course of the deployment by a factor of 2 or more. This may indicate algae accumulation. (+1 POINT)	The diurnal amplitude is greater than 4 mg/L. (+0 points)
IF redundant observations are available…	Both sets of data are similar and display characteristics of high quality data. (+2 POINTS for one data set; discard the other).	Only one data set displays multiple characteristics of low quality data. (+1 POINTS for the higher quality data set; discard the other).	Both data sets display multiple characteristics of low quality data. (+0 POINTS)

Explanation of acceptance/rejection:
The primary objective in this part of the update is to identify which data is usable and which is not. The most important comment that can be made is that we are not trying to reject data that doesn't seem to fit the "usual" pattern (diurnal). Instead we are trying to reject data that seems to have been caused by mechanical failure. Therefore it is important to realize exactly what is usable and what is useless. The first place to look for this is in the original excel file that supplied the data. Check the charts that are in the file and look for any red comments about mechanical failure. If this is the case, then the data should be rejected in those regions. The Excel file "TF_Acceptance_Criteria.xls" has a series of worksheets which help decide if the data should be rejected or not. Looking at the plot, decide on an appropriate number of sections that are needed. For example, if there seems to be a section of questionable data between 2 sections of good data, you would need 3 sections. Make a copy of one of the templates depending on the sections required and rename the sheet for the respective deployment. Complete the sheet to help gauge if the data should be rejected or not.

How to select which regions to reject:

- Open the TaconyFrankford Database :"**TaconyFrankford.mdb**".
- Open the sheet called **"RejectedDates"**.
- For each region you wish to reject, enter the deployment, start dtime to reject and end dtime to stop rejecting.
- For single point rejections, enter the same dtime for start and stop.
- For multiple rejection ranges for the same deployment, use the same deployment number and add a new record with more rejection times.
- Update the "**TF_Acceptance_Criteria**" worksheet. Add a new worksheet for each new deployment using the template sheets in the front. For 2 rejection regions use Template2, for 3 use Temp3 etc.
- Fill in the proper point values as was described above.

DO Flagging:

Program 5 – "update do flag optimized.vb" - Module inside database

- This program takes the rejected date ranges and flags the TF_Sonde table accordingly.
- Run the module, if there are any errors, read the comments in the program. You may comment out the **fillw1** query.
- Export the table **"TF_Sonde"** with the export query. Output is **"TF_Export_Sonde.csv".**
- Rerun the program **DOPlots.sas.** Output will be several graphics files.

Check the graphs for consistency

Appendix E: The diurnal oxygen-curve method for estimating primary productivity and community metabolism in the Tookany-Tacony-Frankford Creek

The diurnal oxygen-curve method for estimating primary productivity and community metabolism in streams (USGS 1987) was applied for single station analysis to TTF using continuous sonde DO, Temperature, and level data. This approach provides an estimate of gross primary productivity and community respiration by estimating the total amount of oxygen produced and consumed over a 24-hour period. It assumes that the daytime respiration rate varies linearly with time from pre-dawn to post-dusk. The net consumption or production of oxygen in the stream is estimated from measured DO concentration changes over time using finite difference methods. The measured DO concentrations and subsequent rates of DO change are adjusted for atmospheric reaeration rates which are estimated to be directly proportional to the DO saturation deficit at the measured temperature. The reaeration rate constant was estimated as a function of average stream cross-sectional velocity and hydraulic radius using the Churchill-Elmore-Buckingham formula (Churchill 1962) given by equation E1.

$$k_2 = 5.026\,(V^{9.69})\,(R^{-1.673}) \qquad \text{(E1)}$$

- V is the average stream cross-sectional velocity (ft/s)
- R is the hydraulic radius (ft)
- k_2 is the reaeration rate constant (day^{-1}) at $20^{o}C$

The reaeration rate constant was adjusted for temperature (T) using:

$$K = 1.024^{(T-20)}\,k_2 \qquad \text{(E2)}$$

And, the reaeration rate was estimated by:

$$D_a = K\,(C_s - C_o) \qquad \text{(E3)}$$

- Where Da is the change in DO due to reaeration in mg / l / hour
- C_s is the DO saturation concentration at measured water temperature
- C_o is the measured DO concentration
- K is the temperature adjusted reaeration rate constant from equation (E2)

Note that in shallow turbulent streams the time needed to achieve equilibrium between the atmosphere and water may be too short for the diurnal oxygen-curve method to be used reliably (Britton 1987).

Stream cross-sectional velocity was estimated using rating curves and sonde depth measurements corrected for atmospheric pressure and adjusted for sensor offset based on relative baseflow values at the USGS stream gauge station at Frankford Creek and Castor Avenue. The rating curves were developed by field measurement over the dry weather flow regime at cross-sections near each monitoring location.

Night-time respiration rate was estimated directly from measured changes in DO concentration over time and adjusted for atmospheric reaertion rates as described above. During daytime, however, photosynthesis and respiration together account for observed changes in adjusted DO concentrations over time. Daytime respiration, therefore, was estimated to vary linearly from early morning to late evening and gross productivity determined by difference from changes in measured DO concentrations. Productivity and respiration rates estimated in this manner for site TF280 on April 30 and May 1, 2003 are shown in Figure E1. Gross daily oxygen production and consumption, expressed in mg/l, were determined by numerical integration of these rates over time seen as the area between the curves and the zero rate of DO change line in Figure E1. In addition, net daily productivity and production respiration ratio (P:R) were determined.

Productivity and respiration estimates were determined in this manner using only complete days of accepted sonde data collected to date. Each accepted day was then characterized by the number of days since the last rainfall recorded at any PWD raingage station surrounding the watershed, and only dry days with 2 or more days since the last rainfall were used in further analyses. In addition, “post” and “pre” rainfall days were identified as having either 3 to 5 and more than eight days, respectively, since the last rainfall.

In order to characterize community metabolism and better understand the role of periphytic algae between sites along the TTF creek and across seasons, various statistical analyses of productivity and respiration estimates were performed. The results of these analyses are presented in figures E2 through E5. It can be readily seen that peak metabolism rates occur during the springtime across all sites.

In addition, comparisons of “pre” and “post” storm metabolism were performed across seasons for each site. These results are presented in figures E6 through E21. There appears to be potentially significant reductions in gross productivity, gross respiration, and to a lesser extent P:R ratio between “pre” and “post” storm estimates taken during the fall samplings. Further investigation is needed.

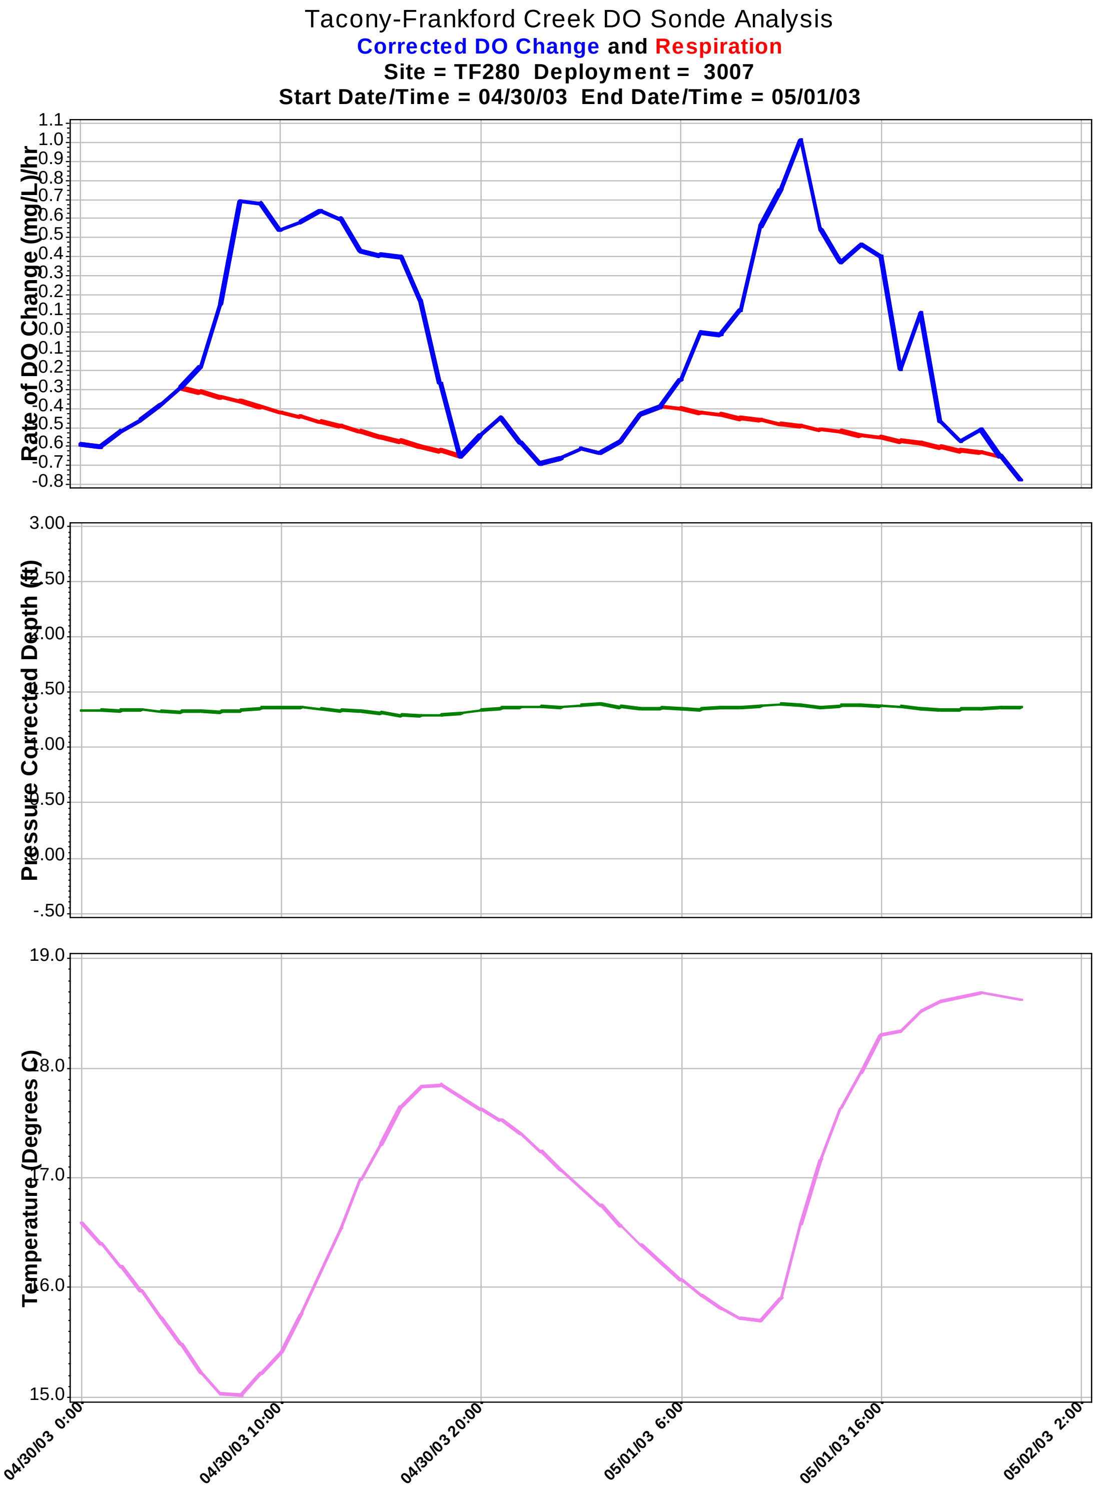

Figure E1: TTF continuous monitoring results at site TF280 for April 30 and May 1, 2003 (Top) Corrected rate of DO change and estimated daytime respiration (Middle) Pressure corrected sonde depth (Bottom) sonde Temperature measurement.

Figures E2 through E5: Comparison of statistical analysis results showing seasonal variations in gross productivity, gross respiration, net productivity, and P:R ratios across TTF monitoring locations.

Appendix J: List of Terms

a priori	latin, literally “from the former”; describing a hypothesis made without prior knowledge, before experimentation, or based upon assumption
Acute	describing an effect or response, such as toxicity, that is measured or occurs over a relatively short amount of time; not chronic
Adaptive management	Process of continually monitoring progress and adjusting the approach
Algae	any of a number of several groups of single-celled or multi-cellular organisms, all of which lack leaves, roots, flowers, and other organ structures that characterize higher plants.
Ammonia/ Ammonium	a Nitrogen-containing molecule that exists naturally in both gaseous (NH3) and ionized (NH_4+) forms. The gaseous form is corrosive and toxic, while the ionized form is a usable source of nitrogen for plant growth. Ammonia may be produced by decomposition of nitrogen-containing molecules such as proteins.
Amphipoda	an order of small, shrimp-like crustaceans
Anadromous	describes fishes that migrate from salt water to fresh water to spawn or reproduce
Anoxic	lacking oxygen; especially water lacking dissolved oxygen
Anthropogenic	man-made or human in origin; influenced by mankind
Aquatic	relating to water, particularly freshwater
Aquifer	An underground geologic feature containing water
Autotroph/ Autotrophic	Describes organisms that can produce their own food, such as plants, algae or certain specialized bacteria.
Bankfull discharge	The high flow stage of a fluvial system distinguished by the highest stage elevation a stream can reach before spilling over. In fluvial geomorphology, the bankfull stage is used to describe the flow stage that is most important in shaping the stream channel. Often defined as the flow with recurrence interval 1.3-1.5 years on average, but urbanization tends to decrease this interval.
Baseflow	flow in a stream that is not influenced by precipitation
Basic	alkaline; containing oxide or hydroxyl ions; not acidic

Benthic	Used to describe aquatic organisms living at the bottom of a body of water
Benthic macroinvertebrates	Aquatic insect larvae that live on stream bottom. Because of a short lifespan and relative immobility, they reflect the chemical and physical characteristics of a stream and chronic sources of pollution.
Bioaccumulation	describes the condition or process through which living things concentrate substances, such as toxins, in excess of ambient concentrations
Bioassessment	an evaluation technique that uses measures of the structure, condition, or distribution of biological communities
Bioavailable	describes a substance, such as a pollutant, that can be taken up or incorporated by living things.
Bioindicator	an organism that exhibits sensitivity or tolerance of environmental conditions and may be used in assessing an environmental condition, such as water pollution
Biotic	living, relating to life or biology
BMP -	Best Management Practice – Also called a "management option," BMP is a technique, measure, or structural control that addresses one or more objectives (e.g., a detention basin that gets built, an ordinance that gets passed, and an educational program that gets implemented).
BOD	biological or biochemical oxygen demand, an empirical test procedure that measures the ability of a water sample to deplete oxygen
BOD_{30}	a BOD test that is carried out over 30days
BOD_5	a BOD test that is carried out over 5 days
Caddisfly	an insect of the order Trichoptera, a group of insects usually having an aquatic life stage which are generally sensitive to organic pollution. Often used as a bioindicator of organic pollution.
Cadmium	(Cd) a toxic heavy metal element
Calcium	(Ca) a metallic element found in limestone and numerous naturally occurring compounds
$CaCO_3$	Calcium Carbonate
Catadromous	describes fishes that migrate from fresh water to salt water to spawn or reproduce

Cation	a positively charged ion. Common cations in streamwater are Calcium (Ca) and Magnesium (Mg)
Catchment	see Drainage area
CBOD	carbonaceous oxygen demand; a BOD test in which oxidation of nitrogen is inhibited
CCD	County Conservation District(s)
CCTV	Closed Circuit Television
Channelization	the process of modifying the natural course of a stream in order to make it flow into or along a restricted path
Chlorophyll	any of a group of green pigments necessary for photosynthesis, concentrations of which are used as a surrogate measurement of producer biomass
Chl-*a*	chlorophyll-α, a form of chlorophyll that is found universally in autotrophic organisms
Chironomid	a midge; a small fly of the family Chironomidae, many of which are used as bioindicators of water pollution
Chromium	(Cr) a heavy metal element, occurring naturally in trivalent [CrIII] and hexavalent [CrIV] forms. The latter form is highly toxic
Chronic	describing an effect or response, such as toxicity, that occurs or can be measured over a relatively long period of time; not acute
Cladocera/ Cladoceran	an order of microcrustaceans that are common zooplankton in fresh water and used in toxicity testing
Clay	inorganic sediment particles smaller than 0.002mm
CO_3^{2-}	carbonate ion
Cobble	a stream particle with diameter between 64 and 256mm
Coliform	of or relating to the bacilli (bacteria) that inhabit the intestines of warm-blooded animals
Collector-gatherer	a functional feeding group of aquatic organisms characterized by feeding upon particulate matter that is gathered or manipulated rather than filtered from flowing water by specialized appendage or apparatus
Conductance/	a measure of the ability of a water sample to conduct an electric current; a

Conductivity	measure of dissolved ionic strength
Copper	an essential metallic nutrient that can be toxic in relatively small concentrations
Criterion	an established standard, such as concentration of a pollutant, that is limited or regulated by law
Crustacea/ Crustacean	a class of arthropods that includes shrimp, crabs, crayfish and many types of zooplankton
CSO	Combined Sewer Overflow
CSS	Combined Sewer System
Culvert	a metal, concrete, or plastic pipe that allows water to flow under a road or any other obstruction
CWA	Clean Water Act –Federal Amendment that authorizes EPA to implement pollution control programs and set water quality standards for all contaminants in surface waters. "The Act made it unlawful for any person to discharge any pollutant from a point source into navigable waters, unless a permit was obtained under its provisions. It also funded the construction of sewage treatment plants under the construction grants program and recognized the need for planning to address the critical problems posed by nonpoint source pollution." (EPA website)
CWA Section 104(b)(3) Program	Promotes the coordination and acceleration of research, investigations, experiments, training, demonstrations, surveys, and studies relating to the causes, effects, extent, prevention, reduction and elimination of pollution.
CWA Section 208 Wastewater Planning	Intended to encourage and facilitate the development and implementation of area-wide waste treatment management plans.
CWA Section 319(b) Non-point Source Management Program	Designed to address mine drainage, agricultural runoff, construction/urban runoff, hydrologic and habitat modifications, on-lot wastewater systems, and silviculture.
Daphnia	a genus of small cladoceran; common in ponds/lakes, used in toxicity testing
DCIA	Directly Connected Impervious Area
Deamination	a stage in the decomposition of protein in which amine groups are removed, usually through hydrolysis; produces ammonia

Decomposition	decay; process through which a complex substance, such as dead organic matter, is broken down into smaller molecules
Defective lateral	a plumbing problem in which a lateral pipe is damaged, potentially leading to sanitary waste in a storm sewer and the receiving water body
Designation/ Designated Use	describes the uses a waterbody is intended to support, such as stocking trout for recreational fishing
Detection limit/ Method Detection Limit (MDL)	the smallest amount of a substance that can be measured with a laboratory technique or instrument (see method reporting limit)
Diatom	Single-celled alga of the class bacillariophyceae, having a cell wall composed of silica. Diatoms are primary producers in streams and lakes.
Diffusion	spontaneous, random movement of molecules that tends to result in equalization of concentrations over time as net movement occurs from areas of greater concentration to areas of lower concentration
Diluent/Dilutant	a thinning agent, such as water, which reduces the concentration of a solution. Pollution may be diluted by streamwater.
Dilute/Dilution	the process through which a solution is made less concentrated through the addition of a diluent/dilutant
Discharge	Flow; a measure of the volume of water flowing through a defined area in a given time. Discharge is often abbreviated as Q, and measured in cubic feet per second (cfs)
Dissolve	cause to pass into solution. In laboratory testing, substances may be considered dissolved if they pass through a 0.45µm filter
Diurnal	Relating to or occurring in a 24-hour period; daily.
DO	Dissolved Oxygen
Drainage area	The area of land that drains to a particular body of water or site on a waterbody.
DRBC	Delaware River Basin Commission
DVRPC	Delaware Valley Regional Planning Commission
DWO	Dry-Weather Outlet - connector pipe between a CSO regulator and interceptor sewer.
Dynamic	relating to conditions that change or are in motion; not static

E. coli	a common rod-shaped bacterium that is found in the intestinal tract of warm blooded animals. Used as an indicator of contamination by feces/sewage.
EACs	Environmental Advisory Councils
Ecoregion	a relatively large area of land characterized by a unique set of communities, physical, and climatological characteristics
Ecosystem	a collection of living things and their environment
Ecotoxicology	the study of environmental toxins
Effluent	outflow of liquid waste, such as discharge from a sewage treatment plant
Empirical	of or related to direct observation; not theoretical
Encapsulated	enclosed or covered, such a stream that has been built into a sewer
Endogenous	coming from or produced wholly from within, such as an enzyme produced by bacteria
E.P.A.	United States Environmental Protection Agency
EPT	(Ephemeroptera + Plecoptera + Trichoptera) three insect orders that are generally sensitive to organic pollution and are used to measure stream water quality
Epifaunal	of or relating to stream surfaces upon which attached alga and other living things may grow or find shelter
Epiphyte	a type of plant or algae that grows upon another plant or algae
Equilibrium	a steady state or condition in which opposing influences balance one another out
Erosion	the process by which soil particles are removed or displaced, usually by wind or water
Estuary	a body of water intermediate between an ocean and river, usually tidal and highly productive
ET	Evapotranspiration – the sum of water vapor evaporation from the earth's surface and transpiration from plants.
Eutrophic	characterized by abundant or overabundant life, such as a stream or river that is nutrient enriched and has dense growth of algae or aquatic vegetation

Eutrophication	the process through which a waterbody comes to have an overabundance of life, usually caused by nutrient enrichment
EVAMIX	A multi-criteria evaluation program to help choose objectively between various alternatives
FGM	Fluvial Geomorphology is the study of a stream's interactions with the local climate, geology, topography, vegetation, and land use; the study of how a river carves its channel within its landscape.
Filamentous	characterized by an elongated, sometimes repeating growth pattern, such as that exhibited by some types of green and blue-green algae
Filterer-collector	a functional feeding group of aquatic organisms characterized by feeding upon particulate matter that is filtered from flowing water by specialized appendage or apparatus, such as a silken net
Fluvial	of or relating to flowing waters, especially rivers
Floatables	Waterborne waste material and debris (e.g., plastics, polystyrene, paper) that float at or below the water surface.
Functional feeding group	a group of aquatic organisms defined by a common feeding strategy, such as predation on other living things
Generalist	describes a species that tolerates a broad range of environmental conditions
Geometric mean	A measure of the central tendency of a set of numbers defined as the product of all numbers of the set raised to a power equal to the reciprocal of the total number of members of the set. The geometric mean is always smaller than the Arithmetic mean
GIS	Geographic Information Systems
H_2CO_3	Carbonic acid
Handheld DO	Dissolved oxygen readings taken with a handheld meter.
Hardness	a measure of the concentration of Calcium and Magnesium ions in water
HCO_3-	Bicarbonate ion
Heterotrophic	describes organisms that cannot synthesize their own food through photosynthesis or other chemical means
Hexavalent	having valence number 6, such as hexavalent Chromium, a toxic metal
Hilsenhoff Biotic	A biological index of stream health that employs a scale of sensitivity of

Index (HBI)	macroinvertebrates to organic pollution
HNO_3	nitric acid, a source of atmospheric nitrogen pollution and acid rain
HSI	Habitat Suitability Indices
Humic	derived from decomposing organic matter, such as leaf litter.
Hydraulic	of or relating to forces exerted by a fluid, often water, under pressure
Hydrograph	A graphical representation of the change in stage or discharge of a stream as a function of time
Hydrolysis	a chemical reaction in which water reacts with another molecule, often resulting in new compounds. The breakdown of urea is a hydrolytic reaction
Hyetograph	a graphical representation of rainfall intensity as a function of time
IDD&E	Illicit Discharge, Detection, and Elimination – one of the six minimum control measures required of permittees under the Phase II NPDES Stormwater Regulations. Program steps include developing maps of municipal separate storm sewer system outfalls and receiving waterbodies; prohibiting illicit discharges via PADEP-approved ordinance; implementing an IDD&E Program that includes a field screening program and procedures, and elimination of illicit discharges; conducting public awareness and reporting program. A similar program is being followed by PWD in the Long Term Control Plan (LTCP) for CSOs.
Illicit connection	An illegal sewer connection, particularly connection of a sanitary sewer, household or industrial waste pipe to a storm sewer. Illicit connections may result in sewage or other pollution inputs to receiving waterbodies.
Impairment	weakening, damage, or instability, such as the effects caused by pollution
Impervious	incapable of being penetrated, such as a surface that does not absorb water
in situ	Latin, literally “in place”, refers to types of measurements and observations made directly in the natural environment, such as a water quality instrument installed in a stream
Index/Indices	A number, ratio, or value on a scale of measurement that can reveal differences between observations or reveal changes over time. Numerous indices are used to assess the health of aquatic communities, such as the Hilsenhoff Biotic Index or HBI

Infrastructure	The basic system of utilities and services needed to support a society. Structures such as culverts, pipes, bridges, dams, and flood control measures can cause instability of streams and affect aquatic habitats.
Inimical	harmful; injurious
Insoluble	unable to pass into solution
Instantaneous	immediate; occurring, such as a change, quickly. Some continuous water quality parameters are observed instantaneously
Invertebrates	animals, such as insects and crustaceans, that lack backbones (vertebrae)
Ion	an atom or molecule that has lost or gained an electron or electrons, resulting in a charged state
IPM	Integrated Pest Management
Iron	(Fe) a common metallic element; an essential nutrient that may be toxic in relatively large concentrations. Iron can cause problems with taste and color of drinking water.
Kjeldahl nitrogen test	a laboratory procedure for determining the concentration of ammonia and organically-bound nitrogen in a water sample
Kruskal-Wallis ANOVA	a non-parametric test that can be used to compare sample means when the assumptions of parametric statistics are not met
Larva/larvae	Immature life stage of an invertebrate, such as a beetle or fly. Many insects that have aquatic larval stages are used as bioindicators of water pollution.
LD50	in toxicity testing, an endpoint, such as toxin concentration, where 50% of the test organisms die over a specified exposure interval
Lentic	of or relating to still water, such as lakes, ponds, or bogs
LID	Low-Impact Development (similar to "better site design" and "conservation site design")
Ligand	An atom or molecule that can form a bond with a one or more central atoms (usually metals), forming a complex. Naturally occurring ligands compete with gill surface interaction sites for metals and metallic ions, reducing metal toxicity
Lotic	of or relating to flowing water, such as streams and rivers
LTCP	Long-Term CSO Control Plan – part of the EPA's CSO Control Policy for

	regulation of CSOs under NPDES that guides municipalities, state, and federal permitting agencies in reaching full compliance with the CWA.
Macroinvertebrates	Macroinvertebrates are invertebrate animals that can be seen without the aid of a microscope.
Macronutrient	a nutrient, such as nitrogen or phosphorus, needed in relatively large amounts for biological growth
Magnesium (Mg)	a common cation that contributes to hardness in water
Mainstem	the main flow or central channel of a stream drainage network into which tributaries flow
Manganese	a relatively common metallic element; an essential nutrient that may be toxic in relatively large concentrations
Mayfly	Aquatic insect of the order Ephemeroptera. Mayflies are recognized as being generally sensitive to pollution and are used as indicators of water pollution
Mean/ Arithmetic mean	average; a measure of the central tendency of a set of numbers equal to the sum of all members of a set divided by the number of members of the set
Median	In descriptive statistics, the value in a set of numbers for which half the members of the set are greater and half are smaller. In some instances, the median value may be more informative than the arithmetic mean if a small number of extreme values tends to skew the mean
Mesotrophic	characterized by a moderate amount of biological growth; not eutrophic
Metabolism	all the biochemical processes exhibited by a living organism
Methemoglobinemia	A medical condition in which the oxygen carrying capacity of hemoglobin is disrupted by a faulty gene or exposure to toxins. Infants are especially susceptible to methemoglobinemia due to exposure to nitrates, a condition termed “blue baby syndrome”
mhos	A unit of electrical conductance; a measure of the ability to pass electric current. Water itself is an insulator, but dissolved ions increase its ability to conduct electricity
Microcrustacean	A crustacean that is not readily visible to the unaided eye
Microgram (µg)	A unit of mass equivalent to 1/1,000,000 of a gram
Microhabitat	Fine scale habitat, features of which are important to small living things

Micronutrient	A nutrient, such as a trace metal, needed in relatively small concentrations for biological growth. Micronutrients may limit growth if macronutrients are very abundant
Microorganism	An organism, such as a bacterium or alga, that is observable only under magnification
Microsiemen (µS)	A unit of electrical conductance, Microsiemens/cm is a common unit of measure in water chemistry.
Minnow	Any of a number of species of fish, typically small, of the family Cyprinidae. Minnows are an important link in the aquatic ecosystem, consuming invertebrates and being preyed upon by larger fish
Model	A useful representation, such as a computer simulation, that can be used to simplify and study systems and processes
MPC	Municipalities Planning Code
MRL	Method reporting limit, a measure of the accuracy of a laboratory procedure that takes actual test conditions and characteristics of the environmental sample into account. MRLs are always smaller than method detection limits (MDLs) and may change from laboratory to laboratory or from day to day depending upon the actual performance of an instrument or technique
MS4	Municipal Separate Storm Sewer System
NH_3	Ammonia (gaseous, un-ionized)
NH_4+	Ammonium ion
Nitrate (NO_3)	An oxidized form of Nitrogen; an essential plant nutrient. Elevated Nitrate concentration may result in eutrophication of water bodies and in very great concentrations may be toxic (see methemoglobinemia)
Nitrification	Process of converting ammonia to nitrite and nitrate in the presence of oxygen, especially by the action of naturally occurring bacteria
Nitrite (NO_2-)	An oxidized ion of nitrogen; an intermediate form in the reaction that converts ammonia to nitrate. Nitrite is usually not available for plant growth
Nitrogen	A macronutrient needed for biological growth. Inert nitrogen gas makes up a large portion of the Earth's atmosphere
NLREEP	Natural Lands Restoration and Environmental Education Program (a unit of Philadelphia's Fairmount Park Commission)

NOAA	National Oceanic and Atmospheric Administration
Nonferrous	not containing iron; especially metals and alloys that do not contain iron
Nonparametric statistics	a collection of statistical analysis tools, used when the data to be analyzed do not meet the assumptions of parametric statistics, such as homogeneity of variances
Non-point source pollution	Pollution that comes from a diffuse source such as atmospheric deposition, stormwater runoff from pasture and crop land, or individual on-lot domestic sewage systems discharging through shallow groundwater.
Non-structural BMPs	These BMPs will require no operation or maintenance. Examples are use of open space and vegetated buffers in development design, minimization of soil disturbance and compaction during construction, and minimization of directly-connected impervious areas.
NPDES	National Pollutant Discharge Elimination System
NPDES Phase I	The stormwater management component of the NPDES program instituted in 1990, which addressed the storm runoff sources most threatening to water quality. Under this phase, industrial activity, and construction sites within large communities (population 100,000 or more) are required to obtain permits for the storm water leaving the site.
NPDES Phase II	Additional stormwater management regulations enacted in 1999, applying to smaller communities and construction sites.
NRCS	Natural Resource Conservation Service
NTU	nephelometric turbidity units; a unit of measure describing the light scattering properties of a water sample
Nutrient	An element or molecule needed for biological growth. When nutrients such as phosphorus are present in great concentrations, biological growth (algae in particular) can become overabundant, causing problems for aquatic ecosystems
Oligotrophic	characterized by a relatively small amount of biological growth
OLDS	On-Lot sewage Disposal Systems
O&M	Operations and Maintenance
OOW	PWD’s Office of Watersheds
Orthophosphate	a dissolved, inorganic form of phosphorus, available as a nutrient for

(OPO_4)	plant growth; soluble reactive phosphorus
Outfall	a pipe or other structure that discharges flow, such as treated sewage effluent or stormwater, to receiving waters
Outlier	in statistics, a data point or observation that is far away from the rest of the data. Statistical techniques can be used to identify and remove outliers from a data set, if desired
Oxidation	chemical process in which a molecule or atom reacts with oxygen or generally, a reaction in which an atom loses electrons and increases in valence state; the opposite of a reduction reaction
Oxygen	an element, common in Earth's atmosphere and dissolved in water, necessary for most forms of complex animal and plant life
PA Act 167	Stormwater Management Act
PA Act 537	Sewage Facilities Planning Act
PADCNR	Pennsylvania Department of Conservation and Natural Resources
PADEP	Pennsylvania Department of Environmental Protection
Parameter	A chemical constituent or physical characteristic of water quality (*e.g.*, dissolved oxygen is a chemical constituent, temperature is a physical characteristic)
Parametric statistics	a collection of powerful statistical tools that assume certain qualities of the data being analyzed, such as homogeneity of variances
Parasite	a functional feeding group of aquatic organisms characterized by feeding usually upon bodily fluids of other organisms, rather than direct predation and consumption. The organism that is fed upon need not die due to the effects of feeding
PEC	Pennsylvania Environmental Council
Periphyton	collectively, the algae growing upon stream surfaces; a group or growth form of algae defined by a bottom or surficial growth habit
PFBC	Pennsylvania Fish and Boat Commission
Phenolics	Any of a group of aromatic compounds having at least one hydroxl group**.** Phenolics in surface waters generally originate from industry and are toxic in relatively small concentrations.
Phosphatases	any of a group of enzymes, such as those produced by some algae, that can convert or liberate phosphorus from an organically bound to soluble, usable form

Phosphate	An oxidized form of phosphorus, which may be organic or inorganic. Inorganic phosphates are generally more likely to be available as nutrients for biological growth
Photosynthesis	A set of chemical reactions in which plants and other organisms, such as blue-green algae, can synthesize their own food using light and inorganic carbon. Photosynthetic activity in water increases dissolved oxygen concentration during daylight hours.
Physicochemical	physical and chemical properties of water; a term used to group water quality parameters of interest
Phytoplankton	collectively, algae suspended in water; a group or growth form of algae defined by passive or active suspension in the water column
PO_4	phosphate
Point source	Pollution discharged from a single point, defined in the CWA as "any discernable, confined and discrete conveyance, including but not limited to any pipe, ditch, channel, tunnel, conduit, well, discrete fissure, container, rolling stock, concentrated animal feeding operation, vessel, or other floating craft from which pollutants are or may be discharged."
Potassium (K)	an elemental macronutrient required for biological growth
POTW	Publicly Owned Treatment Works
PRD	Planned Residential Development
Predator	a functional feeding group of aquatic organisms characterized by actively feeding upon captured prey
Preferenda/ preferendum	a preferred environmental condition, such as the temperature range an organism will tend to occupy when presented with a gradient
Producers	collectively, the components of an ecosystem, predominantly plants and plant-like living things, that make their own food by chemical means from inorganic building blocks; the base of the food chain
Productivity	a measure of the amount of biological growth that occurs in an ecosystem
PWD	Philadelphia Water Department
QA/QC	Quality Assurance/Quality Control
RBP	Rapid Bioassessment Protocol (developed by the EPA) a standard method to assess aquatic health through fish and macroinvertebrate diversity (EPA Website).

RBPIII	(Rapid Bioassessment Protocol III) EPA approved technique for evaluating macroinvertebrate communities of a river or stream
RBPV	(Rapid Bioassessment Protocol V) EPA approved technique for evaluating the fish communities of a river or stream
RCP	PA DCNR’s Rivers Conservation Planning Program
Reach	a segment of a stream as defined by the study being undertaken
Recoverable	a substance, such as a metal, that can be removed, dissolved or taken away in a chemical reaction or physical process
Redfield ratio	an approximation of the relative molar concentrations of the most common elements (Carbon, Nitrogen, and Phosphorus) present in organic matter, usually expressed as 106:16:1
Reduction	a reaction in which an atom or molecule gains electrons, decreasing valence state; not oxidation
Reference	A condition or value used for comparison. Many types of biological assessment techniques require comparison to references
Regulator	in sewer infrastructure, a physical gate, valve, or other control structure that routes flow between two or more receiving pipes, usually one of which terminates in a CSO
Replicate	additional sample(s) or observation(s) which can be used to measure the accuracy or repeatability (precision) of an experimental result
Respiration	biological metabolic process in which a large molecule is broken into smaller pieces to yield usable energy. Aerobic respiration, the efficient respiration reaction favored by complex living things, requires oxygen.
Riffle	a reach of stream that is characterized by shallow, fast moving water broken by the presence of rocks and boulders
Riparian	related to, within, or near a river or its banks
Riparian corridor	The area of land along the bank or shoreline of a body of water (EPA website).
Riparian woodlands	Woodlands that grow within the riparian corridor.
RTC	Real Time Control - a dynamic system of hydraulic controls to provide additional storage and reduce overflows from a combined sewer system
Run	a reach of stream that is characterized by smooth flowing water

Runoff	generally, precipitation that is not absorbed by surfaces or evaporated, but allowed to flow over the surface to a receiving body of water
Scraper	a functional feeding group of aquatic organisms characterized by feeding upon living attached material, usually algae, by means of a specialized scraping apparatus or mouthparts
Sediment	particles, especially inorganic soil particles, that settle upon stream surfaces
SEO	Sewage Enforcement Officers (designated by PADEP)
Seston/Sestonic	of or relating to the collection of inorganic and organic particles that settle to the bottom of a body of water; usually used to describe the predominantly organic detrital particles that settle to the bottom of a lake or pond.
Shear	generally, the physical force applied perpendicularly or at an angle to a surface, such as the hydraulic force applied to stream banks and surfaces by flowing water
Shredder	a functional feeding group of stream invertebrates that consume coarse particulate matter, such as leaves
Sinuosity	a measure of the degree to which a stream, viewed from above, deviates from a linear path, expressed as the ratio of stream length between two points divided by the valley length, or point-to-point distance between the same two points
Slough	to scour or remove from a surface, such as the removal of surficial algae by physical hydraulic force
Significant	when describing the results of scientific or experimental study, describes a comparison or relationship that has been determined to be more likely real than related to randomness or chance to a stated degree of confidence
Silt/Siltation	Inorganic sediment particles between 3.9 and 62.5 µm in diameter. also the process of being covered by or embedded in silt
SOD	sediment oxygen demand; a measure of the oxygen depleting capabilities of decomposing organic material and oxidizable inorganic material in sediment, often expressed as a mass of oxygen per unit area over time
Soluble/Solubility	The quality or state of being able to pass into solution. In water chemistry analysis, a substance may be considered soluble or dissolved if it passes through a 0.45µm filter
Sonde	a continuous water quality monitoring instrument

Speciation	the process of distinguishing between different forms of a substance through analytical or chemical means; or the process through which a substance is converted to two or more different forms
Species	the level of biological taxonomic classification at which living things are separated from one another by the ability to reproduce yielding fertile offspring
SRP	soluble reactive phosphorus; see orthophosphate
SSA	Separate-Sewered Area stormwater runoff
SSET	Sewer Scanner and Evaluation Technology
SSMS	Sanitary Sewer Management System
SSO	Sanitary Sewer Overflow
Stage	level of a stream's water surface, as measured on a gauge or reference datum
Stonefly	An insect of the order Plecoptera, a group of insects usually having an aquatic life stage which are generally sensitive to organic pollution. Often used as a bioindicator of organic pollution.
STORET	USEPA's water quality database (STOrage and RETrieval)
Stormwater Management Program Protocol ("Protocol")	PADEP guidance for implementing the requirements of the NPDES Phase II stormwater regulations
Structural BMPs	These BMPS will require proper operation and maintenance. Examples include wet ponds, grassed swales, infiltration basins and bioretention areas.
Substrate	a surface upon which living things grow; commonly, the bottom of a stream or river
Supersaturation	the condition in which a substance, such as dissolved oxygen, is dissolved in a solvent in a concentration exceeding the usual maximum concentration for the solute under given conditions. When algae are very abundant, they may increase dissolved oxygen concentration to the point of supersaturation
SWMM	Storm Water Management Model
Taxon/taxa	a distinct unit of biological taxonomic organization, such as a family or species

TDR	Transfer of Development Rights
Temporal	of or relating to time, such as a change observed over time
TIGER	Topologically Integrated Geographic Encoding and Referencing (U.S. Census database)
Tipulid	cranefly; an insect of the family Tipulidae, of which many secies are aquatic or semi-aquatic as larvae
TMDL program	Total Maximum Daily Load program - EPA/PADEP program for limiting and allocating discharges of a pollutant within a watershed.
TOC	total organic carbon
Toxic/toxicity	describing a substance that is harmful, able to cause injury or death; also the concentration at which a substance may cause injury or death
Transpiration	The process by which water vapor passes through the membrane or pores of plants to the atmosphere.
Trivalent	having valence 3, such as Cr[III], a non toxic, trace nutrient form of Chromium
Trophic	describing or relating to food, food type, or the process through which a living thing acquires food
TSS	Total Suspended Solids
TTFIWMP	The Tookany/Tacony-Frankford Integrated Watershed Management Plan
Turbidity	a measure of the light scattering properties of water
UA	Urban Areas
UAA	Use Attainability Analysis
Unimpaired	natural, unmolested; describing an unaltered or undisturbed state
Urea	a nitrogen-containing breakdown product of protein metabolism
USDA	United States Department of Agriculture
USGS	United States Geological Survey
Velocity	a vector quantity that describes speed in a stated direction or along an axis
Vertebrate	a complex living thing having a backbone (vertebrae)

Violation	an instance or time period during which a regulated water quality parameter was exceeded
Watershed	The area of land draining to a stream, river, or other water body. Watershed boundaries are established where any precipitation falling within the boundary will drain to a single water body. Precipitation falling outside the boundary will drain to a different watershed. These boundaries are typically formed on high elevation ridges. The water bodies formed from the watershed drainage are usually at the lowest elevation in the watershed. Watersheds can also be called drainage basins.
WLA	waste load allocation
WMP	Watershed Management Plan
WQS	Water Quality Standards
WRAS	PADEP's Watershed Restoration Action Strategy

TTFIWMP User Guide

Below is a brief orientation to the type of content found in each section of this report. These "snapshots" are repeated on the first page of each section as well.

Section 1: Background

Details the reasons for developing the Tookany/Tacony-Frankford Integrated Watershed Management Plan, or TTFIWMP, and the purposes the plan is intended to serve. Provides an orientation to various facets of the TTF Watershed itself (geographical, ecological, historical, cultural, etc.), and describes the TTF Partnership, which was involved throughout the plan's development and will be instrumental to its implementation. Finally, the overall watershed planning and regulatory framework is outlined in Sections 1.4 – 1.7.

Section 2: Integrated Watershed Management for the TTF Watershed

Describes the watershed planning approach behind the TTFIWMP. Outlines the types of existing and new data that were assembled and analyzed, as well as the process for modeling stormwater flow under various scenarios. Introduces several key concepts of the TTFIWMP: the overall goals and objectives (detailed in Section 3), the 21 watershed "indicators" (Section 4); and the screening of numerous methods, or "management options," for meeting the goals (Section 7). In addition, introduces the approach of setting multiple strategies – Targets A, B, and C – for promoting successful implementation of the TTFIWMP.

Section 3: Goals and Objectives

Describes the process for setting overall watershed goals for the TTFIWMP, as well as numerous objectives for helping to reach those goals. The seven prioritized goals, referenced throughout this document, are useful for evaluating the wide range of possible management options for implementing the plan.

Section 4: Watershed Indicators: TTF Study Results

Details the 21 measurable "watershed indicators" that were created in order to assess historic and current conditions, and to track progress as the TTFIWMP is implemented over time. The information presented can serve as a basis for understanding the state of the TTF Watershed, its relative environmental quality, and trends in the management of factors that influence its quality.

Section 5: Problem Definition and Analysis

The watershed indicators described in Section 4 are used both to characterize the current state of the TTF Watershed, and to set a baseline for future comparison. Section 5 identifies the wide range of potential problems that have been identified in the watershed, and describes the analysis tools used to define them.

Section 6: Causes of Impairment

Discusses the causes of the various watershed problems identified through field study, stakeholders input, modeling, and data analysis. This section forms the link between the problem analysis presented in Section 5, and the identification of alternative solutions, or management options, presented in Section 7.

Section 7: Development and Screening of Management Options

Summarizes a comprehensive list of stormwater and watershed corrective measures, or "management options," that the TTF Watershed Partnership judged to be potentially applicable to their watershed. This list serves as the starting point for the screening and evaluation steps (Section 7.2) that lead to the array of recommendations contained in the Implementation Guidelines (Section 8).

Section 8: Implementation Guidelines

Presents guidelines for watershed-wide implementation of the management options identified by the Tookany/Tacony-Frankford Watershed Partnership as best meeting the goals and objectives of the TTF Integrated Watershed Management Plan. Following extensive screening and evaluation (described in Section 7), only those options that are likely to be cost-effective and feasible under the specific conditions found in the TTF Watershed are carried over and included in these guidelines. The section begins with tips on how to navigate the information presented.

Section 9: Cost and Institutional Analysis

Presents cost estimates for the various recommended management options, and for the full set of Implementation Guidelines (from Section 8). Those cost estimates are then broken down by county and by municipality within the TTF Watershed. Finally, the section outlines the primary roles and responsibilities for the various levels of stakeholders in the implementation of the TTFIWMP.

Executive Summary

Tookany/Tacony-Frankford Integrated Watershed Management Plan (TTFIWMP)

Foreword

This plan presents a logical and affordable roadmap for the restoration and protection of the beneficial and designated uses of the Tookany/Tacony-Frankford Creek basin. The Tookany/Tacony-Frankford Integrated Watershed Management Plan (TTFIWMP) is based on extensive physical, chemical, and biological assessments. It explores the nature, causes, severity, and opportunities for control of water quality impairments in the TTF Watershed. The primary intent of this planning process is to improve the environmental health and safe enjoyment of the Tookany/Tacony-Frankford Creek by sharing resources and through cooperation among residents and other stakeholders in the watershed.

The goals of the initiative are to protect, enhance, and restore the beneficial uses of the Tookany/Tacony-Frankford waterway and its riparian areas. This plan recommends appropriate remedial measures for the Tookany/Tacony-Frankford Creek basin and a financial commitment to initiate implementation of recommendations right away. This planning process has sought to provide the impetus for stakeholders of the Tookany/Tacony-Frankford basin to follow suit.

The Philadelphia Water Department conducted a comprehensive, multi-year assessment of the Tookany/Tacony-Frankford Watershed (see Figure E.1). Results of the watershed-wide assessment suggests that at some times during dry weather periods, bacteria contamination of the Tookany/Tacony-Frankford's waters prevents the achievement of water quality standards that would support swimming or other forms of primary contact recreation in the creek. (For a detailed account of the assessment methodology and data results, see the 2004 Tookany/Tacony-Frankford Comprehensive Characterization Report.) Stream aesthetics, accessibility, and safety are compromised due a number of factors, including litter and illegal dumping, trash from stormwater discharges, channelization of portions of the stream, and bank deterioration along stream corridors. The existing aquatic and riparian habitats have been degraded by urban runoff, limiting the diversity of fish and other aquatic life and preventing the development of healthy living resource conditions necessary to support recreational activities such as fishing. Wet weather water quality is limited by bacteria discharged from combined and separate storm sewers. High rates of urban runoff cause flooding during larger storms, and flood flows that erode the stream banks and bottoms and have subsequently exposed and compromised utility infrastructure.

The good news is that measurable progress can be made towards restoring the legislated designated uses of the stream. To this end, this plan provides a commitment from the Philadelphia Water Department to an investment strategy for achieving definable levels of environmental return in the Tookany/Tacony-Frankford Creek basin. It is estimated that significant progress towards improving the various areas of environmental concern can be made for an investment of less than $290 per household per year over a 20-year horizon.

The plan proposes that the upstream municipalities of Montgomery County in the Tookany/Tacony-Frankford basin make similar financial commitments to implementation in order to ensure the restoration and preservation of the waters that flow through and from their communities, helping to shape their quality of life along the way. A significant portion of this funding is directed towards work that reflects the widely recognized national need to renew our water resources infrastructure. It is proposed that a combination of Federal, state and local government, along with private funding, be brought to bear in order to implement this plan watershed-wide. The Philadelphia Water Department has expended over $1 million for the development of the plan, and will commit an additional $2-3 million per year or more towards implementing its recommendations over the next 20 years.

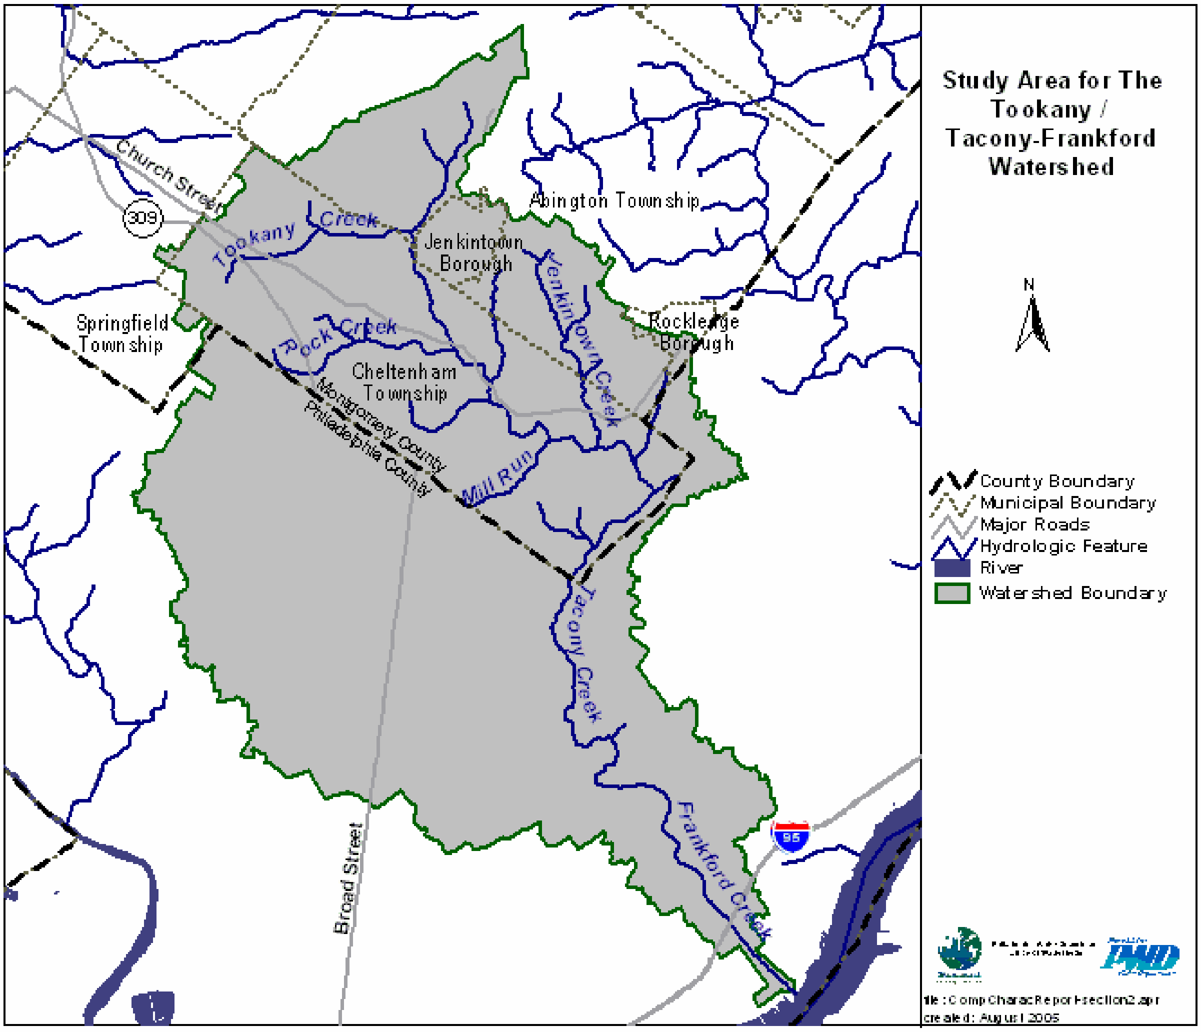

Figure E.1 Tookany/Tacony-Frankford Watershed

Background

Stewardship of a river must be built around the needs of the community. It will grow by making visible the critical way the health of the watershed is integral to basic quality of life issues. Once the seeds of stewardship have been planted, members of the community can be recruited to take action in protecting their watershed.

In 2000, PWD acted as the municipal sponsor of the Tookany/Tacony-Frankford Watershed Partnership, an exciting and groundbreaking effort to connect residents, businesses, and government as neighbors and stewards of the watershed. PWD hired the Pennsylvania Environmental Council (PEC), a well-respected, non-profit institution with a reputation for supporting watershed-based, holistic planning in the form of smart growth planning, as the facilitator and outreach coordinator of this partnership. PEC pulled together a diverse representation of the watershed including municipalities, “friends” groups, educators, agencies, residents, and other nonprofit organizations for participation in this planning process. Since then, the Partnership has been active in developing a vision for the watershed and guiding and supporting subsequent planning activities within the Tookany/Tacony-Frankford watershed.

The mission of the TTF Partnership was summarized as follows:

- To increase public understanding of the importance of a clean and healthy watershed.
- To instill a sense of appreciation and stewardship among residents for the natural environment.
- To improve and enhance our parks, streams, and surrounding communities in the Tookany/Tacony-Frankford Watershed.

With this Tookany/Tacony-Frankford Integrated Watershed Management Plan, PWD, supported by the TTF Partnership, has now completed the multi-year watershed planning effort intended to lead to the restoration of the Watershed as one that can boast fishable, swimmable, and enjoyable streams.

The main purposes of the plan, as articulated by the stakeholders, are: to mitigate wet weather impacts caused by urban stormwater runoff and combined sewer overflow (CSO); to identify ways to improve water quality, aesthetics, and recreational opportunities in dry weather; and to restore living resources in the stream and along the stream corridor. PWD placed a high priority on the development of the TTFIWMP because it represents one of the three major components of the City of Philadelphia’s CSO Long Term Control Plan strategy. This component entails a substantial commitment from the City to watershed planning to identify long term improvements throughout its watersheds, including any additional CSO controls that will result in an improvement of water quality and, ultimately, the attainment of water quality standards.

PWD was not alone in this planning effort. Significant support from other agencies has helped to fund various components of the plan and helped to better integrate this effort with other regulatory programs. The U.S. EPA provided funding under its Wetland Program Grant to help assess existing wetlands within the Tookany/Tacony-Frankford Watershed and provide basic data for developing wetland restoration projects. Through the Act 167 Stormwater Management Program, PA DEP provided funding to PWD for modeling and analysis to support stormwater planning, as well as to initiate the creation of an Act 167 Plan for this watershed. Finally, initial planning efforts and the development of planning goals were embodied in two Rivers Conservation Plans (one for the Montgomery County portion and one for Philadelphia portion of the watershed) funded by PA DCNR.

Plan Goals

Considerable stakeholder input towards developing watershed goals was sought from the beginning of this planning effort. Stakeholder input was primarily organized through the Partnership; through a weighting and evaluation process, consensus on a set of planning goals and objectives was achieved. In addition, the plan sought to integrate goals derived from other relevant regulatory programs and both Rivers Conservation Plans to more fully achieve the ideal of integrated water resource planning. The resulting integrated planning goals, and their relation to the major regulatory programs, are summarized in Table E.1.

Table E.1 Regulatory Support for Stakeholder Goals for the Tookany/Tacony-Frankford Watershed

Goal Description	Act 167 Stormwater	Act 537 Sewage Facilities	TMDL Program	NPDES Stormwater	CSO Program	RCPs
1. Streamflow and Living Resources. Improve stream habitat and integrity of aquatic life.	X		X	X	X	X
2. Instream Flow Conditions. Reduce the impact of urbanized flow on living resources.	X				X	X
3. Water Quality and Pollutant Loads. Improve dry and wet weather stream quality to reduce the effects on public health and aquatic life.		X	X	X	X	X
4. Stream Corridors. Protect and restore stream corridors, buffers, floodplains, and natural habitats including wetlands.						X

7. Stewardship, Communication, and Coordination. Foster community stewardship and improve inter-municipal, inter-county, state-local, and stakeholder cooperation and coordination on a watershed basis.	X	X	X	X	X	X

Planning Approach

Once the Partnership had established the goals and objectives for the TTFIWMP, a planning approach was designed to achieve the desired results through a cooperative effort between the City of Philadelphia and upstream municipalities. The approach has four main elements:

- Data collection, organization, and analysis
- Systems description
- Problem identification and development of plan objectives
- Strategies, policies, and approaches

Watershed Status and Problem Identification

An integral part of this plan is the assessment and description of existing conditions within the watershed and stream. This assessment has identified specific problem areas, while establishing a "watershed baseline" from which we can measure our future progress as recommendations are implemented. Based upon these existing conditions, a series of "watershed indicators" were developed so that as implementation occurs in the coming years, progress can be quantified. "Indicators" are specifically designed to be measurable. For the TTF Watershed, 21 indicators (discussed in Section 4) were used for assessing current conditions and will be revisited annually to measure progress.

Through the extensive field studies, modeling, and data analysis, the highest priority problems in the Tookany/Tacony-Frankford Creek were identified, and the means for addressing the problems were developed. Given that the Tookany/Tacony-Frankford Watershed is highly urbanized with both CSOs and significant stormwater flows, some of the highest priority problems included:

Dry Weather Water Quality and Aesthetics

- Water quality concerns including high fecal coliform during dry weather
- Potential dry weather sewage flows in separate sewered areas
- Trash-filled, unsightly streams that discourage residential use
- Safety concerns along streams and stream corridors

Healthy Living Resources

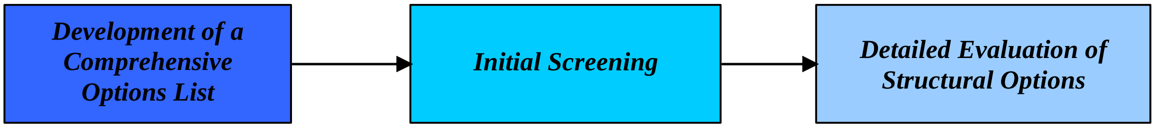
- Degraded aquatic and riparian habitats
- Loss of wetlands
- Channelized stream sections
- Limited diversity of fish and other aquatic life
- Periodic, localized occurrences of low dissolved oxygen in downstream areas
- Wide diurnal swings in dissolved oxygen
- Utility infrastructure threatened by bank and streambed erosion
- Limited public awareness and sense of stewardship for the creek

Wet Weather Water Quality and Quantity

- Water quality concerns including high fecal coliform, and nutrients and metals during wet weather flows
- CSO impacts on water quality and stream channels
- Little volume control and treatment of stormwater flows in separate sewered areas

Development and Screening of Management Options

Lists of options were developed as potential "solutions" to address the identified problems and to meet each of the goals and objectives established for the Tookany/Tacony-Frankford Watershed. Only those options deemed feasible and practical for the TTF Watershed were considered in the final list of management options. Options were developed and evaluated in three steps:



Since the plan cannot prescribe actions to be undertaken by all the participants in the planning process, recommendations and guidelines for implementation were developed. Modeling and other analyses were used to help recommend an approach for municipalities. Ultimately, it will be up to the TTF Partnership and the Montgomery County municipalities to turn these recommendations into a watershed-wide implementation plan.

Implementation Approach

In developing a recommended watershed management alternative and discussing goals and objectives with stakeholders, it became clear that implementation could best be achieved by defining three distinct targets to meet the overall plan objectives. Targets A and B were defined so that they could be fully met with full implementation of a limited set of options. For Target C, it was agreed to set interim objectives, recommend measures to achieve the interim objectives, implement those controls, and monitor and reassess the effectiveness of the plan in meeting the objectives.

Target A: Dry Weather Water Quality and Aesthetics

The first target is to meet water quality standards in the stream during dry weather flows. Target A was defined for Tookany/Tacony-Frankford Creek with a focus on trash removal and litter prevention, and the elimination of sources of sewage discharge during dry weather.

Sewers must be assessed to identify segments in need of rehabilitation, particularly where leakage is directly flowing into the stream. In separate sewered areas, a detection program for potential cross-connections is needed in order to eliminate dry weather flows.

Target A is also associated with improving the esthetic quality of the stream so that it can be viewed and treasured as a resource. Stream clean-ups are a way to achieve this while also involving residents and volunteers in the process.

Target B: Healthy Living Resources

Improvements to the number, health, and diversity of benthic macroinvertebrate and fish species in the Tookany/Tacony-Frankford Creek will require investment in habitat improvement and measures to provide the opportunity for organisms to avoid high velocities during storms. Improving the ability of an urban stream to support viable habitat and fish populations must focus primarily on the elimination or remediation of the more obvious impacts of urbanization. These include loss of riparian habitat, eroding and undercut banks, scoured streambed or excessive silt deposits, channelized and armored sections, trash buildup, and invasive species.

Target B is focused on improving the instream conditions of the Tookany/Tacony-Frankford Creek. Implementation projects are aimed at habitat improvements as well as measures to provide the opportunity for organisms to avoid high velocities during storms. Improvements to the number, health, and diversity of the benthic macroinvertebrate and fish species are anticipated as a result of these measures.

Target C: Wet Weather Water Quality and Quantity

The third target is to restore water quality to meet fishable and swimmable criteria during wet weather and address flooding issues. Improving water quality and flow conditions during and immediately following storms is the most difficult target to meet in the urban environment. The only rational approach to achieve this target must include stepped implementation with interim targets for reducing wet weather pollutant loads and stormwater flows, along with monitoring for the efficacy of control measures.

Initial load reduction goals for parameters such as stormwater flow, metals, total suspended solids, and bacteria were set in conjunction with the stakeholders. Based on preliminary work by PWD, a 20% reduction has emerged as a challenging but achievable interim goal.

Implementation Guidelines

All management options were thoroughly screened and evaluated using a variety of approaches, including computer simulation modeling and cost-effectiveness. This resulted in the selection of only those options appropriate and deemed effective for the particular conditions found in the Tookany/Tacony-Frankford Watershed. The Implementation Guidelines (Section 8) seek to present the options in such a way that each major stakeholder or responsible party understands what is expected. The guidelines are designed such that, if implementation follows the recommendations, all plan objectives associated with Targets A and B will be fully met, and the interim objectives for Target C will be met or even exceeded.

In Section 8, each recommended option is fully described, and a recommended level of implementation is provided. Where possible, locations for on-the-ground implementation are indicated.

Implementation Plans

The Implementation Guidelines presented in this document are intended to present a long-range vision for implementation over the upcoming 20-year horizon, and to be used as a reference by parties creating actual Implementation Plans in the future. Such plans will be designed to provide a detailed blueprint for specific tasks during a shorter planning period. Detailed planning for implementation of the TTFIWMP will be broken into four sequential 5-year periods to cover our 20-year implementation horizon.

The Philadelphia Water Department has created and committed to a detailed 5-year Implementation Plan for the portion of the Tookany/Tacony-Frankford Watershed within the City of Philadelphia (see summary in Appendix E). This plan has been designed to begin in 2006 and run through 2011; however, many recommended projects had already been initiated prior to 2006.

Planning Level Costs

Planning-level cost estimates have been developed for the majority of the options recommended. Because actual costs are highly dependent on site specific conditions and the extent to which implementation occurs, cost estimates are only approximate. These estimates are useful, however, in providing order of magnitude funding needs, and also as a comparison to potential costs associated with more traditional approaches to CSO control (e.g., large scale storage tanks designed to reach the 85% capture goal).

Estimated costs to PWD are separated from those to outside agencies (primarily municipalities) by apportioning costs based on ownership of facilities or simply by the relative areas of the watershed within and outside of Philadelphia City limits. “Cost per acre” values (Table E.2) are provided as a simple measure of the way costs are apportioned in the tables. Actual costs will depend on the exact mix of options ultimately implemented.

Table E.2 Total Watershed Plan Cost

Total		Philadelphia		Montgomery County	
Annual Cost	One-Time	Annual Cost	One-Time	Annual Cost	One-Time
$6,172,000	$148,459,000	$3,532,000	$68,839,000	$2,637,000	$79,625,000
$290/ac	$7,060/ac	$290/ac	$5,650/ac	$300/ac	$9,000/ac

The affordability of the costs associated with this plan was also analyzed. The results of this analysis are presented in Table E.3 for Philadelphia and for the combined suburban communities comprising the remainder of the watershed. For Philadelphia, the affordability calculation indicates that the incremental cost of the Tookany/Tacony-Frankford improvements would be approximately $10 per household per year, representing 0.03% of median household income. For the combined suburban communities, the cost would be $157 per household per year, representing 0.26% of the weighted median household income for those areas. Both of these values are well within U.S. EPA affordability guidelines, and represent relatively limited increases in the current rates being paid for water, sewer, and stormwater in Philadelphia.

The overall impact on affordability would need to be evaluated in the context of all the programs comprising water quality improvement within a given community. For example, residents of Philadelphia will ultimately help pay for management programs in five or more watersheds, while residents of Cheltenham, for example, will pay only for this one program. Because residents of Philadelphia will ultimately pay for improvements in a number of watersheds, the total cost per household in Philadelphia likely will be similar to the cost for households in the suburban communities.

Table E.3 Incremental Affordability Measure

		Philadelphia	Suburban Communities *(Combined)*
1	**One-time cost (annualized)**	$3,338,000	$3,875,000
2	**Annual cost**	$2,598,733	$2,268,386
3	**Total annual cost associated with TTFIWMP**	$5,936,733	$6,143,386
4	**Cost per acre in watershed**	$487	$694
5	**2000 MHI (median household income)**	$30,746	$59,621
6	**Estimated annual sewer user charge***	$343	$250
7	**WMP cost per household in watershed (in entire municipalities)**	$52.53 ($10.06)	$258.93 ($157.00)
8	**WMP cost as % of MHI in watershed (in entire municipalities)**	0.17% (0.03%)	0.43% (0.26%)
9	**Existing sewer cost + TTFIWMP cost in watershed (in entire municipalities)**	1.59% (1.15%)	0.62% (0.46%)

** The sewer user charge in Philadelphia includes a stormwater collection and treatment fee. Stormwater-related charges outside Philadelphia were not investigated.*

Tables E.4 and E.5 provide data to help communities outside Philadelphia place projected TTFIWMP costs in a local context. Table E.4 expresses estimated costs for communities per acre and per household inside the watershed boundaries; Table E.5 presents costs within the boundaries of all municipalities that intersect the watershed. These cost tables are but one illustration of a possible cost distribution, and are provided to help municipalities decide what funding and institutional mechanisms may be most appropriate given local conditions.

Table E.4 Distribution of Costs among Rate Payers in Tookany/Tacony-Frankford Watershed in Communities Outside Philadelphia

	Abington	Cheltenham	Jenkintown	Philadelphia	Rockledge
Municipality area in watershed (ac)	2,712	5,691	367	12,178	81
Area of municipality in watershed (% of municipality total)	27%	98%	99%	13%	37%
Households in municipality and watershed	7,147	14,218	2,013	113,022	348
Annual cost associated with TTFIWMP	$807,899	$1,695,749	$109,277	$3,532,000	$24,075
Cost per acre (within watershed)	$297.95	$297.95	$297.95	$290.03	$297.95
Cost per household (within watershed)	$113.04	$119.27	$54.29	$31.25	$69.18
Median household income ($/year)	$59,921	$61,713	$47,743	$30,746	$47,958
Cost per household (% of MHI)	0.19%	0.19%	0.11%	0.10%	0.14%

Watershed area in municipality (% of watershed total)	12.9%	27.1%	1.7%	57.9%	0.4%
Households in municipality	21,690	14,346	2,035	590,071	1,060
Annual cost associated with TTFIWMP	$807,899	$1,695,749	$109,277	$3,532,000	$24,075
Cost per acre (whole municipality)	$81.66	$293.42	$296.36	$38.69	$109.91
Cost per household (whole municipality)	$37.25	$118.20	$53.70	$5.99	$22.71
Median household income ($/year)	$59,921	$61,713	$47,743	$30,746	$47,958
Cost per household (% of MHI)	0.06%	0.19%	0.11%	0.02%	0.05%

Section 1
Background

This section details the reasons for developing the Tookany/Tacony-Frankford Integrated Watershed Management Plan, or TTFIWMP, and the purposes the plan is intended to serve. It provides an orientation to various facets of the TTF Watershed itself (geographical, ecological, historical, cultural, etc.), and it describes the TTF Partnership, which was involved throughout the plan's development and will be instrumental to its implementation. Finally, the overall watershed planning and regulatory framework is outlined in Sections 1.4 – 1.7.

The Tookany/Tacony-Frankford Integrated Watershed Management Plan (TTFIWMP) is based on a carefully developed approach to meet the challenges of watershed management in an urban setting. It is designed to meet the goals and objectives of numerous water resources related regulations and programs, and it utilizes adaptive management approaches to prescribe implementation recommendations. Its focus is on attaining priority environmental goals in a phased approach, making use of the consolidated goals of the numerous existing programs that directly or indirectly require watershed planning.

1.1 What Is a Watershed and Why a Plan?

Consider this vision, as presented by the Tacony-Frankford River Conservation Plan:

> *"Welcome to our world – a world that includes a Tacony Creek that is beautiful and full of life. A world that boasts a Tacony Creek Park and a host of community green spaces that make the heart leap at the beauty of nature. A world that offers the residents of the watershed opportunities to bike, run and play at its recreation centers and parks. A world that recognizes that a community that values and protects its natural spaces is a community that will economically and culturally thrive."*

A watershed is a natural formation including land and communities connected by the drainage area of a water body (Figure 1.1). Simply said, the health of a stream depends on the quality of the land surrounding it, which in turn relies on the people charged with the care for that land. How do we care for an urban watershed? By addressing practices of the past, including paving the land and piping the stormwater, which took place as the area was urbanized. These practices were deemed an important step in development at the time, but they have had a devastating impact on the natural environment. As scientific knowledge and values have changed over time, we have realized that we can have both a vibrant community and healthy natural resources, and that the two can reinforce one another.

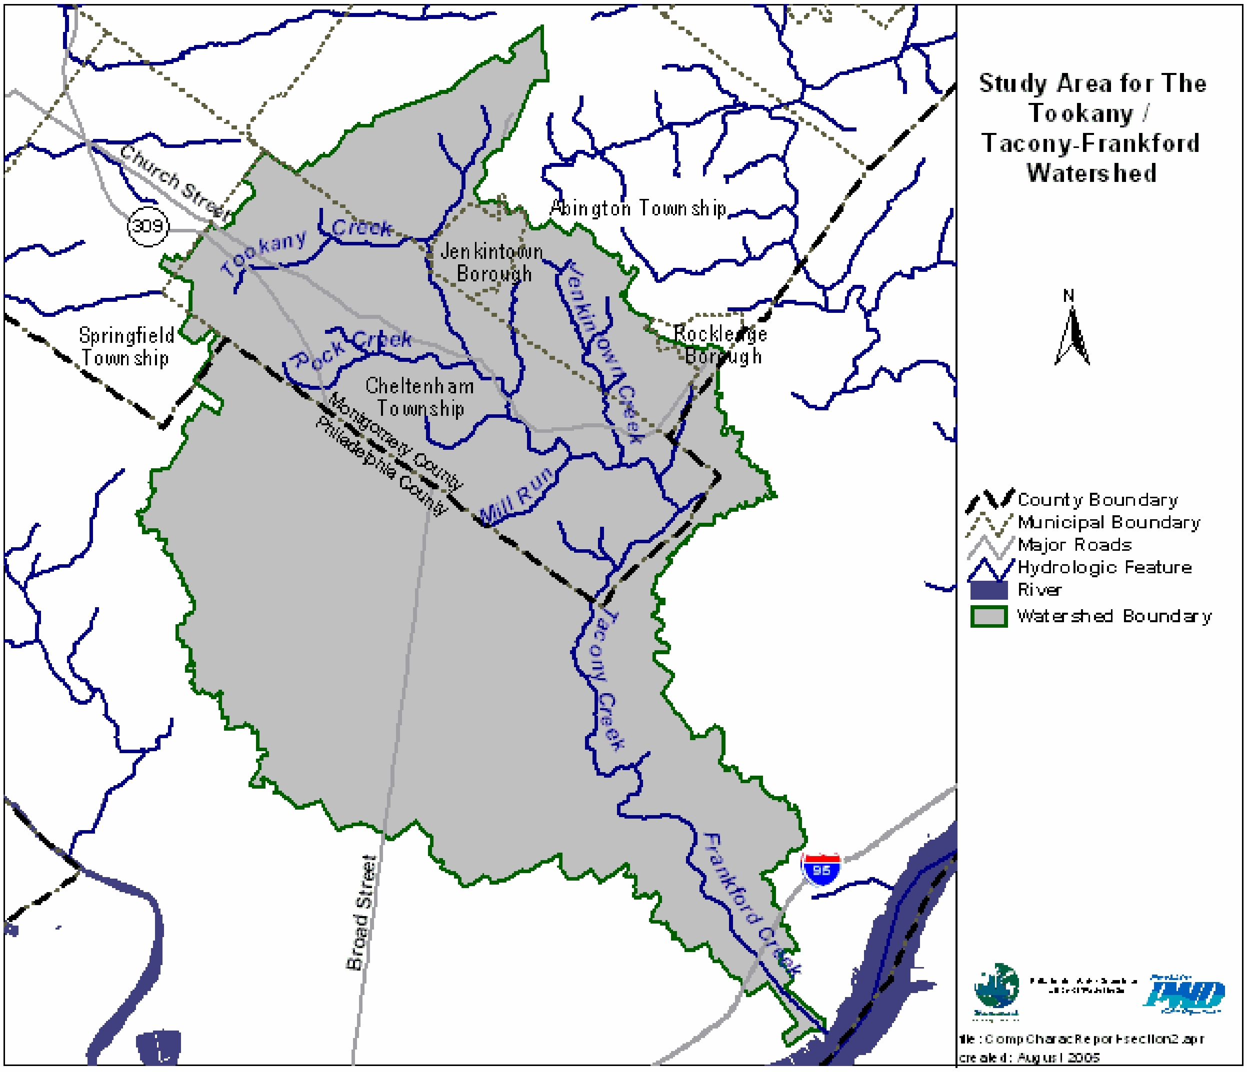

Figure 1.1 Tookany/Tacony-Frankford Watershed Study Area

An integrated watershed management plan is a long-term road map designed to achieve these twin goals of a healthy community and healthy natural resources. An integrated plan embraces the laws designed to save our streams, preserves the streams’ ecology, and enhances the parkland and riparian buffers that shelter these streams. The plan also reaches out to include the best of municipal and conservation planning that strives to ensure that growth within the watershed occurs with particular care to the environment. Most importantly, the plan incorporates a diversity of people who live, work, and dream in all areas of the watershed. People provide the catalyst for change, the energy to create the plan, and the vigilance to sustain the plan. These people, the stakeholders, become the watershed’s guardians – the keepers of the integrated plan.

The Tookany/Tacony-Frankford Partnership has provided a forum for stakeholders to work together to develop strategies that embrace our dual focus of improving stream water quality as well as the quality of life in our communities. Stakeholders care with their minds, hearts, and hands. TTF stakeholders include various government agencies – regulatory agencies, whose jobs empower them to guard the quality of our rivers and streams, as well as counties and municipalities, separate political entities bound together by nature. Stakeholders also include all those groups – nonprofit groups, neighborhood groups, religious groups, and schools – who define themselves as environmental advocates. Finally, stakeholders include concerned citizens who care about the state of their natural environment and their own quality of life.

Stakeholders have come together to discuss visions for the watershed. They shared thoughts of what they would like to see in our streams, parks, and neighborhoods. They are passionate about the possibilities – of revived aquatic and plant life, of streams that flow naturally, of parks that appear lush and inviting, of wetlands, and of meadows and woods that abound with wildlife. Together, we decide that our visions must become a reality.

The TTF Partnership discussed priorities and the actions necessary to make our initiative a successful one. These actions have become our strategy, and they address our desire to improve our water and land environment through a number of avenues. The TTFIWMP is built upon the foundation of environmental regulations, already in place and providing the impetus for stakeholders to work together to meet watershed goals. The plan's framework includes a number of elements – innovative land use controls and best management practices, improvements to piping and other conveyance systems, restoration of damaged stream corridors, and education and public awareness. These components, like good building materials, can result in a solid, sustainable structure, a plan that will result in a healthier and greener environment.

Stakeholders are committed to implementing the plan while canvassing for funds to nurture and sustain it, and they look to our governments and to stakeholders to contribute the dollars, expertise, and people to make their vision a reality. We will review our plan on a regular basis to ensure that it remains vital and to measure incremental successes that place us on the path of achieving our long-term goals. We share our plan with the residents of the watershed, showing how it works, and how each of them plays a part in its success. We empower them to share in our vision of a vital, dynamic watershed.

We look for solutions on the land where rainfall drains to our waterways, in the underground infrastructure that carries rainwater and wastewater away, and in and along our streams where natural ecosystems should thrive. As champions of our water resources, we believe this approach benefits not only our water environment, but also the region's physical, social, and economic environment.

1.2 Brief History of the Tookany/Tacony-Frankford Watershed

As part of both River Conservation Planning (RCP) initiatives, the Tookany/Tacony-Frankford Watershed Partnership has compiled a brief history of the watershed, including Tookany Creek. Portions of this history are reproduced here exactly as they appear in the RCPs.

Prior to the European settlement in the early 1600s, the area that is now Philadelphia was inhabited by the Lenape Indian tribe. The Lenape people, referred to as Delaware Indians by European Settlers, considered themselves the "original people." Lee Sultzman, in his *History of Delaware,* indicates that there was a widespread belief among native peoples that the Lenape were the original tribe of Algonquin speaking peoples to inhabit the area.

The Unami bank of Lenapes occupied the territory of Pennsylvania and New Jersey from Staten Island to just south of Philadelphia. The Unamis were not a politically cohesive group, but shared common language and cultural characteristics.

The Lenape people lived in villages and depended on agricultural crops such as squash and corn as their primary source of sustenance. Men of the tribe supplemented the tribe's diet through hunting and fishing. Tribal government consisted of three sachems or captains that represented the three matrilineal clans that comprised Lenape society. The head chief was always from the Turtle clan, although the position was elected and not strictly hereditary. The other two clans were the Wolf and Turkey clans.

First contact between the Lenape and Europeans (primarily Dutch explorers) occurred in the early 1600s. The Tacony-Frankford Watershed was colonized in the mid seventeenth century by different groups of immigrants. Swedes and Finns traveling up the Delaware River were the first European inhabitants of the Tacony Creek Valley, while Germans fleeing religious persecution settled in the western portion of the watershed in what is now Germantown. In 1664, the land that is southeastern Pennsylvania was surrendered to the English by the Dutch. In 1681, King Charles II of England granted William Penn 40,000 acres of land in the Delaware Valley as repayment for a debt owed to Penn's father. The entire Tookany/Tacony-Frankford Watershed lies within the area of this land grant. With the establishment of Penn's colony, English settlers flocked to the region, establishing homesteads, plantations, and towns.

The Tacony Creek and surrounding valley was primarily developed as an area of agriculture and milling operations. The Tacony Creek was dammed several times for mills and become a center for industrial operations during the late eighteenth and early nineteenth centuries. Expansion of the city in the late 1800s converted farmland into residential neighborhoods. Active agriculture persisted in the upper watershed until the early 1900s. Land for the Tacony Creek Park was purchased by the city in 1915, while land was being consumed for the need for new housing. The park was added to in 1939, and now occupies 302 acres. High-density housing characterizes the development of the area after the 1940s.

1.3 Watershed Description and Demographics

The Tookany/Tacony-Frankford Watershed is defined as the land area that drains to the Delaware River via that variously named creek. The Tookany/Tacony-Frankford study area includes parts of Montgomery County and a portion of Philadelphia County and covers a total of approximately 29 square miles, or about 20,000 acres. Figure 1.1 includes the watershed boundaries, hydrologic features, and political boundaries. The creek is referred to as the Tookany Creek until it enters Philadelphia at Cheltenham Avenue. It is then called the Tacony Creek from that Montgomery County border until the confluence with the historical Wingohocking Creek in Juniata Park. The section of stream from Juniata Park to the Delaware River is referred to as the Frankford Creek, and is underlain by a concrete channel.

The streams in the western portion of the watershed are contained in pipes and combined sewer infrastructure. Historic streams, including the Wingohocking Creek, Rock Run, and Little Tacony Creek, were encapsulated in combined sewers to facilitate the development of this watershed in the early twentieth century. Combined sewers convey sanitary waste, as well as stormwater to the city's wastewater treatment facilities. The total number of stream miles in this study is 14.4 miles in the mainstem creek and approximately 31.9 miles of encapsulated tributaries.

The drainage area is highly urbanized both in the lower reaches, which are primarily located in Philadelphia County, and in the upper reaches; however, that upper portion, included mainly in Montgomery County, is characterized by a more varying mixture of land uses. The population of the entire drainage area, based on 2000 census data, is approximately 331,400 people. This yields an average population density of approximately 16 -17 persons/acre.

In addition to CSO discharges to Frankford Creek from the City of Philadelphia, the drainage area receives a significant amount of point and non-point source discharges that impact water quality. According to the USGS data for the study area, the breakdown by sewer type is as follows: combined sewer areas make up 9,800 acres, or 47% of the drainage area; separate sewers, including areas outside of the City of Philadelphia, account for 9,200 acres or 44% of the drainage area; and non-contributing sewers make up 1,900 acres or 9% of the drainage area.

The waters in the drainage area receive point source discharges including CSOs and other urban and suburban stormwater, sanitary sewer overflows, and industrial storm, process, and cooling waters. Non-point sources in the basin include atmospheric deposition, overland runoff from urban and suburban areas, and potentially some remaining individual on-lot domestic sewage systems discharging through shallow groundwater.

In a relatively undisturbed watershed, the watershed boundaries follow topographic high points or contours. The U.S. Geological Survey (USGS) has further subdivided the Tookany/Tacony-Frankford Watershed based on topography, as shown in Figure 1.2. These USGS subwatersheds are determined from the land area draining to a particular point of interest, such as a stream confluence or gauging site. These boundaries allow initial determinations of drainage areas and modeling elements. However, it is important in the urban environment to include the effects of man-made changes to natural drainage patterns. In the Philadelphia portion of the watershed, drainage areas were adjusted to account for the combined sewer system drainage boundaries.

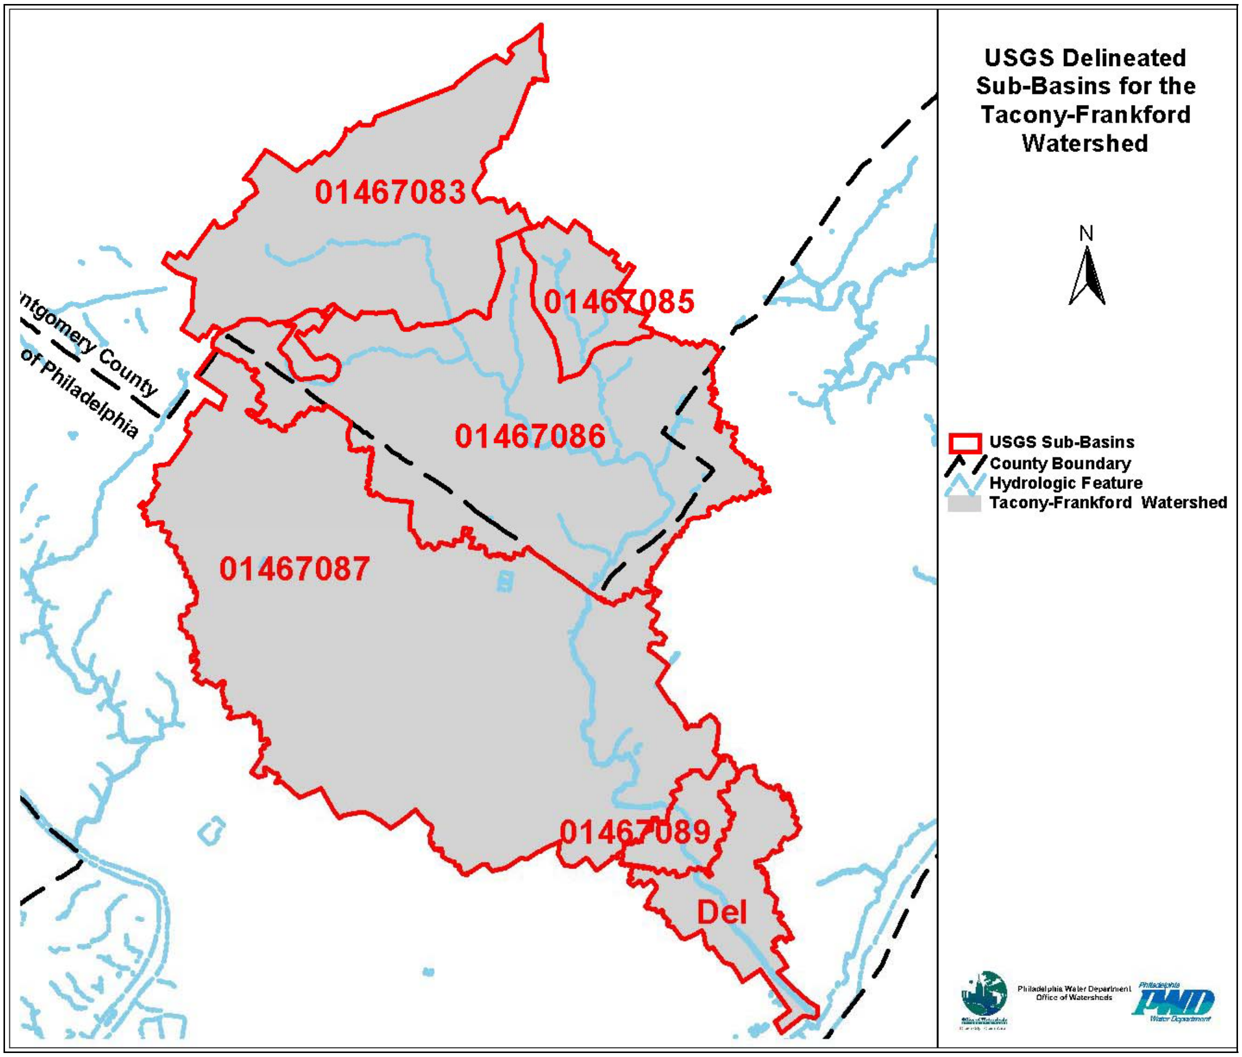

Figure 1.2 USGS Topographic Subwatersheds of the Tookany/Tacony-Frankford Watershed

Geology and Soils

Geology and soils play a role in the hydrology, water quality, and ecology of a watershed. The middle and upper reaches of the study area are in the Northern Piedmont Ecoregion (EPA Enviromapper). The Piedmont is characterized by ridges, hills, and deep narrow valleys. Elevation can vary from 40 feet at the fall line to 400 feet at the ridge tops. The topography of the study area is level except for steep slopes along the banks of the Tacony Creek. This section of the watershed is generally underlain by metamorphic and igneous geologic formations, predominately the Wissahickon Formation with small areas of gneiss and hornblende. These formations are exposed where the Tacony Creek has eroded overlying sediments to the bedrock (PA DEP 2001).

The lower portion of the watershed lies within the Middle Atlantic Coastal Plain Ecoregion. This is an area of low relief. Historically, the coastal plain in the city of Philadelphia was tidal marsh. These marshes were filled and paved over for urban development (PA DEP 2001). The topography of the coastal plain is gently sloping with elevations from 0 to 40 feet above sea level. The coastal plain is mainly comprised of unconsolidated sand and clay. These sands and clays are represented by the Pennsauken Formation, which was deposited in the Cretaceous period, and unconsolidated sand and clay (Trenton Gravel) deposited during the current quaternary geologic period.

Figure 1.3 displays a map of the geologic formations within the study area. The following are generalized descriptions of the geologic formations:

- **Wissahickon formation:** Typically a phyllite comprised of quartz, feldspar, muscovite, and chlorite. Moderately resistant to weathering. Fractures in platy patterns.
- **Mafic Gneiss, horneblend bearing:** Medium to fine grained, dark colored calcic plagioclase, hyperthene, augite, and quartz. Highly resistant to weathering.
- **Pennsauken formation:** Sand and gravel yellow to dark reddish brown, mostly comprised of quartz, quartzite, and chert. Deeply weathered floodplain formation.
- **Bryn Mawr formation:** White, yellow, and brown gravel and sand. Deeply weathered formation.
- **Quaternary deposits (Trenton gravel):** Unconsolidated sand and clays deposited by the Delaware River during the current geologic period.

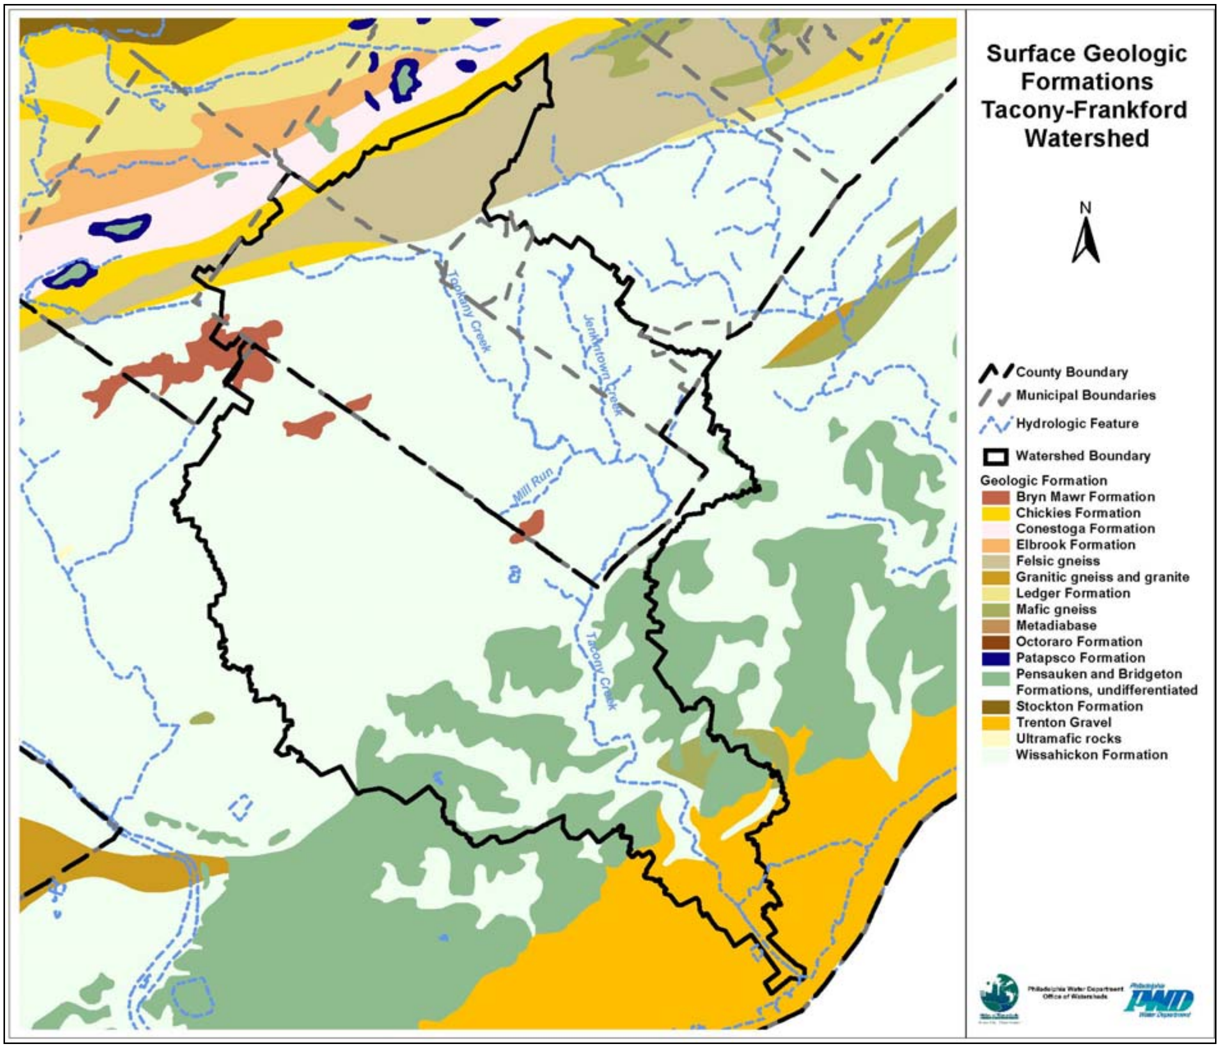

Figure 1.3 Surface Geologic Formations of the Tookany/Tacony-Frankford Watershed

Soils in the United States have been assigned to Hydrologic Soil Groups (HSG). The assigned groups are listed in Natural Resources Conservation Service Field Office Technical Guides, published soil surveys, and local, state, and national soil databases. The Hydrologic Soil Groups, as defined by NRCS engineers, are A, B, C, D, and dual groups A/D, B/D, and C/D.

Soils in hydrologic group A have low runoff potential. These soils have a high rate of infiltration when thoroughly wet. The depth to any restrictive layer is greater than 100 cm (40 inches) and to a permanent water table is deeper than 150 cm (5 feet).

Soils that have a moderate rate of infiltration when thoroughly wet are in hydrologic group B. Water movement through these soils is moderately rapid. The depth to any restrictive layer is greater than 50 cm (20 inches) and to a permanent water table is deeper than 60 cm (2 feet).

Hydrologic group C soils have a slow rate of infiltration when thoroughly wet. Water movement through these soils is moderate or moderately slow; they generally have a restrictive layer that impedes the downward movement of water. The depth to the restrictive layer is greater than 50 cm (20 inches) and to a permanent water table is deeper than 60 cm (2 feet).

Soils in hydrologic group D have a high runoff potential. These soils have a very slow infiltration rate when thoroughly wet. Water movement through the soil is slow or very slow. A restrictive layer of nearly impervious material may be within 50 cm (20 inches) of the soil surface and the depth to a permanent water table is shallower than 60 cm (2 feet).

Dual Hydrologic Soil Groups (A/D, B/D, and C/D) are given for certain wet soils that could be adequately drained. The first letter applies to the drained and the second to the undrained condition. Soils are assigned to dual groups if the depth to a permanent water table is the sole criteria for assigning a soil to hydrologic group D.

The HSG rating can be useful in assessing the ability of the soils in an area to recharge stormwater or to accept recharge of treated wastewater or to allow for effective use of septic systems. Figure 1.4 shows the hydrologic soil groups in the study area. The map indicates that most of the study area contains soil in the hydrologic category B, with some areas at the downstream end shown as category C. This means that most of the study area has soils that have a moderate to high rates of infiltration when thoroughly wet, and water movement through these soils is generally rapid. This has implications for the design of stormwater infiltration systems, and also affects the amount of water that needs to be infiltrated in newly developing areas to maintain predevelopment or natural infiltration rates. The HSG classification is also used when doing stormwater runoff calculations for site development design, and was used in this study in developing the SWMM model runoff calculations.

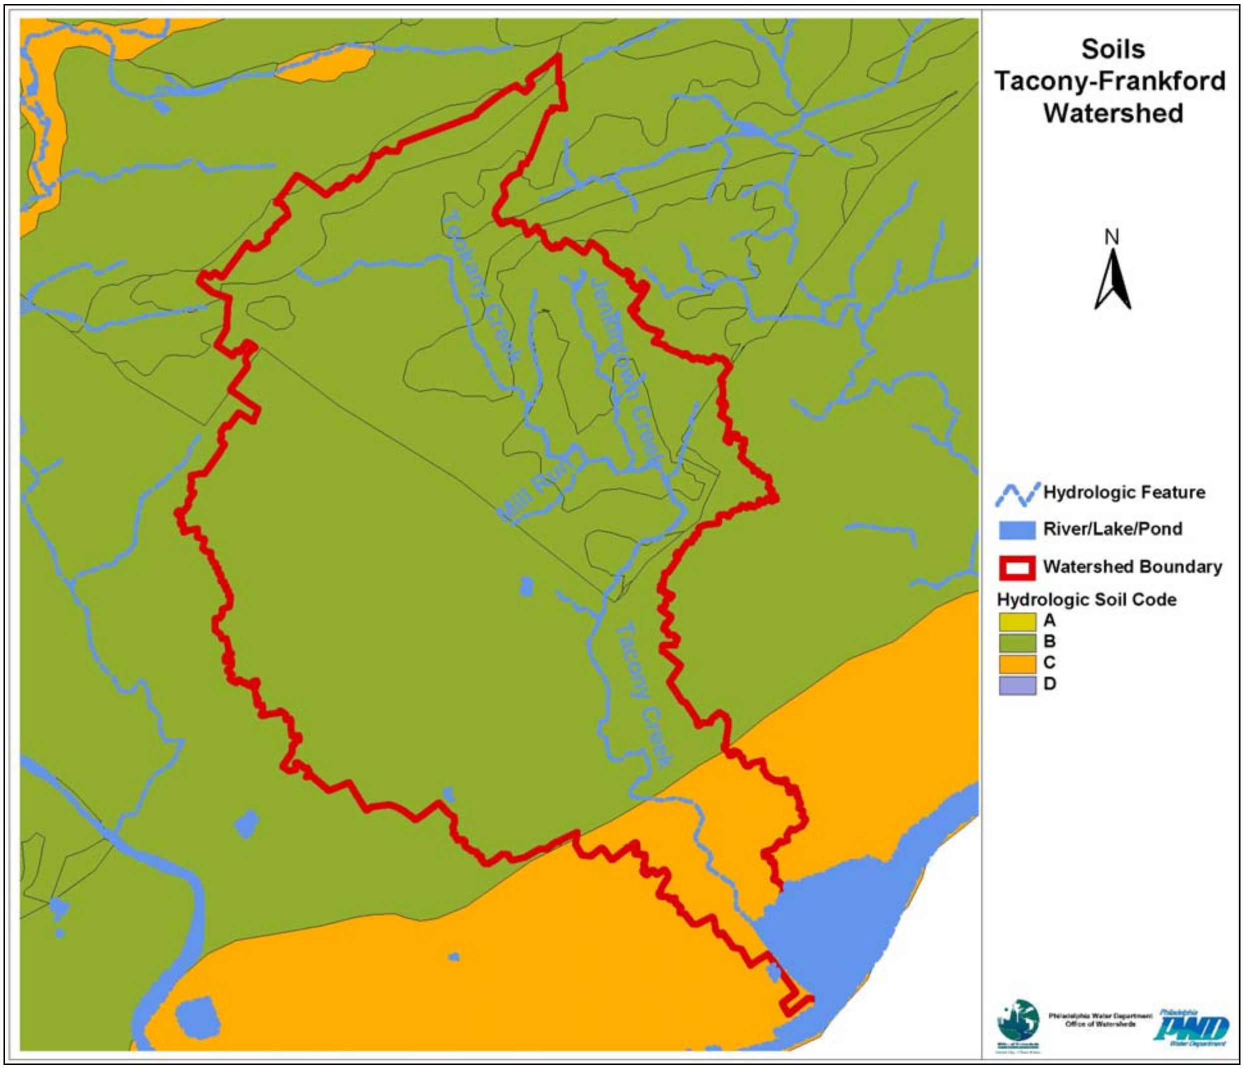

Figure 1.4 Hydrologic Soil Groups in the Tookany/Tacony-Frankford Watershed

Demographic Information

Population density and other demographic information in the watershed are available from the results of the 2000 Census. Approximately 357,104 people live within the drainage area of the Tookany/Tacony-Frankford Creek. Figure 1.5 shows the population density in the watershed at the census block level. Spatial trends in population correspond closely to land use, with multiple-family row homes displaying the greatest population density of 20 people per acre or more, single-family homes displaying a lower density, and other land use types displaying the lowest density. In addition to population data, the U.S. Census Bureau provides a range of socioeconomic data that are often useful in watershed planning and general planning studies. Median household income and mean home value (Figures 1.6 and 1.7) are two of the many sample datasets provided.

The population density of a residential area is related closely to its imperviousness and thus to the quantity and quality of runoff produced. Figure 1.5 depicts the population density in people per acre for the watershed area.

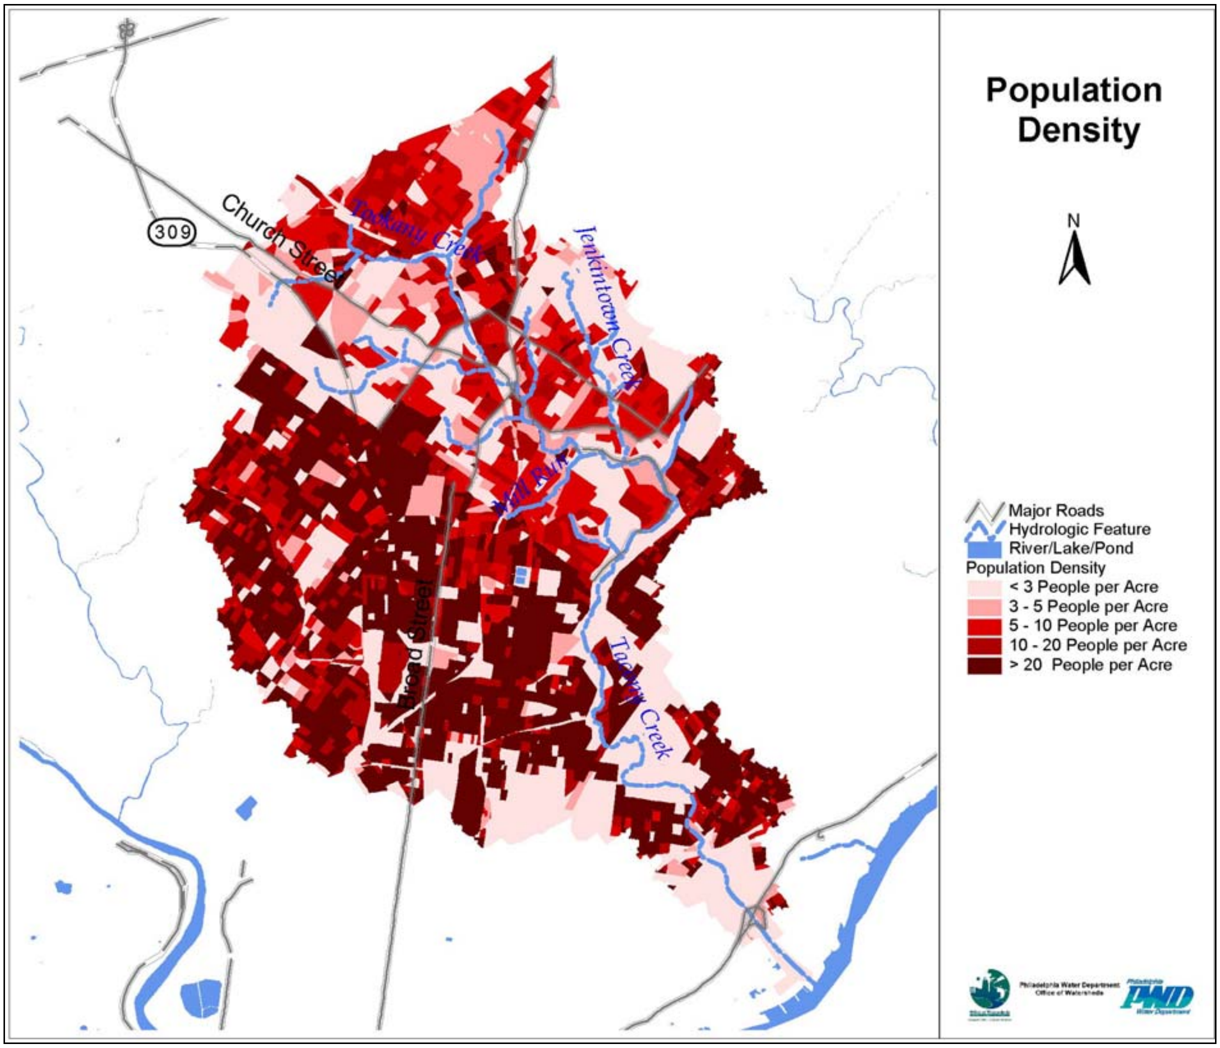

Figure 1.5 Population Density of the Tookany/Tacony-Frankford Watershed (Source: 2000 US Census)

Within the Tookany/Tacony-Frankford drainage area, based on 2000 census data, are 357,104 people. Represented by county, this corresponds to 59,456 people in the Montgomery County portion and 297,648 people in the Philadelphia County portion. The average population/acre in each county is determined to be 7 people/acre for Montgomery County and 24 people/acre for Philadelphia County. Based on this quantitative data and the visual data from the figure above, it is evident that Philadelphia County is more heavily populated than Montgomery County. Therefore, the combination of contributions from both counties yields an overall average (area-weighted) population density of approximately 17 persons/acre.

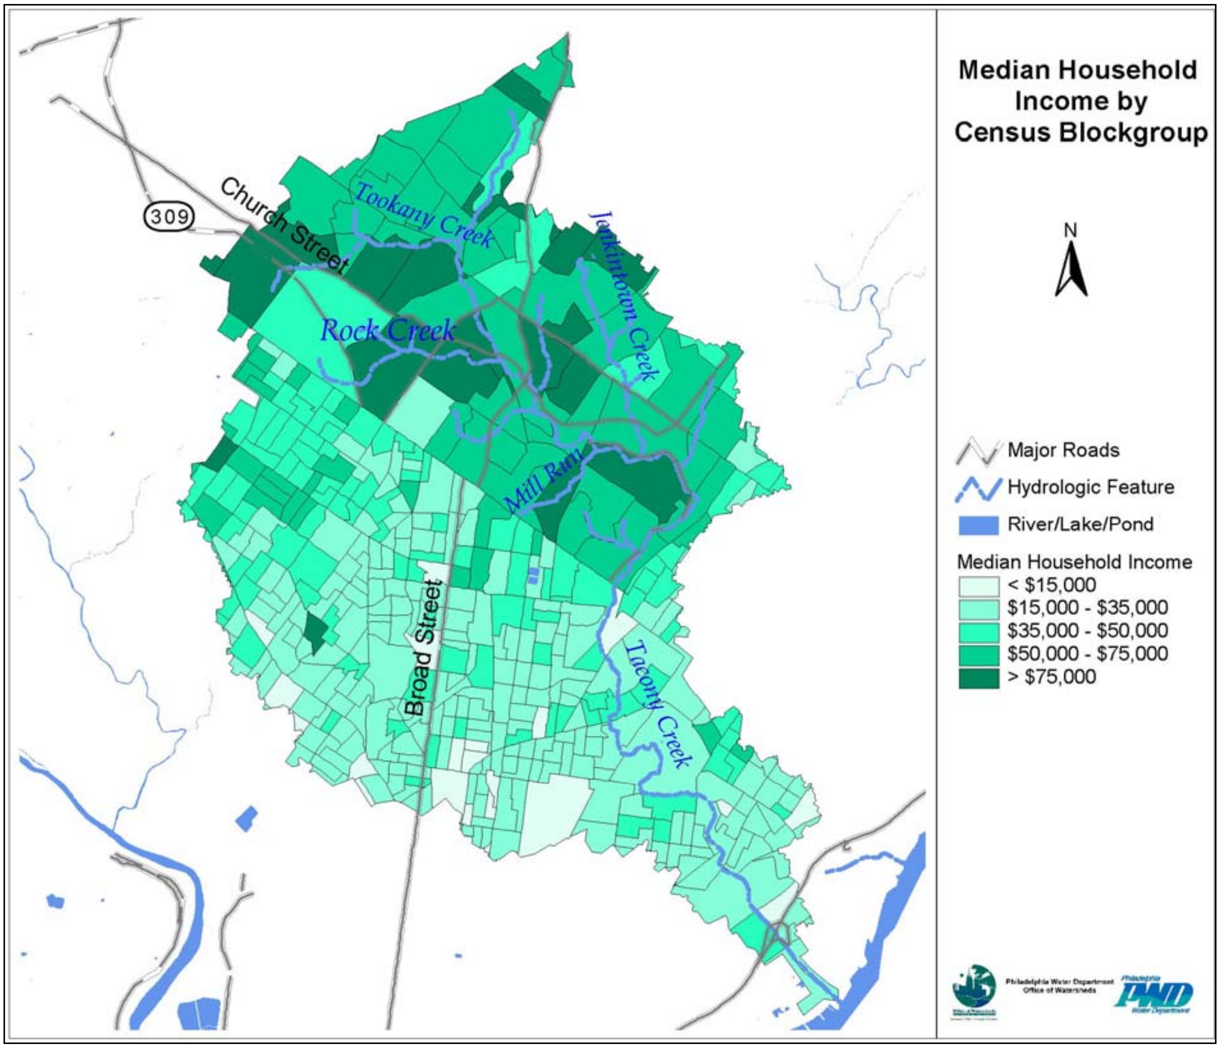

Figure 1.6 Median Household Income in the Tookany/Tacony-Frankford Watershed (Source: 2000 US Census)

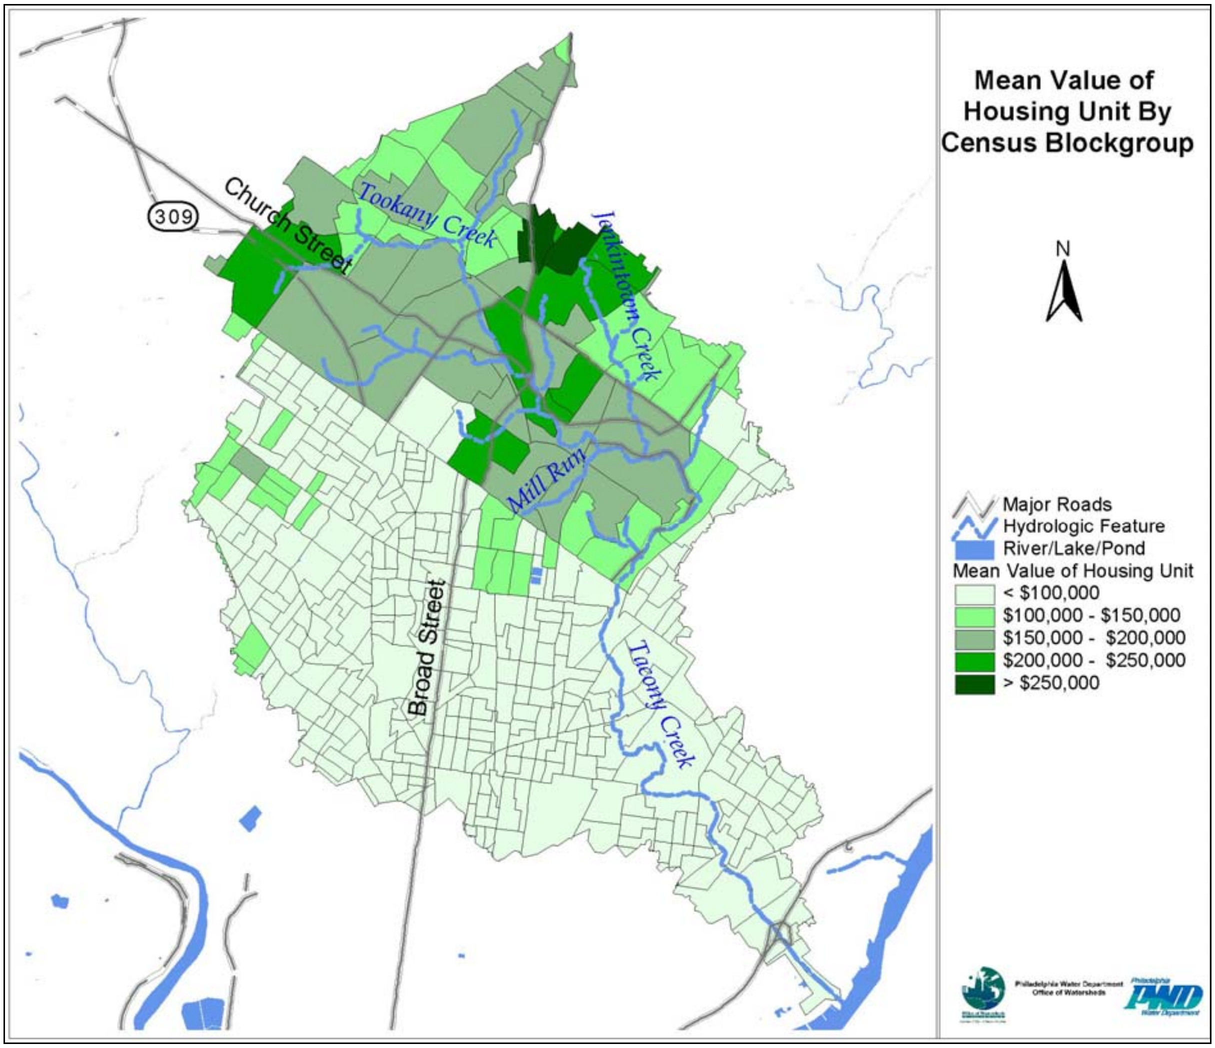

Figure 1.7 Mean Home Value in the Tookany/Tacony-Frankford Watershed (Source: 2000 US Census)

Figure 1.8, below, shows numerical population change, based on municipality areas within the watershed, from the 1990 to year 2000 census. This graph shows that all municipalities except Cheltenham have experienced slight losses in population and also a loss in population watershed-wide.

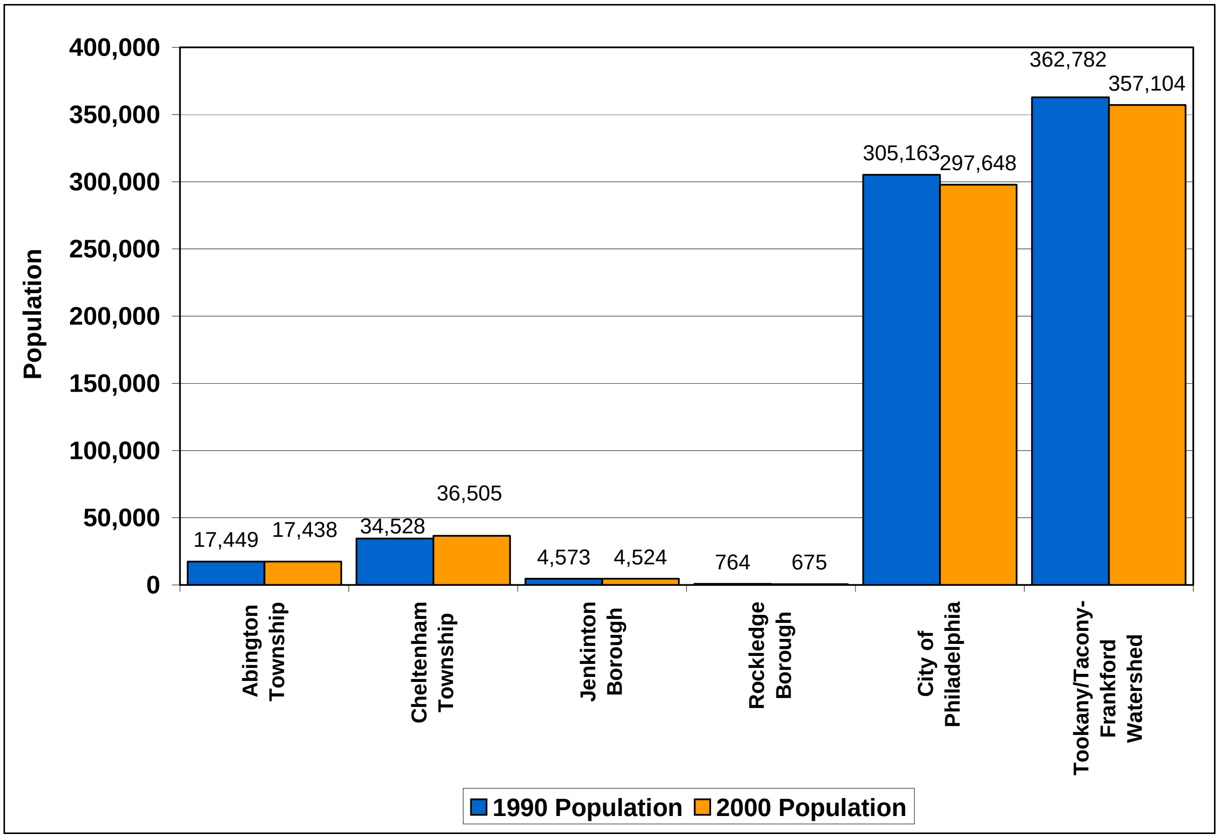

Figure 1.8 Population Change 1990-2000 in Tookany/Tacony-Frankford Watershed (Source: 2000 US Census)

1.4 Comprehensive Planning and the Regulatory Framework

In many states, numerous federal and state regulations and programs are aimed at improving the water quality and flow patterns in urban streams, while at the same time reducing flooding. Pennsylvania is no exception; the U.S. EPA and the Pennsylvania Department of Environmental Protection (PA DEP) have a complex regulatory framework for managing water resources with frequently overlapping demands and requirements. There are five major regulatory programs that contain significant elements related to watershed management in the Tookany/Tacony-Frankford Watershed. These are:

- the NPDES Phase I and Phase II stormwater regulations to control pollution due to stormwater discharges from municipal stormwater systems;
- the stormwater management PA Act 167 to address management of stormwater runoff quantity particularly in developing areas;
- PA Act 537 sewage facilities planning to protect and prevent contamination of groundwater and surface water by developing proper sewage disposal plans;
- the TMDL process to improve water quality on impaired streams and water bodies; and
- EPA's Combined Sewer Overflow (CSO) Control Policy to minimize mixed sewage and stormwater overflowing directly into streams.

Each of these programs, described on the pages that follow, provides guidelines that are transformed into a series of planning objectives within the watershed management planning process, leading directly to the selection of watershed management options to address those objectives.

1.4.1 NPDES Stormwater Rules

In response to the 1987 Amendments to the Clean Water Act (CWA), the Environmental Protection Agency (EPA) developed Phase I of the NPDES Stormwater Program in 1990. Phase I required NPDES (National Pollutant Discharge Elimination System) permits for all stormwater discharging from storm sewers (MS4s) of medium and large urban areas with populations of 100,000 or more. It also required permits from eleven categories of industrial activity, including construction activities that disturb five or more acres of land. Permit coverage can be either under an individually tailored NPDES permit (used by MS4s and some industrial facilities) or a general NPDES permit (used by most industrial facilities and construction sites).

Phase II of the NPDES Stormwater Program was published in November 1999. The Phase II regulation requires NPDES permit coverage, mostly general permits, for stormwater discharges from most small-urbanized areas (small MS4s) and construction activities that disturb from 1 to 5 acres of land. A list of affected communities has been published in the Federal Register.

There are six "minimum control measures" (MCMs) that communities must implement as part of a municipal stormwater management program whose goal is Phase II compliance. These are:

1. **Public Education and Outreach:** Distributing educational materials and performing outreach to inform citizens about the impacts polluted stormwater runoff discharges can have on water quality.
2. **Public Participation and Involvement:** Providing opportunities for citizens to participate in program development and implementation, including effectively publicizing public hearings and/or encouraging citizen representatives to be part of a stormwater management panel.
3. **Illicit Discharge Detection and Elimination:** Developing and implementing a plan to detect and eliminate illicit discharges to the storm sewer system. Includes the developing of a system map as well as informing the community about hazards associated with illegal discharges and improper waste disposal.
4. **Construction Site Runoff Control:** Developing, implementing, and enforcing an erosion and sediment control program for construction activities that disturb one or more acres of land (controls could include for example, silt fences, and temporary stormwater detention ponds).
5. **Post Construction Runoff Control:** Developing, implementing, and enforcing a program to address discharges of post-construction stormwater runoff from new development and redevelopment areas. Applicable controls could include preventative actions such as protecting sensitive areas (e.g., wetlands) or the use of structural BMPs such as grassed swales or porous pavement.
6. **Pollution Prevention/Good Housekeeping:** Developing and implementing a program with the goal of preventing or reducing pollutant runoff from municipal operations. The program must include municipal staff training on pollution prevention measures and techniques (e.g., regular street sweeping, reduction in the use of pesticides or street salt, and frequent catch-basin cleaning).

The EPA has listed the following municipalities within the Tookany/Tacony-Frankford watershed for inclusion in the Phase II program: Cheltenham Township, Jenkintown Borough, and Rockledge Borough. The permit cycle for these permits started in 2003.

1.4.2 Act 167 Stormwater Management

The Stormwater Management Act 167 of 1978 is administered by PADEP and is designed to address the inadequate management of accelerated stormwater runoff resulting from development. An Act 167 plan must address a wide range of hydrologic impacts due to development on a watershed basis, and include such considerations as tributary timing, flow volume reduction, base flow augmentation, water quality control, and ecological protection. Watershed runoff modeling is usually a critical component of the study, with modeled hydrologic responses to 2, 5, 10, 25, 50, and 100-year storms.

The primary purposes of Act 167 are to:

- Encourage planning and management of stormwater runoff;
- Authorize a comprehensive program of stormwater management designed to preserve and restore the flood carrying capacity of Commonwealth streams;
- Preserve natural stormwater runoff regimes;
- Protect and conserve groundwater.

Act 167 requires that each county – in consultation with affected municipalities – prepare and adopt a stormwater management plan for each watershed that falls wholly or partially within the county. The Act focuses on reduction of stormwater runoff quantities, rather than on water quality. Each stormwater plan will include, but is not limited to:

- A survey of existing runoff characteristics in small as well as large storms, including the impact of soils, slopes, vegetation, and existing development;
- A survey of existing significant obstructions and their capacities;
- An assessment of projected and alternative land development patterns in the watershed, and the potential impact of runoff quantity, velocity, and quality;
- An analysis of present and projected development in flood hazard areas, and its sensitivity to damages from future flooding or increased runoff;
- A survey of existing drainage problems and proposed solutions;
- A review of existing and proposed stormwater collection systems and their impacts;
- An assessment of alternative runoff control techniques and their efficiency in the particular watershed;
- An identification of existing and proposed state, federal, and local flood control projects located in the watershed and their design capacities;
- A designation of those areas to be served by stormwater collection and control facilities within a 10-year period;
- An estimate of the design capacity and costs of such facilities;
- A schedule and proposed methods for financing the development, construction, and operation of the facilities;

- An identification of the existing or proposed institutional arrangements to implement and operate the facilities;
- An identification of floodplains within the watershed;
- Standards for the control of stormwater runoff from existing and new development which are necessary to minimize dangers to property and life;
- Priorities for implementation of action within each plan;
- Provisions for periodically reviewing, revising, and updating the plan.

After adoption and approval of a stormwater plan, the location, design, and construction within the watershed of stormwater management systems, flood control projects, subdivisions and major land developments, highways, and transportation facilities must all be conducted in a manner consistent with the approved plan.

An Act 167 Plan is under preparation for the Tookany/Tacony-Frankford Creek watershed by Cheltenham Township with assistance from Philadelphia and Montgomery Counties.

1.4.3 Act 537 Sewage Facilities Planning

Act 537, enacted by the Pennsylvania Legislature in 1966, requires every municipality in the state to develop and maintain an up-to-date sewage facilities plan. The Act requires proper planning of all types of sewage facilities, permitting of individual and community on-lot disposal systems, and uniform standards of design.

The main purpose of a municipality's sewage facilities plan is to correct existing sewage disposal problems including malfunctioning on-lot septic systems, overloaded treatment plants or sewer lines, and improper sewer connections. The program is also designed to prevent future sewer problems and to protect the groundwater and surface water of the locality. To meet these objectives, PADEP uses the Official Sewage Planning requirements of Act 537 that prevent and eliminate pollution of the waters of the Commonwealth by coordinating planning for the sanitary disposal of sewage with a comprehensive program of water quality management.

Official plans contain comprehensive information, including:

- Planning objectives and needs;
- Physical description of planning area;
- Evaluation of existing wastewater treatment and conveyance systems;
- Evaluation of wastewater treatment needs.

Currently, all of the municipalities in the watershed have an Act 537 Plan, which provides for the resolution of existing sewage disposal problems, future sewage disposal needs of new land development, and future sewage disposal needs of the municipality. As of December 2005, Abington Township's Act 537 Plan is more than 5 years old and Philadelphia's is more than 10 years old. However, some plans are older than 30 years: Cheltenham, Rockledge, and Jenkintown boroughs. Also, the plans vary in their level of detail.

1.4.4 Impairment Designations and the TMDL Process

Section 303(d) of the Clean Water Act and the U.S. EPA's Water Quality Planning and Management Regulations (40 CFR Part 130) provide a framework for watershed planning based on Total Maximum Daily Loads. TMDLs are the sum of individual waste load allocations (point sources) and load allocations (non-point sources) plus a margin of safety. They establish a link between water quality standards and water quality based controls. The objective of TMDLs is to allocate allowable loads among different pollutant sources so that the appropriate control actions can be taken and water quality standards achieved.

The basic steps in the water quality based approach to TMDLs include:

- Identification of the water quality-limited waters and the quality parameters of concern;
- Prioritizing the locations by ranking and targeting;
- Establishing the TMDL;
- Implementing the control actions;
- Assessment of the control actions.

Pennsylvania has listed water quality-limited waters according to point and non-point sources for toxic, conventional (BOD, TSS, fecal coliform, oil, and grease), and non-conventional (ammonia, chlorine, and iron) pollutants. Streams that are listed under Section 303(d) of the CWA are particularly targeted for improvement. The Tacony Creek Watershed is within Subbasin 03J, which also includes Jenkintown Creek, Mill Run, and Chester Creek watersheds. Within the Tookany-Tacony/Frankford Watershed, the following stream segments are listed as impaired (Figure 1.9):

- 13.4 miles of Tookany Creek and 13.0 miles of tributaries outside of Philadelphia are impaired due to habitat modification, siltation, and water/flow variability from urban runoff and storm sewers.
- 3.1 miles of Tacony-Frankford Creek inside the City are impaired due to habitat modification, siltation, and water/flow variability from urban runoff and storm sewers.
- The tidal portion of the creek (illustrated in blue) flowing toward the confluence with the Delaware River has not been assessed.

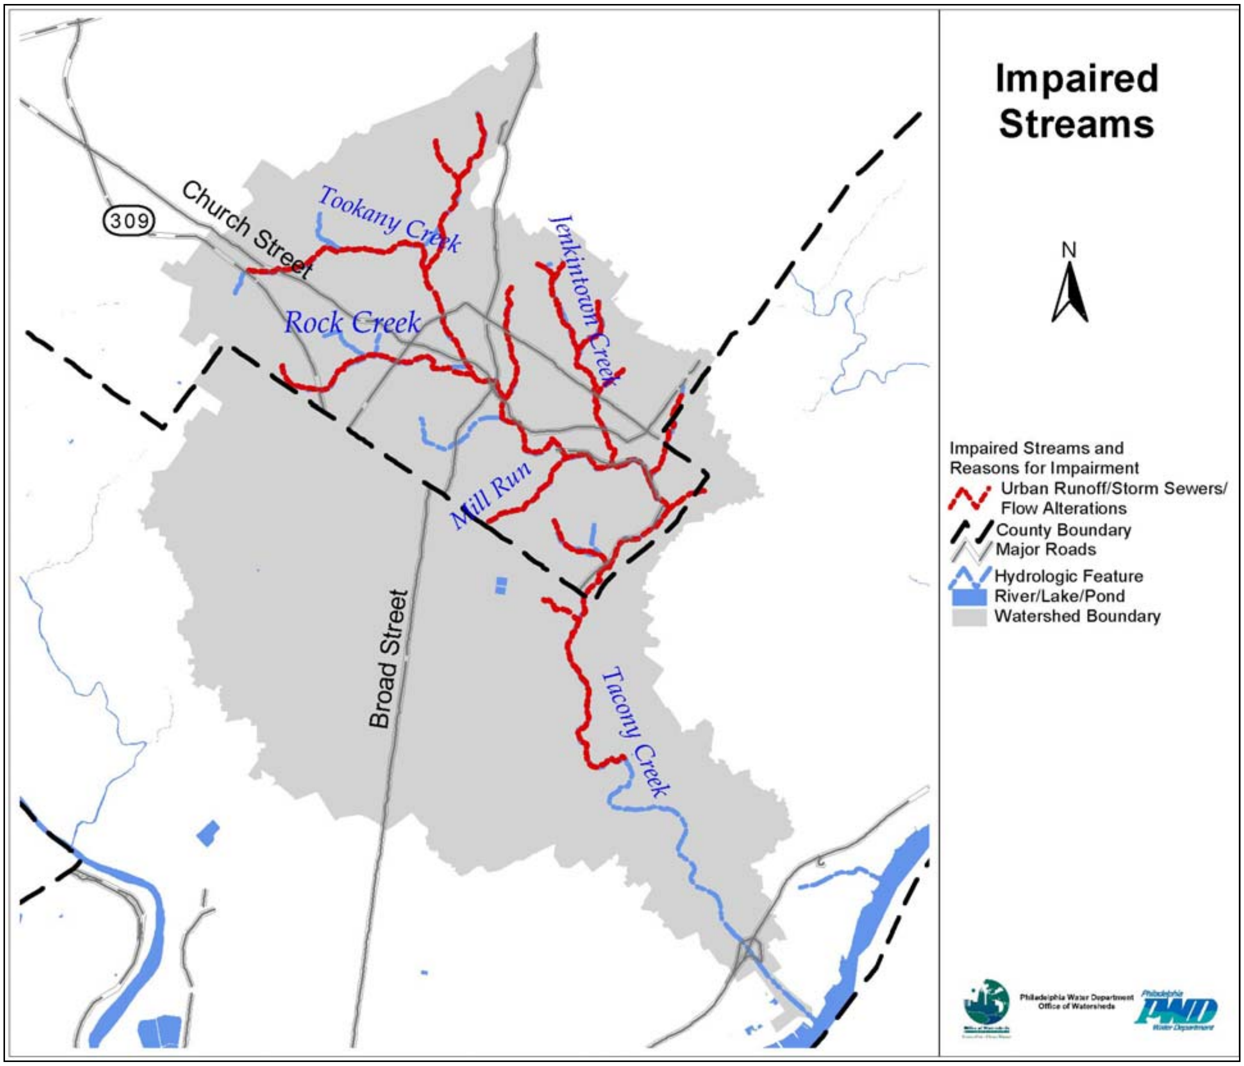

Figure 1.9 Impaired Streams in the Tookany/Tacony-Frankford Watershed

The next step in the statewide TMDL process includes prioritization of the list and the development of TMDLs for high-priority water bodies. It is this phase of the TMDL process that is of interest to the integrated watershed planning process.

Prioritization must take into account the severity of the pollution and the designated uses of the water body. It should consider the following:

- Risks pertaining to human health and aquatic life;
- Degree of public interest and support;
- Recreational, economic, and aesthetic importance;
- Vulnerability or fragility of the aquatic habitat.
- New permit applications for discharges or revisions to existing permits;
- Court orders and decisions;
- National policies and priorities.

TMDL development requires the quantification of pollutant sources and the allocation of maximum discharge loads to contributing point and non-point sources in order to attain water quality standards. TMDLs are best developed on a watershed basis in order to efficiently and effectively manage the quality of the water. The TMDL process may be developed using a phased approach that includes monitoring requirements and it generally includes the following five activities:

- Selection of the pollutants;
- Evaluation of the water body's assimilative capacity;
- Assessment of the pollutants discharged from all sources;
- Predictive analysis of the water body's response to pollution and determination of the total allowable pollutant load;
- Allocation (with a margin of safety) of the allowable pollutant load among the different sources.

The National Pollutant Discharge Elimination System's (NPDES) permitting process is used to implement control measures to limit effluent from point sources. In the case of non-point sources, state and local laws can be used to implement best management practices (BMPs), as well as Section 319 state management programs. These programs must be coordinated in order to effectively achieve the required non-point source reductions.

1.4.5 Combined Sewer Overflow (CSO) Control Policy

EPA's CSO Control Policy, published in 1994, provides the national framework for regulation of CSOs under NPDES. The policy guides municipalities and state and federal permitting agencies in meeting the pollution control goals of the CWA in as flexible and cost-effective a manner as possible. As part of the program, communities serviced by combined sewer systems are required to develop CSO Long-Term Control Plans (LTCPs) that will result in full compliance with the CWA, including attainment of water quality standards.

As the first step under the CSO policy, nine technology-based minimum controls are required; these are measures that can reduce the prevalence and impacts of CSOs and that are not expected to require significant engineering studies or major construction.

- Proper operation and regular maintenance programs for the sewer system and the CSOs;
- Maximum use of the collection system for storage;
- Review and modification of pretreatment requirements to assure CSO impacts are minimized;
- Maximization of flow to the publicly owned treatment works for treatment;
- Prohibition of CSOs during dry weather;
- Control of solid and floatable materials in CSOs;
- Pollution prevention;
- Public notification to ensure that the public receives adequate notification of CSO occurrences and CSO impacts;
- Monitoring to effectively characterize CSO impacts and the efficacy of CSO controls.

In the longer term, the CSO policy includes four requirements to ensure that the CSO systems meet the pollution control goals and local environmental objectives in a cost-effective manner:

- Clear levels of control to meet health and environmental objectives;
- Flexibility to consider the site-specific nature of CSOs and find the most cost-effective way to control them;
- Phased implementation of CSO controls to accommodate a community's financial capability;
- Review and revision of water quality standards during the development of CSO control plans to reflect the site-specific wet weather impacts of CSOs.

One of the three major components of the City of Philadelphia’s CSO LTCP strategy involves a substantial commitment by the City to watershed planning to identify long term improvements throughout its watersheds, including any necessary additional CSO controls, which will result in further improvements in water quality and, ultimately, the attainment of water quality standards. The need for this watershed initiative is rooted in the fact that insufficient physical, chemical, and biological information currently exists on the nature and causes of water quality impairments, sources of pollution, and appropriate remedial measures. Because of this deficiency, at the time the CSO LTCP was developed, it was impossible to determine what needed to be done for additional CSO control or control of other wet weather sources throughout the watershed. This deficiency, especially with respect to the effects of wet weather discharges and receiving water dynamics, was increasingly recognized nationwide and led to a broader recognition of the need for watershed-based planning and management to properly define water quality standards and goals. In its LTCP, PWD suggested that the National CSO Policy, state and federal permitting and water quality management authorities, cities, environmental groups, and industry all recognized that effective long-term water quality management could be accomplished only through watershed-based planning.

The CSO Control Policy acknowledges the importance of watershed planning in the long term control of CSOs by encouraging the permit writer "... to evaluate water pollution control needs on a watershed management basis and coordinate CSO control efforts with other point and non-point source control activities" (1.B). The watershed approach is also discussed in the section of the CSO Control Policy addressing the demonstration approach to CSO control (II.B.4.b, and Chapter 3 of the U.S. EPA Guidance for Long Term Control Planning), which, in recommending that NPDES permitting authorities allow a demonstration of attainment of water quality standards (WQS), provides for consideration of natural background conditions and pollution sources other than CSOs.

The EPA Long Term Control Planning Guidance suggests that EPA is committed to supporting the implementation of a comprehensive watershed management approach. EPA has convened a Watershed Management Policy Committee consisting of senior managers to oversee the reorientation of all EPA water programs to support watershed approaches.

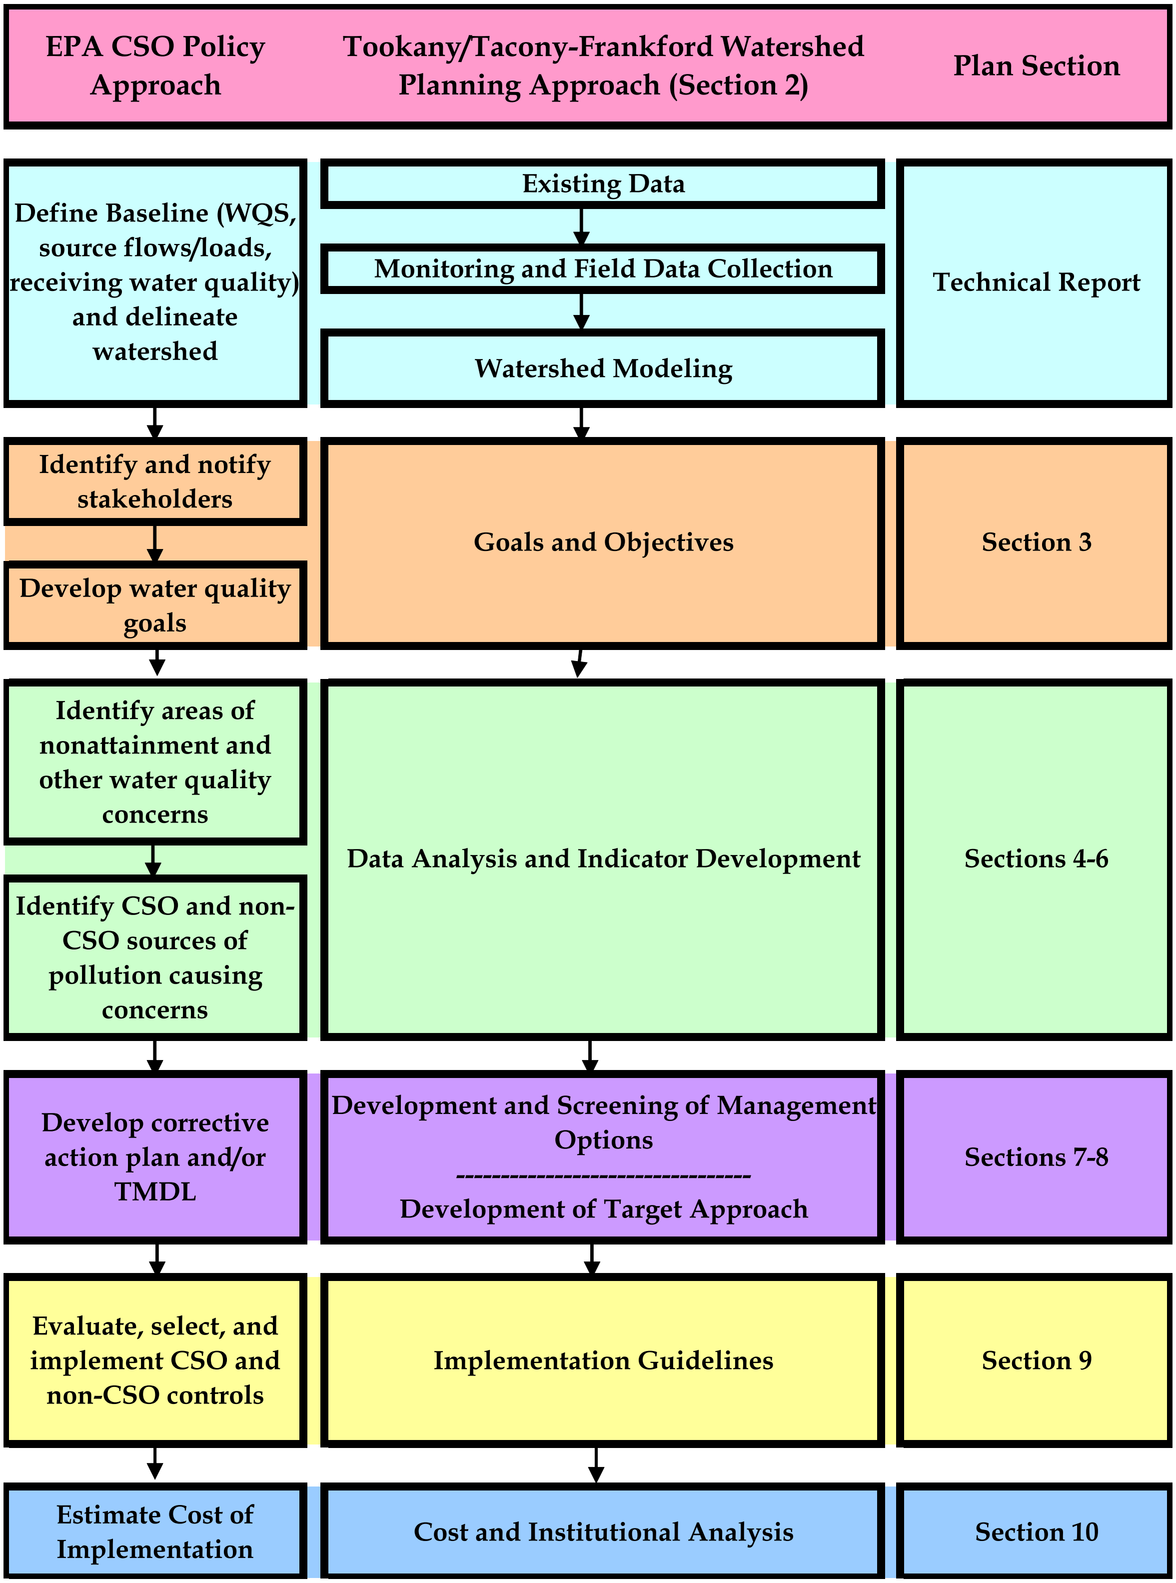
Of particular importance to CSO control planning and management is the NPDES Watershed Strategy. This strategy outlines national objectives and implementation activities to integrate the NPDES program into the broader watershed protection approach. The strategy also supports the development of basin management as part of an overall watershed management approach.

The Long Term Control Planning Guidance suggests that the sources of watershed pollution and impairment, in addition to CSOs, are varied and include other point source discharges; discharges from storm drains; overland runoff; habitat destruction; land use activities, such as agriculture and construction; erosion; septic systems; and landfills. The benefits to implementing a watershed approach are significant and include:

- Consideration of all important sources of pollution or impairment;
- Closer ties to receiving waters;
- Greater flexibility;
- Greater cost effectiveness (through coordination of monitoring programs, for example);
- Fostering of prevention as well as control;
- Fairer allocation of resources and responsibilities.

The Guidance notes that the major advantage of using a watershed-based approach to develop an LTCP is that it allows the site-specific determination of the relative impacts of CSOs and non-CSO sources of pollution on water quality. For some receiving water reaches within a watershed, CSOs could be less significant contributors to nonattainment than stormwater or upstream sources. In such cases, a large expenditure on CSO control could result in negligible improvement in water quality.

The EPA LTCP Guidance outlines a conceptual framework for conducting CSO planning in a watershed context (Figure 1.10). The approach is intended to identify CSO controls for each receiving water segment based on the concepts of watershed management and use attainability. The Tookany/Tacony-Frankford Watershed planning approach outlined in this document is conceptually identical. It moved from data collection through analysis and modeling to arrive at a set of recommended measures or options designed to meet the goals and objectives agreed upon through the stakeholder process. Figure 1.10 also identifies which section of this TTF Integrated Watershed Management Plan documents each step in the process.



EPA CSO Policy Approach	Tookany/Tacony-Frankford Watershed Planning Approach (Section 2)	Plan Section

Watershed-Based CSO Control Planning Approach for a Receiving Water Segment – from U.S. EPA Guidance for Long Term Control Plan (1995)

1.5 Overlapping Aspects of Regulatory Programs

Integrated watershed planning includes various tasks, ranging from monitoring and resource assessment to technology evaluation and public participation. The scope and importance of each task varies for each watershed, depending on site-specific factors such as environmental features of the watershed, regulatory factors such as the need to revise permits or complete TMDLs, available funding, extent of previous work, land use, and the size and degree of urbanization of watershed.

There are numerous activities required by each of the five programs mentioned above, and those activities demand a wide range of data collection. Table 1.1 gives an overview of the types of data required under each program, and Table 1.2 shows the corresponding types of activities required. Both tables highlight the fact that the task performed or the data collected under one program is often identical or very similar to the work done under other programs. It is clear that significant savings can be achieved through coordination of the programs and the development of one comprehensive plan for a watershed that meets all five program needs.

Table 1.1 Overview of Data Collection Required by Watershed Programs

**Note: An RCP includes some but not all elements of an integrated watershed management plan.*

Watershed-based planning is now the preferred approach on both the federal and state level. General water quality and water quantity goals have been established at a state level, and the next step is to develop specific goals for each watershed. Table 1.3 shows the watershed planning goals for Tookany/Tacony-Frankford Creek and how they correspond to many of the overlapping goals of the five major regulatory programs.

Table 1.3 Overview of the Statement of Goals of the Watershed Programs

Goal Description	Act 167 Stormwater	Act 537 Sewage Facilities	TMDL Program	NPDES Stormwater	CSO Program	RCPs
1. Streamflow and Living Resources. Improve stream habitat and integrity of aquatic life.	X		X	X	X	X
2. Instream Flow Conditions. Reduce the impact of urbanized flow on living resources.	X				X	X
3. Water Quality and Pollutant Loads. Improve dry and wet weather stream quality to reduce the effects on public health and aquatic life.		X	X	X	X	X
4. Stream Corridors. Protect and restore stream corridors, buffers, floodplains, and natural habitats including wetlands.						X
5. Flooding. Identify flood prone areas and decrease flooding by similar measures intended to support Goals 1, 2, and 4.	X					X
6. Quality of Life. Enhance community environmental quality of life (protect open space, access and recreation, security, aesthetics, historical/cultural resources).	X	X	X	X	X	X
7. Stewardship, Communication, and Coordination. Foster community stewardship and improve inter-municipal, inter-county, state-local, and stakeholder cooperation and coordination on a watershed basis.	X	X	X	X	X	X

1.6 Other Relevant Programs

Other programs, both regulatory and non-regulatory, influence the watershed management planning approach and are briefly described under this section.

1.6.1 Rivers Conservation Program (RCP)

One significant non-regulatory program is the PA Department of Conservation and Natural Resources' (DCNR) Rivers Conservation Program (RCP), which was developed to conserve and enhance stream resources by implementing locally initiated plans.

The program provides technical and financial assistance to municipalities and stream support groups for the conservation of local streams. Generally, the RCP plans intend to assess the river's resources, identify potential threats, and recommend restoration/maintenance options. That involves the statement of goals to be accomplished and the listing of recommendations for the development and implementation of the plan.

The goals and recommendations from an RCP can be an important building block for an integrated watershed management plan (IWMP). The programs are similar in structure and approach; they have the same geographic scope, require overlapping data collection; and they involve the statement of goals and listing of recommendations. However, an RCP is narrower in scope than an IWMP and focuses more on quality of life along the stream corridor rather than on regulatory compliance. The RCP for the Tookany Watershed was completed in October 2003 by Abington Township, Cheltenham Township, Jenkintown Borough, and Rockledge Borough. The Tookany/Tacony-Frankford Watershed Partnership completed the Tacony-Frankford RCP in February 2004. The goals and objectives from both RCPs are incorporated into this TTF Integrated Watershed Management Plan.

1.6.2 Summary of Other Programs

Other relevant programs that have been incorporated or that may affect the watershed management program are listed on Table 1.4.

Table 1.4 Other Programs that May Influence the Watershed Management Plan

Sanitary Sewer Overflow (SSO) Policy Requires revisions to the NPDES permit regulations to improve the operation of municipal sanitary sewer collection systems, eliminate the occurrence of sewer overflows, and provide more effective public notification when overflows do occur.
PA DEP On-Lot Sewage Disposal Regulations Require local agencies to administer a permitting program for the installation of on-lot sewage disposal systems.
PENNVEST State Revolving Fund Program Provides funding for sewer, stormwater, and water projects throughout the Commonwealth.
Delaware River Basin Commission (DRBC) Programs Regulate both groundwater and surface water use for withdrawals greater than 100,000 gpd based on average 30-day use in a large portion of the study area, which drains to the Delaware River.
Delaware Valley Regional Planning Commission (DVRPC) Programs Address transportation, land use, and environmental protection issues in addition to economic development. Also provide services in planning analysis, data collection, and mapping.
PA DCNR Greenways Program An Action Plan for Creating Connections is designed to provide a coordinated and strategic approach to creating connections through the establishment of greenways in the state.
CWA Section 104(b)(3) Program Promotes the coordination and acceleration of research, investigations, experiments, training, demonstrations, surveys, and studies relating to the causes, effects, extent, prevention, reduction, and elimination of pollution.
CWA Section 208 Wastewater Planning Intended to encourage and facilitate the development and implementation of area-wide waste treatment management plans.
CWA Section 319(b) Non-point Source Management Program Designed to address mine drainage, agricultural runoff, construction/urban runoff, hydrologic and habitat modifications, on-lot wastewater systems, and silviculture.

1.7 Regulatory Agency and Stakeholder Partnerships

Beginning in 2000, PWD acted as the municipal sponsor of the Tookany/Tacony-Frankford Watershed Partnership, an exciting and groundbreaking effort to connect residents, businesses, and government as neighbors and stewards of the watershed. PWD hired the Pennsylvania Environmental Council (PEC), a well-respected, non-profit institution with a reputation for supporting watershed-based, holistic planning, as facilitator and outreach coordinator of this partnership. PEC pulled together diverse representatives from the watershed: municipalities, "friends" groups, educators, citizens, agencies, and watershed organizations.

Within the partnership there were originally two standing committees: the Public Participation and Outreach Committee and the Technical Advisory Committee. The partnership as a whole was called together for general planning status updates and what were called "focus group" meetings, which were initiated to elicit input on the management planning process. Additionally, in 2004 a third committee called the Structure Committee was initiated. Generally, partnership meetings were devoted to education about watershed concepts and to understanding the visions and concerns of participants as they related to their communities' environmental health. The TTF Partnership participated in the selection and prioritization of goals and objectives for this watershed management plan.

The Public Participation Committee was open to all partnership members. It consisted largely of watershed organizations, educators, residents, and educational non-profits. The committee established a number of projects to raise general awareness about watershed issues and to recruit further partnership membership. Projects included two watershed surveys (as a part of the two River Conservation Planning initiatives), a large-scale public event celebrating "the return of the Great Blue Heron" to the watershed area, a stream signage program, a rain barrel implementation program, clean-ups, participation in Philadelphia Cares Day, and many more.

The Technical Committee was also open to all members of the partnership, though the participants consisted mainly of representatives from local, state, and federal government agencies. This committee reviewed the technical documents produced by PWD, including a watershed reconnaissance of past and existing water quality studies, a current water quality sampling and modeling report, a sediment pollutant loading report, and a bioassessment summary. This technical data is essential for justifying and prioritizing the goals and objectives of the watershed management plan.

The Structure Committee was born out of a recommendation of the Public Participation Committee. It had become apparent to the partnership that in order to fully realize their watershed vision and to move forward with implementation of the recommendations put forth by the TTFIWMP, they would need to evaluate their own organizational structure for its feasibility in making this possible. The result of a series of Structure Committee meetings was that the Tookany/Tacony-Frankford Watershed Partnership evolved into an independent nonprofit watershed organization, with a mission of implementing the recommendations of the TTFIWMP. To view a copy of the new Tookany/Tacony-Frankford Watershed Partnership 501(c)3 bylaws, see Appendix C.

The role of the TTF Partnership will continue to evolve and become more critical to implementation of the plan.

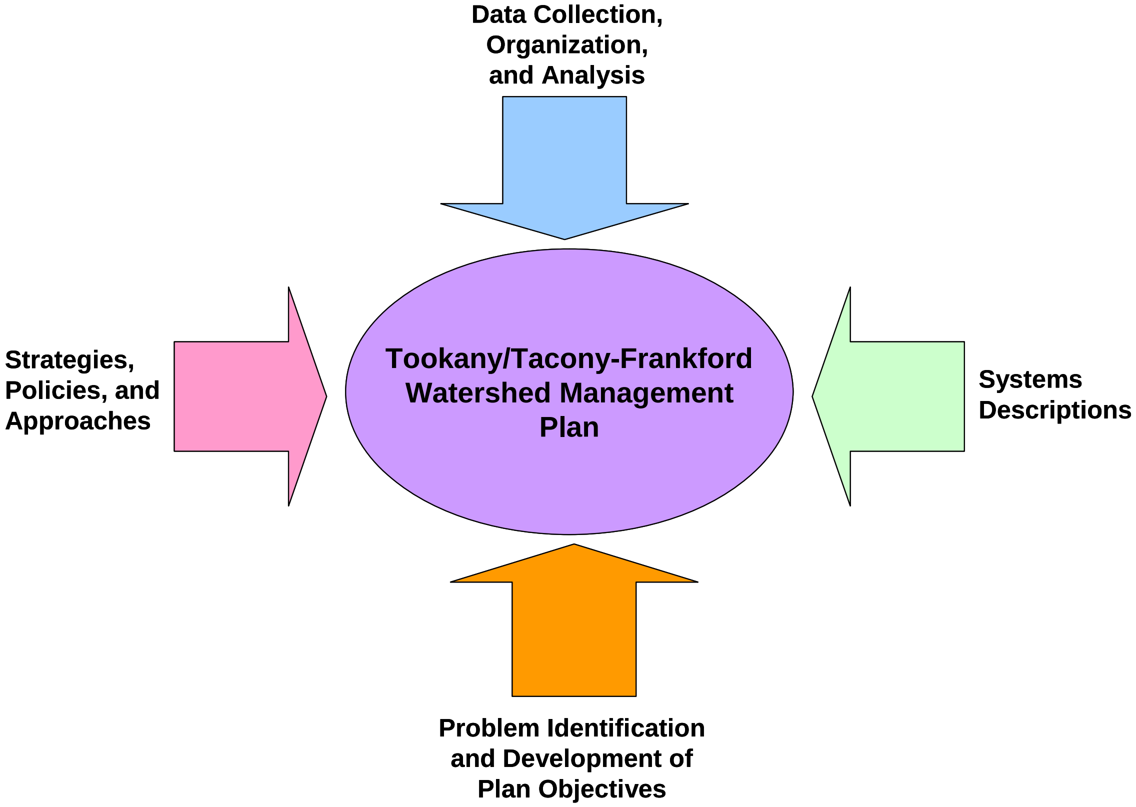
Section 2
Integrated Watershed Management for the Tookany/Tacony-Frankford Watershed

This section describes the watershed planning approach behind the TTFIWMP. It outlines the types of existing and new data that were assembled and analyzed, as well as the process for modeling stormwater flow under various scenarios. Several key concepts of the TTFIWMP are introduced: the overall goals and objectives (detailed in Section 3), the 21 watershed "indicators" (Section 4); and the screening of numerous methods, or "management options," for meeting the goals (Section 7). In addition, this section introduces the approach of setting multiple strategies – Targets A, B, and C – for promoting successful implementation of the TTFIWMP.

The watershed planning approach that serves as the framework for the Tookany/Tacony-Frankford Integrated Watershed Management Plan (TTFIWMP) contains many of the activities included in Philadelphia's CSO Long Term Control Plan and coordinates each of the five regulatory programs discussed in Section 1.4.

2.1 General Planning Approach

The general approach followed for the TTFIWMP has four major elements, as illustrated below, each with multiple tasks specific to the planning efforts within the TTF Watershed.



Data Collection, Organization, and Analysis

The initial step in the planning process is the collection and organization of existing data on surface water hydrology and quality, wastewater collection and treatment, combined sewer overflows, stormwater control, land use, stream habitat and biological conditions, and historic and cultural resources. In addition, existing rules, regulations, and guidelines pertaining to watershed management at federal, state, basin commission, county, and municipal levels also are examined for coherence and completeness in facilitating the achievement of watershed planning goals.

Data are collected by many agencies and organizations in various forms, ranging from reports to databases and Geographic Information System (GIS) files. Field data collection efforts were undertaken prior to the study, and expanded once data gaps were identified.

Systems Description

The planning approach for an urban stream must focus on the relationship between the natural watershed systems (both groundwater and surface water) and the constructed systems related to land use that influence the hydrologic cycle, such as water supply, wastewater collection and treatment, and stormwater collection. A critical step in the planning process is to examine this relationship in all its complexity and to explore the adequacy of the existing regulatory structure at the federal, state, county, and municipal level to properly manage these natural and built systems. In urban watersheds, the natural systems are, by definition, influenced by the altered environment, and existing conditions reflect these influences. It is not, however, always obvious which constructed systems are having the most influence, and what that influence is. Analyzing and understanding the water resources and water supply/wastewater/stormwater facilities and their interrelationship provides a sound basis for subsequent planning, leading to the development of a realistic set of planning objectives.

Problem Identification and Development of Plan Objectives

Existing problems and issues of water quality, stream habitat, and streamflow related to the urbanization of the watershed can be identified through analyses of:

- Prior studies and assessments;
- Existing data;
- New field data;
- Stakeholder input.

Problems and issues identified through data analysis must be compared with problems and issues brought forward by stakeholders. An initial list of problems and issues then are transformed into a preliminary set of goals and objectives. These goals and objectives may reveal data gaps and may require additional data collection and analysis. Ultimately, with stakeholder collaboration, a final list of goals and objectives is established that truly reflects the conditions of the watershed. These goals and objectives are prioritized by the stakeholders based on the results of the data analysis.

The priority of objectives becomes the basis for developing a recommended alternative. Potential constraints on implementation require that the objectives be broken down into phased targets, in which an alternative is developed to meet interim objectives. In this way, the effectiveness of implementation can be monitored, and targets adjusted, as more is learned about the watershed, its physical characteristics, and evolving water quality regulations.

Strategies, Policies, and Approaches

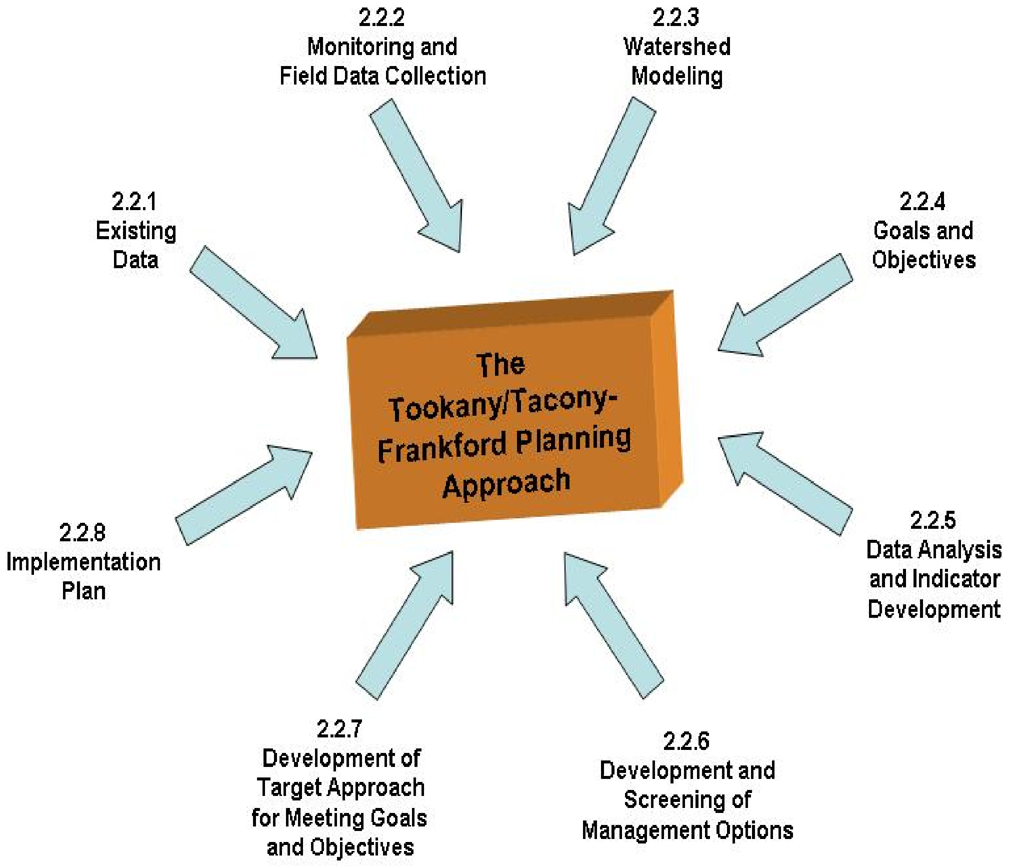
Once end targets and interim targets are established, with a clear list of associated planning objectives based on sound scientific analysis and consensus among stakeholders, a recommended alternative can be developed to meet the agreed upon targets and objectives. This alternative combines selected options from among the many suggested municipal actions, recommendations on water supply and wastewater collection system improvements, potential measures to protect water quality from point sources, best management practices for stormwater control, measures to control sanitary and combined sewer overflows, changes to land use and zoning, stream channel and streambank restoration measures, etc.

Section 8 of this plan provides Implementation Guidelines on how best to combine the many options in a coherent fashion within the context of the watershed-wide management objectives. The plan is designed to provide an implementation process and guidelines to achieve the stated objectives over a specified period of time.

2.2 The Tookany/Tacony-Frankford Planning Approach

As mentioned above, the approach and specific tasks for the TTFIWMP are intended to meet the criteria of the five major regulatory programs discussed in Section 1.4.

In order to establish environmental goals and identify the indicators that measure progress toward these goals, the Tookany/Tacony-Frankford planning strategy utilizes the "plan-do-check-review" methodology often called the "adaptive management approach." To satisfy the five elements included in this procedure, the Tookany/Tacony-Frankford planning process moved from data collection and analysis to plan development in an organized manner, with constant interaction with the established stakeholder groups. The primary data collection, analysis, and technical planning activities of the TTFIWMP are outlined below, and the stakeholder process is discussed in Section 3.



2.2.1 Existing Data

PWD assembled relevant existing data and information collected in the past by other agencies and by prior studies. Several types of geographic and physical data were collected.

Geographic and Demographic Data

The base map for the project study area was prepared from U.S. Census Bureaus TIGER (Topologically Integrated Geographic Encoding and Referencing) database. These files contain local and state political boundaries, rivers and waterways, roads and railroads, and census block and block group boundaries for demographic analysis.

Meteorological Data

In addition to U.S. Census data, meteorological data was gathered to analyze streamflow responses to seasonal changes, climate variation, and storms, and to model stormwater flows. Long-term rainfall data was obtained from the National Oceanic and Atmospheric Administration's rainfall gauge at the Philadelphia International Airport. This gauge has over 100 years of hourly precipitation data, from 1902 through the present. In addition to this long-term rainfall gauge, the PWD CSO Program has over 10 years of 15-minute rainfall data from 24 rain gauges. Ten of these gauges are in the vicinity of the TTF Watershed. The available rainfall data for each gauge is summarized in Table 2.1, and Figure 2.1 shows their locations (next page). Data from each gauge was analyzed for accuracy and completeness and then subjected to statistical analyses to check for changes in the gauge location or physical layout, as well as to explore correlations among gauges to identify potential over- or under-catch trends.

Rain Gauge Data: PWD maintains a database of 15-minute accumulated precipitation depths collected from its county-wide 24 tipping bucket rain gauge network for the period 1990 to the present. The uncorrected, 2.5-minute accumulated, 0.01 inch tip count, rain gauge data is subjected to preliminary quality assurance and quality control procedures. Identification and flagging of bad or missing data is performed for each rainfall event on a monthly basis by visual inspection comparing 15-minute accumulated measurements at nearby gauges and looking for patterns of obvious gauge failures, including plugged gauges and erratic tipping. Next, a bias adjustment procedure is performed to normalize systematic rain gauge biases across the network. Finally, all data flagged as bad or missing is filled with data from up to five nearby gauges using inverse-distance-squared weighting. A continuous rainfall record at each gauge location is thereby produced for use in continuous hydrologic model simulations.

Radar Rainfall Data: Gauge calibrated radar rainfall estimates have been obtained from Vieux and Associates for seven wet weather events sampled during 2003. The spatial resolution of this data is approximately 1km x 1km grid covering the extended watershed area. The 15-minute accumulated rainfall depths are derived from the National Weather Service's Mount Holly, NJ, level 2 radar reflectivity data that has been calibrated to PWD's rain gauge data using mean field bias adjustment. Mean field bias adjustment preserves the average rainfall depth measured at the rain gauges along with the spatial distribution represented by the radar reflectivity data.

Representative Wet Weather Year: A representative year of rainfall data was constructed to more easily evaluate the effectiveness of stormwater management options. This was done by comparing the 100-year hourly rainfall record from the NOAA Philadelphia International

Airport rain gauge station to individual quarterly records for the years 1991 through 2002. Each quarter year was evaluated against the long term record by comparing total quarterly rainfall along with the cumulative distributions of rainfall intensities and storm total depths. The resulting representative year was constructed using data from quarter 1 of 1997, quarter 2 of 1998, quarter 3 of 1996, and quarter 4 of 1997.

Table 2.1 Rainfall Data Available for the Tookany/Tacony-Frankford Watershed Gauges

Gauge Name	Available Data
RG-07	1991-2003
RG-08	1991-2001, 2003
RG-10	1991-2001
RG-11	1991-2000, 2002-2003
RG-13	1991-1998, 2001-2003
RG-14	1991-1998, 2001
RG-17	1991, 1993-2003
RG-18	1992-2003
RG-19	1991-2003

Land Use

Land use information for the Tookany/Tacony-Frankford Watershed was obtained from the Delaware Valley Regional Planning Commission (DVRPC) for Montgomery and Philadelphia counties. The DVRPC land use maps are based on aerial photography from March through May of 1995. The residential areas were updated based on the 2000 Census populations. A useful representation of the existing land use information for hydrologic analyses was developed as shown in Figure 2.2.

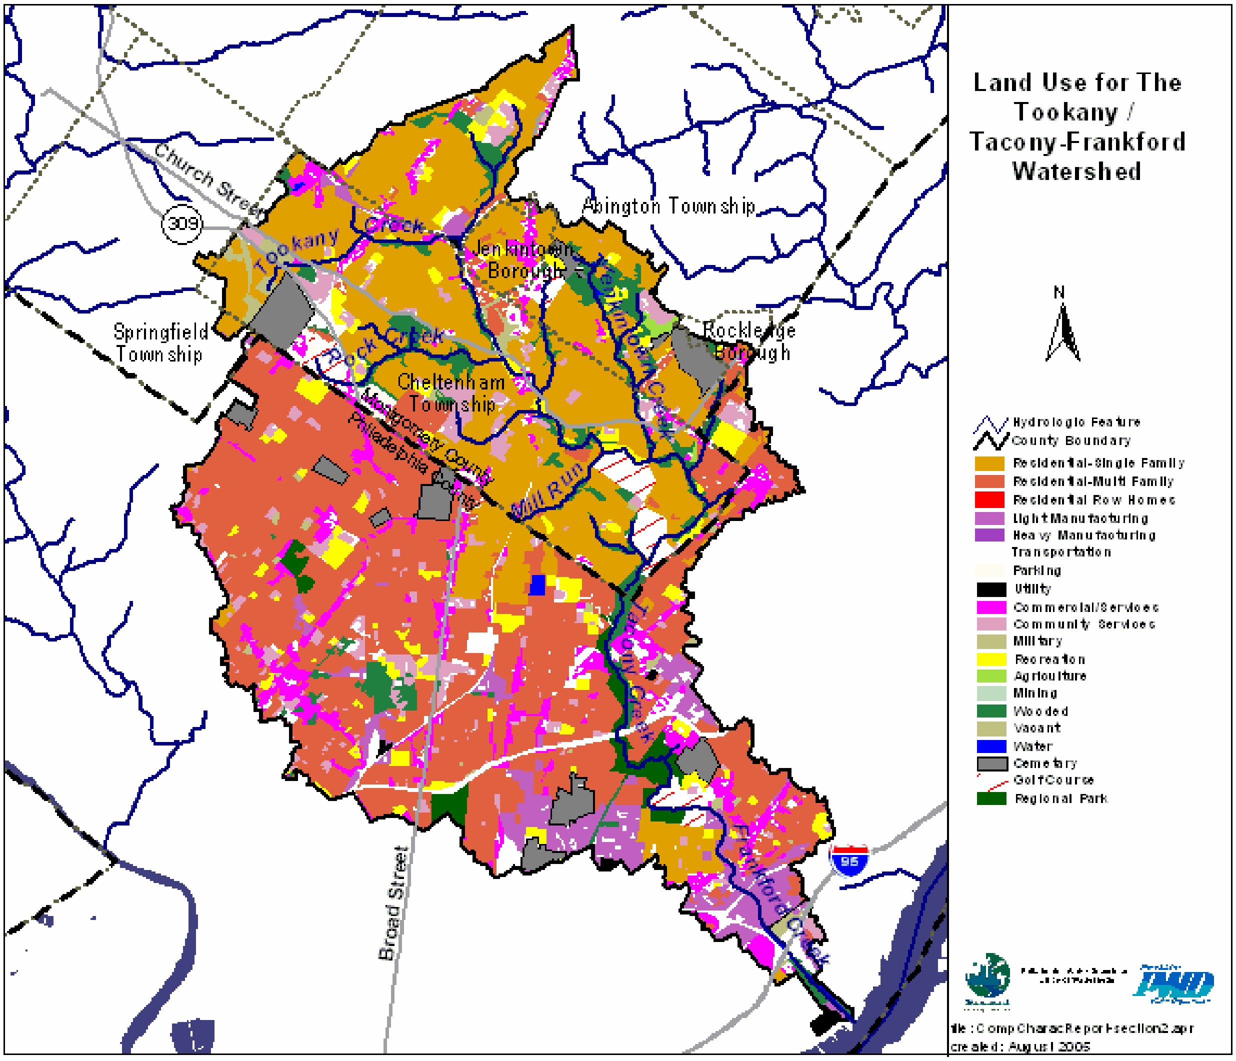

Figure 2.2 Land Use Map for the Tookany/Tacony-Frankford Watershed (Source: DVRPC)

Streamflow

During the 1960s, the United States Geological Survey (USGS), in cooperation with PWD, established streamflow-gauging stations at five locations in the Tookany/Tacony-Frankford Watershed. While only one of these gauges still is active today, the two to three decades of historic record they provided is invaluable in characterizing the hydrologic response of the watershed. The locations of the gauges are listed in Table 2.2 and shown in Figure 2.3, below. Daily streamflow records from the gauges were analyzed, and baseflow separation performed to identify patterns along the stream of baseflow and stormwater runoff. (The results of these analyses are presented in Section 4.2.1 and Section 5.2.)

Water Quality

In the early 1970s, the Philadelphia Water Department began a study in cooperation with the U.S. Geological Survey (USGS) titled, "Urbanization of the Philadelphia Area Streams." The purpose of this study was to quantify the pollutant loads in some of Philadelphia's streams and document any degradation in water quality due to urbanization. The study included three sampling sites in the headwaters and two on the main stem of Tacony-Frankford Creek (see Figure 2.3, next page). Monthly discrete water quality samples were collected at each site and analyzed for a variety of water quality parameters between 1970 and 1980. The USGS established streamflow gauging stations at five locations in the Tacony-Frankford Watershed, partially as a result of its participation in the Cooperative Program. The majority of the data currently available from STORET, U.S. EPA's water quality database, was collected as part of this study.

Table 2.2 USGS Gauges and Periods of Record

Gauge No.	Name	Drainage Area (sq. mi.)	Period of Record
01467089	Frankford Creek at Torresdale Ave.	33.8	10/1/65 - 9/30/81, 5/14/82 - 6/29/82
01467087	Frankford Creek at Castor Ave.*	30.4	7/1/82 - 9/30/98
01467086	Tacony Creek at County Line	16.6	10/1/65 - 11/17/88
01467085	Jenkintown Creek At Elkins Park	1.17	10/01/73 - 9/30/78
01467083	Tacony Creek near Jenkintown	5.25	10/1/73 - 9/30/78

2.2.2 Monitoring and Field Data Collection

To supplement existing data, PWD conducted an extensive sampling and monitoring program to characterize conditions in the TTF Watershed. The program was designed to document the condition of aquatic resources, to provide information for the planning process needed to meet EPA and PA DEP regulatory requirements, and to monitor trends as implementation proceeds.

Water Quality Sampling

PWD performed three types of sampling at eight sites (Figure 2.4). Discrete sampling was done from June 2000 through July 2003. Wet weather sampling involved collecting discrete samples before and during 12 wet weather events from March 2001 through October 2003, allowing the characterization of water quality responses to stormwater runoff and sanitary and combined sewer overflows. The third type of sampling was continuous monitoring, carried out by YSI 6600 and 600 XLM Sondes, shallow depth continuous water quality monitors, and probes that record dissolved oxygen, pH, and turbidity. The equipment was deployed to three locations periodically for a number of days to collect continuous data samples and observe water quality fluctuations. The Sonde data for the Tookany/Tacony-Frankford Watershed includes over 80 deployments.

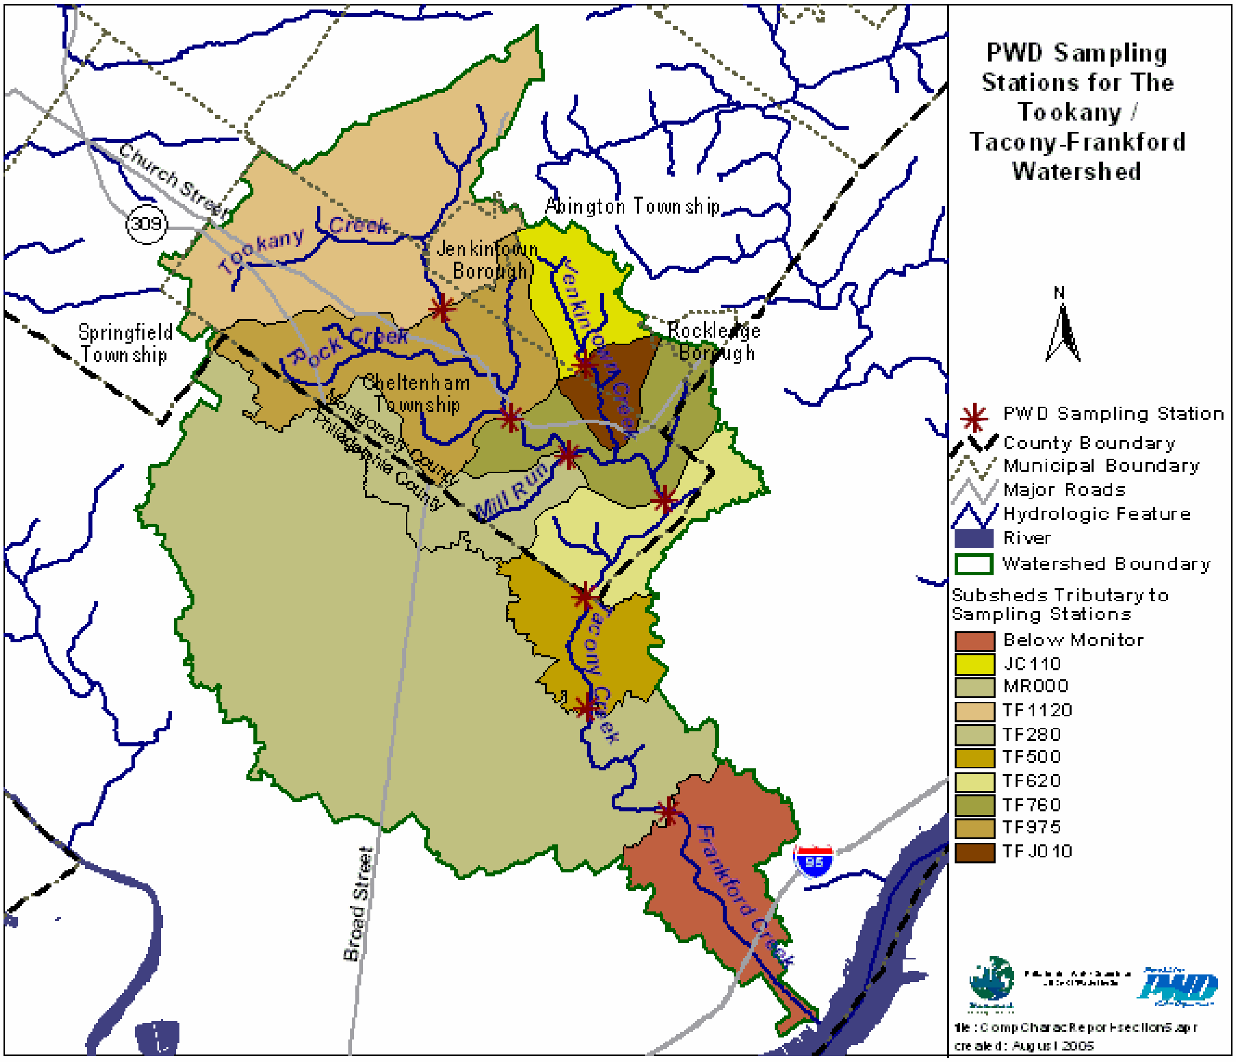

Figure 2.4 Water Quality Monitoring Locations in the Tookany/Tacony-Frankford Watershed

Biological Monitoring

Biological monitoring is a useful means of detecting anthropogenic impacts to the aquatic community. Resident biota (e.g., benthic macroinvertebrates, fish, and periphyton) in a water body are natural monitors of environmental quality and can reveal the effects of episodic and cumulative pollution and habitat alteration (Plafkin et. al. 1989, Barbour et al. 1995). The Philadelphia Water Department's Office of Watersheds and Bureau of Laboratory Services, along with the Philadelphia Academy of Natural Sciences and the Pennsylvania Department of Environmental Protection have been developing a preliminary biological database to assess the aquatic integrity of the Tookany/Tacony-Frankford Watershed. During the winter of 2000-2001, the Philadelphia Water Department conducted biological assessments (Rapid Bioassessment Protocols III and V) at seven non-tidal locations along the Tacony-Frankford Watershed to investigate the various point and non-point source stressors. Macroinvertebrate and ichthyfauna monitoring was conducted at specific locations within the watershed. Geographical Information Systems (GIS) databases and watershed maps were constructed to provide accurate locations of the sampling sites.

An ichthyfauna (fish) assessment occurred at four sampling stations on the mainstem of the Tookany/Tacony-Frankford Creek. Six metrics were used to assess the quality of the fish assemblages in the study stream.

1. Species richness
2. Species diversity
3. Trophic composition relationships
4. Pollution tolerance levels
5. Disease and parasite abundance/severity
6. Introduced (exotic) species

In addition to the fish assessment, the results of a PA DEP Rapid Bioassessment Protocol (RBP) assessment of seven sites in the Tookany/Tacony-Frankford Watershed were also compiled. PA DEP biologists used a combination of habitat and biological assessments to evaluate the Tookany/Tacony-Frankford under the Unassessed Waters Program. Biological surveys included kick screen sampling of benthic macroinvertebrates, which were identified by family and by their tolerance to pollution. Benthic macroinvertebrates mainly are aquatic insect larvae that live on the stream bottom. Since they are short-lived and relatively immobile, they reflect the chemical and physical characteristics of a stream and chronic sources of pollution. The biological integrity and benthic community composition was determined using U.S. EPA guidelines for RBP III.

Upon completion of the total biological scoring criteria, each site was compared to a reference site according to its drainage area and geomorphological attributes. The reference site chosen was French Creek, located at Coventry Road Bridge, South Coventry Township, Chester County. The comparison of the biological assessment of each site with the reference site was designed to create a baseline for monitoring trends in benthic community structure that might be attributable to improvement or worsening of conditions over time. Several Biological Condition Categories were developed:

- Non-impaired
- Slightly impaired
- Moderately impaired
- Severely impaired

Habitat Assessment

Habitat assessments evaluate how deeply the stream substrate is embedded, the degree of streambank erosion, the condition of riparian vegetation, and the amount of sedimentation. Data from the PA DEP surveys were available for the Tookany/Tacony-Frankford Creek. Habitat assessments at seven non-tidal sites were completed based on the Stream Classification Guidelines for Wisconsin (Ball, 1982) and Methods of Evaluating Stream, Riparian, and Biotic Conditions (Platts et al., 1983). Reference conditions were used to normalize the assessment to the Tookany/Tacony-Frankford (mainstream) "best attainable" situation. Habitat parameters were separated into three principal categories to characterize the site:

- Primary or microscale habitat
- Secondary or macroscale habitat (stream channel)
- Tertiary or riparian and bank structure

Resource based Habitat Suitability Indices (HSI) were developed to add aquatic life-based habitat and flow requirement criteria to the watershed assessment. HSIs integrate the expected effects of a variety of physicochemical and hydrological variables on a target species of environmental or economic concern. Data is used to construct sets of suitability index curves, each of which relates a habitat parameter to its suitability for the species of interest. Curves rate habitat variables on a scale of 0 to 1.0, and were developed to measure food and cover, water quality, and reproduction (e.g., substrate type, percent pools, percent cover, depth of pools, pH, DO, turbidity, temperature).

Fluvial Geomorphological Assessment

For the Tacony Creek Watershed, members of the Philadelphia Water Department performed a fluvial geomorphological (FGM) assessment which included baseline determination of stream stability and habitat parameters. The measurement of geomorphic parameters and physical and hydraulic relationships were performed at both Level I and Level II using the Rosgen classification methodology (D.L. Rosgen Applied River Morphology 1996).

Level I: Desktop survey included desktop delineation of the stream using generalized major stream types based on available topographic information, geological maps, soils maps, and aerial photographs. The purpose of the inventory was to provide an initial framework for organizing and targeting subsequent field assessments of important reaches where problems are known to occur or are anticipated to occur. Available topographic information, geological maps, soils maps, and aerial photographs were reviewed.

Level II: Reach stream survey was performed for approximately 30 miles of stream including the Main Stem Tookany/Tacony-Frankford Creek and 14 tributaries within the Watershed. A field team consisting of engineers and biologists walked the designated lengths of each stream and tributary and estimated several parameters related to channel morphology:

- Bankfull elevations/widths
- Floodprone elevations/widths
- Bankfull/Floodprone discharges
- Entrenchment ratios
- Width/Depth ratios
- Sinuosity
- Channel/Water surface slopes
- Channel materials (pebble count) – D50's
- Meander pattern
- Rosgen stream types
- Velocities
- Shear stresses

Wetland Study Method

Wetlands play a significant role in ecosystem health and water quality in a watershed. For this reason, two wetland field investigations were conducted to characterize the presence and condition of wetlands in the Tookany/Tacony-Frankford Watershed. Potential wetlands within Philadelphia were evaluated in July of 2001, and potential wetlands in Montgomery County were evaluated in August 2003. The wetland field investigation was designed to survey existing wetlands, evaluate potential wetland enhancement actions, and identify potential wetland creation sites.

The field investigation plan was developed based on orthophoto basemaps, and indicator information such as National Wetlands Inventory (NWI) mapping, hydric soil information, Fairmount Park Commission (FPC) mapping, and Delaware Valley Regional Planning Commission (DVRPC) existing open space mapping.

The wetland field investigation evaluated the hydrology, vegetation, soils, general location, estimated acreage, and landscape position of the wetlands in the riparian corridors. Although wetlands were not delineated, all identified wetlands within the watershed met the criteria for jurisdictional wetlands as described in the 1987 *U.S. Army Corps of Engineers* (USACE) *Wetlands Delineation Manual* (Environmental Laboratory 1987). Where possible, significant and representative points were mapped using global positioning systems (GPS).

Existing wetlands located during the field survey were also evaluated for existing wetland functions using the Oregon Assessment Method. The *Oregon Freshwater Wetland Assessment Methodology* (Roth, et al. 1996) and the Human Disturbance Gradient (Gernes and Helgen, 2002) were applied to each wetland location. The Oregon Assessment Method values were calculated for Wildlife Habitat, Fish Habitat, Water Quality, Hydrologic Control, and Sensitivity to Future

Impact. An additional function, termed Wetland Improvement, was evaluated using relevant questions from other areas of the Oregon Assessment Method. The Wetland Improvement Function was intended to reflect field observations that the potential for wetland enhancement may exist without a significant buffer, so long as there was sufficient access to create the enhancement.

Water quality is a factor of both the Oregon Assessment Method and the Human Disturbance Gradient (HDG). A combination of field observations, including the location of the wetland and waterway within the watershed or sub-watershed, as well as the PA DEP's *2002 Section 303(d) List of Impaired Waterbodies* (PA DEP 2002) was used as a measure of water quality. Four PWD monitoring stations within the Tookany/Tacony-Frankford Watershed that assess chemical, macroinvertebrate, and fish habitat data also contributed data to the Oregon and HDG analyses.

Where applicable, the redirection of outlets was considered in determining sites for streambank restoration and/or wetland restoration. Existing undeveloped areas were considered as potential wetland creation sites; factors included proximity to a waterway, the presence of stormwater outlets, the presence of existing wetlands nearby, whether these wetlands would be negatively impacted by the creation of additional wetland, and construction access and physical limitations of the site.

2.2.3 Watershed Modeling

An important tool for developing the watershed plan is a hydrologic and hydraulic model of the stream and stormwater system. In most streams in the eastern U.S., stormwater flows can range from less than 30% of total annual streamflow in less-developed watersheds to over 70% in highly urbanized settings. Modeling of stormwater flows is, therefore, a critical component of a watershed management plan. The model should, at a minimum, be built to provide storm-by-storm flows to the streams as well as estimates of pollutant loads carried by the stormwater reaching the streams.

A Stormwater Management Model (SWMM) was built for the entire Tookany/Tacony-Frankford Watershed. SWMM is a comprehensive set of mathematical models originally developed for the simulation of urban runoff quantity and quality in storm, sanitary, and combined sewer systems. The model subdivides the watershed into approximately 300 subwatersheds and estimates flow and pollutant loading from each land use type within each of the subwatersheds. It simulates the hydraulics of combined sewers, the open channel of the creek itself, and the floodplain. Thus, the model is useful for simulation of stormwater runoff quantity and quality, combined sewer overflow, and streamflow. The model was calibrated by comparing stormwater runoff to estimated runoff, calculated through hydrograph separation at the USGS gauges in the watershed. Model simulations included:

- Existing conditions using a long-term rainfall record from Philadelphia Airport;
- Annual average pollutant loads for key pollutants found in stormwater. The list of pollutants includes parameters such as nitrate, phosphorus, total suspended solids, heavy metals, biochemical oxygen demand, and dissolved oxygen;
- Numerous simulations to test the effectiveness of various BMPs within the Tookany/Tacony-Frankford Watershed. Effectiveness was judged based on reductions in stormwater discharges, CSOs, and reduced pollutant loading during wet weather.

The model results helped identify areas where stormwater runoff or pollutant loads are particularly high and in need of control. Model flow results, in combination with the results of the fluvial geomorphic assessment, provided excellent tools for identifying areas of the watershed that are undergoing stormwater-related stress and an efficient way of developing alternative integrated watershed management approaches, particularly with regard to the Wet Weather “Target C” objective (described in Section 2.2.7).

2.2.4 Goals and Objectives

Early in the planning process, project goals and objectives were developed in conjunction with the stakeholders. In general, goals represent consensus on a series of "wishes" for the watershed. Seven project goals were established that encompass the full spectrum of goals from all the relevant regulatory programs as well as the River Conservation Plans (as summarized in Table 1.3). A significant effort was made to consolidate the various goals into a single, coherent set that avoids overlap and is organized into clear categories:

1. Streamflow and Living Resources
2. Instream Flow Conditions
3. Water Quality and Pollutant Loads
4. Stream Corridors
5. Flooding
6. Quality of Life
7. Stewardship, Communication, and Coordination

Once the preliminary set of goals was established, a series of associated objectives was developed. Objectives translate the goals into measurable quantities; "indicators" (described below) are the means of measuring progress toward those objectives. This relationship is the link between the more general project goals and the indicators developed to assess the watershed and to track future improvement.

The preliminary planning goals and objectives were presented to stakeholders for initial review. However, the final, prioritized goals and objectives were subjected to final review and approval when the data analysis and modeling work were completed. (See Section 3 for more detail.)

2.2.5 Data Analysis and Indicator Development

An integral part of this plan is the assessment and description of existing conditions within the watershed and stream. This assessment has identified specific problem areas, while establishing a "watershed baseline" from which we can measure our future progress as recommendations are implemented. Based upon these existing conditions, a series of "watershed indicators" were developed so that as implementation occurs in the coming years, progress can be quantified. These indicators were developed to represent the results of the data collection efforts and the data analysis and modeling. An indicator is a measurable quantity that characterizes the current state of at least one aspect of watershed health. Every indicator is directly linked to one or more project objectives. Thus, they serve to describe the current conditions, and provide a clear method of monitoring progress and achievement of objectives as watershed management strategies are implemented over time.

The 21 indicators selected for their potential use in assessing both current conditions and future progress in improving conditions are listed in Table 2.3 (next page) and discussed in detail in Section 4.

Table 2.3 Tookany/Tacony-Frankford Watershed Indicators

The Land Use and Stream Health Relationship

Indicators	
1	Land Use and Impervious Cover

Flow Conditions and Living Resources

Indicators

18	Recreational Use and Aesthetics
19	Local Government Stewardship
20	Business and Institutional Stewardship
21	Cultural and Historic Resources

2.2.6 Development and Screening of Management Options

Clear, measurable objectives provided the guidance for developing options designed to meet the project goals. A "management option" is a technique, measure, or structural control that addresses one or more objectives (e.g., a detention basin that gets built, an ordinance that gets passed, an educational program that gets implemented).

The following example clarifies the difference among a goal, an objective, and a management option.

> **Goal**: Improve water quality.
>
> **Objective:** Maintain dissolved oxygen levels above 5 mg/L.
>
> **Management Option:** Eliminate deep, poorly mixed plunge pools where low DO is detected.

Lists of management options were developed to meet each of the goals and objectives established for the Tookany/Tacony-Frankford Watershed. Only those options deemed feasible and practical were considered in the final list of management options. Options were developed and evaluated in three steps:

1. **Development of a Comprehensive Options List.** Virtually all options applicable in the urban environment were collected. These options were identified from a variety of sources, including other watershed plans, demonstration programs, regulatory programs, literature, and professional experience.
2. **Initial Screening.** Some options could be eliminated as impractical for reasons of cost, space required, or other considerations. Options that already were implemented, were mandated by one of the programs, or were agreed to be vital, were identified for definite implementation. The remaining options were screened for applicability to the TTF Watershed and for their relative cost and the degree to which they met the project objectives. Only the most cost-effective options were considered further.
3. **Detailed Evaluation of Structural Options.** Structural best management practices (BMPs) for stormwater and combined sewage were subjected to a modeling analysis. Effects on runoff volume, overflow volume, peak stream velocity, and pollutant loads were evaluated at various levels of coverage.

Detailed evaluation of structural options (step 3) used the SWMM model to assess the effectiveness of each option and used planning-level cost estimates of each option. All options that had an effect on CSOs or stormwater-related pollutant loads were modeled at several degrees of implementation. Graphs of effectiveness versus degree of implementation were developed, and the results were then combined with more accurate cost estimates to provide guidance on selecting effective options or combinations of options.

2.2.7 Development of Target Approach for Meeting Goals and Objectives

In developing a recommended watershed management alternative and discussing goals and objectives with stakeholders, it became clear that implementation could best be achieved by defining three distinct targets to meet the overall plan objectives. Targets A and B were defined so that they could be fully met with a limited set of options that are fully implemented. Target C fit better with an adaptive management approach. In other words, it was agreed to set interim objectives, recommend measures to achieve the interim objectives, implement those controls, and reassess the capability to meet the objectives or agree to raise the bar to more complete achievement of the final objectives.

These three targets represent groups of objectives that each focus on a different problem related to the urban stream system. They can be thought of as different parts of the overall goal of fishable and swimmable waters through improved water quality, more natural flow patterns, and restored aquatic and riparian habitat. The targets are specifically designed to help focus plan implementation.

By defining these targets, and designing the recommended alternative to address the targets simultaneously, the plan will have a greater likelihood of success. It also will result in realizing some of the objectives within a relatively short time frame, providing positive incentive to the communities and agencies involved in the restoration, and more immediate benefits to the people living in the watershed.

The targets for the Tookany/Tacony-Frankford Integrated Watershed Management Plan are defined as follows:

Target A: Dry Weather Water Quality and Aesthetics

Target A was defined for Tookany/Tacony-Frankford Creek with a focus on trash removal and litter prevention, and the elimination of sources of sewage discharge during dry weather. Streams should be aesthetically appealing (look and smell good), be accessible to the public, and be an amenity to the community. Access and interaction with the stream during dry weather has the highest priority, because dry weather flows occur about 60-65% of the time during the course of a year on the Tookany/Tacony-Frankford Creek. These are also the times when the public is most likely to be near or in contact with the stream. The water quality of the stream in dry weather, particularly with respect to bacteria, should be similar to background concentrations in groundwater.

In many urban streams, monitoring indicates that the water quality rarely meets the standard for bacteria, and occasionally exhibits dissolved oxygen (DO) problems, even during baseflow or dry weather conditions. Thus, the first target focuses on dry weather water quality, coupled with the visual aesthetics of the stream, primarily the removal of trash and the elimination of illegal dumping so often associated with degraded, urban waterways. Target A also includes a range of regulatory and nonstructural options that address both water quality and quantity concerns. Because the options under consideration are aimed at the total elimination of dry weather sources of trash and sewage, virtually all options related to this target were included in the implementation plan.

Target B: Healthy Living Resources

Based on the results of the water quality monitoring, habitat assessment, and biological monitoring, water quality was not identified as the primary cause of the low diversity and impaired nature of the fish population in the stream. Improvements to the number, health, and diversity of the benthic macroinvertebrate and fish species in the Tookany/Tacony-Frankford Creek need to focus on habitat improvement and the opportunity for organisms to avoid high velocities during storms. Fluvial geomorphological studies, wetland and streambank restoration/creation projects, and stream modeling should be combined with continued biological monitoring to ensure that correct procedures are implemented to increase habitat heterogeneity within the aquatic ecosystem.

Improving the ability of an urban stream to support viable habitat and fish populations focuses primarily on the elimination or remediation of the more obvious impacts of urbanization on the stream. These include loss of riparian habitat, eroding and undercut banks, scoured streambed or excessive silt deposits, channelized and armored stream sections, trash buildup, and invasive species. Thus, the primary tool to accomplish Target B is stream restoration.

Restoration will focus on improving channel stability, improving instream and riparian habitat, providing refuges for fish from high velocity conditions during storms, and managing land within the stream corridor. Restoration strategies include:

- Bank stabilization, including boulder structures, bioengineering, root wads, plantings, and log and woody structures;
- Bed stabilization, including rock/log vanes with grade control, rock/log cross vanes, and using naturally occurring boulders and bedrock;
- Realignment and relocation, used only on severely degraded stream sections;
- Dam and debris removal;
- Reforestation, with priority to floodplains, steep slopes, and wetlands;
- Invasive species management to increase biodiversity;
- Wetland creation, often used in conjunction with stream realignment to improve floodplain areas subject to annual flooding;
- Forest preservation;
- Fish holding areas, with low- to no-current zones created to provide fish with places to hold position during high flows.

Stream restoration measures to meet Target B were identified, and all options required to meet the target are planned for implementation.

Target C: Wet Weather Water Quality and Quantity

The third target is to restore water quality to meet fishable and swimmable criteria during wet weather. Improving water quality and flow conditions during and after storms is the most difficult target to meet in the urban environment. Because wet weather conditions on Tookany/Tacony-Frankford Creek occur to some degree about 35-40% of the time during the year, measures to improve wet weather quality have a somewhat lower priority than measures designed to address dry weather water quality. During wet weather, extreme increases in streamflow are common, accompanied by short-term changes in water quality. Stormwater generally does not cause immediate DO problems.

A comprehensive watershed management approach must also address flooding issues. Where water quality and quantity problems exist, options may be identified that address both. Any BMP that increases infiltration or detains flow will help decrease the frequency of damaging floods; however, the size of such structures may need to be increased in areas where flooding is a major concern. (Reductions in the frequency of erosive flows and velocities also will help protect the investment in stream restoration made as part of the Target B.)

Target C must be approached somewhat differently from Targets A and B. Full achievement of this target means meeting all water quality standards during wet weather, as well as eliminating all flooding. Meeting these goals will be difficult. It will be expensive and will require a long-term effort. The only rational approach to achieve this target must include stepped implementation with interim goals for reducing wet weather pollutant loads and stormwater flows, along with monitoring for the efficacy of control measures.

Initial load reduction targets for parameters such as metals, total suspended solids (TSS), and bacteria were set in conjunction with the stakeholders. Based on preliminary work by PWD, a 20% reduction is a challenging but achievable initial interim target.

It is expected that changes to the approach, and even to the desired results, will occur as measures are implemented and results are monitored. This process of continually monitoring progress and adjusting the approach is known as "adaptive management." The NPDES permit programs for stormwater and CSO outfalls can lead to a cycle of monitoring, planning, and implementation that helps define a time frame to this process.

2.2.8 Implementation Plan

Implementation plan guidelines were developed to provide Philadelphia and the upstream municipalities with a blueprint for improving water quality and habitat conditions. The guidelines (detailed in Section 8) include:

- Specific recommendations and a schedule for meeting Target A objectives;
- Specific recommendations and a schedule for meeting Target B objectives;
- Guidance on which BMPs or mixes of BMPs are most effective in Tookany/Tacony-Frankford Creek for meeting Target C objectives;
- Guidance on the needed degree of implementation to achieve Target C objectives;
- Guidance on areas of the watershed where BMPs would be most effective;
- Recommendations on Target C options for the CSO areas and separate storm sewer areas;
- Planning level cost estimates for implementation.

Section 3
Goals and Objectives

This section describes the process for setting overall watershed goals for the TTFIWMP, as well as numerous objectives for helping to reach those goals. The seven prioritized goals, referenced throughout this document, are useful for evaluating the wide range of possible "management options" for implementing the plan.

Developing a focused and prioritized list of goals (general) and objectives (specific, measurable) is critical to a successful planning process. Goals and objectives need to be:

- initially developed by stakeholders and regulatory agencies;
- analyzed and informed by the watershed data collection, analysis, and modeling carried out by the project team;
- finalized by the project team and stakeholders;
- prioritized by the stakeholders.

3.1 Stakeholder Goal Setting Process

Considerable stakeholder input toward developing watershed goals was sought from the beginning of this planning effort. Responses were summarized, and additional stakeholder input organized through further contacts with the stakeholders.

Tookany/Tacony-Frankford Partnership Mission Statement

The mission for the Tookany/Tacony-Frankford planning effort, developed by the stakeholders, is to improve the environmental health and safe enjoyment of the Tookany/Tacony-Frankford Watershed by sharing resources through cooperation of the residents and other stakeholders in the watershed. The goals of the initiative are to protect, enhance, and restore the beneficial uses of the Tookany/Tacony-Frankford waterways and riparian areas. Watershed management seeks to mitigate the adverse physical, biological, and chemical impacts of land uses as surface and groundwater are transported throughout the watershed to the waterways. The TTF Partnership seeks to achieve higher levels of environmental improvement by sharing information and resources.

Goals of Related Studies and Programs

Other studies have already provided a list of goals. Generally, the goals in this section are those identified through the Rivers Conservation Planning process, supplemented by those goals that are required as a result of various environmental regulatory requirements. Additional goals identified in the Tookany/Tacony-Frankford stakeholder meetings were also included once consensus was established.

Existing goals included:

- Aquatic life designated use attainment goal (warm water fishery)
- Public health: Contact recreation (bacteria, noxious plants)
- Aesthetics: Visual and olfactory conditions (noxious plants, bank erosion, litter, odor, etc.)
- Riparian corridors
- Wetlands, woodlands, and meadows
- Wildlife
- Act 167 plan goals
- Act 537 goals
- TMDL-related goals
- NPDES program goals (including stormwater management and CSO control)
- Environmental Futures Program goals
- River Conservation Plan goals

3.2 Consolidated Watershed Planning Goals and Objectives

The large list of goals from the existing stakeholder process needed to be organized. This was accomplished by consolidating goals from various sources into a coherent set for the integrated plan. Other considerations included stakeholders' desire to restore the living resources, and the preference for achieving goals through innovative, land-based, low-impact, and cost-effective management options. Consensus was reached around the following seven goals. Under each goal, more specific objectives are listed.

Goal 1 – Streamflow and Living Resources. Improve stream habitat and integrity of aquatic life.

- Improve quantitative measures of fishery health.
- Improve quantitative measures of benthic macroinvertebrate quality.
- Adapt or develop quantitative measures of attached algae to assess current stream conditions.
- Improve migratory fish passage.
- Increase miles of stable stream banks and stream channels by reducing deposition and scour.

Goal 2 – Instream Flow Conditions. Reduce the impact of urbanized flow on living resources.

- Increase baseflow as a percentage of total flow.
- Increase groundwater recharge.
- Prevent increases in the stormwater flow peaks in future development/redevelopment areas.
- Reduce directly connected impervious cover in developed and new development areas.
- Revise municipal codes to encourage new development and redevelopment using responsible stormwater management techniques.
- Reduce the frequency of occurrence of bankfull flow.

Goal 3 – Water Quality and Pollutant Loads. Improve dry and wet weather stream quality to reduce the effects on public health and aquatic life.

- Develop a phased approach to meeting appropriate water quality criteria in dry weather and wet weather.
- Work with regulatory agencies to re-evaluate designated uses.
- Prevent fish consumption advisories.
- Decrease loads of targeted water quality parameters from stormwater.
- Identify and eliminate SSOs and storm sewer cross-connections.
- Minimize CSO volume and frequency.
- Decrease inputs of floatables, debris, and litter from all sources.
- Increase "Inflow & Infiltration" studies, sewer cleanings, and inspections.
- Eliminate septic tank failures.

Goal 4 – Stream Corridors. Protect and restore stream corridors, buffers, floodplains, and natural habitats including wetlands.

- Maximize open space and habitat by responsibly managing new development and redevelopment of existing, vacant, and abandoned lands.
- Inventory and protect existing wetlands.

- Identify and pursue opportunities for wetland enhancement and wetland creation for stormwater treatment.
- Improve floodplain conditions through restoration or improvement of the connections between streams and their floodplains.
- Protect and restore riparian and upland habitats along stream corridors with native species.

Goal 5 – Flooding. Identify flood prone areas and decrease flooding by similar measures intended to support Goals 1, 2, and 4.

- Reduce the effects and frequency of out-of-bank flooding through management of stormwater.
- Remediate stream-related flooding in known problem areas without increasing the problem in other areas.
- Increase regular storm drain maintenance and cleaning programs throughout the watershed.
- Incorporate sound floodplain management principles in flood planning.
- Minimize the effects of structural floodway and stream encroachments with regard to sediment load and natural streamflow.

Goal 6 – Quality of Life. Enhance community environmental quality of life.

- Increase community green and open space.
- Increase community access and recreational activities in city parks and streams (e.g., by increasing miles of greenways and trails along stream corridors).
- Increase the public sense of security along stream corridors (e.g., by lighting, signage, park maintenance, increased police presence).
- Improve and protect aesthetics along stream corridors (e.g., by litter/graffiti removal, enforcement against illegal practices such as dumping, controls on ATV use).
- Identify and protect historical and cultural resources along stream corridors.

Goal 7 – Stewardship, Communication, and Coordination. Foster community stewardship and improve inter-municipal, inter-county, state-local, and stakeholder cooperation and coordination on a watershed basis.

- Increase public awareness of the value of streams to the community.
- Improve public, business, and institutional awareness of and accountability for activities that affect water quality.
- Encourage and support establishment of watershed organizations, EACs, and the like, to bear the watershed banner.
- Engage local officials and planners.
- Increase volunteer participation in implementing management options.
- Increase school-based education.

3.3 Goals Prioritization

The goals and objectives represent the collective ideas of the stakeholders on what the watershed management plan should achieve. Not all goals, however, are of equal importance. It is helpful to elicit from the stakeholders a collective opinion on the relative importance of each goal for the Tookany/Tacony-Frankford Watershed. Because the achievement of goals is a key aspect of measuring the effectiveness of the management plan, some numerical representation of the importance of each goal is useful.

To develop a set of numerical weights that represent the importance of each goal relative to the other goals, a workshop was held in May 2003, with participation from members of the partnership. The goal of the workshop was to drive towards a consensus on a numerical set of weights that best represent the collective opinion on the importance of each goal. Each participant filled in a worksheet weighting each of the seven goals with the percentage that described the individual contribution of each goal to the overall goal of watershed management. These sheets provided a variety of opinions on how the goals should be weighted, and served as a guide to a discussion on the relative importance of each goal. Through the group discussion, a consensus set of goal weights was developed that best represents the importance of each goal as defined by the stakeholders. Table 3.1 shows the weights assigned to each goal. The weights represent a percentage of the overall importance of each goal relative to all goals.

Table 3.1 Stakeholder Priorities as Weights for Goals

1. Streamflow and Living Resources. Improve stream habitat and integrity of aquatic life.	**15**
2. Instream Flow Conditions. Reduce the impact of urbanized flow on living resources.	**15**
3. Water Quality and Pollutant Loads. Improve dry and wet weather stream quality to reduce the effects on public health and aquatic life.	**20**
4. Stream Corridors. Protect and restore stream corridors, buffers, floodplains, and natural habitats including wetlands.	**15**
5. Flooding. Identify flood prone areas and decrease flooding by similar measures intended to support Goals 1, 2, and 4.	**5**
6. Quality of Life. Enhance community environmental quality of life (protect open space, access and recreation, security, aesthetics, historical/cultural resources).	**10**
7. Stewardship, Communication, and Coordination. Foster community stewardship and improve inter-municipal, inter-county, state-local, and stakeholder cooperation and coordination on a watershed basis.	**20**

The weights assigned to each goal were important in screening and evaluating the many possible alternative water management approaches to arrive at the recommended options.

The workshop participants also offered their opinions on the relative priority – high, medium, or low – of each of the objectives within the goals. A consensus building process was not attempted for all of the objectives, however, since these play a lesser role in the overall evaluation.

Section 4
Watershed Indicators: TTF Study Results

This section details the 21 measurable "watershed indicators" that were created in order to assess historic and current conditions, and to track progress as the TTFIWMP is implemented over time. The information presented can serve as a basis for understanding the state of the TTF Watershed, its relative environmental quality, and trends in the management of factors that influence its quality.

This section summarizes the results of the numerous recent studies of the Tookany/Tacony-Frankford Watershed. When available, results are included for the combined Montgomery County (Tookany) and Philadelphia County (Tacony-Frankford) portions of the watershed; however, several studies have provided more detailed information within Philadelphia. These assessments have identified problem areas for future focus, while establishing a "watershed baseline" from which we can measure our progress as recommendations are implemented. The 21 indicators fall into six broad categories, covered in the following sections:

Section 4.1	**The Land Use and Stream Health Relationship**
Section 4.1.1	Indicator 1: Land Use and Impervious Cover
Section 4.2	**Flow Conditions and Living Resources**
Section 4.2.1	Indicator 2: Streamflow
Section 4.2.2	Indicator 3: Stream Channels and Aquatic Habitat
Section 4.2.3	Indicator 4: Restoration and Demonstration Projects
Section 4.2.4	Indicator 5: Fish
Section 4.2.5	Indicator 6: Benthic Macroinvertebrates
Section 4.3	**Water Quality**
Section 4.3.1	Indicator 7: Effects on Public Health (Bacteria)
Section 4.3.2	Indicator 8: Effects on Public Health (Metals and Fish Consumption)
Section 4.3.3	Indicator 9: Effects on Aquatic Life (Dissolved Oxygen)
Section 4.4	**Pollutants**
Section 4.4.1	Indicator 10: Point Sources
Section 4.4.2	Indicator 11: Non-point Sources
Section 4.5	**The Stream Corridor**
Section 4.5.1	Indicator 12: Riparian Corridor
Section 4.5.2	Indicator 13: Wetlands and Woodlands
Section 4.5.3	Indicator 14: Wildlife
Section 4.6	**Quality of Life**
Section 4.6.1	Indicator 15: Flooding
Section 4.6.2	Indicator 16: Public Understanding and Community Stewardship
Section 4.6.3	Indicator 17: School-Based Education
Section 4.6.4	Indicator 18: Recreational Use and Aesthetics
Section 4.6.5	Indicator 19: Local Government Stewardship
Section 4.6.6	Indicator 20: Business and Institutional Stewardship
Section 4.6.7	Indicator 21: Cultural and Historic Resources

4.1 The Land Use and Stream Health Relationship

Urbanization of natural lands affects watershed hydrology, water quality, stream stability, and ecology.

4.1.1 Indicator 1: Land Use and Impervious Cover

One of the primary indicators of watershed health is the percent of impervious cover in the watershed. Based on numerous research efforts, studies, and observations, a general categorization of watersheds has been widely applied to watershed management based on percent impervious cover (Schueler 1995). Table 4.1 summarizes several of the impacts of traditional development on streams and watersheds, most of which are created by the addition of impervious cover across portions of the land surface.

Table 4.1 Impervious Cover as an Indicator of Stream Health (Schueler 1995)

Characteristic	Sensitive	Degrading	Non-Supporting
Percent Impervious Cover	0% to 10%	11% to 25%	26% to 100%
Channel Stability	Stable	Unstable	Highly Unstable
Water Quality	Good to Excellent	Fair to Good	Fair to Poor
Stream Biodiversity	Good to Excellent	Fair to Good	Poor
Pollutants of Concern	Sediment and temperature only	Also nutrients and metals	Also bacteria

This indicator measures:

- **GIS-estimated impervious cover of each municipality (% of total area)**
- **Model-estimated Directly Connected Impervious Area (DCIA) of each subwatershed (% of total area)**
- **Open space in each municipality (% of total area)**
- **Publicly-owned land in each municipality (% of total area)**
- **Vacant land**

Where We Were:

By 1820, the majority of the woodland in the watershed had been cut down for use as fuel and for construction. After this time, the land use of the watershed began to change drastically. During the 1890s, there were transportation improvements which brought to the watershed new industries that were seeking to take advantage of the growing riverfront industrial community. Streets were laid, and roads, houses, churches, and stores were built. During the 19th and early 20th centuries, the Tookany/Tacony-Frankford Watershed became an industrial center for textile production. Many mills and factories were built in the flood plains of the stream and the tributaries. In the early 20th century, in order to protect the creek from further pollution, the City of Philadelphia set aside hundreds of acres of parkland along the creek, called the Fairmount Park System, which included Juniata Park and Tacony Creek Park in the Tacony-Frankford Watershed.

Since World War II, half a million people have left Philadelphia, which has increased the amount of vacant land within the city. The incentives for construction of single homes in the suburbs created a flight of people out of the city, leaving many building and lots vacant and untended. These abandoned properties decrease the value of homes within the neighborhood and are a drain on city resources.

<u>Where We Are</u>:

The geographic breakdown of land use within the Tookany/Tacony-Frankford watershed was displayed in Figure 2-2; the spatial distribution of land use is shown here in Figure 4.1. Land use within the watershed is predominantly residential (around 59% of total land use). Headwater regions located in Montgomery County are dominated by single-family residences (26.5% of the total watershed), while mid-portions of the watershed located in the City of Philadelphia are predominantly multi-family residential, such as row or cluster housing (32.9% of the total watershed). The lower portions of the watershed are characterized mainly by industrial facilities (4.9% of the total watershed) and multi-family residential. The section of Tookany/Tacony-Frankford Watershed within the City of Philadelphia is dominated by urban land uses. Furthermore, the lack of a well-defined riparian corridor and forested regions within the watershed is evident, with only 5.8% of land attributed to parklands and natural surfaces and 5.1% classified as wooded regions.

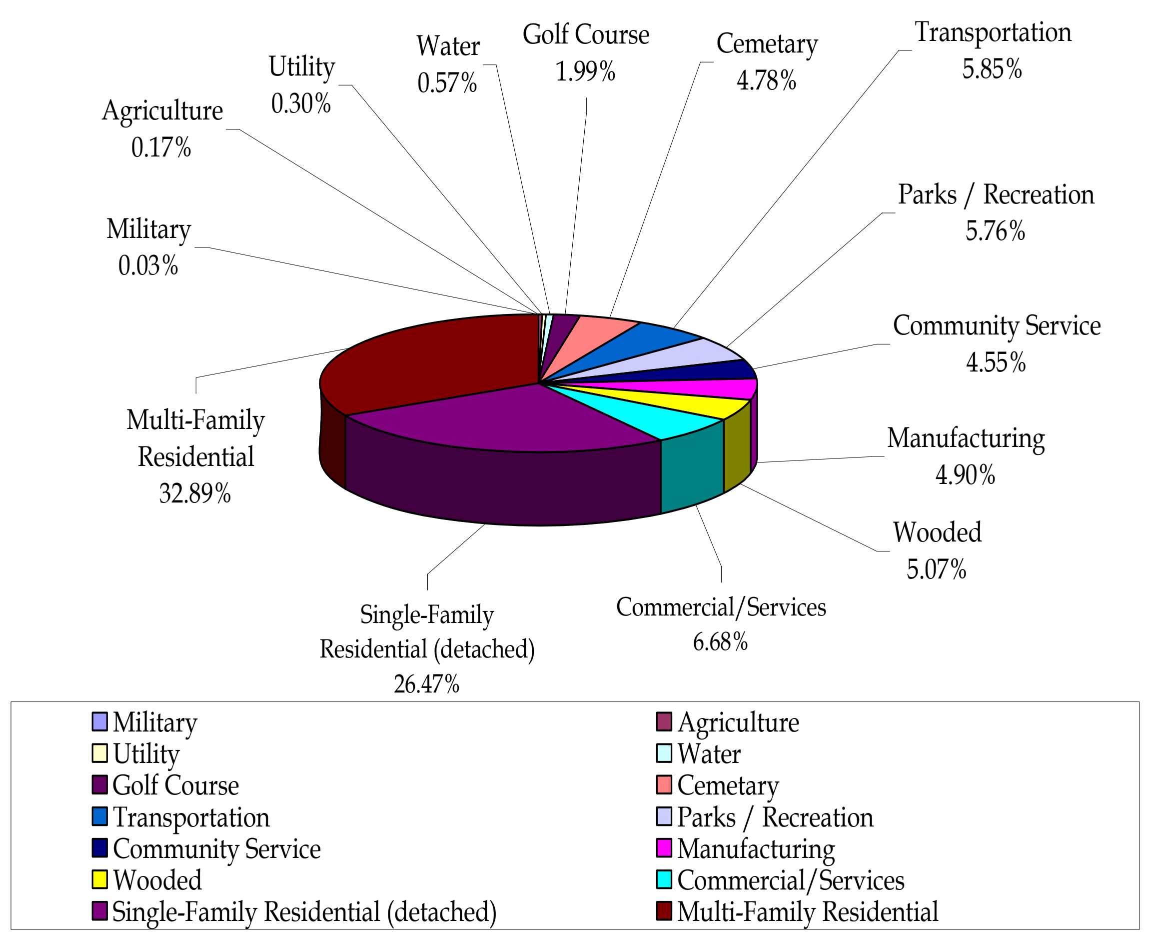

Figure 4.1 Land Use Breakdown in Tacony-Frankford Watershed

As seen in Table 4.2, Abington Township has the lowest percentage of impervious cover in the watershed, with just under 32% of their land within the watershed listed as impervious. Philadelphia has the highest percent impervious, with more than 47% of the land within the watershed listed as impervious. The entire watershed is at a level where stream channels are highly unstable, water quality is either fair or poor, and there is poor stream biodiversity (Table

4.1). Many of the pollutants associated with watersheds at this level of percent impervious cover include sediment, temperature, nutrients, metals, and bacteria.

Table 4.2 Breakdown of % Imperviousness by Municipality (within watershed boundaries)

Municipality	County	Total Area Within Watershed (acres)	% Impervious
Abington	Montgomery	2,661	31.9%
Cheltenham	Montgomery	5,609	32.6%
Rockledge	Montgomery	97	35.3%
Springfield	Montgomery	66	38.0%
Jenkintown	Montgomery	332	43.5%
Philadelphia	Philadelphia	12,161	47.3%

From the land use data, the part of each municipality that lies within the watershed was analyzed to determine the percentage of open space and publicly owned land. The watershed on a whole averages about 17% open space and 19% publicly owned land. As seen in Table 4.3, the amount of open space varies by municipality within the watersheds, with Jenkintown with as little as 3.5% open space and Rockledge with as much as 30% of their land within the watershed as open space. Included in our open space calculation were categories such as agriculture, cemeteries, golf courses, regional parks, urban recreation areas, water, wetlands, and wooded areas. The percentage of publicly owned land varied greatly depending on municipality, with the small portion of Springfield that lies within the watershed having 8% of this area publicly owned, while Rockledge had the most publicly owned land at almost 28% of the total acreage within the watershed. Publicly owned land included cemeteries, commercial, transportation, regional parks, urban recreation areas, water, and wetlands.

Table 4.3 Estimated Open Space and Publicly Owned Land

Municipality	County	Total Area Within Watershed (acres)	Publicly Owned (% of total)	Open Space (% of total)
Abington	Montgomery	2,661	17.2%	27.0%
Cheltenham	Montgomery	5,609	15.0%	23.6%
Rockledge	Montgomery	97	27.9%	30.6%
Springfield	Montgomery	66	8.1%	5.9%
Jenkintown	Montgomery	332	20.5%	3.5%
Philadelphia	Philadelphia	12,161	25.9%	14.4%

The City of Philadelphia began the Neighborhood Transformation Initiative (NTI) in 2001; the goal of the program is revitalizing Philadelphia neighborhoods. The NTI includes a vacant lot program that cleans and maintains vacant lots throughout the City. The program includes the removal of debris from vacant lots, and when possible, the transformation of some of them into green space. Through the NTI program, 31,000 of the City's vacant lots were cleaned at least once and 33,950 tons of debris was removed. Additionally, as of June 2003, the City had "greened" 470 vacant parcels of land (over 13 acres). Figure 4.2 displays the vacant lands within the Tookany/Tacony-Frankford Watershed. Another aspect of NTI is the demolition of dangerous vacant buildings. From 2000-2003, more that 4100 vacant buildings were demolished in Philadelphia.

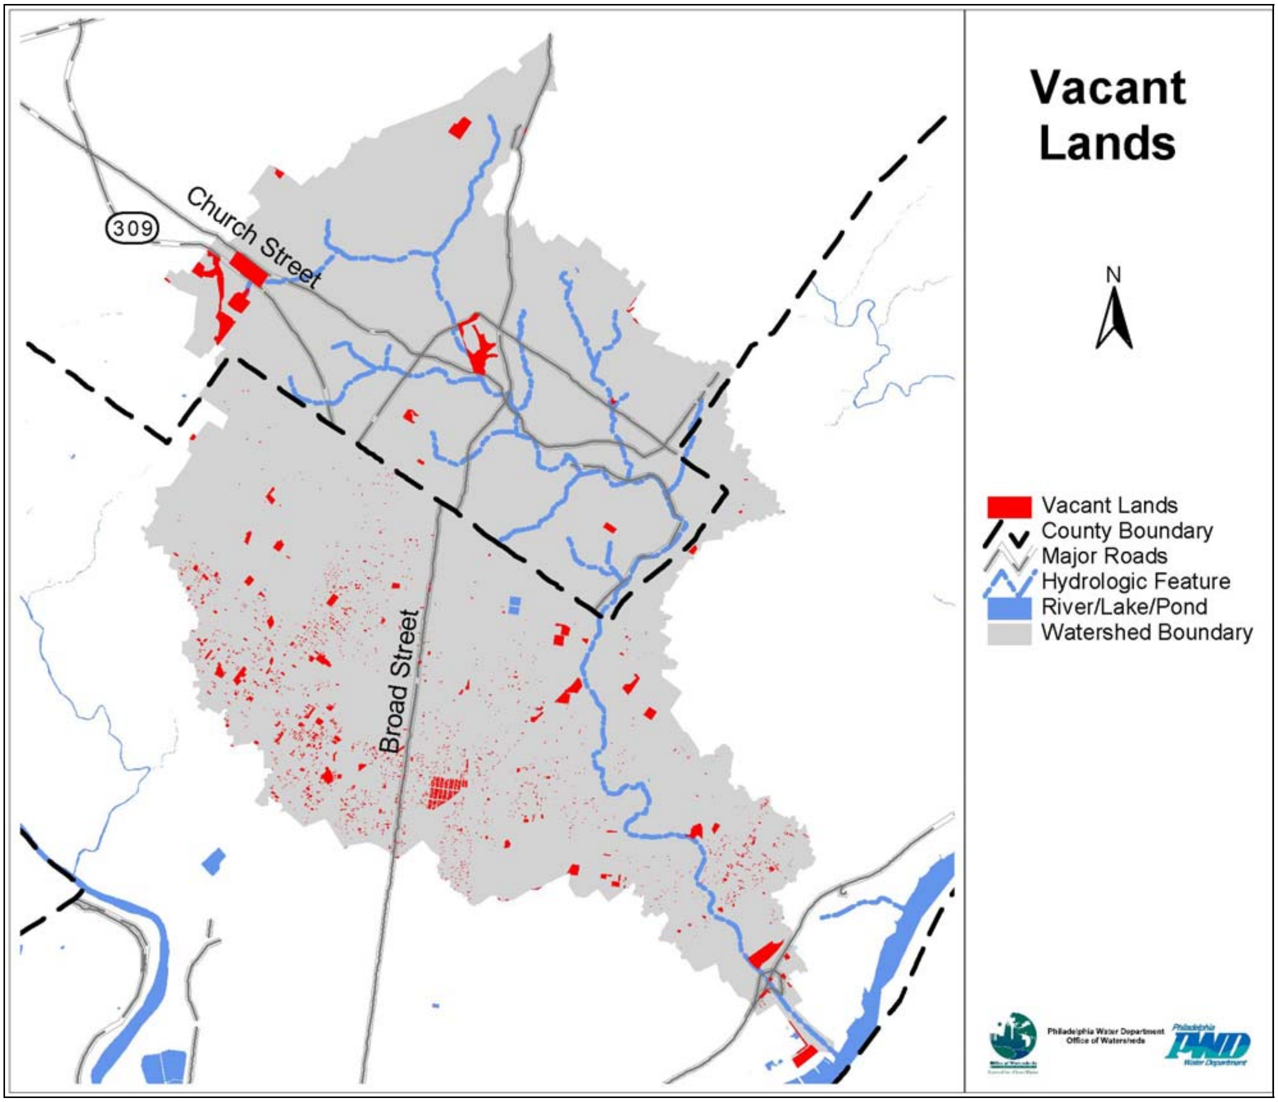

Figure 4.2 Vacant Lands in the Tookany/Tacony-Frankford Watershed

4.2 Flow Conditions and Living Resources

Urbanized land uses affect stormwater runoff, streamflow, the shape of stream banks and channels, water quality, and aquatic habitat and ecosystems.

4.2.1 Indicator 2: Streamflow

Increases in impervious cover affect stream hydrology in a variety of ways:

- Increased magnitude and frequency of severe floods;
- Increased frequency of erosive bankfull and sub-bankfull floods;
- Reduced groundwater recharge leading to reduced baseflow;
- Higher flow velocities during storm events.

This indicator measures:

- **Average annual baseflow (% of total flow)**
- **Average annual baseflow (% of annual precipitation)**
- **Average annual stormwater runoff (% of annual precipitation)**

As discussed in Indicator 1, the entire watershed is highly urbanized and contains a large proportion of impervious cover. The hydrologic impact of urbanization can be observed through analysis of streamflow data taken from USGS gauges on the Tacony-Frankford Creek. In addition, data from French Creek in Chester County provides a picture of a nearby, less-developed watershed to utilize for comparison as a “reference stream.”

<u>Where We Were</u>:
The analysis below represents a long-term period of record for each stream gauge. It is difficult to establish a trend over time, but an attempt will be made when the watershed is reassessed.

<u>Where We Are</u>:
Streamflow data were separated into two main components: baseflow and stormwater runoff. In perennial streams, baseflow is the portion of streamflow caused by groundwater inflow and streamflow will be present in both dry and wet weather conditions. The stormwater runoff component is the portion of streamflow that is contributed during wet weather as a result of excess stormwater runoff flowing over the land surface and through the storm drainage system to the creek.

The results of a hydrograph decomposition analysis support the relationship between land use and hydrology discussed above. In Table 4.4, the results for the Tacony-Frankford Creek analysis are compared with that of French Creek, our unimpaired reference stream, and the Darby Creek, a stream in a mixed urban and suburban watershed similar to the Tookany/Tacony-Frankford. The table demonstrates how the three chosen statistics help describe the hydrologic condition of the streams, ranging from rural to highly urbanized. Results for French Creek are somewhat typical of an undeveloped watershed, with baseflow comprising 64% of mean annual streamflow and stormwater only 17% of annual precipitation.

Table 4.4 Summary of Hydrograph Separation Results over the Period of Record

	Baseflow (% of total flow)	Baseflow (% of precip.)	Stormwater Runoff (% of precip.)
French Creek 01475127	64	31	17
Darby Creek 01475510	62	34	21
Tacony Creek 01467086	58	29	21
Frankford Creek 01467087	38	17	27

The Frankford Creek gauge represents most of the urbanized area in the Tookany/Tacony-Frankford watershed. At this gauge, the stormwater component of streamflow is a much greater percentage of total annual streamflow (62%), and baseflow represents a much smaller percentage of total annual streamflow (only 38%). These results confirm that Tacony-Frankford is a highly urbanized stream. Figure 4.3 displays the hydrograph decomposition for the Frankford Creek USGS gauge for a six month period in 2000. The daily baseflow is estimated and plotted on top of the total flow. The area above the baseflow curve indicates the daily runoff. Storm events can be seen clearly by the peaks in runoff.

The Tacony Creek USGS gauge, representing the headwaters of the Tacony-Frankford watershed, exhibits behavior intermediate between the two extremes. However, the statistics suggest that it is more urbanized than the Darby Creek watershed, another urbanized watershed in Philadelphia.

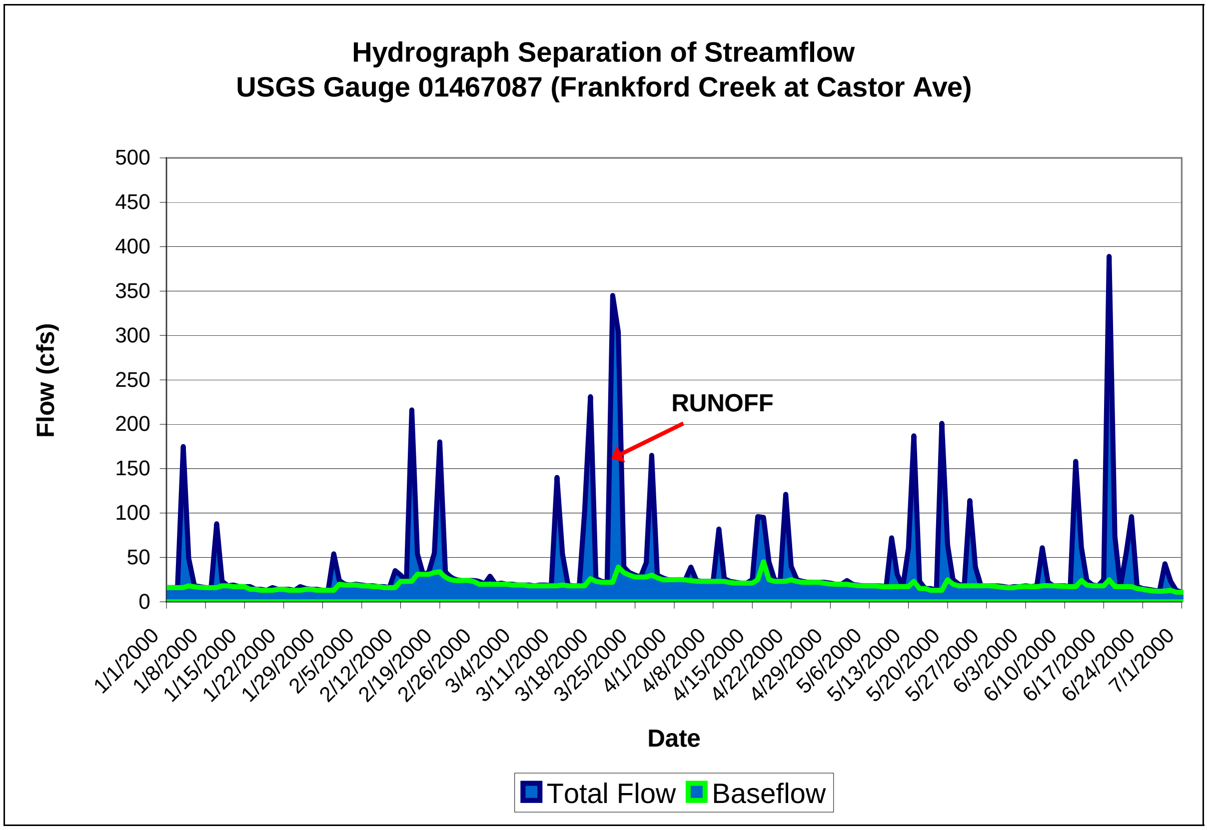

Figure 4.3 Hydrograph Separation at Frankford Creek gauge (USGS gauge 01467087)

4.2.2 Indicator 3: Stream Channels and Aquatic Habitat

Stream life (fish, invertebrates, and plants) require physical habitat features that allow them to feed, reproduce, and seek shelter during periods of high flow. In the urban environment where significant erosion and deposition occur, these areas often are not available (Figure 4.4).

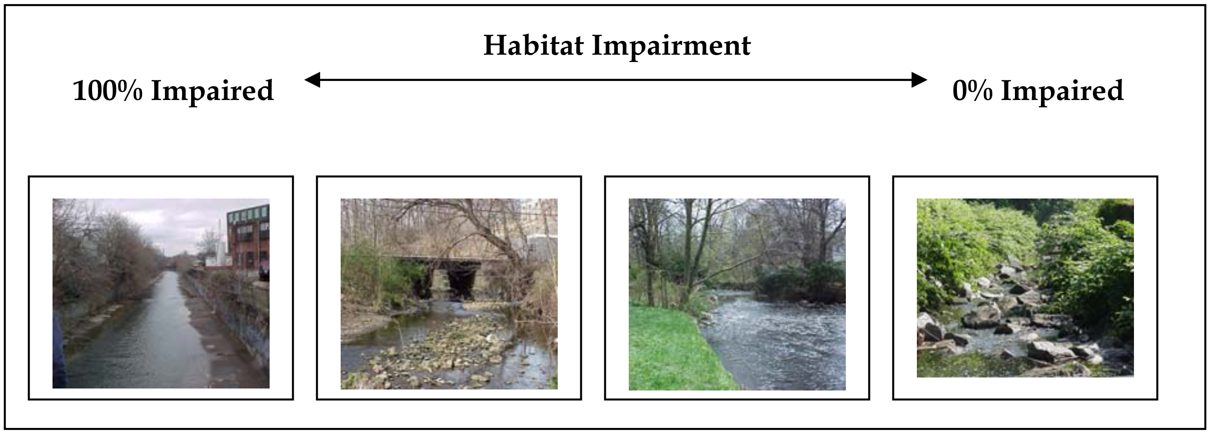

Figure 4.4 Photo Comparison of Impaired and Unimpaired Habitats

Fluvial geomorphology (FGM) is the study of landforms associated with river channels and the processes that form them. The Rosgen classification system was used to assess the physical channel conditions. The Rosgen classification system was developed by Dave Rosgen and assigns a channel type based on channel slope, width-to-depth ratio, bed material, entrenchment ratio, and sinuosity. This classification system is based primarily on the appearance of a stream in combination with a number of delineative criteria associated with the stream's morphology.

This indicator measures:

- **Habitat score relative to reference condition at various sites**
- **Channel type and expected trend**

<u>Where We Were</u>:
There is no historical data available for this indicator. Habitat and stream channels most likely degraded over a long period of time as development took place within the watershed. A trend will be established the next time this area is reassessed.

<u>Where We Are</u>:
Habitat assessments were performed at the seven sites where benthic macroinvertebrate community assessments were completed. Each site was assessed on habitat conditions for Epifaunal Substrate/Available Cover, Pool Substrate Characterization, Pool Variability, Sediment Deposition, Embeddedness, Velocity/Depth Regime, Frequency of Riffles (or bends), Channel Flow Status, Channel Alteration, Channel Sinuosity, Bank Stability, Vegetative Protection, and Riparian Vegetative Zone Width. Habitat assessments are scored in comparison with a healthy stream, as a percentage of the expected diversity found in an unimpaired reach. The results show two sites found to be "Partially Supporting," and the other five sites found to be "Non-Supporting"(Table 4.5 and Figure 4.5). This is a clear indication of the impacts of urbanization on the stream habitat.

Table 4.5 Habitat Assessment Scores

Site	Score	Percent Comparison	Assessment Category
TF 280	108.5	52%	Non-Supporting
TF 500	97	47%	Non-Supporting
TF 620	147.5	71%	Partially Supporting
TFM 000	91	44%	Non-Supporting
TF 975	122	59%	Non-Supporting
TF 1120	120.5	58%	Non-Supporting
TFJ110	128	70%	Partially Supporting

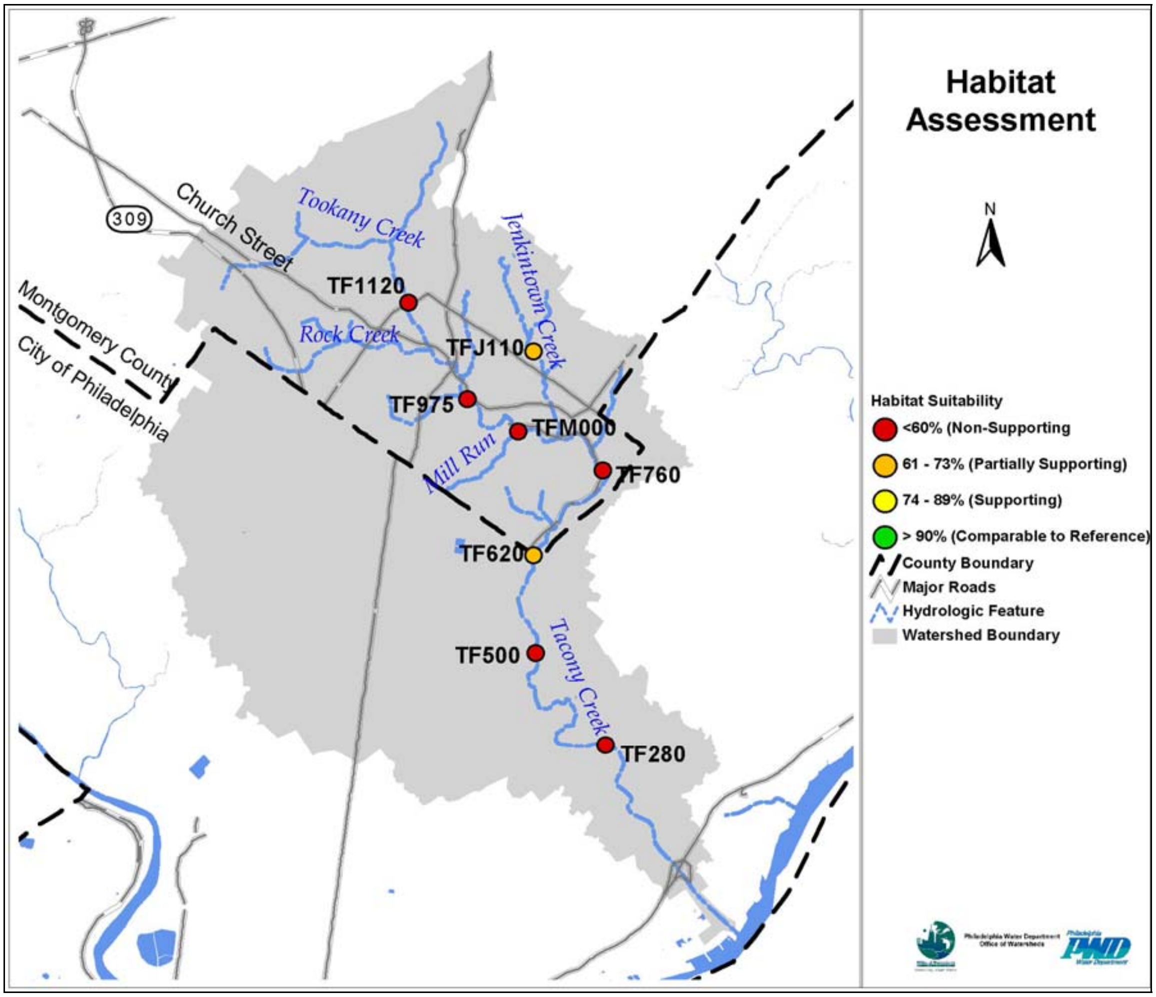

Figure 4.5 Tookany/Tacony-Frankford Watershed Habitat Assessment

4.2.3 Indicator 4: Restoration and Demonstration Projects

Funding for watersheds and water–related projects has been increasing throughout the country in recent years. Grants are being issued to complete various types of projects throughout the state of Pennsylvania. The Growing Greener program has been an enormous source of environmental funding over the last few years and has become the largest single investment of state funds in Pennsylvania's history. There are also many other organizations and governmental agencies offering grant money and technical assistance for communities and other associations to accomplish their environmental projects for improving our watersheds. Figure 4.6 is one example of a stream reach that is planned for eventual restoration.

This indicator measures:

- **Lists of completed, in progress, and planned projects**

Figure 4.6 Streambank Restoration in the Tookany/Tacony Frankford Creek

<u>Where We Were</u>:

There is no historical data available for this indicator. The number of restoration and other environmental projects in this watershed has increased with the introduction of the Growing Greener program and other funding programs.

<u>Where We Are</u>:

There has been a flurry of environmental projects in the Tookany/Tacony-Frankford Watershed over the past few years. There has been an influx of grant monies from programs such as the Growing Greener Program and the League of Women's Voters. The types of projects that are underway or have been completed include wetlands assessment, technical assistance, demonstration projects, education, watershed planning, property acquisition, and restoration projects. A list of many of the grants for environmental projects in the Tacony-Frankford Watershed issued from 1999 to 2004 has been assembled. Table 4.6 represents a profile of the grants received and the projects being performed. The list includes 20 projects either completely or partially in the watershed with a total amount of over $1.7 million in grants received.

One example project conducted by the TTF Partnership was the Rain Barrel Implementation Project. This project demonstrated the use of rain barrels as a method to reduce stormwater runoff. The rain barrel project enlisted members of the communities in and around Philadelphia, as well as several environmental organizations to install rain barrels on their personal property or on the property of their organization. This project included an educational component that consisted of instruction on the assembly and maintenance of the rain barrel, as well as the uses and benefits. The primary goal was to implement an individual "property-level" Best Management Practice (BMP) to help reduce the volume of stormwater reaching the receiving stream and to increase the length of time it takes the stormwater to reach the receiving stream.

Table 4.6 Grants Awarded in the Tookany/Tacony-Frankford Watershed

Funding Agency	Funding Program	Year	Lead Agency	Project Title	Amount Awarded	Project Description
PA League of Women Voters	Watershed Education for Pollution Prevention Projects	1999	Awbury Arboretum	Tacony- Frankford Watershed Lesson	$3,000	To develop a watershed education program, including brochures and lessons plans, about the Tacony-Frankford Watershed. The program will include the theme of Backyard Conservation and will be targeted at school age children who visit Awbury Arboretum.
DCNR	Rivers Conservation Program	1999	Cheltenham Township	Tookany Creek River Conservation Plan	$25,000	To prepare a River Conservation Plan for the Tookany Creek watershed from its headwaters to the Montgomery/Philadelphia county line.
DEP	Growing Greener	1999	Awbury Arboretum	Tacony-Frankford watershed education initiative	$13,000	To implement a new watershed-protection education initiative which aims to greatly increase the public's awareness of the Tacony-Frankford Watershed.
DCNR	Rivers Conservation Program	2001	Philadelphia Water Department	Tacony-Frankford Watershed River Conservation Plan	$100,000	To develop a River Conservation Plan for the Philadelphia County portion of the Tacony-Frankford watershed.
EPA	Five Star Restoration Challenge Grant Program	2001	Township of Cheltenham	Tookany Park Streambank Restoration	$15,000	The project will revitalize and restore one section of flood-ravaged Tookany Creek. Along with this comprehensive creekside restoration, the project will develop watershed information and a training manual for middle school students about issues related to the Tookany Creek Watershed. Partial funding for this grant is provided by Lockheed Martin Corporation.
DCNR	Growing Greener	2001	Fairmount Park Commission	Acquisition of the Delaware River/ Kensington Tacony Trail	$350,000	To acquire 16 acres of rail line property to develop the Delaware River/Kensington Tacony Trail.
DEP	Growing Greener	2002	Awbury Arboretum	Awbury Arboretum watershed restoration project	$42,000	This project will redirect stormwater runoff from adjacent properties; remove obstructions to the flow from two natural springs; daylight a stretch of stream; enhance existing meadow; and restore degraded areas with native plantings.

Funding Agency	Funding Program	Year	Lead Agency	Project Title	Amount Awarded	Project Description
DEP	Growing Greener	2002	Philadelphia Water Department	Rain barrel Implementation project	$28,000	To install rain barrels on properties of the communities comprising the Tacony-Frankford Watershed as a method of reduction of stormwater runoff. This project includes an educational component that consists of instruction on the assembly and maintenance of the rain barrel, as well as the uses and benefits.
EPA	Five Star Restoration Challenge Grant Program	2002	Township of Cheltenham	Tookany Park Streambank Restoration II	$10,000	The project will continue efforts to revitalize and restore one section of flood-ravaged Tookany Creek. Along with this comprehensive creekside restoration, the project will develop watershed information and a training manual for middle school students about issues related to the Tookany Creek Watershed. Partial funding for this grant is provided by EPA Region III and Lockheed Martin Corporation.
NFWF	Foundation Grants	2002	Township of Cheltenham	Tookany Park Streambank Restoration	$10,000	Continue efforts to revitalize and restore one section of flood-ravaged Tookany Creek in Pennsylvania. Project will also develop a watershed information and a training manual for middle school students about issues related to the Tookany Creek watershed.
DEP - CZM	CNPP	2002	Pennsylvania Environmental Council	Kensington & Tacony Trail Pre-Acquisition & Development	$50,000	Complete all pre-acquisition activities as well as develop appropriate communications and stakeholder educational materials describing the importance of the trail for recreational activity and coastal zone access.
DEP	Growing Greener	2003	Township of Cheltenham	Streambank restoration on Tookany Creek	$100,000	Streambank restoration on Tookany Creek.
DEP	Growing Greener	2003	Philadelphia Water Department	Restore Tacony Creek using natural channel design	$25,000	The primary goal of this project is to identify and document existing stream conditions of the Tacony Creek stream corridor near Whitaker Avenue in Northern Philadelphia.
DEP - CZM	CNPP	2004	Township of Cheltenham	Tookany Creek stabilization and restoration	$50,000	For stabilization and restoration of 3,900 feet of streambank along the Tookany Creek in a Cheltenham Township riparian park. The project will use bioengineering techniques and non-structural best management practices.
DEP	Act 167	2002	Philadelphia Water Department	Tacony-Frankford Act 167 SW Plan Phase I	$15,000	Preparation and submission of a Scope of Study to DEP for a watershed stormwater plan.
EPA	Wetland Program Development Grants	2002	Philadelphia Water Department	Southeast Regional Wetland Inventory and Water Quality Improvement Initiative	$250,000	This project is to expand Philadelphia Water Department's existing wetland inventory and assessment program to define opportunities for wetland protection and enhancement for four watersheds in the Southeast region of the commonwealth of Pennsylvania. *(includes other watersheds)*

Funding Agency	**Funding Program**	**Year**	**Lead Agency**	**Project Title**	**Amount Awarded**	**Project Description**
DEP	Act 167	2004	Philadelphia Water Department	Tacony-Frankford Act 167 SW Plan Phase II	$363,000	Preparation and adoption of the detailed watershed stormwater plan; includes modified Level 2 FGM assessment.
DEP	Growing Greener	2003		Norris Square Civic Association Mercado	$140,000	Build a green roof and rain garden at the Mercado.
USACE	Southeastern Pennsylvania Environmental Assistance Program	2000	City of Philadelphia	Logan Sinking Homes Study	$150,000	Sinking homes in the Logan neighborhood – The focus of the project was to gather and develop data to perform a preliminary analysis of the potential magnitude, extent, and scope of the problem and its possible causes.
DEP	Growing Greener	2003	City of Philadelphia	Technical Assistance Grant	$232,000	This project provides a wide range of assistance to community-based conservation efforts in urban settings of Southeastern Pennsylvania. *(includes other watersheds)*

4.2.4 Indicator 5: Fish

Fish are good indicators of stream health because their presence requires favorable environmental conditions within a certain range of streamflow, water temperature, water quality, and channel habitat. Abundance and diversity of fish are indicators of good water quality. The number of pollution tolerant fish and the presence of fish with abnormalities will indicate degraded or poor water quality. Having a large percentage of the fish population made up of pollution tolerant species is undesirable because it is an indication of habitat deterioration and water quality degradation.

This indicator measures:

- **Abundance and pollution tolerance of species found at various sites**
- **Fish community integrity relative to reference condition at various sites**
- **Whether stream meets criteria for trout-stocking**

Where We Were:

There is no historical data available for this indicator. A trend will be established the next time this area is reassessed.

Where We Are:

A biological assessment of the Tookany/Tacony-Frankford Watershed was completed in 2001 by the Philadelphia Water Department, with fish assessments at four locations on the main stem of the creek. The biological assessment locations are named according to river mile (where TF 0 is where the Tookany/Tacony-Frankford meets the Delaware River, and TF 280 is 2.8 miles upstream from that point), and the four locations with fish assessments completed are TF 280, TF 620, TF 975, and TF 1120. The fish assessments looked at a variety of quantitative and qualitative analyses including species richness, species diversity, trophic composition relationships, pollution tolerance levels, Modified Index of Well-Being (MIWB), biomass per unit area, and species descriptions.

The pollution tolerance metric identifies the abundance of tolerant, moderately tolerant and pollution intolerant individuals at the study site. Figure 4.7 shows the percentage of the total number of fish at each site, by their tolerance level. Both pollution tolerant and moderately tolerant species were found at each site, with pollution tolerant species being the predominant at every site. No pollution intolerant species were found during the fish assessment.

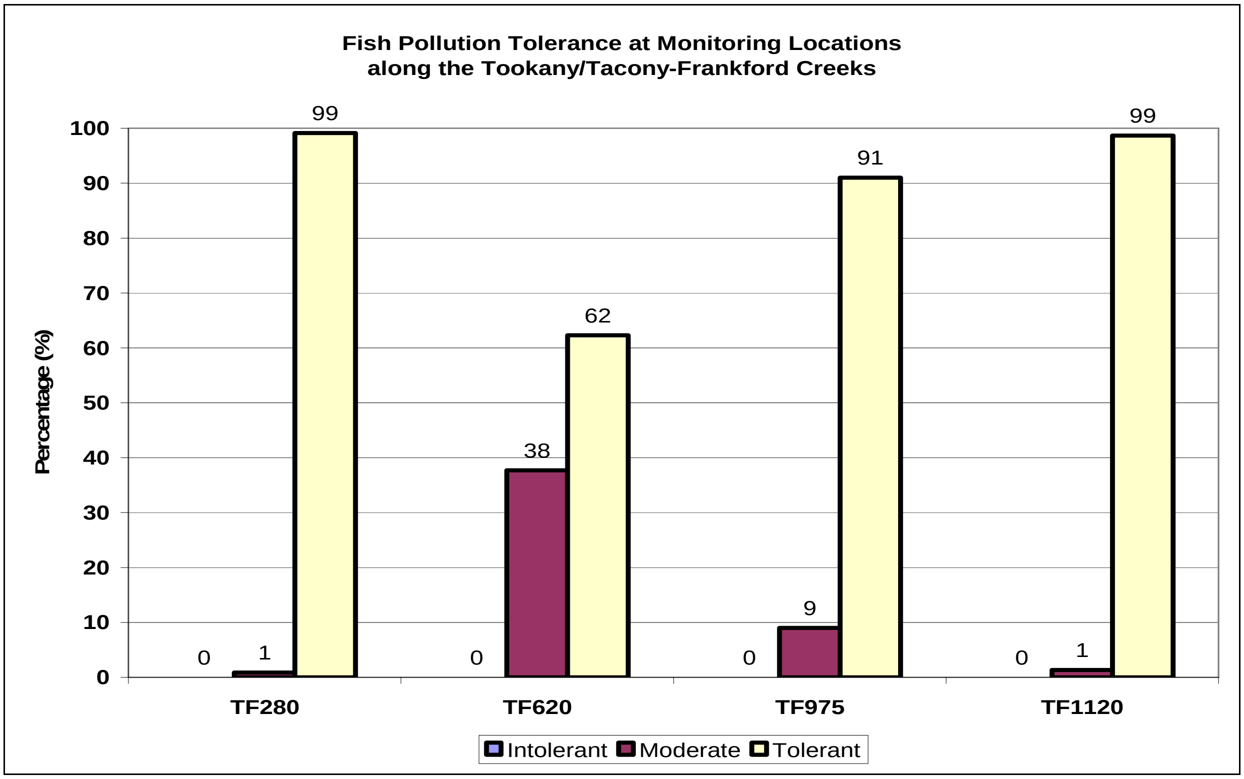

Figure 4.7 Fish Tolerance at Specific Monitoring Sites

Also, sites were classified based on their fish community integrity and compared to a reference condition. On a rating scale of poor, marginal, fair, and optimal, sites TF 280 and TF1120 received ratings of poor and sites TF 620 and TF 975 received ratings of marginal (Figure 4.8). Follow-up baseline assessments are planned every five years for this watershed, with the latest assessment completed in 2005, to be revisited next in 2010.

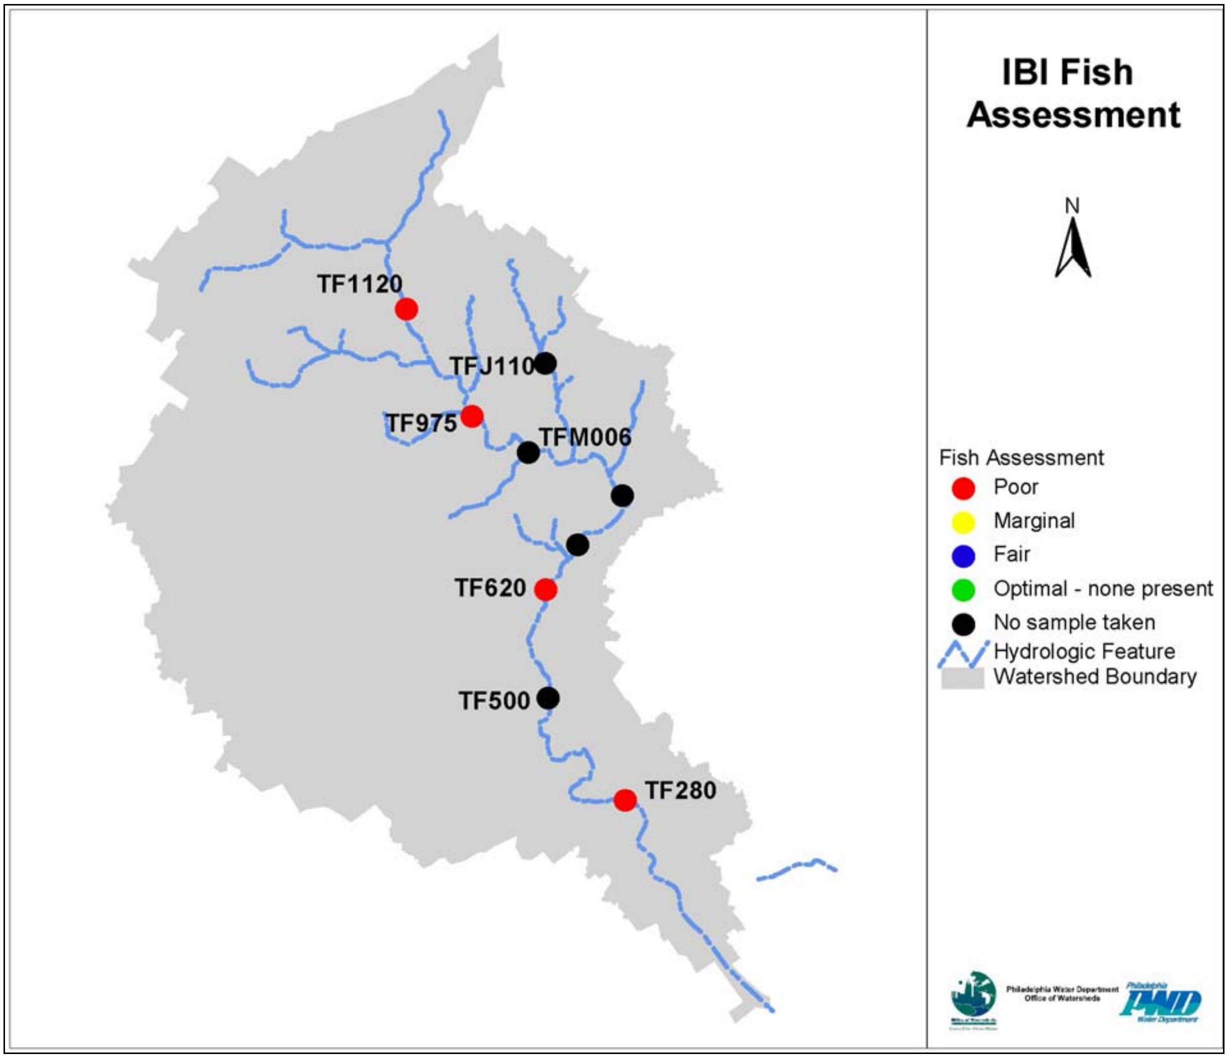

Figure 4.8 Tookany/Tacony-Frankford Fish Assessment (Philadelphia Water Department, 2001)

There were a total of 14 different species found in the watershed, some in more abundance then others. A breakdown of the relative abundance of each species at each assessment site can be seen in Figure 4.9, along with the pollution tolerance category of each fish species.

Pennsylvania Fish and Boat Commission biologists are continuously monitoring the Commonwealth’s waters and adding and removing lengths of streams to be trout-stocked. Factors to determine whether a stream is stocked are water quality, public access, use, and a variety of other factors. There are no stream lengths in the Tookany-Tacony-Frankford Watershed that meet the criteria qualifying them to be stocked with trout by the Fish & Boat Commission.

4.2.5 Indicator 6: Benthic Macroinvertebrates

The community of organisms on the bottom of water bodies is a good indicator of long-term water quality and the overall health of an aquatic system. Organisms inhabiting the stream bottom play roles in the aquatic ecosystem similar to the ones terrestrial small plant and animal species play in land-based communities. Benthic macroinvertebrate communities respond to changes in the aquatic environment and often provide an indication of concerns or evidence of successful restoration projects. Figure 4.10 is an example of a benthic macroinvertebrate.

This indicator measures:

- **State designation of attained and unattained reaches**
- **Benthic macroinvertebrate community integrity relative to reference condition at various sites**

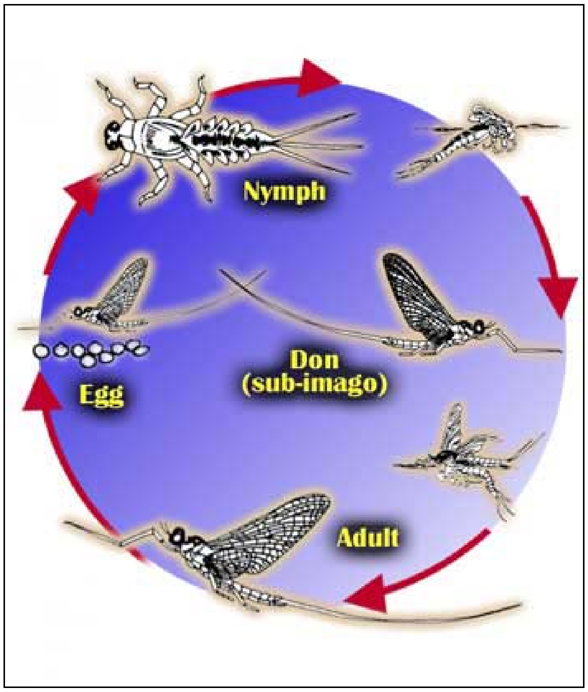

Figure 4.10 Life Cycle of a Mayfly

<u>Where We Were</u>:
There is no historical data available for this indicator. A trend will be established when this area is reassessed.

<u>Where We Are</u>:
The Pennsylvania DEP assesses the water quality of water bodies throughout the state and categorizes them according to their water quality status attainment. The assessments are found in the Pennsylvania Integrated Water Quality Monitoring and Assessment Report. Water bodies that do not meet water quality standards are designated as "impaired" and those that meet the designated water quality standards are designated as "attained."

Table 4.7 summarizes the impairments for the Tookany/Tacony-Frankford Creek. The tidal portion of the watershed, Frankford Creek (4.11 miles), has not been assessed since it is not wadeable, and therefore has no established procedure for assessment. The remaining streams in the watershed, including the main branch Tacony, Jenkintown, and East Branch Jenkintown Creek, all were placed in the category of "Streams Impaired by Pollution Not Requiring a TMDL." Figure 4.11 shows the delineation of the sections identified as attained, not attained (impaired), and unassessed. The streams were assessed for aquatic life, and the main source for impairment was identified as Urban Runoff/Storm Sewers. The main causes for impairment were identified as Flow Alterations, Other Habitat Alterations, and Water/Flow Variability.

Table 4.7 Descriptions of Impairment Causes and Sources (from the Commonwealth Of Pennsylvania Assessment and Listing Methodology for the 2004 Integrated Water Quality Monitoring and Assessment Report)

Impairment Cause / Source	Description
Urban Runoff / Storm Sewers	Runoff from impervious or urban areas to surface waters from precipitation, snowmelt, and subsurface drainage, and may be conveyed by storm sewers. The most obvious probable causes of impairment associated with this source are habitat removal caused by bank erosion, or streambed scouring, or smothering of habitat by siltation. Other probable causes are oils and grease, metals, pathogens, and nutrients.
Flow Alterations	Changes in hydrologic regime as a result of water regulation (including dams without or with insufficient minimum releases), or dewatering as a result of bedrock fracturing from mining activities, or lack of base flow due to reduced rain water infiltration in urban areas, or reduction in base flow caused by ground water withdrawals.
Other Habitat Alterations	Habitat changes due to severe bank erosion, removal or lack of riparian vegetation, and concrete channels and streambeds.
Water / Flow Variability	Changes in hydrologic regime caused by water releases, increased surface runoff from impervious surfaces during storm events, scouring, and drought. Results in unstable environment for macroinvertebrates and fishes. Habitat alterations include stream widening, substrate paving, shallower pools, etc.

The biological assessment of the Tookany/Tacony-Frankford Watershed completed in 2000-2001 by the Philadelphia Water Department looked at macroinvertebrates in the streams and collected data which led to a biological condition score. The macroinvertebrate assessments took place at all seven monitoring sites in the watershed, identified as TF 280, TF 500, TFM0000, TF 620, TF 975, TFJ 110, and TF 1120. Each site is given a biological score based on conditions in the stream – such as Taxa Richness, Taxa Comparison, Hilsenhoff Biotic Index (modified), Modified EPT Taxa, Percent Modified Mayflies, Dominant Family, Ratio of Scrapers/ Filter Collectors, Ratio of Shredders/Total, Community Loss Index, Biological Quality, Biological Assessment, Habitat Quality, and Habitat Assessment – and then compared to a reference stream. Every site in this watershed received a rating of either moderately impaired or severely impaired (Figure 4.11 and Table 4.8). The impaired benthic macroinvertebrate community is a result of habitat deterioration and episodic water quality degradation throughout the entire watershed. Increases in flow, sediment deposition, and scouring in the Tacony-Frankford Creek have impeded reproductive and feeding strategies of many species of macroinvertebrates.

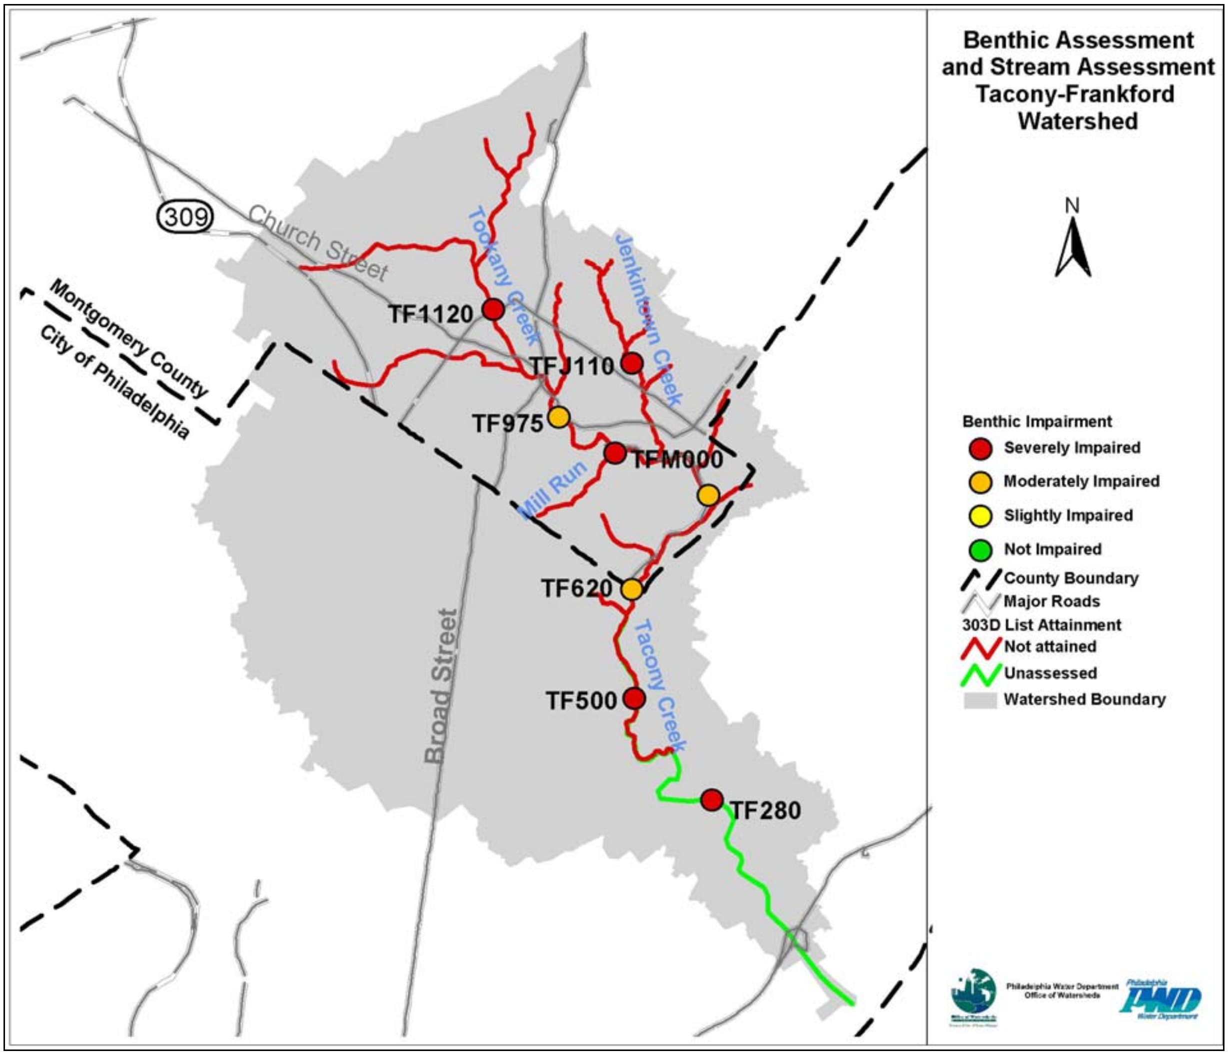

Figure 4.11 Benthic Macroinvertebrate Community Assessment Sites and Impaired Reaches

Table 4.8 Biological Condition Category as Percent Comparison to a Reference Score

% Comparison to Reference Score *	Biological Condition Category	Attributes
>83%	Nonimpaired	Comparable to the best situation within an ecoregion. Balanced trophic structure. Optimum community structure for stream size and habitat quality.
54-79%	Slightly impaired	Community structure less than expected. Species composition and dominance lower than expected due to loss of some intolerant forms. Percent contribution of tolerant forms increases.
21-50%	Moderately impaired	Fewer species due to loss of most intolerant forms. Reduction in EPT index.
<17%	Severely impaired	Few species present. If high densities of organisms, then dominated by one or two taxa.

** Scores that fall between score ranges are assigned based on best professional judgment*

4.3 Water Quality

The following three indicators for assessing watershed health and tracking changes concern factors that influence water quality conditions.

4.3.1 Indicator 7: Effects on Public Health (Bacteria)

Fecal contamination may originate from both human and animal sources and poses a threat to human health. Stormwater runoff transports waste from pets, livestock, and other animals to surface waters. Wet weather sewer overflows (SSOs and CSOs) introduce domestic wastewater constituents to surface water. Illegal or accidental cross-connection of sanitary sewers to storm sewers may also result in discharges of raw wastewater to the creek. Additionally, septic systems release some bacteria to surface waters, but these inputs are generally small.

Fecal coliform bacteria are abundant in the intestines of warm blooded animals, including humans. Fecal coliform is a fairly accurate indicator of harmful bacteria in natural water, drinking water, and wastewater. Measures taken to reduce the input of fecal coliform to natural waters are likely to reduce other microorganisms found in sewage and surface runoff as well.

The water quality standard for fecal coliform is as follows: during the swimming season (May through September), the maximum level shall be a geometric mean of 200 per 100 mL based on five consecutive samples, each collected on a different day; for the remainder of the year, the maximum level shall be a geometric mean of 2000 per 100 mL based on five such samples.

This indicator measures:

- **Percent of fecal coliform samples meeting state standards at various sites**

<u>Where We Were</u>:
Approximately 100 samples of fecal coliform were taken between 1970 and 1980 at five different sites. For samples taken in the headwaters in Tacony and Jenkintown Creeks, approximately one-half to two-thirds met the current standard. For samples taken in Rock Creek and on the main stem at the Philadelphia-Montgomery county line, only one-quarter of the samples met the standard. At the most downstream site at Castor Avenue, less than 15% of samples taken met the standard. Conditions under wet weather are not significantly worse than dry weather, suggesting that dry weather inputs were the main source of bacteria in the stream.

<u>Where We Are</u>:
Samples were collected between June 2000 and October 2003 at seven sites in the watershed. Table 4.9 compares the data collected to water quality standards. At each of three of the seven sites, roughly half of dry weather samples met the standard. At the remaining four sites, no more than one-quarter of dry weather samples met the standard. And in wet weather, fewer than one-tenth of all samples taken at each of the seven sites met the water quality standard.

The two sites on the lower main stem were sampled in both the historical and 2000–2003 periods and can be directly compared. Over time, the percent of samples meeting the standard in dry weather improved slightly at both the main stem county-line site and the Castor Avenue site. There was a decrease in the percentage of samples meeting the standard from the historical data to current data at the two main stem sites, suggesting that wet weather conditions may have declined over time.

Table 4.9 Percent of Samples Meeting Bacteria Standards

Site	Percent of Samples that Meet the Standard					
	Historical			Current		
	All Data	Dry Weather	Wet Weather	All Data	Dry Weather	Wet Weather
19	60%	67%	50%			
18	55%	67%	38%

33%	<= % meeting <=	67%	YELLOW
0%	<= % meeting <=	33%	RED

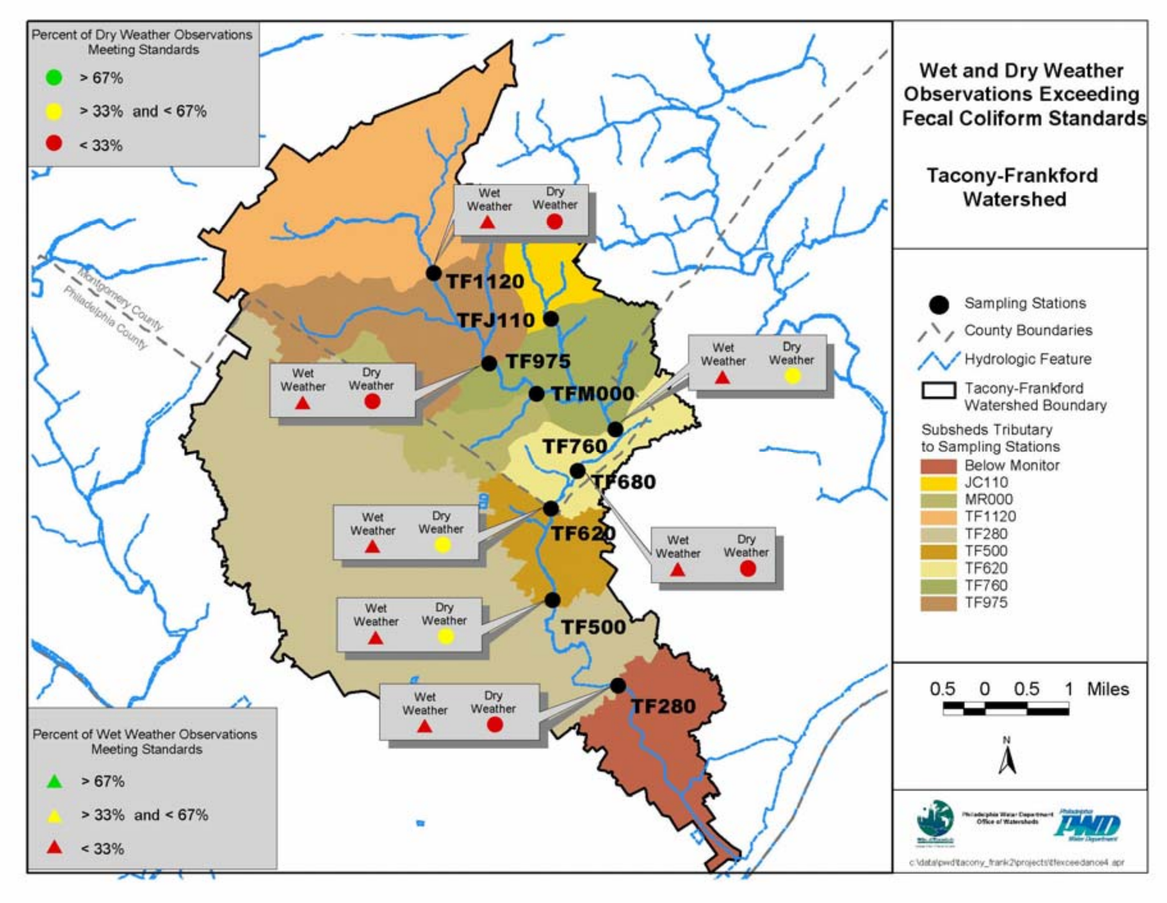

Figure 4.12 Current Water Quality Data for Fecal Coliform

4.3.2 Indicator 8: Effects on Public Health (Metals and Fish Consumption)

Toxic substances, including metals (such as mercury) and organic substances (such as PCBs), are sometimes introduced into the aquatic environment due to human activity. These substances exist in some sediments as a result of historical discharges, are introduced to the atmosphere through burning of fossil fuels, and are deposited on the land surface through industrial and transportation activities. Precipitation and surface runoff introduce small concentrations of these substances to surface waters. Over time, fish ingest the toxic chemicals from the water they live in and the food they eat, in some cases developing harmful concentrations in their tissues. Because toxic substances in the environment can affect aquatic life and humans who eat fish, the PA DEP has set maximum allowable concentrations for the water column. The standards based on aquatic life protection are generally strict. In addition, the DEP samples fish tissue and issues advisories designed to warn the public about species that may contain toxic chemicals. These contaminants can build up in the human body over time, possibly leading to health effects.

This indicator measures:

- **Areas with fish consumption advisories (graphical)**
- **Percent of aluminum (Al), cadmium (Cd), chromium (Cr), copper (Cu), lead (Pb), and zinc (Zn) samples meeting state standards at various sites**

Where We Were:

Pennsylvania updates its fish consumption advisories at least yearly. Table 4.10 shows the Fish Consumption Advisory for 2003. This advisory applies only to tributaries of the Delaware River such as the Tacony-Frankford, only to the head of tide, which can be seen on Figure 4.13.

Table 4.10 Commonwealth of Pennsylvania Public Health Advisory – 2003 Fish Consumption

Water Body	Area Under Advisory	Species	Meal Frequency	Contaminant
Delaware River and Estuary, including all tributaries to head of tide and the Schuylkill River to the Fairmount Dam (Bucks, Philadelphia, and Delaware counties)	Yardley to PA/Delaware state line	White perch, Flathead catfish, Striped bass, Carp	1 meal/month	PCB
		Channel catfish	6 meals/year	PCB
		American eel	Do Not Eat	PCB
		Smallmouth bass	2 meals/month	Mercury

Historical information on concentrations of toxins in fish tissue is not readily available. Data on some metals was collected in the 1970s, and can be compared to current water quality standards. Approximately 60 samples were collected at each of three sites between 1970 and 1980 for lead, cadmium, chromium, copper, and zinc together. Metals concentrations frequently exceeded standards at the observation sites, in both dry and wet weather. With the exception of Site 7 during wet weather, which met the standard 82% of the time, samples from all three sites during both dry and wet weather only met that standard roughly 50-60% of the time (Table 4.12).

Where We Are:

The 2004 Fish Consumption Advisory (Table 4.11) recommended limiting consumption of white perch, flathead catfish, striped bass, carp, channel catfish, and American eel due to PCB contamination in an area that includes the Tacony-Frankford Creek, up to the head of tide (area below TF 280, Figure 4.13). The only change seen from the previous year's advisory was that an advisory for mercury in smallmouth bass was lifted.

Table 4.11 Commonwealth of Pennsylvania Public Health Advisory – 2004 Fish Consumption

Waterway	Area Under Advisory	Species	Meal Frequency	Contaminant
Delaware River and Estuary, including the tidal portion of all PA tributaries and the Schuylkill River to the Fairmount Dam (Bucks, Philadelphia, & Delaware Co.)	Yardley to PA/Delaware state line	White perch, flathead catfish, striped bass, carp	1 meal/month	PCB
		Channel catfish	6 meals/year	
		American eel	Do Not Eat	

Samples collected between June 2000 and October 2003 at seven sites were tested for aluminum, cadmium, chromium, copper, lead, and zinc (Figure 4.13 and Table 4.12). At each site, at least 90% of dry weather samples met the standard for each metal, with the exception of copper at two sites; 100% of samples met the dry weather standard for lead and cadmium; and at two upstream sites, every sample met all dry weather metal standards. Wet weather data varied from site to site and for the individual metals, but the samples usually met the standard less than 90% of the time.

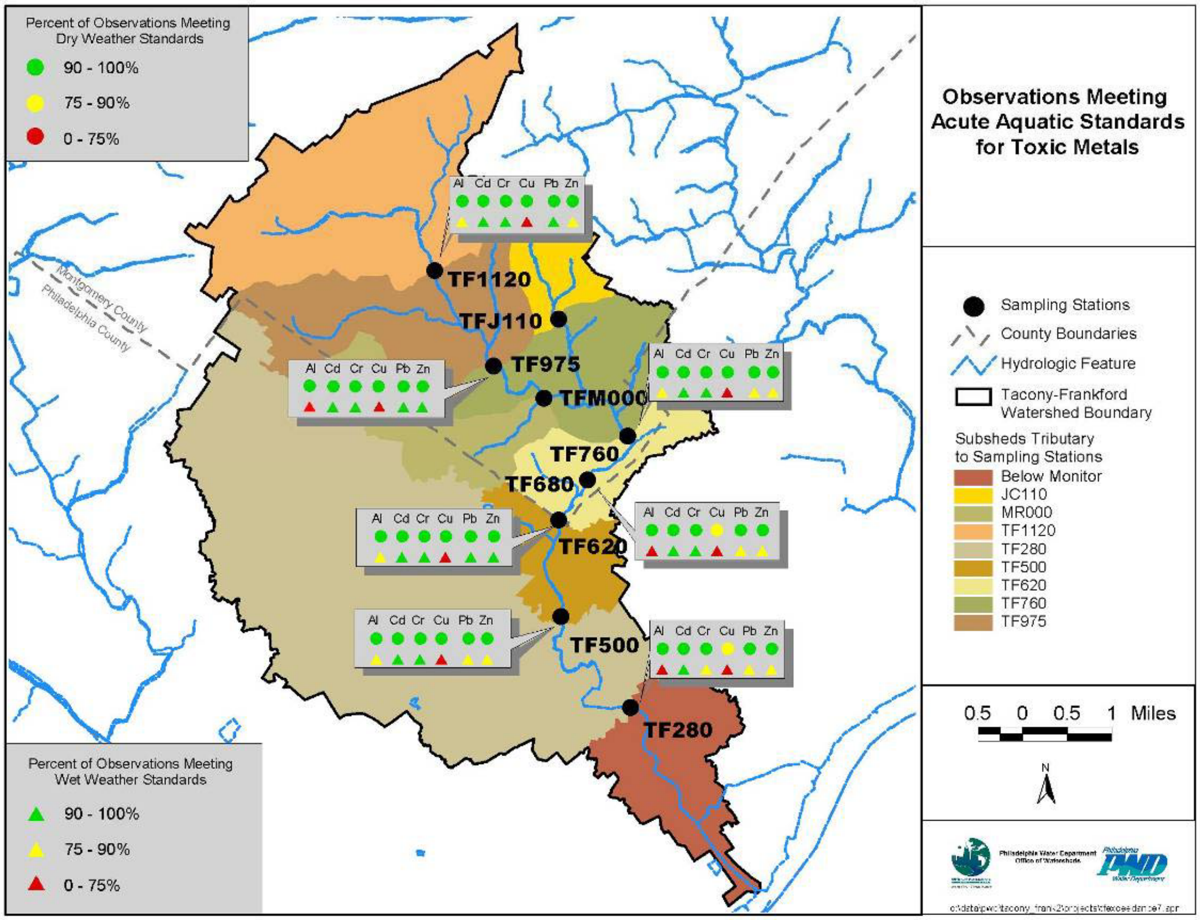

Figure 4.13 Current Metals Water Quality Data with Fish Consumption Advisory Areas

Of the three sites for which historical data exist, two of those sites also have corresponding current data. At both of the sites, the percent of samples meeting the water quality standard has increased dramatically over the last 20 to 30 years, in both wet and dry weather. Historical data showed dry weather samples met the standard an average of 50% of the time; current data shows an average at those two sites of meeting the standard 98% of the time. With wet weather sampling, the average increased from around 60% to 82% of the samples meeting the standard.

Table 4.12 Percent of Samples Meeting Toxic Metals Standards

	Percent of Samples that Meet the Standard					
	Historical			**Current**

75%	<= % meeting <=	90%	YELLOW
0%	<= % meeting <=	75%	RED

4.3.3 Indicator 9: Effects on Aquatic Life (Dissolved Oxygen)

Just as humans require oxygen gas for respiration, most aquatic organisms require dissolved oxygen (DO). Oxygen dissolves in water through air-water interaction at the surface of the flow and through photosynthesis of plants and algae. At the same time, DO is depleted through the respiration of microorganisms, animals, plants, and algae. In a healthy system, the balance between oxygen-depleting and oxygen-providing processes maintains DO at a level that allows aquatic organisms to survive and flourish. In a less healthy system, dissolved oxygen may be depleted below levels needed by aquatic organisms. The minimum dissolved oxygen concentration required by many common fish species found in rivers and streams is approximately 5 mg/L. The PA DEP has set a water quality standard, or minimum allowable concentration, of 5 mg/L as a daily average and 4 mg/L as an instantaneous value for the Tookany/Tacony-Frankford Creek.

This indicator measures:

- **Percent of DO samples meeting state standards at various sites**

Where We Were:

Discrete samples of DO were taken at five sites in the watershed in the 1970s and 1980s. At all five sites, 100% of the wet weather samples met the average minimum standard. Dry weather samples met the standard 100% of the time at three of the sites, and met the standard 95% and 98% of the time at the remaining two sites.

Where We Are:

Both discrete and continuous samples were collected between 2000 and 2003 (see Figures 4.14 and 4.15). Discrete samples produce a single DO value at the time the sample is taken; continuous monitoring measures DO over the entire photic period, including the night when DO is lowest due to algal respiration. Both the discrete and continuous samples suggest that dissolved oxygen is rarely below the standard under dry or wet conditions. At each of the seven sites where discrete samples were taken, 100% of the discrete samples taken in both wet weather and dry weather met both the average minimum standard and the instantaneous minimum standard, with the exception of one site downstream, TF280. At this site, 4 out of 19 samples were below the average minimum standard in dry weather and 2 out of 19 samples were below the instantaneous minimum standard in dry weather. No discrete samples at any of the sites were below the standard in wet weather.

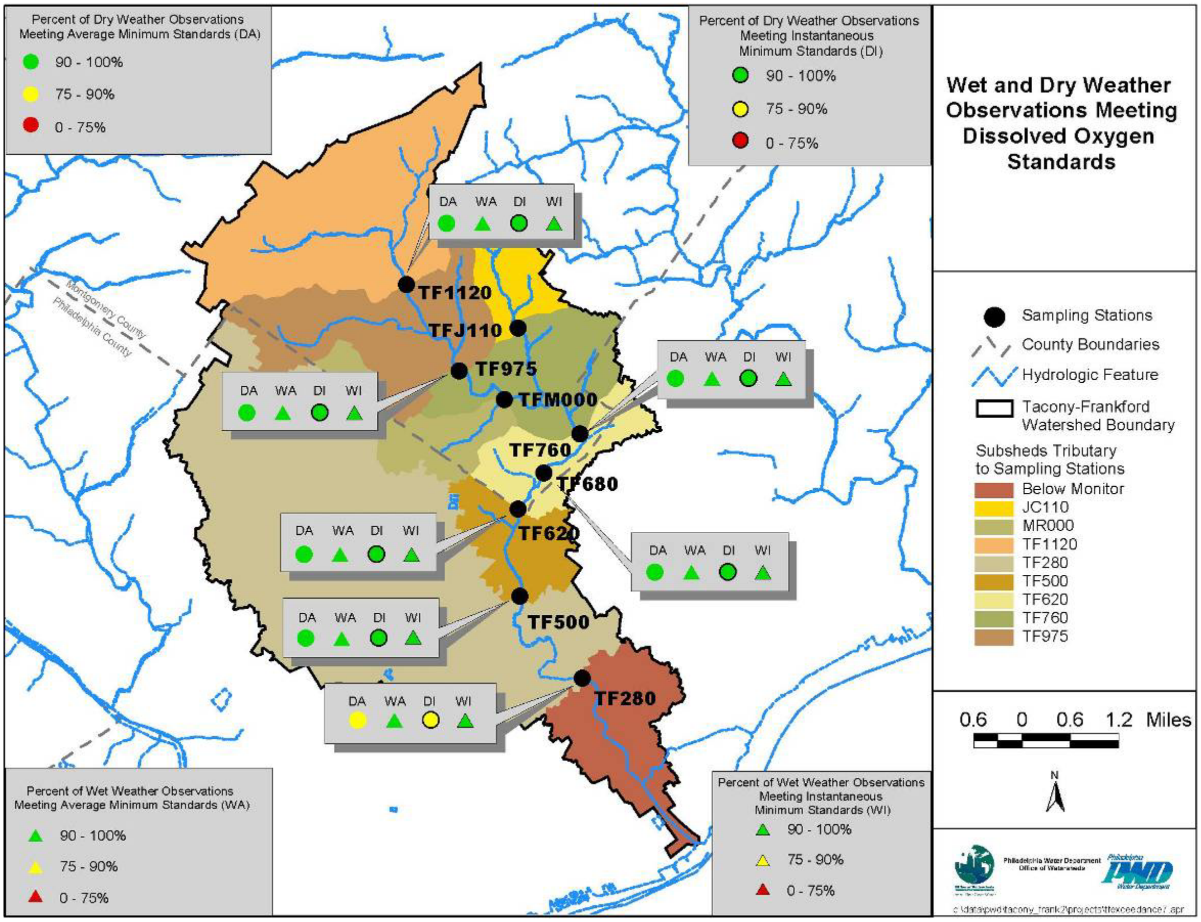

Figure 4.14 Current Water Quality Discrete Data for Dissolved Oxygen

With the continuous samples, 100% of the samples taken at each of six sites at which discrete sampling occurred met the DO daily mean standard, except for at site TF280. At least 90% of the samples at each site met the DO daily minimum standard. Again, for the DO daily minimum standard, site TF280 shows the highest number of samples that do not meet the standard. Overall, 100% of the discrete samples met the standard for DO daily mean and 94% of the samples met the standard for DO daily minimum.

The continuous Sonde data collected shows more than 2% of the readings below the DO daily minimum near the downstream end of the watershed and just upstream of the City boundary. Figure 4.15 displays the Sonde DO data compared to the daily minimum standard.

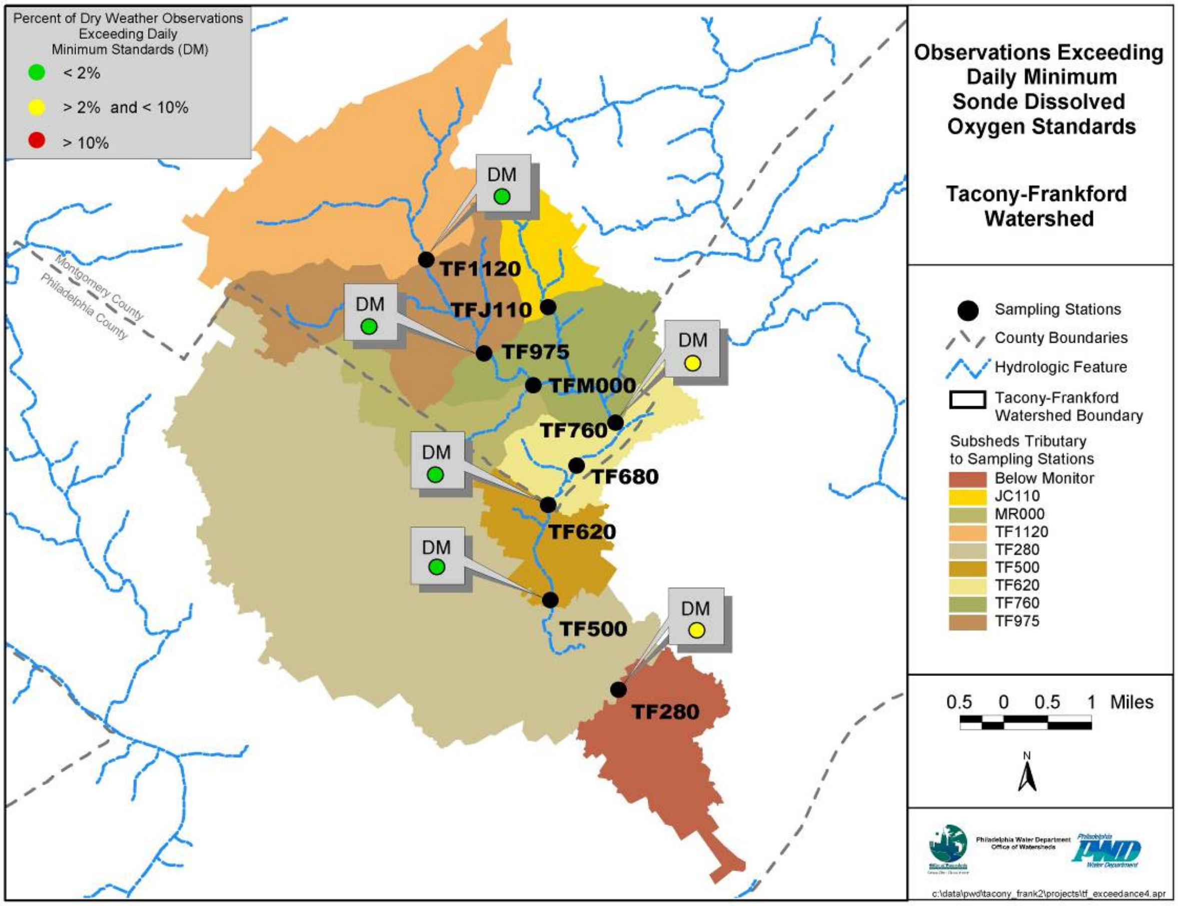

Figure 4.15 Current Water Quality Continuous Data for Dissolved Oxygen

Comparing the current data with historical data for two sites in the watershed, TF280 and TF 620, the number of samples not meeting the average minimum standard has increased. Historically, 100% of wet weather samples met the standard at both sites, which is consistent with current sampling results. With dry weather samples, the results have remained fairly consistent at site TF620 with 98% of samples meeting the standard historically and 100% of the samples meeting the standard currently. At site TF280, dry weather sampling results show a decrease in the number of samples meeting the standard. Historically, 95% of dry weather samples met the standard at this site while currently only 79% of the samples are meeting the standard.

4.4 Pollutants

The following two watershed indicators categorize pollutants broadly by their sources: "point" and "non-point."

4.4.1 Indicator 10: Point Sources

A point source is any point where pollutants enter the water, such as a pipe, channel, or ditch (Figures 4.16 to 4.18). Point source discharges can include treated municipal wastewater, combined sewer overflows (CSOs), separate sanitary overflows (SSOs), industrial process water, municipal separate storm sewer system (MS4) discharges, and/or cooling waters. Point sources are regulated under the Clean Water Act by the National Pollutant Discharge Elimination System (NPDES).

Figure 4.16 Stormwater Outfall

Figure 4.17 CSO Outfall

Figure 4.18 Municipal Wastewater Treatment Plant

A municipal separate storm sewer system (MS4) collects stormwater runoff from the land surface and discharges it directly to a receiving stream.

Combined sewer systems use one pipe to convey sanitary sewage and stormwater runoff to a combined sewage regulator chamber. The regulator captures all of the sanitary sewage in dry weather, and some of the combined sewage in wet weather, and sends it to a wastewater treatment plant. The balance of the wet weather flow is discharged to an area water body through a CSO outfall.

Sanitary Sewer Overflows (SSOs) occur when a municipal separate sanitary sewer system becomes overcharged in wet weather and overflows unintentionally to an area water body.

Municipal Wastewater Treatment Plants are facilities that process municipal sanitary waste and industrial and commercial discharges to the sewer system. These facilities treat the waste stream and discharge it to a local stream.

Industrial processes use water in manufacturing, power generation, or other activities to produce a product. The by-products from the process can be discharged to area waterways with varying levels of treatment.

This indicator measures:

- **Number of industrial and municipal point sources permitted to discharge to water bodies (if available, number meeting permit requirements)**
- **Estimated annual percent capture of combined sewage**
- **Model-estimated pollutant contributions of industrial/municipal, CSO, and stormwater outfalls**

Where We Were:

Point source discharges from treatment plants and industrial facilities were a priority for increased control during the 1970s and 1980s as secondary wastewater treatment requirements and industrial pre-treatment regulations were imposed. Historical data indicated that there were three facilities in the watershed with National Pollutant Discharge Elimination System (NPDES) Permits.

Historical SSO and CSO discharges are not well documented, and there is only limited current data on SSOs. However, it can be inferred from water quality data that dry weather sewage discharges were much more common in the past (see Indicator 8). It is reasonable to conclude that the frequency and volume of CSO discharges in the Philadelphia portion of the Tacony-Frankford Watershed have decreased over the past 20 years due to improved sewer maintenance and CSO control measures (discussed in detail later in this section).

Where We Are:

Active Industrial and Municipal Point Source Dischargers

Current facilities with NPDES permits to discharge to the Tookany, Tacony, Frankford, and Baeder creeks are believed to be SPS Technologies, Allegheny Iron Radiation, Bayway Refining Company, Roadway Express, BFI Waste Services Of Pa, S D Richman Sons Incorporated, and Sunoco Incorporated Frankford Plant. The Philadelphia Water Department is also permitted for its CSO outfalls. The permit for one facility, Biello Auto Parts Inc, that was once listed as active has expired. All municipalities in the watershed – Abington, Jenkintown, Rockledge, Cheltenham, Springfield, and Philadelphia – have MS4 permits, which all large, medium, and regulated small municipal separate storm sewer systems need in order to discharge pollutants.

Estimated Annual Percent Capture of Combined Sewage

Portions of Philadelphia County, including 47% of the Tookany/Tacony-Frankford Creek Watershed, are serviced by combined sewer. The City of Philadelphia has 31 regulator structures within the watershed, as shown in Figure 4.19. Since the 1980s, PWD has made significant progress in reducing CSO discharges to the Tacony-Frankford Creek. As required under EPA's CSO Control Policy, PWD has developed and implemented a CSO Long Term Control Plan (LTCP) to improve and preserve the water environment in the Philadelphia area. Table 4.13 lists estimated capture percentages for regulator structures in the Tacony-Frankford Watershed, based on the modeling results listed in PWD's CSO Annual Reports.

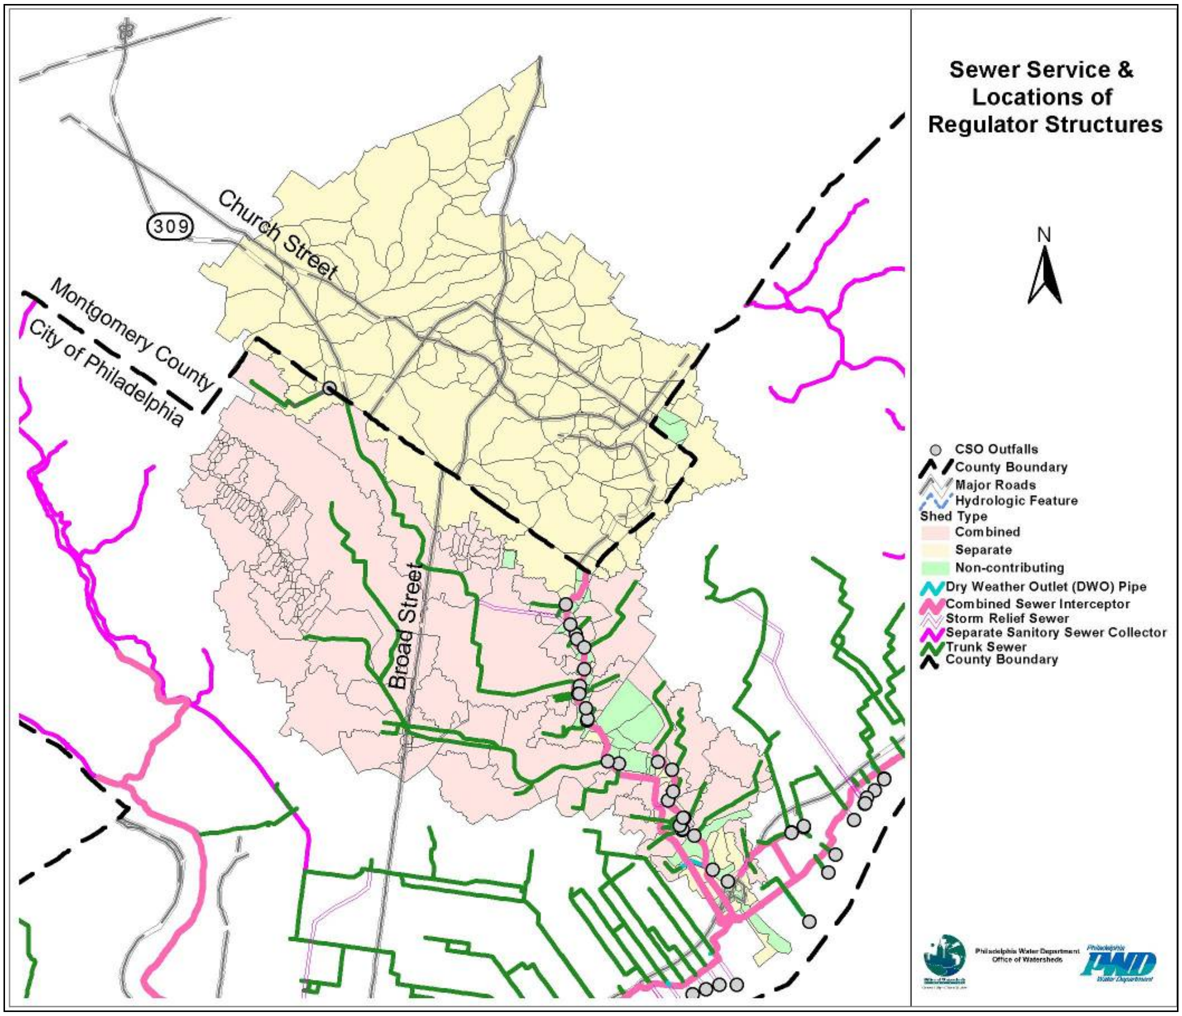

Figure 4.19 Types of Sewer Service and Locations of Regulator Structures

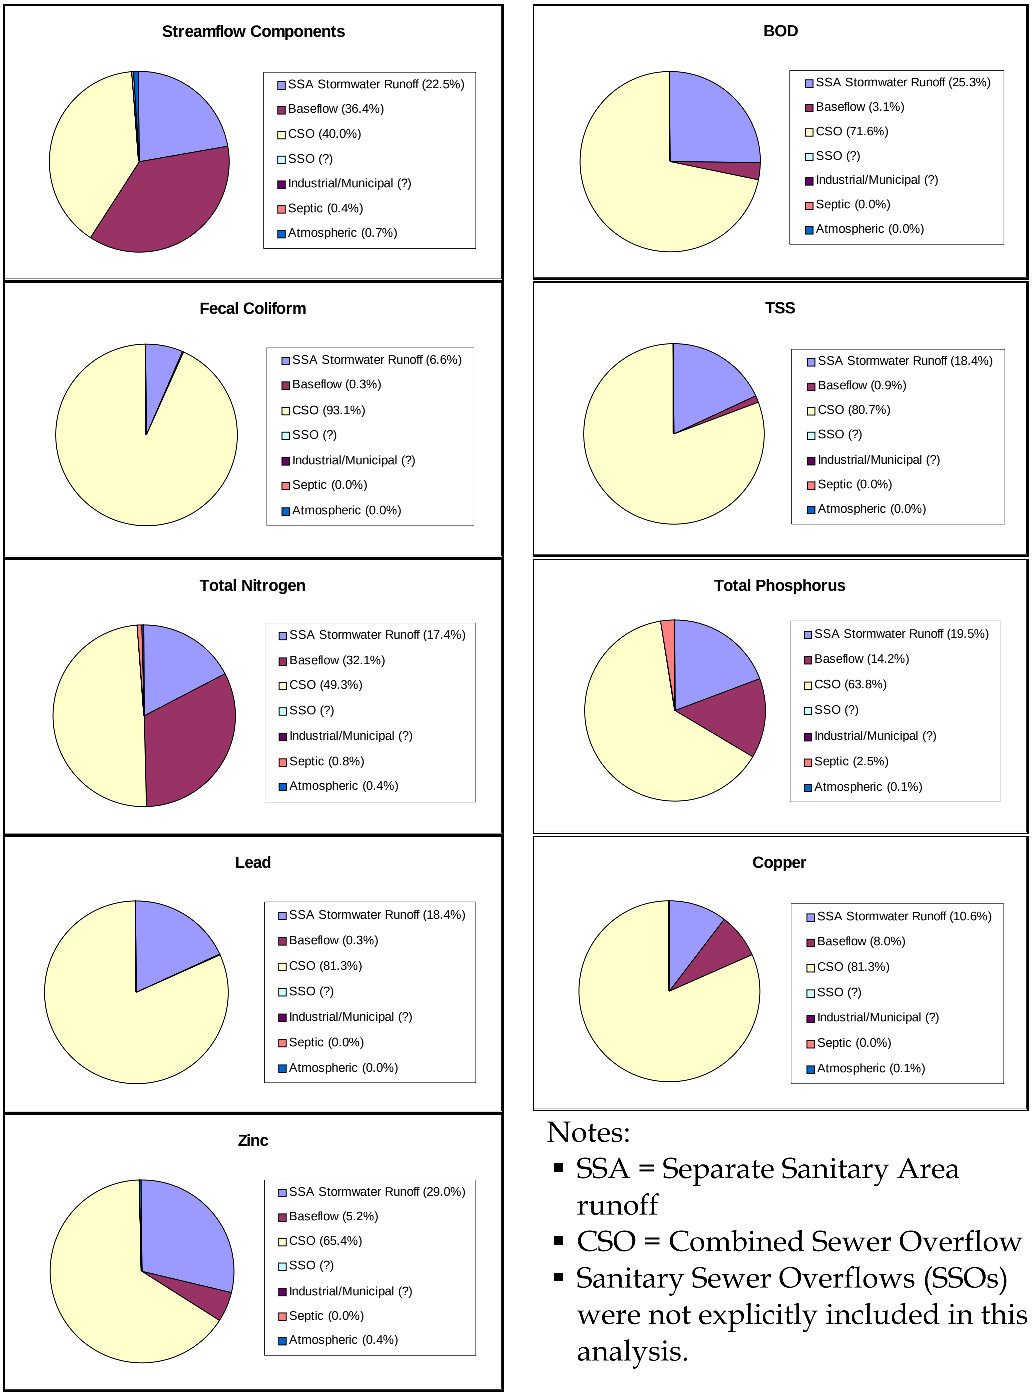
A capture percentage is defined as the percentage of combined sewage (mixed sanitary sewage and stormwater) that is sent to a treatment plant during rainfall events over the course of a year. 85% capture is considered to be an ultimate goal for many communities, as they implement CSO Long Term Control Plans (since it is not possible to capture and treat large storms). It is important to note that percent capture for a given year is strongly dependent on the frequency and magnitude of rainfall events during that year. The five years of data listed in Table 4.13 are not sufficient to determine whether an increasing or decreasing trend has taken place. However, as the amount of data increases throughout implementation of the Long Term Control Plan, it will ultimately be possible to evaluate the effectiveness of the control measures

Table 4.13 Estimated Annual Combined Sewage Capture Percentages

Year	Precipitation (in)	Capture (%) – Lowest and Highest Structure	
		Tacony	Upper Frankford Low Level
2003	46.72	43 - 45	64 - 65
2002	34.11	59 - 64	76 - 79
2001	30.62	51 - 53	70 - 72
2000	43.26	40 - 42	58 - 60
1999	48.6	39 – 40	57 - 59

Model-Estimated Pollutant Contributions of Different Sources

Estimated annual pollutant contributions to the Tookany/Tacony-Frankford Creek are shown below. CSO is the largest source associated with urban and suburban runoff, including nutrients such as phosphorus and metals such as lead. Stormwater outfalls are a smaller but significant source of these constituents. CSO discharges are the main source of fecal coliform. Permitted industrial and municipal point source discharges make up less than 1% of annual streamflow in both systems. SSOs are thought to occur in both watersheds but have not been well documented.



Notes:
- SSA = Separate Sanitary Area runoff
- CSO = Combined Sewer Overflow
- Sanitary Sewer Overflows (SSOs) were not explicitly included in this analysis.

Figure 4.20 Annual Pollutant Contribution

Spatial distributions of model-based constituent loads are shown in Figures 4.21 through 4.28. The darker areas represent areas of higher loads per acre per year. For BOD, a significant amount is within the City from combined-sewered areas. Highest fecal coliform estimates are found in the City portion of the watershed. Metals (lead and zinc) are generally higher in the more urbanized areas of the watershed. Total suspended solids (TSS) loads follow a similar trend to metals. Nutrients (phosphorus and nitrogen) have significant contributions throughout the watershed, with the highest near the Philadelphia County line. (For more information about modeling used to estimate this annual loading to the Tookany/Tacony-Frankford Creek, see Section 9 of the Tookany/Tacony-Frankford Watershed Comprehensive Characterization Report, 2005.)

4.4.2 Indicator 11: Non-point Sources

Non-point source pollution is any source of water contamination not associated with a distinct discharge point. This type of pollution is a leading cause of water quality degradation in the United States. Non-point sources include atmospheric deposition, stormwater runoff from pasture and crop land, and individual on-lot domestic sewage systems discharging through shallow groundwater. Stormwater from urban and suburban areas is considered a point source for regulatory purposes because it is collected in a pipe system and discharged at a single point.

Figure 4.29 Pasture Land

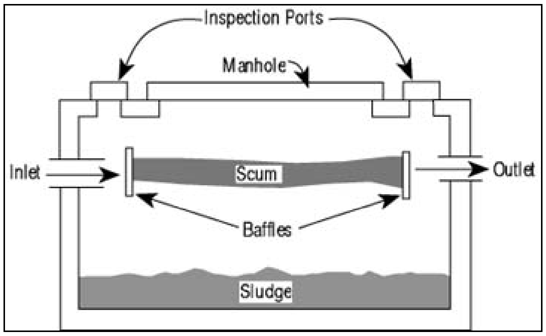

Figure 4.30 Septic System
Source: Ohio State University Extension

Agricultural activity is a major source of non-point source pollution in many areas. Animal manure and fertilizers applied to crops may lead to pollutant inputs to surface water and groundwater.

A properly sited and maintained **septic system** should not result in inputs of nutrients to groundwater. However, failing septic systems are common and can result in nutrient inputs to shallow groundwater and ultimately to stream baseflow.

Background concentrations of some water quality constituents are present in groundwater and may be transferred to stream baseflow. Some constituents may be introduced through agricultural activity or failing septic systems, while others may be present as a result of local geology.

This indicator measures:

- **Model-estimated percent of total pollutant loads contributed by septic tanks**
- **Evidence that sanitary sewers are leaking during dry weather, or are in direct contact with the stream**

<u>Where We Were</u>:

Since most point sources were addressed in the 1970s and 1980s, regulatory agencies have been turning attention towards controlling non-point sources of pollution. Many of these sources began to be addressed during the 1990s.

<u>Where We Are</u>:

Non-point sources in the Tookany/Tacony-Frankford Watershed include atmospheric deposition, stormwater runoff from a very small amount of agricultural land, background concentrations in groundwater, and individual on-lot disposal systems (OLDS) discharging through shallow groundwater. The number of septic tanks within the watershed is hard to accurately quantify. According to 1990 census data, about 1075 septic tanks were present in the watershed; however, this is believed to be a high estimate of the actual number. Figure 4.31 shows the septic areas within the watershed. Based on modeling estimates (Figures 4.32 and 4.33), septic tanks contribute less than 1% of total nitrogen and 2.5% of phosphorus loads. Atmospheric loads to wetlands and open water were estimated to be less than 1%. Background groundwater concentrations of total nitrogen were a large source of loading through stream baseflow at over 30%. Dry weather contributions from leaking sanitary sewers could not be estimated based on current data; however, evidence that leaking is occurring is presented below.

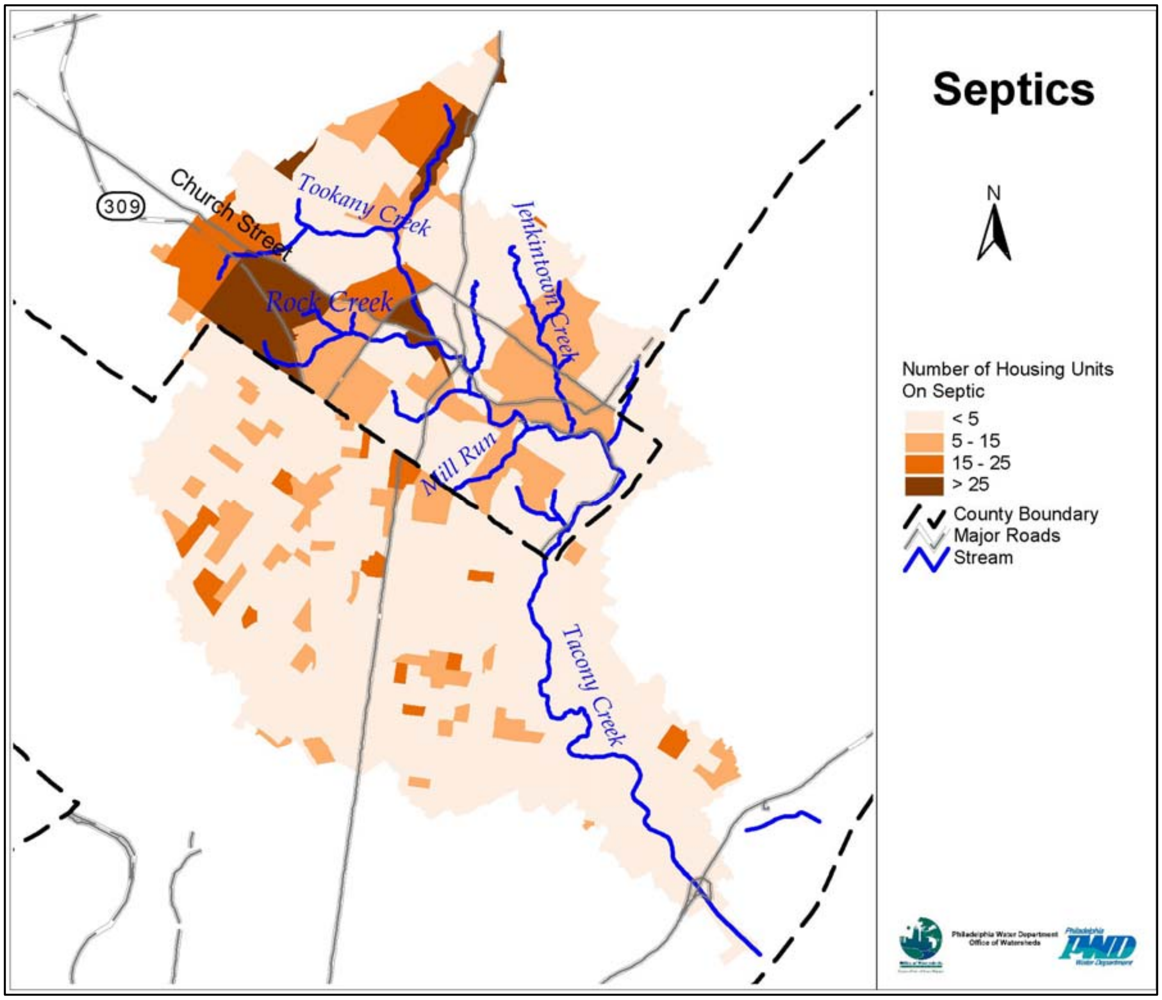

Figure 4.31 Septic Housing Units in the Tookany/Tacony-Frankford Watershed

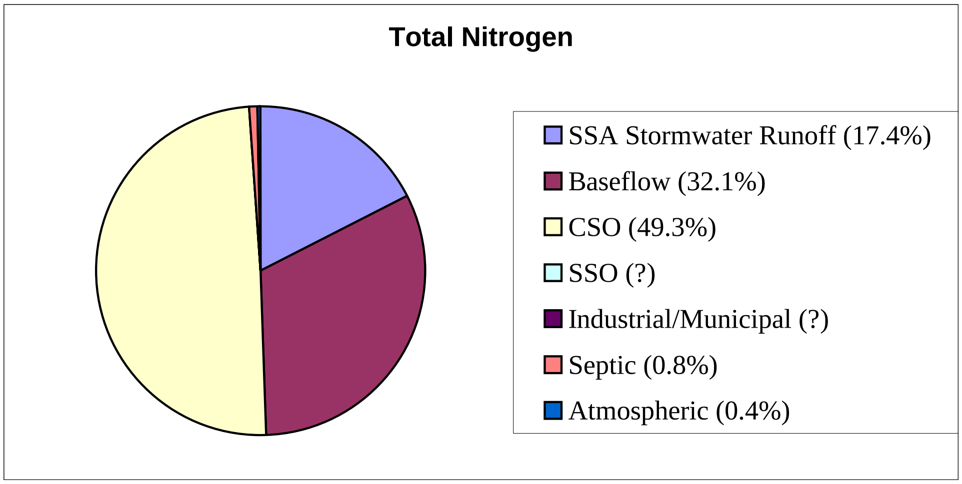

Figure 4.32 Estimated Nitrogen Inputs

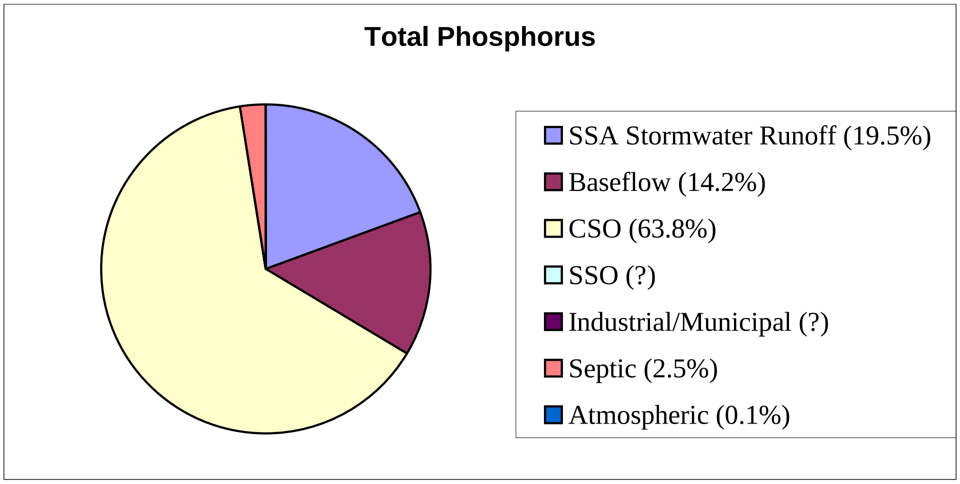

Figure 4.33 Estimated Phosphorus Inputs

4.5 Stream Corridor

The next three indicators of watershed health address environmental features of the lands immediately surrounding the waterway.

4.5.1 Indicator 12: Riparian Corridor

The riparian areas buffering streams, rivers, lakes, and other water bodies are especially sensitive watershed zones. In their naturally vegetated and undisturbed state, floodplains and riparian areas provide stormwater management and flood control functions, providing both water quantity and water quality benefits.

This indicator measures:

- **Miles of stream with a minimum buffer of 50 feet and 50 percent canopy cover**

Figure 4.34 Riparian Corridor in Jenkintown

<u>Where We Were</u>:
There is no historical data available for this indicator. A trend will be established the next time this area is reassessed.

<u>Where We Are</u>:
In the Tacony Creek Park, riparian zones no longer function as they should due to a loss of native community assemblages, which has had a deleterious effect on the riparian zone's ability to efficiently sequester pollutants and stormwater runoff. Japanese knotweed, an exotic plant species, has invaded the banks of the creek and contributes to the vulnerability of the banks to erosion during storms. There are currently volunteer efforts underway to eradicate this species from riparian zones, but it still persists. The riparian areas along the creeks in the Fairmount Park System are superior in quality compared to most of the areas in the watershed, which have almost completely lost their riparian buffers.

Buffers along stream corridors can be an important factor in enhancing stream habitat and preventing erosion. In 2002, the Heritage Conservancy was funded to develop a rapid assessment method to identify and map sections of stream lacking riparian forest buffers. The conservancy assessed watersheds in southeastern Pennsylvania and mapped waterways lacking riparian forest buffers. Interpretation of 1" = 200' black-and-white high altitude aerial photographs and videotape from helicopter flyovers were used to determine the presence or absence of a forested buffer for 975 miles of stream. For this analysis, a stream bank was classified as having a forested buffer if it was determined to have a 50 foot wide buffer of trees and 50 percent canopy cover. Each stream bank was analyzed independently. Table 4.14 shows that there are about 8½ miles of stream within the watershed that are lacking forested riparian buffers on one or both banks, which amounts to about one-third of the stream miles assessed.

Table 4.14 Lack of Riparian Forested Buffer

Riparian Buffer	Length (Stream Miles)
Buffer Lacking on One Bank	5.4
Buffer Lacking on Both Banks	3.1
Total Miles Lacking Buffer	8.5
Total Miles Assessed	27.3
% of stream lacking buffer	31.1%

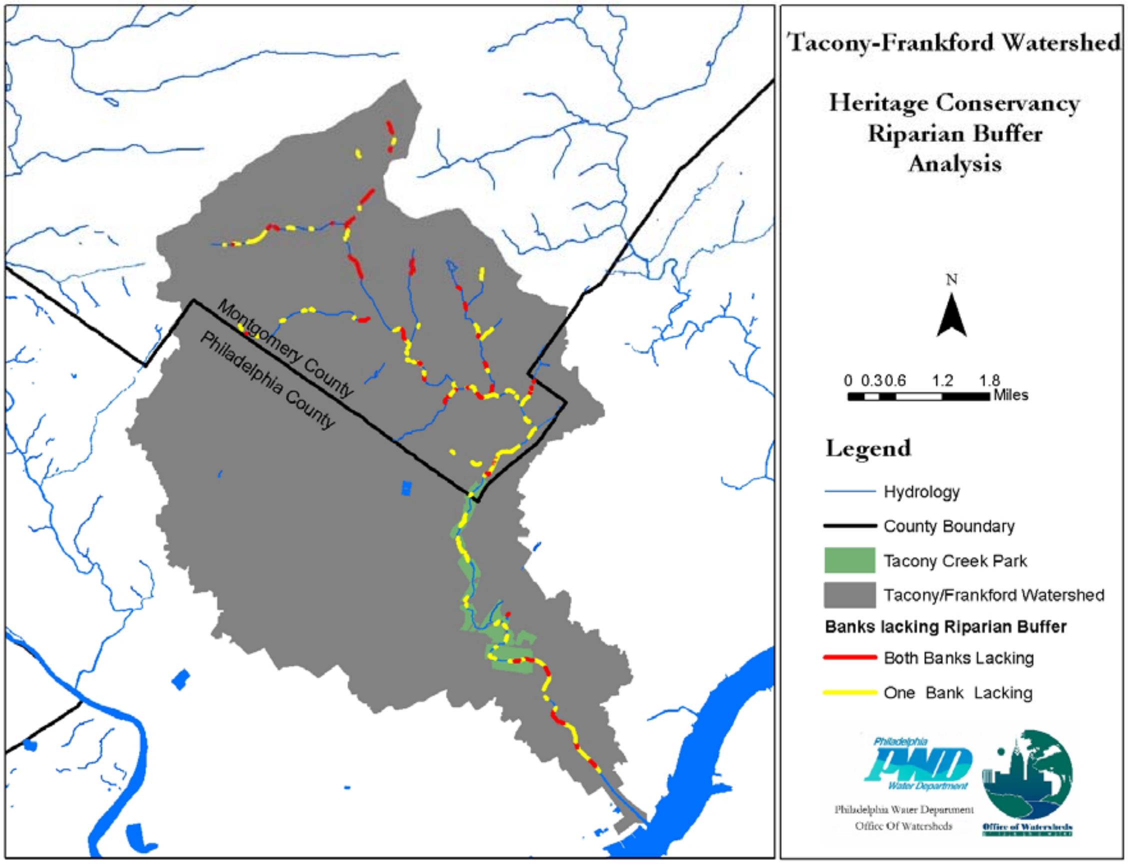

Figure 4.35 Heritage Conservancy's Forested Riparian Buffer Analysis (2002)

4.5.2 Indicator 13: Wetlands and Riparian Woodlands

Wetlands and riparian woodlands are important natural filters for pollutants in stormwater. They increase diversity of vegetation while providing feeding and nesting habitat for birds and animals. They are important in preventing slope erosion and mitigating flood peaks by slowing runoff, and they promote natural infiltration of rainfall and groundwater recharge.

The most significant functions that wetlands perform are:

- Wildlife habitat
- Fish habitat
- Water quality improvement (nutrient and toxicant reduction)
- Hydrologic (flood flow) modification
- Groundwater recharge

The location and size of a wetland influence the functions it can perform. For example, the geographic location may determine its habitat functions, and the location of a wetland within a watershed can influence its hydrologic and water-quality functions. Many factors determine how well a wetland will perform these functions – such as the size and type of wetland, the quantity and quality of water entering the wetland, and the disturbances or alteration within the wetland or in the surrounding ecosystem.

Wetlands of the Tookany/Tacony-Frankford Watershed were evaluated for the first four of the functions listed above, and were further studied to understand the degree to which they have experienced disturbance and their potential for enhancement and improvement, where they have experienced disturbance. Figure 4.36 shows a typical wetland in the watershed.

This indicator measures:

- **Approximate area of wetland in the watershed**
- **Area of riparian buffer along waterways**
- **The quality of (and disturbance to) the wetlands**
- **The ability of the wetland and woodlands to improve water quality**

Figure 4.36 Example of a Wetland Area

Where We Were:

There is little data available about the historical presence of wetlands and riparian woodlands in the watershed. The Fairmount Park Commission (FPC) compiled some information regarding historic wetlands in their 1999 Natural Lands Restoration Master Plan. FPC reported that Philadelphia had an abundance of wetlands along the Delaware and Schuylkill Rivers in pre-Colonial times. These included a variety of inter-tidal channels, marshes and mudflats, and gravel bars. Much of the south and southwestern parts of the city, including what is now FDR Park, were a mix of tidal channels and marshes. Non-tidal wetlands were present inland from the tidal marshes and along streams (FPC, 1999).

Urban and suburban development has resulted in the piping of historic streams, destruction of wetlands, and deforestation and modification of historic floodplains. Stormwater is piped directly to waterways, and no longer flows overland through vegetation, wetlands, and woodlands. Also, because stormwater runoff frequently flows over impervious surfaces and is then piped to the streams, the flow and volume of runoff is intensified. Stream channels of the watershed exhibit many effects of urbanization: degradation of the stream channel (including overwidening), bank erosion, loss of sinuosity, loss of the floodplain-stream connection, and loss/degradation of aquatic habitat. Because most stormwater is piped directly to the channel of the waterways of the Tookany/Tacony-Frankford Watershed and does not flow over land, there is no longer a source of water input to maintain many of the wetlands that once existed.

Extensive development in the Tookany/Tacony-Frankford Watershed has resulted in conversion of natural riparian lands to residential, institutional, and active recreational land use. Primary land uses in the watershed, for the most part, preclude the existence of natural vegetated areas due to the high density of development. For example, 33% of the residential land uses are row or multi-family homes, which typically have relatively little vegetated open area that might control, improve, and recharge stormwater runoff.

In summary, the number and area of wetlands and riparian woodlands in the Tookany/Tacony-Frankford Watershed have declined significantly over time as a result of development close to the stream edges, changes to the floodplain from concentrated stormwater flows, and routing of nearly all stormwater flow into pipes.

Where We Are:

The Tookany/Tacony-Frankford Watershed is 21,000 acres in size, or about 31 square miles. The watershed is nearly totally developed: 87% (18,200 acres) of the watershed now hosts residences, businesses, industries, and utilities.

Land use data indicates that only 13% of the Tookany/Tacony-Frankford Watershed land area is non-urbanized (e.g., agriculture, cemetery, recreation, woodland), and only 5% of the watershed land area remains as woodland (1,060 acres). The undeveloped riparian corridor, which comprises the undeveloped land directly adjacent to the Tookany/Tacony-Frankford waterways, totals about 3.3% (685 acres) of the watershed land area. The undeveloped riparian corridor is illustrated in Figure 4.37. About one-third of the total woodland is located within the Tookany/Tacony-Frankford undeveloped riparian corridor. (Also see Indicator 1: Land Use and Impervious Cover.)

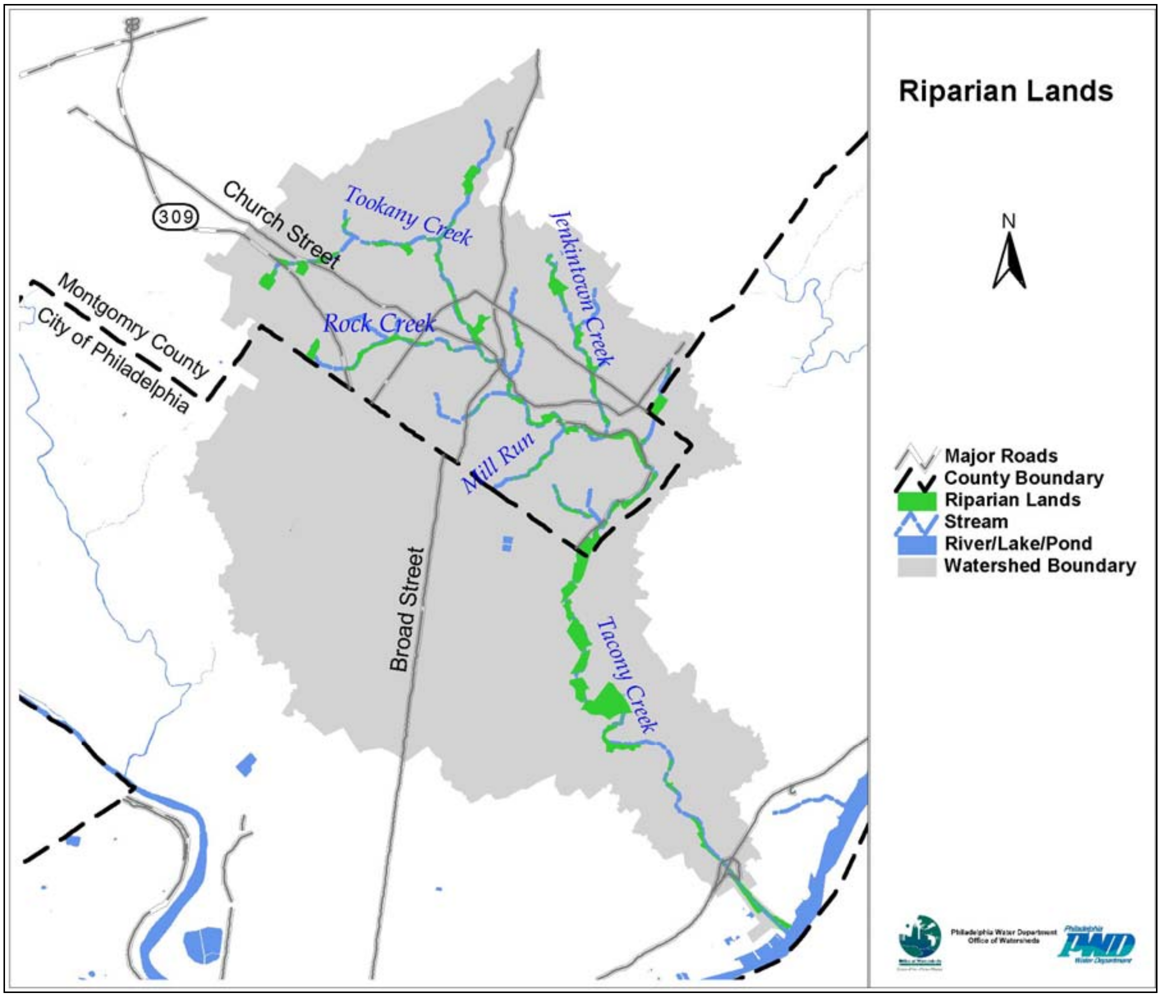

Figure 4.37 Undeveloped Riparian Lands in the Tookany/Tacony-Frankford Watershed

Forested areas in the Tookany/Tacony-Frankford Watershed are generally more contiguous within the Fairmount Park lands, where several large areas of woodland are found. In upstream areas, where there is greater urban encroachment in the riparian corridor, wooded areas are more fragmented, creating habitat for exotic, aggressive tree species. Regrowth of understory and herbaceous layers is usually limited once these non-indigenous species become established. Exotic control, replanting, and trash removal are components of riparian woodlands restoration.

A field study conducted by the Philadelphia Water Department found only small, scattered wetlands remaining along the riparian corridor (see Figure 4.38 and Tables 4.15 and 4.16). The estimated area of these remnants is roughly 15 acres (based on field survey, not jurisdictional mapping), which means wetlands are present in only 2.2% of the undeveloped riparian lands. Wetland communities of native vegetation are also scarce along the riparian corridor.

If runoff from the developed parts of the watershed could be settled and filtered by flowing through a restored riparian corridor, a substantial portion of the total solids in the stormwater could be removed before it reached the creek. However, most stormwater in the watershed is piped directly to the stream channel, bypassing the wetlands and riparian woodlands that could improve water quality through detention, trapping sediment, and recharge. Much of the woodland along the creek and its tributaries is now largely public open space (or in some cases, privately owned residential yards). Return of these lands to their original stormwater functions requires a public discussion and decision-making process for resolving competing uses for riparian lands (which currently include active and passive recreation).

As noted above, the total area of wetland in the watershed is small considering the 29 miles of waterways. Field investigation found only about 24 wetlands, totaling approximately 15 acres, along the creek and its tributaries. The wetlands range in size from 0.01 acre to approximately 2.5 acres. Most are very small: 13 of the 24 wetlands surveyed were less than one-quarter acre in size, and all but two of those were in the upstream Montgomery County reaches.

Functional Assessment of Wetlands

The Tookany/Tacony-Frankford Watershed wetlands were evaluated for their value as wildlife and fish habitat, potential for water quality improvement (nutrient and toxicant reduction), and potential for hydrologic (flood flow) modification. Nearly all wetlands in the watershed exhibit impaired functions that indicate extensive disturbance and deterioration.

Results of the wetland functional field assessments (Table 4.17) indicate that the remaining wetlands in the TTF Watershed are degraded, and do not serve as high quality habitats or perform many of their water quality improvement or ecological functions. If stormwater was redirected to the small areas of remaining wetlands, rather than being rerouted directly to the Tookany/Tacony-Frankford Creek, water quality improvement would be minimal given the current compromised conditions of most of the wetlands. The water quality improvement potential for surveyed wetlands is mapped in Figure 4.39, and illustrates the extensively compromised ability of wetlands to perform their natural water quality improvement functions.

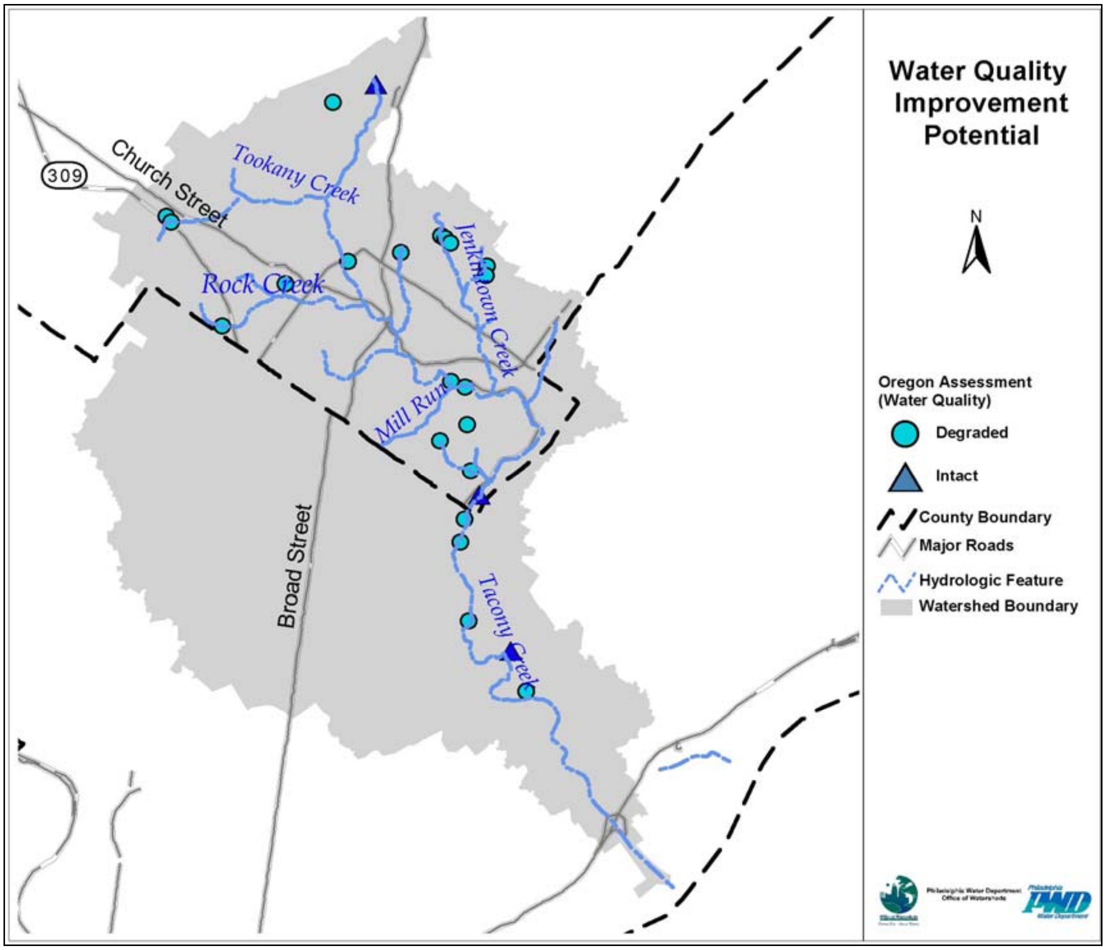

Figure 4.39 Results of Tookany/Tacony-Frankford Creek Functional Assessments for the Water Quality Improvement Function (2002 – 2003)

Human Disturbance of Wetlands

The wetlands that exist along the riparian corridor have been extensively disturbed by urbanization and the related hydrologic alterations to natural overland stormwater flows. A human disturbance score was calculated for each wetland based on several factors: disturbance to the immediate and intermediate wetland buffer zone; habitat alteration (specifically to soils and vegetation); hydrologic alteration (draining and disconnection from the surface drainage network); and chemical pollution from runoff, dumping, and spills.

Table 4.18 Wetland Human Disturbance Gradient Results

Human Disturbance Gradient Rank	Number of Wetlands
Moderately Low Disturbance	10
Moderately High Disturbance	12
Highly Disturbed	2

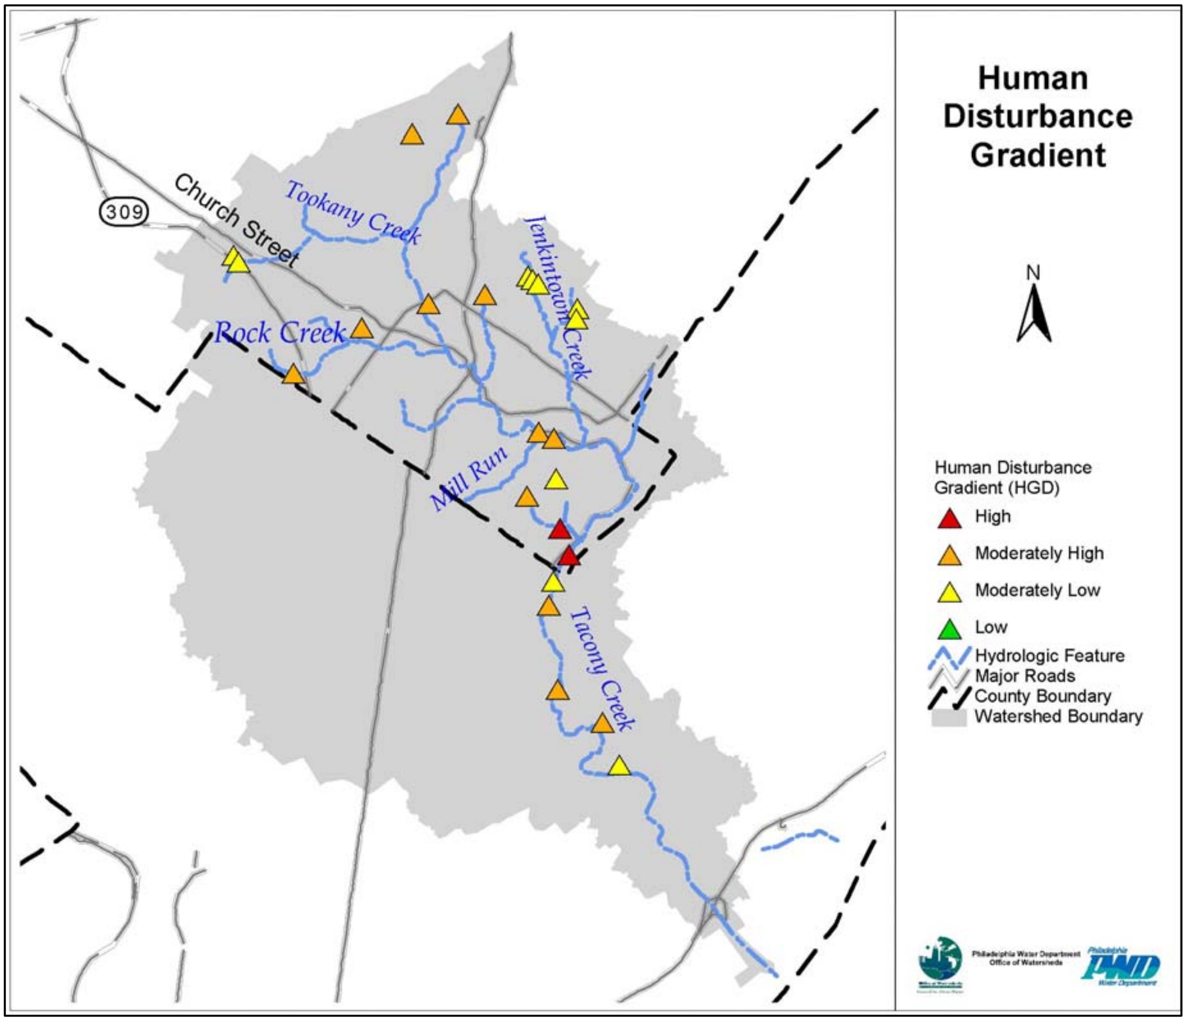

Figure 4.40 Human Disturbance Gradient Scores for Wetland Assessments (2002 – 2003)

4.5.3 Indicator 14: Wildlife

Wildlife includes birds, amphibians, and other animals that make their home in the watershed. Quality and diversity of wildlife habitats are also indicators of watershed health. Many species have specific habitat requirements. Their presence or absence indicates the health of the habitats. For example, healthy, naturally reproducing amphibian communities indicate the presence of appropriate habitats.

This indicator measures:

- **Species inventory**
- **Identification of any threatened and endangered species**

Figure 4.41 Photo of a Baltimore Oriole in Tacony Creek Park

<u>Where We Were</u>:
There is not much information on birds, reptiles, amphibians or mollusk species in Tacony Creek Park before the census was completed in 1998.

<u>Where We Are</u>:
In the Montgomery County section of the watershed, although no formal survey has been completed, there have been reported sightings of northern water snakes, garter snakes, box turtles, and several species of salamanders and frogs.

The Tookany section of the watershed has abundant geese and deer populations. These two animals can act as pests when their populations go unchecked.

In the Philadelphia portion of the watershed, a census was completed in 1998 in Tacony Creek Park (Figure 4.42). It was determined that the Park lacked healthy bird habitat. There were only 39 species of birds, 36 of which are probable breeders in Tacony Creek Park. 20 of these 39 species are indicator species, and only several individuals of each indicator species were found (Table 4.19).

The 1998 inventory found mollusks at six sites, two native Holarctic species, one native North American species and two introduced species. When looking at reptiles and amphibians, bullfrogs and green frogs are common along the creek. Isolated occurrences of two-lined salamanders, a northern red salamander, and northern brown snakes were found. No turtles were documented, though remains of a wood turtle were found. It is believed that a longer study would reveal more reptiles and amphibian species in this Park.

There are no known Pennsylvania Natural Heritage Program (PNHP) – formerly Pennsylvania Natural Diversity Inventory (PNDI) - species within the watershed.

4.6 Quality of Life

This group of watershed indicators relate to factors that affect the daily lives of people who live, work, or dream within the Tookany/Tacony-Frankford community.

4.6.1 Indicator 15: Flooding

Impervious cover and improperly sized or maintained drainage systems in urban watersheds occasionally lead to flooding. Act 167, the Stormwater Management Act of 1978, requires each county in Pennsylvania to prepare and adopt a stormwater management plan for each designated watershed in the county. An official plan provides a mechanism for municipalities to plan for and manage increased runoff associated with possible future development and land use change.

This indicator measures:

- **Areas susceptible to flooding along Tookany/Tacony-Frankford Creek**

Where We Were:
Frequent, serious flooding has not been a major concern in the Tookany/Tacony-Frankford watershed for many years since the stream was channelized. Floodplain mapping studies were conducted by FEMA to establish flood insurance rates for Montgomery County and for Philadelphia County in 1996. These studies include anecdotal evidence of major flooding during tropical storms.

Where We Are:
FEMA studies include stream cross-sections at major road crossings. Figure 4.43 identifies several road crossings where bridge decks are in the 100-year floodplain. As an example, several pictures were taken from the storm on August 1, 2004. The locations of the photos are along the Tacony Creek near Adams Avenue. Figures 4.44 through 4.46 indicate that extensive flooding occurred near the bridge, almost overtopping the bridge. Considerable debris was trapped at the culverts, shown in the photos after the stormflows had subsided.

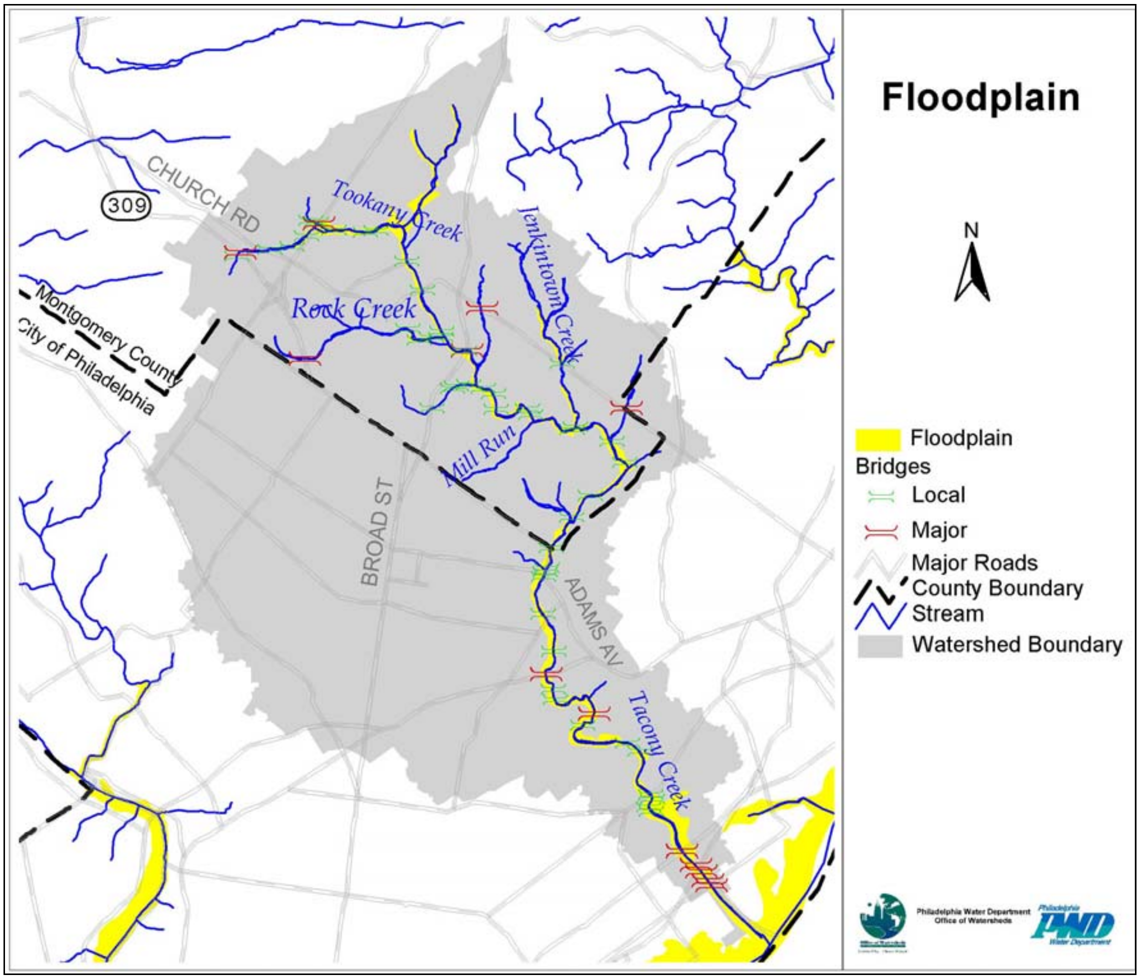

Figure 4.43 Estimated Flood-Prone Areas in the Tookany/Tacony-Frankford Watershed

Figure 4.45 Tacony Creek near the County Border during August 1, 2004 Storm

Figure 4.46 Adams Avenue after August 1, 2004 Storm

4.6.2 Indicator 16: Public Understanding and Community Stewardship

Because a connection to the natural world and its waterways is less apparent in some communities of the Tookany/Tacony-Frankford Watershed, the notion of environmental stewardship does not always top the list of daily priorities for many residents. Stewardship, therefore, must be built around the needs of the community as users of the watershed, as well as by making visible the critical ways in which the health of the watershed is integral to basic quality of life issues. Once this connection has been established, members of the community can be recruited to take action in protecting their watershed. Within this context, citizens need to 1) become aware of the meaning of the term "watershed" and understand the watershed in which they live, 2) become informed about the actions they can take to improve watershed health and 3) move from understanding into action and stewardship. Citizens must also remain informed of the progress made as implementation occurs.

Stakeholders are those who care with their minds and hearts because they already understand their vital connection to the environmental health of their community. The watershed stakeholders include state and federal regulators, those whose jobs empower them to guard the quality of our rivers and streams. The stakeholders include all of the municipalities, separate entities on paper yet bound together by nature including: neighborhood groups, religious groups, schools, and all groups who define themselves as environmental advocates.

This indicator measures:

- **Number of responses to surveys**
- **Number of newspaper stories and letters to the editor about watershed-related issues**
- **Changes in membership in the Tookany/Tacony-Frankford Watershed Partnership**
- **Participation in local environmental stewardship projects**

<u>Where We Were</u>:

A historical baseline has not been established for this indicator. Progress will be assessed next time this plan is updated.

<u>Where We Are</u>:

<u>Surveys</u>

As a part of the Rivers Conservation Planning Program, surveys of residents' understanding of their watershed were conducted by PWD and the Pennsylvania Environmental Council (PEC) for the Philadelphia portion of the watershed and by Heritage Conservancy for the Montgomery County portion of the watershed. The Philadelphia County survey was disseminated in 2002 and can be viewed in Appendix B (Survey 1). The Montgomery County survey was distributed in 2001 and can be viewed in Appendix B (Survey 2). It is evident from the results of both sets of surveys that there is an interest and desire on behalf of the residents to better manage the Tookany/Tacony-Frankford Watershed and to revitalize its creeks. It is also apparent that watershed education and outreach for the residents in both counties are necessary as reflected by a number of the answers in the surveys, in addition to the low response rate on both the Philadelphia County and Montgomery County surveys. A summary of the results of the Tookany survey (Montgomery) is listed at the end of this section. The results of the Tacony-Frankford (Philadelphia) survey and an analysis of the survey results follow (Figure 4.48).

The Tacony-Frankford survey was created with several goals in mind: 1) to provide baseline information on resident knowledge of watershed issues, 2) to understand the residents' hopes and concerns for the Tacony-Frankford Creek, and 3) to educate these residents about the impacts of their actions on the creek. The timeframe for the Tacony-Frankford survey to be completed and returned was approximately seven months. The distribution of the survey was broad, with roughly 800 surveys placed within 16 libraries, 600 surveys distributed through community contacts, 150 distributed at community presentations, and an additional 275 sent to high school teachers at 11 Philadelphia high schools, for a rough total of 1,875 surveys disseminated throughout the watershed. Although there was a low response rate with only 71 completed surveys returned, the surveys did cover a broad area of the watershed. Of the returned surveys, 18 zip codes spanning 31 neighborhoods were represented (Figure 4.47).

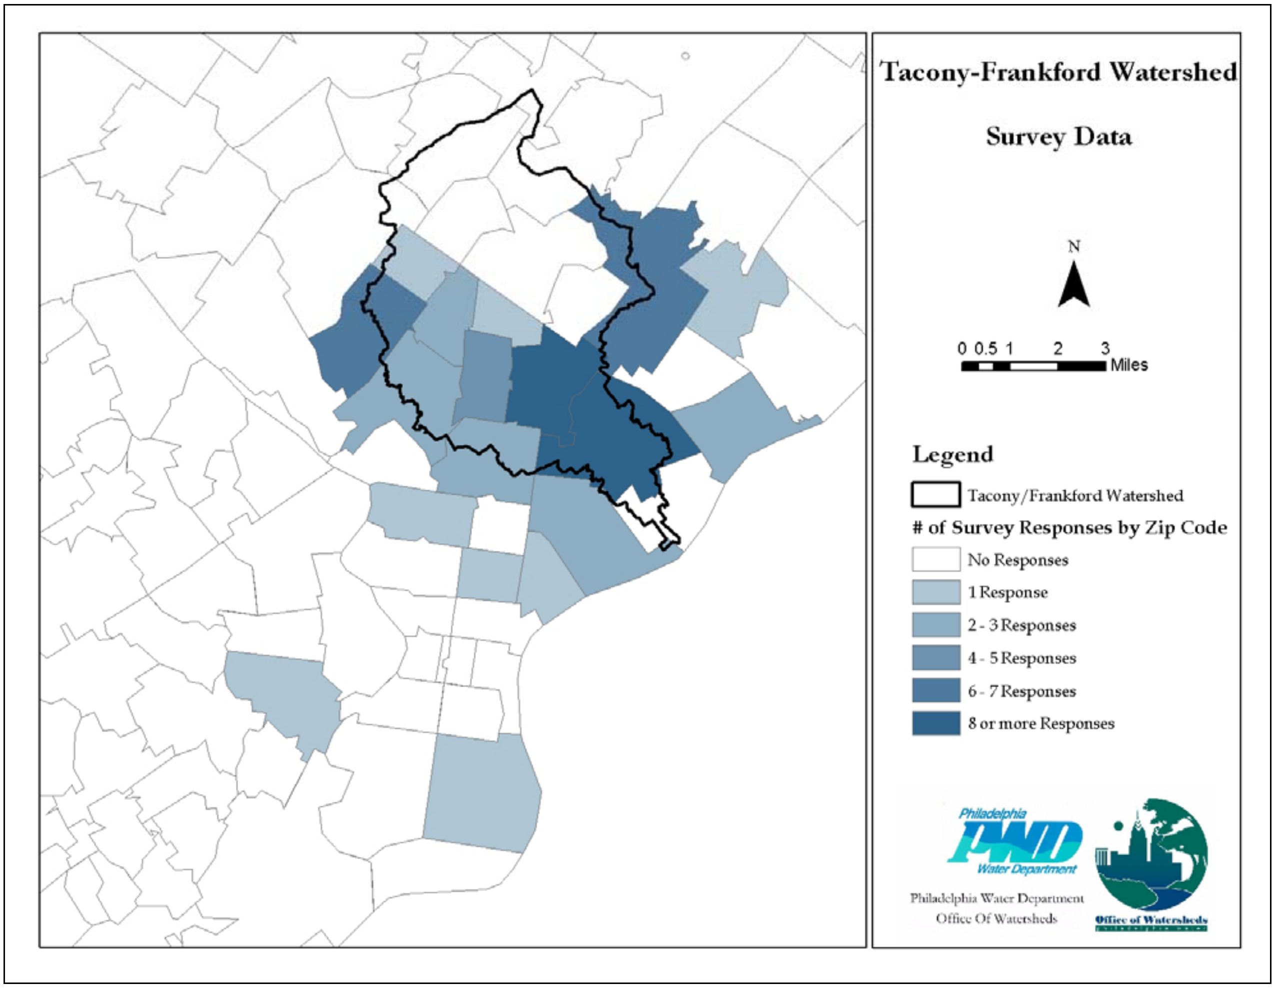

Figure 4.47 Neighborhoods of Respondents to Tacony-Frankford River Conservation Plan Watershed Survey

Results indicate that the majority of residents responding to the Tacony-Frankford survey did not have prior knowledge of the definition of the term "watershed" before reading the brochure. Additionally, only 30% of respondents (21 total responses) thought of themselves as residents of the Tacony-Frankford Watershed.

Sixty four percent (64%) of the Tacony-Frankford survey responses (43 respondents) indicate that residents rarely, if ever, spend recreational time along the creek. Also, more than half of the respondents perceive the water quality of the Tacony-Frankford Creek as poor. The surveyed residents have identified trash and litter in the streams as the most significant source of pollution to the watershed. Sedimentation was ranked as the second most significant source of pollution and illegal dumping ranked third. When asked where money should be directed for the purpose of enhancing the greater community, the answer most frequently rated as most important was the "cleaning of the water in the creek." The removal of trash from the creek area ranked second, and increased safety and security in parks ranked third.

Once the Tacony-Frankford survey results were broken down into two age groups, respondents 18 years and over, and respondents under the age of 18, additional interesting results emerged. Of the 48 individuals surveyed that were 18 years and over, 35 % responded that they knew what a watershed was, and 23% had at least heard of the term before. In contrast, only 6% of the 17 respondents in the category of "under the age of 18 years" knew what a watershed was, although 35% of them claimed to have at least heard the term before.

When asked about the amount of recreational time spent along the Tacony-Frankford Creek, of those under the age of 18, only 12% (2 of the respondents) claimed to spend any time at all along the creek, and then only a few times a year. It seems that residents in the "18 years and over" category have been more likely to make use of the areas along the creek, with 39% (19) of them having visited the area at least a few times a year. Of the 45 respondents who do spend time in the parks, 53% go there to walk, the most frequent recreational activity in the area.

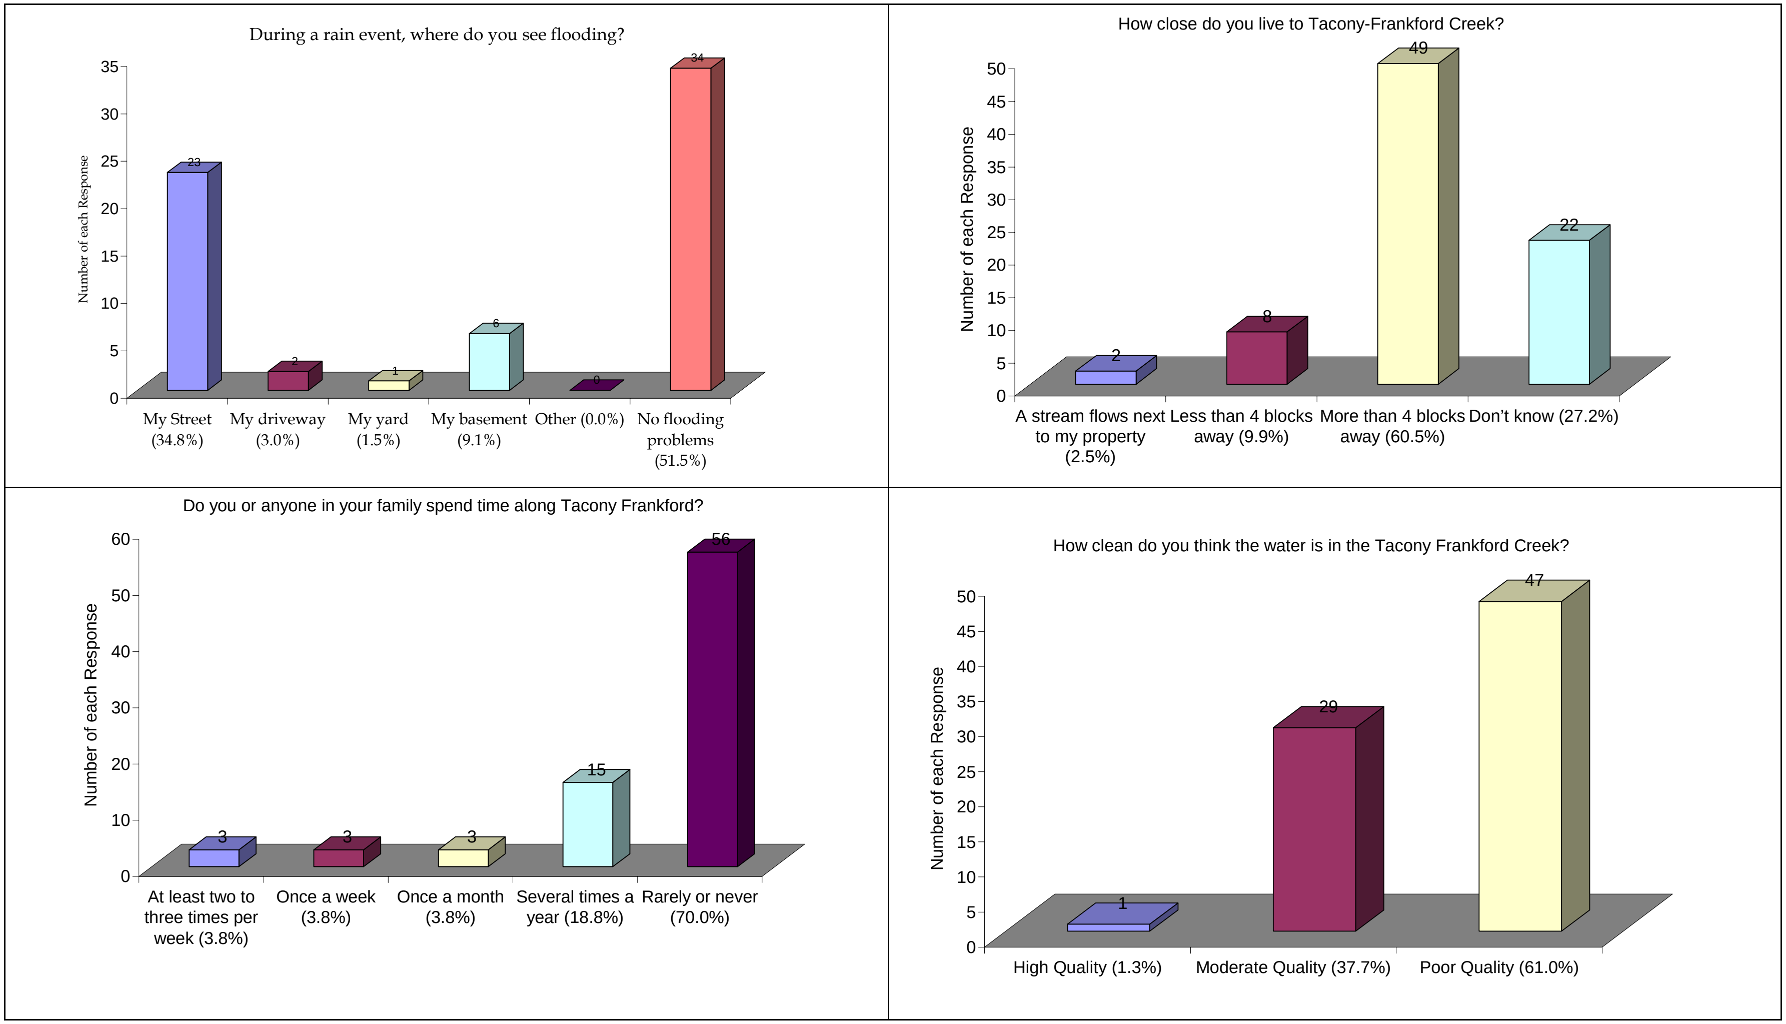

Figure 4.48 Tacony-Frankford Resident Survey Results

For the Tookany survey, 147 (15%) questionnaires were returned out of the 1,000 that were randomly disseminated to the four Montgomery County municipalities. Out of the 147 completed surveys, 101 were returned from Cheltenham County residents. Below is a summary of the Tookany survey results as listed in the "Tookany Creek Watershed Management Plan."

Tookany Creek Survey Results

- The majority (90%) think that the Tookany Creek is an important natural and scenic resource.
- A majority recommended preservation of undeveloped land, preservation of historic resources, preservation of scenic character, protection of wildlife habitat, municipal ordinances that preserve forested land, improvement of water quality, and education.
- A majority also recommended discouraging residential development, shopping centers, retail development, and other commercial and industrial development.
- The main issues that respondents feel need to be addressed are trash, water pollution, and flooding.
- One-half (51%) of respondents said they use the Tookany Creek or its tributaries for nature walks. 29% use it for biking and hiking, 22% use it for jogging, and a small percentage use it for fishing (8%). Respondents participate in the above activities about five times per month.
- When asked what improvements they would like to see, comments included more parking, trails for biking, walking, signage, safety, and better maintenance in general.
- If there were better access to the creeks, more than half would use the creek and its tributaries more.
- 77% feel that municipalities should be responsible for increased conservation and management; 65% feel it should be a county park system responsibility.
- 44% said the money for these projects should come from municipal bonds, and 77% said it should come from federal, state, or private grants.
- When asked to rank eight priority projects, most projects were in the low to average ranking. About one-third (32%) said they want stronger land use ordinances to regulate how land is used along stream corridors, one-third (31%) want streambank restoration to filter pollutants, and 17% indicated that they would want a tree replacement program and physical improvements to reduce flooding.
- Most respondents want education and land use regulations to conserve and protect creek corridors.
- Prior to this survey, 65% of people had not heard about any conservation efforts along the Tookany Creek, and those who did (20%) had read it in the newspaper.
- More than one-half of the respondents (55%) would like to receive written updates on the progress of the TTFIWMP.
- Only 3% of respondents own creek front property.

- Half of the respondents said they do not want to serve on a volunteer coalition or volunteer to participate in a streambank restoration.

Articles

The media greatly influence community perception and may indicate, via public reaction, which events and issues are important to the community. Through an examination of newspaper clipping articles and "letters to the editor" in local weekly and daily papers that serve the Tookany/Tacony-Frankford Watershed, 15 articles specific to the watershed or the TTF Partnership have been identified since 2000.

In the fall of 2002, the Tookany/Tacony-Frankford Watershed Partnership initiated what they called the Tookany/Tacony-Frankford Newspaper Series. They wrote a series of six articles about their watershed history and current issues that were printed on a bi-weekly basis in local newspapers. These six articles (listed below) can be found on the TTF Partnership website at www.phillywater.org/tacony-frankford/Education/education.htm:

1) *Restoring Our Watershed Means Healthier, Safer Communities*
2) *Demographics/ History/ Development of the Tacony-Frankford*
3) *Recent Watershed History*
4) *Natural Amenities*
5) *Challenges*
6) *"What's going on in your Watershed?"*

Membership

Attendance at meetings held by watershed-related groups is another way to gauge interest among citizens. Some 37 stakeholders (Table 4.20) have attended or participated in meetings sponsored by the Tookany/Tacony-Frankford Partnership and other watershed-related forums.

Stewardship

Members of the Tookany/Tacony-Frankford Watershed Partnership have been active in participating in and leading local stewardship projects throughout the watershed. Volunteer groups host stream clean-ups and coordinate restoration projects, such as the planting of native vegetation along the creek's riparian corridors. Partnership members have led rain barrel workshops at their homes and in their communities as a means to educate local residents about the impacts of stormwater runoff and the use of rain barrels as stormwater controls. PWD (on behalf of the TTF Partnership) and the Montgomery County Conservation District have each sponsored rain barrel projects in overlapping areas of this watershed, resulting in the installation of 215 rain barrels in the Tookany/Tacony-Frankford Watershed from the PWD program and 35 rain barrels in the Tookany section of the watershed from the Montgomery County program.

In order to broaden community support and involvement throughout the watershed, Partnership members also coordinated various public events. Self-guided watershed tours and Visual Stream Assessments were sponsored as a way to familiarize residents with the watershed area. The Wingohocking Mystery Tour, which follows the route of the now sewered Wingohocking stream, the largest tributary to the Tacony-Frankford Creek, has now been held annually since 2002. The Return of the Great Blue Heron Day was organized in spring of 2003 to celebrate and bring attention to the good work being done in the watershed that has made it possible to see wildlife return to portions of this region. An overwhelmingly well attended invasive plants workshop was hosted in 2004 in the Tacony Creek Park. This workshop educated stakeholders about types of invasive species and options for removing these plants without damaging the surrounding plant life. An urban streams restoration workshop was held in January 2004 at The Franklin Institute, featuring an urban streams restoration expert who discussed the types of restoration solutions that could be applied in an urban stream such as the Tookany/Tacony-Frankford. The workshop was such a success that it inspired a more detailed follow-up program: the Urban Watersheds Revitalization Conference, a two-day event held in January 2005 at the Franklin Institute.

4.6.3 Indicator 17: School-Based Education

School-aged children of today are the watershed stewards of the future. For that reason, school-based education is an integral component of the long-term health of the watershed. School-based education takes many forms, from lesson plans within the classroom to hands-on activities outside of the classroom such as field trips to the Tookany/Tacony- Frankford Creek and direct involvement in actual restoration projects.

Figure 4.49 Students Collecting Insects in the TTF watershed

Being engaged in actual restoration projects, either through service learning, after-school clubs, or as part of lesson plans translates lessons into action. There are several ways to measure the success of school-based education programs, and each depends on the other.

This indicator measures:

- **Survey of schools on whether they have environmental or watershed management curriculum**
- **Number of schools participating in local environmental stewardship projects**

Where We Were:

A historical baseline has not been established for this indicator. Progress will be assessed next time this plan is updated.

Where We Are:

To date, there are various schools in the watershed that have incorporated environmental or watershed management into the curricula. Furthermore, there are schools that have led local stewardship projects that involve, for example, the creation of a wetland on-campus, participation in a streambank restoration project, and the installation of rain barrels on-campus. Students throughout the watershed also submitted 24 logo entries into the Tookany/Tacony-Frankford Partnership Logo Contest. The winning school's logo became the TTF Partnership's emblem.

In Montgomery County, there are at least seven schools that incorporate environmental and watershed lesson plans into their curricula. These schools include Cheltenham Elementary, Myers Elementary, Wyncote Elementary, Glenside Elementary, Elkins Park Middle School, Cedarbrook Middle School, and Cheltenham High School. In Philadelphia, there are at least 10 schools integrating watershed and environmental education into their curricula. Five of the schools listed below participate in watershed and environmental education programs offered at nearby Awbury Arboretum, while other schools develop their own stewardship projects in their local neighborhoods. Schools in Philadelphia that have incorporated watershed and environmental education into their curricula include Edison Fareira High School, Frankford High School, Grover Washington Junior High School, Hill-Freedman Middle School, Ada Lewis Middle School, Henry R. Edmunds Middle School, Germantown Settlement Charter School, Fulton Elementary School, Hopkinson Elementary, and Holy Innocents Parish Elementary.

The Academic Standards for Science and Technology and Environment and Ecology became a core requirement of the public school curriculum in January 2002 and testing on these topics commenced for the first time in spring 2003 as part of the Pennsylvania System of School Assessment (PSSA). The standards establish the basic elements of what students should know and be able to accomplish at the end of grades 4, 7, 10, and 12. Section 4.1 of these standards is dedicated to watersheds and wetlands. The goals for this topic area are for students to gain knowledge about water cycles, the role of watersheds, physical factors, characteristics and functions of wetlands, and the impacts of watersheds and wetlands. A scope and sequence has been predetermined for each of the aforementioned grades.

4.6.4 Indicator 18: Recreational Use and Aesthetics

People seem to be innately drawn to water and areas of natural beauty. Not surprisingly, park and recreational areas are often centered on scenic water features, such as lakes or rivers. Indeed, many acres of parkland are already established along the Tookany/Tacony-Frankford Creek (see Figure 4.51). However, many miles of the creek are not accessible to the public. If the public has no way to get to the stream, it is less likely to be enjoyed. Parks, and the waterways that flow through them, serve many functions; some obvious and others unseen. For instance, parks and waterways are areas of active and passive recreation. Active recreation includes football, baseball, and canoeing, while passive recreation implies that areas are intended for quiet contemplation or conversation, an essential respite from the concrete and asphalt of the urban world. Natural amenities, when protected and preserved, elevate the quality of life for residents by providing a myriad of recreational, educational, and other activities, in addition to enhancing the market value of homes and institutions.

This indicator measures:

- **Stream accessibility for the Tookany/Tacony-Frankford Creek and its tributaries**
- **Tons of trash removed from the creek and buffer areas**
- **Miles of trails**

Where We Were:

A historical baseline has not been established for this indicator. Progress will be assessed next time this plan is updated.

Where We Are:

Stream Accessibility

An accessibility indicator was developed to determine the degree to which a community is able to reach their waterways (Table 4.21 and Figure 4.50). Accessibility was determined on a scale from 0 through 5, with zero representing a particular segment of a stream that is inaccessible and 5 representing a completely accessible stream segment. The greater the availability of parking, trails, and public recreational land adjacent to the stream, the higher the accessibility rating given to that reach of stream. A segment of a stream running through a private, industrial, or commercial site was given a rating of 0. A segment of a stream running through a public park that has parking and trails leading to the stream was given an accessibility rating of 5. The number of stream miles and the percentage of the total stream miles with each particular accessibility rating were calculated. Fifteen percent of the waterways within the Tacony-Frankford Watershed were given a “Completely Accessible” rating. An additional 20% of the stream miles were rated as “Highly” or “Somewhat Accessible.”

Table 4.21 Accessibility by Stream Miles

Accessibility Rating	Length (miles)	Description	% of Stream Miles
0	3.70	Not Accessible	8%
1	10.50	Minimally Accessible	24%
2	15.28	Moderately Accessible	34%
3	6.11	Somewhat Accessible	14%
4	2.26	Highly Accessible	5%
5	6.48	Completely Accessible	15%

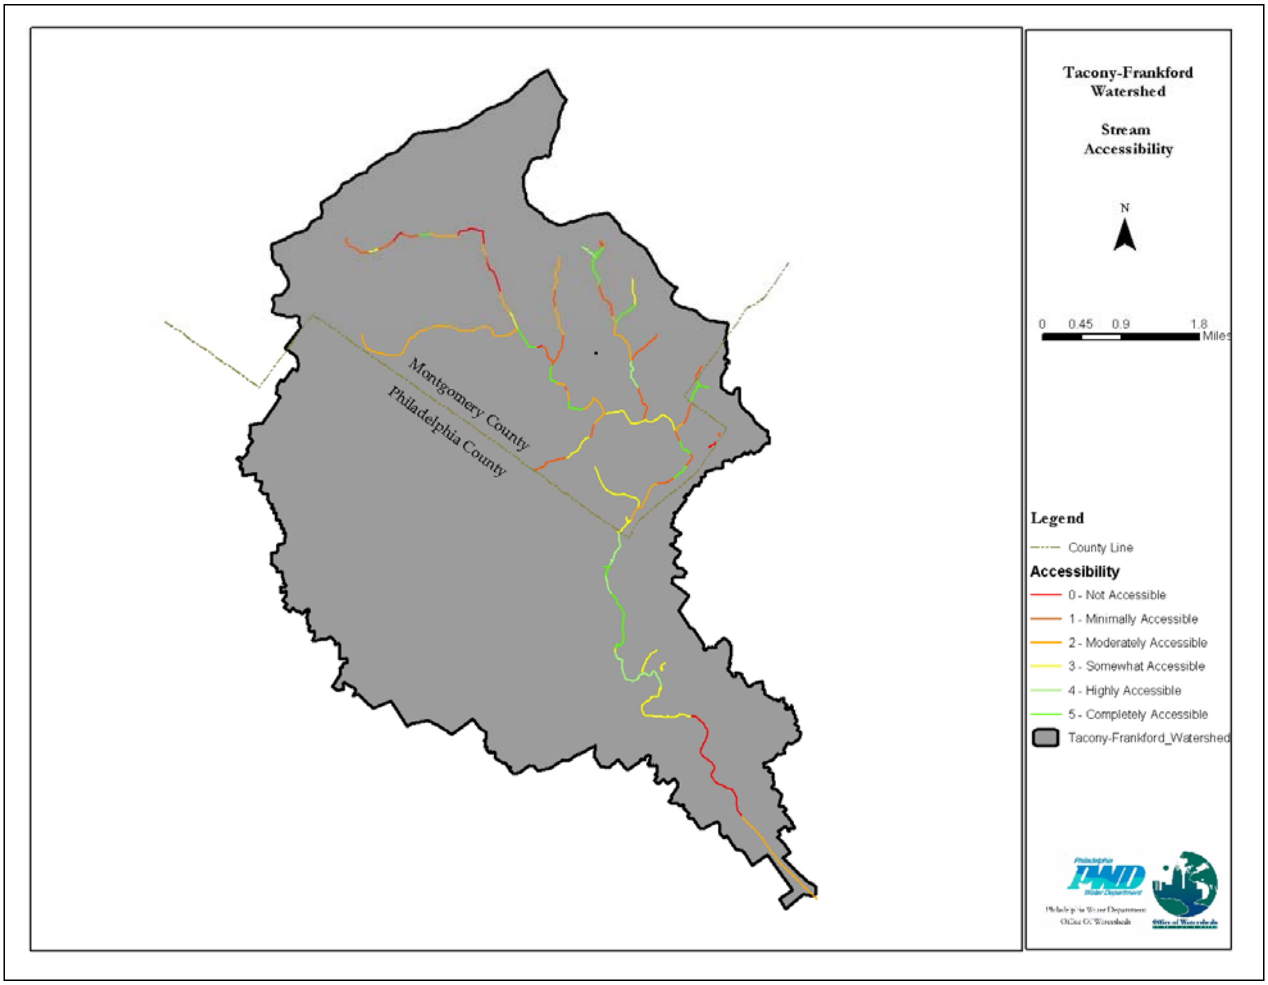

Figure 4.50 Stream Accessibility and Parks in Tacony-Frankford Watershed (2004)

Trash Removal

Maintenance records indicate that 78.45 tons of trash and debris were removed from creeks and riparian buffers in Philadelphia between July 2003 and July 2004 by the Philadelphia Water Department's Waterways Restoration Unit (WRU). The WRU is dedicated to removing large trash and debris – cars, appliances, shopping carts – from our streams in addition to restoring streambanks and streambeds that have been eroded as a result of pipe outfalls. The WRU partners with the Fairmount Park Commission and dedicated volunteers throughout Philadelphia on clean-up and restoration efforts.

Miles of Trails

Burlholme Park and Tacony Creek Park offers residents the opportunity to walk trails along the creek in the watershed. Burlholme's trails parallel an unnamed tributary to the Tookany Creek as it flows into Cheltenham Township. Tacony Creek Park has an extensive trail network along the Tacony Creek, including a trail that extends the length of the park. These trails are the most tangible connection that city residents have to this watershed. Other parks that have walking trails include Awbury Arboretum, Fern Hill, Wister Woods, Kemble, and Fisher Park.

There are 43.8 miles of bike paths within the Tacony Frankford watershed. Most of the bike paths follow major thoroughfares.

The Parkland map (Figure 4.51) details bike routes and walking trails that contribute to the amount of open space within the watershed.

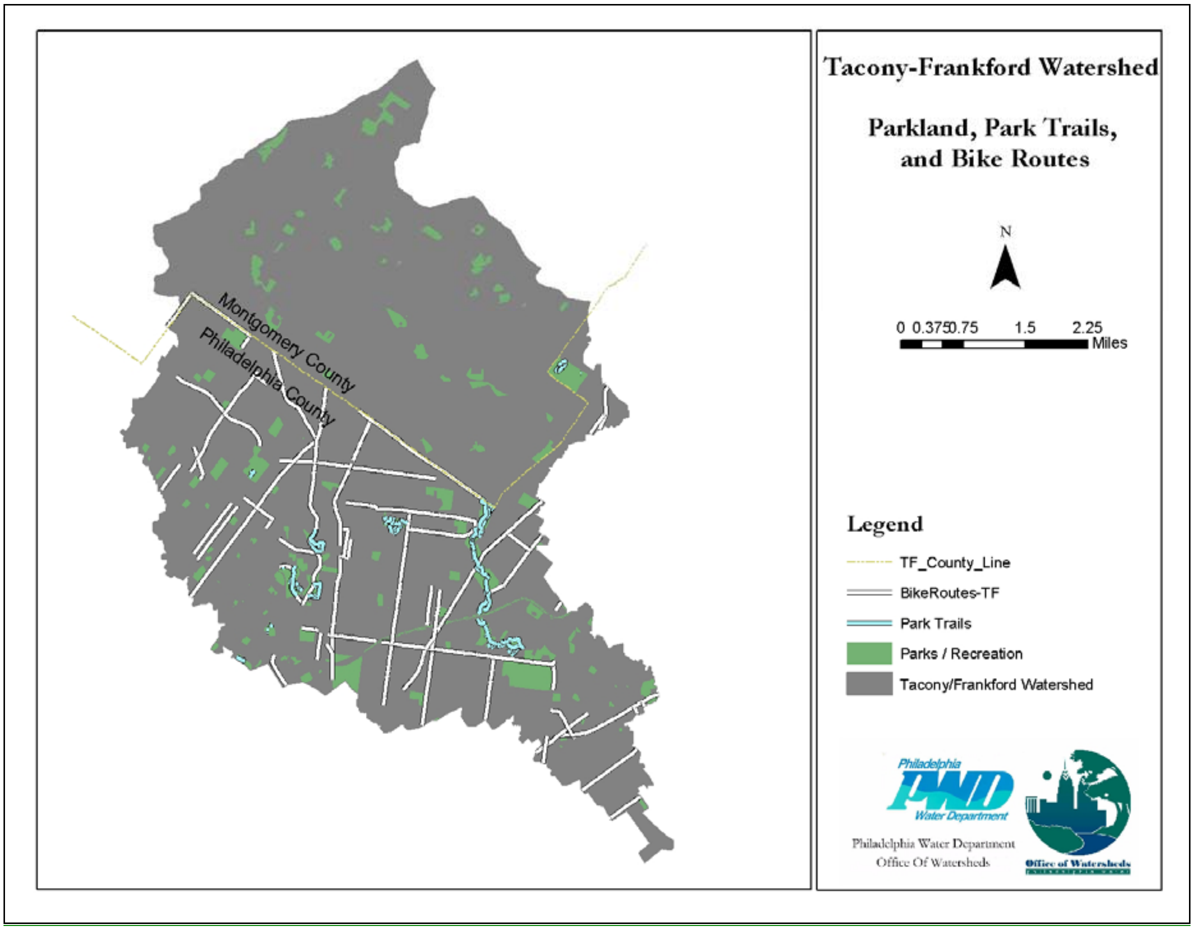

Figure 4.51 Parkland, Park Trails, and Bike Routes in the Tookany/Tacony-Frankford Watershed

4.6.5 Indicator 19: Local Government Stewardship

Local government leadership is essential to ensuring that improvements made under watershed restoration planning are sustainable. Local governments must also support, encourage, and complement the stewardship efforts of individuals, environmental groups, and businesses. A major goal is for local governments to work within their regulatory and statutory obligations while actively supporting the stewardship efforts within the watershed. It is also important that local governments implement voluntary actions to restore the watershed. Most importantly, to ensure the success of the watershed management plan, each local government within the watershed must embrace the goals and implementation strategies of the plan. A formal adoption of this plan would enhance its chance for success tremendously.

This indicator measures:

- **Municipalities participation in initiatives such as Act 167 planning, the TTF Partnership, River Conservation Plans (RCPs), and representation on the Board of the new 501(c)3 organization**
- **Age of sewage facilities (Act 537) plans**

<u>Where We Were</u>:
A historical baseline has not been established for this indicator. Progress will be assessed next time this plan is updated.

<u>Where We Are</u>:
To date, the Philadelphia Water Department and Cheltenham Township have received state grants to develop Act 167 Plans in the Tookany/Tacony-Frankford Watershed. Act 167 Plans require counties to prepare and adopt stormwater management plans for each designated watershed in a county. Consequently, PWD and four municipalities in the Montgomery County portion of the watershed have committed to participating in these plans. Those Montgomery County municipalities include Abington and Cheltenham townships, and the boroughs of Jenkintown and Rockledge (Figure 4.52).

Cheltenham Township is also leading an effort to explore the possibility of creating a watershed-wide Environmental Advisory Council (EAC) in collaboration with the other municipalities in Montgomery County. An EAC is a group of three to seven community residents, appointed by local elected officials, that advises the local planning commission, park and recreation board, and elected officials on the protection, conservation, management, promotion, and use of natural resources within its jurisdictional limits. Municipalities are authorized to establish EACs through Act 177 of 1996 (originally Act 148 of 1973).

As mentioned previously, PWD initiated the Tookany/Tacony-Frankford Watershed Partnership in 2000. The TTF Partnership represents a consortium of proactive environmental groups, municipal officials, community groups, government agencies, businesses, residents, and other stakeholders who have a vested interest in improving the Tookany/Tacony-Frankford Watershed. The Partnership formed various committees and has met periodically ever since.

Soon after the TTF Partnership was formed, a River Conservation Plan (RCP) for the Tacony-Frankford Watershed was developed by PWD and the Partnership members. The RCP Team was comprised of representatives from PWD, Frankford Group Ministry, Fairmount Park

Commission, Heritage Conservancy, and the Pennsylvania Environmental Council. In addition, the Plan was guided by an RCP Steering Committee, which included representatives from LaSalle University, the Philadelphia City Planning Commission, Frankford Community Development Corporation, Cheltenham Township, PA Department of Conservation and Natural Resources, Awbury Arboretum, National Park Service and Trails, Delaware Riverkeeper Network, Friends of Tacony Creek Park, 35th Police District, and the U.S. Army Corps of Engineers.

The Tookany RCP (referred to as the Tookany Creek Watershed Management Plan), led by Heritage Conservancy, was also developed by a diverse team of representatives. The RCP Steering Committee members were made up of officials from each municipality, in addition to representatives from Montgomery County Conservation District and Planning Commission, PECO Energy Company, PWD, and the Old York Road Historical Society.

Today, the Tacony-Frankford River Conservation Plan is complete and currently undergoing an approval process in order to be placed on the PA DCNR's Rivers Registry. The Tookany RCP is also complete and has been approved by the Montgomery County municipalities and listed on the Rivers Registry.

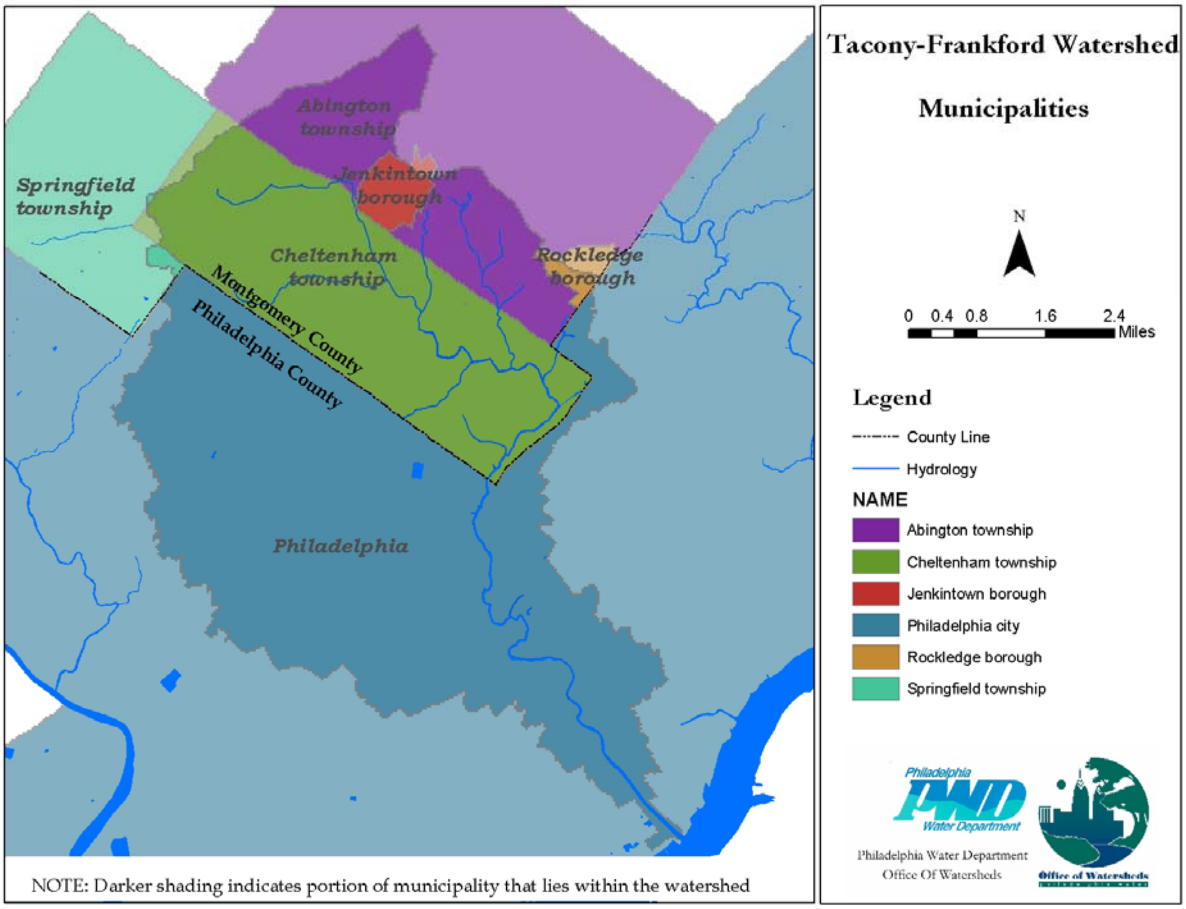
In 2003, a diverse group of Tookany/Tacony-Frankford Partnership members developed a committee to evaluate the group's organizational structure for effectiveness in plan implementation, in order to determine how to effectively guide the TTF Partnership's future progress. The Structure Committee expanded the goals of the Partnership and established the recommendation for transformation of the existing Partnership into an independent nonprofit watershed organization. It was decided that this would enable the Partnership to focus on coordinating the on-the-ground implementation of the recommendations in the TTFIWMP and to broaden community and political support for the revitalization of the watershed. The TTF Partnership was incorporated as an independent 501(c)3 organization in 2005. (See bylaws in Appendix C.)

Garnering political support from all municipal officials is an especially important priority for the TTF Partnership. Members of the Structure Committee included representatives from the Fairmount Park Commission, Awbury Arboretum, Cheltenham Township, Abington Environmental Advisory Council, Frankford Group Ministry, Friends of High School Park, Friends of Tacony Creek Park, Heritage Conservancy, Melrose Park Neighbors Association, Delaware Riverkeeper Network, Montgomery County Planning Commission, PA DEP, PA DCNR, and the U.S. Army Corps of Engineers. Many of those same entities, as well as various others, are represented on the board of directors of the newly incorporated nonprofit organization.

Currently, all of the municipalities in the watershed have an Act 537 Plan, which provides for the resolution of existing sewage disposal problems, future sewage disposal needs of new land development, and future sewage disposal needs of the municipality. However, some plans are newer and more detailed than others (Table 4.22).

Table 4.22 Act 537 Municipal Sewage Facilities Plans

Municipality	County	Plan Approval Date	Status (as of 12/2005)
Abington Township	Montgomery	12/16/99	Plan older than 5 years
Cheltenham Township	Montgomery	1/1/73	Plan older than 30 years
Jenkintown Borough	Montgomery	1/1/73	Plan older than 30 years
Philadelphia	Philadelphia	11/10/93	Plan older than 10 years
Rockledge Borough	Montgomery	1/1/73	Plan older than 30 years



NOTE: Darker shading indicates portion of municipality that lies within the watershed

Figure 4.52 Tookany/Tacony-Frankford Watershed Municipalities and Counties

4.6.6 Indicator 20: Business and Institutional Stewardship

Awareness of the role of businesses and institutions in watershed degradation and restoration is growing. Success of the watershed management plan will require stewardship on the part of stakeholders who represent the diversity of land uses in the watershed, including conservation groups, commercial, industrial, institutional, and residential users. The goal of the TTF Partnership is to have a proportional representation of these groups.

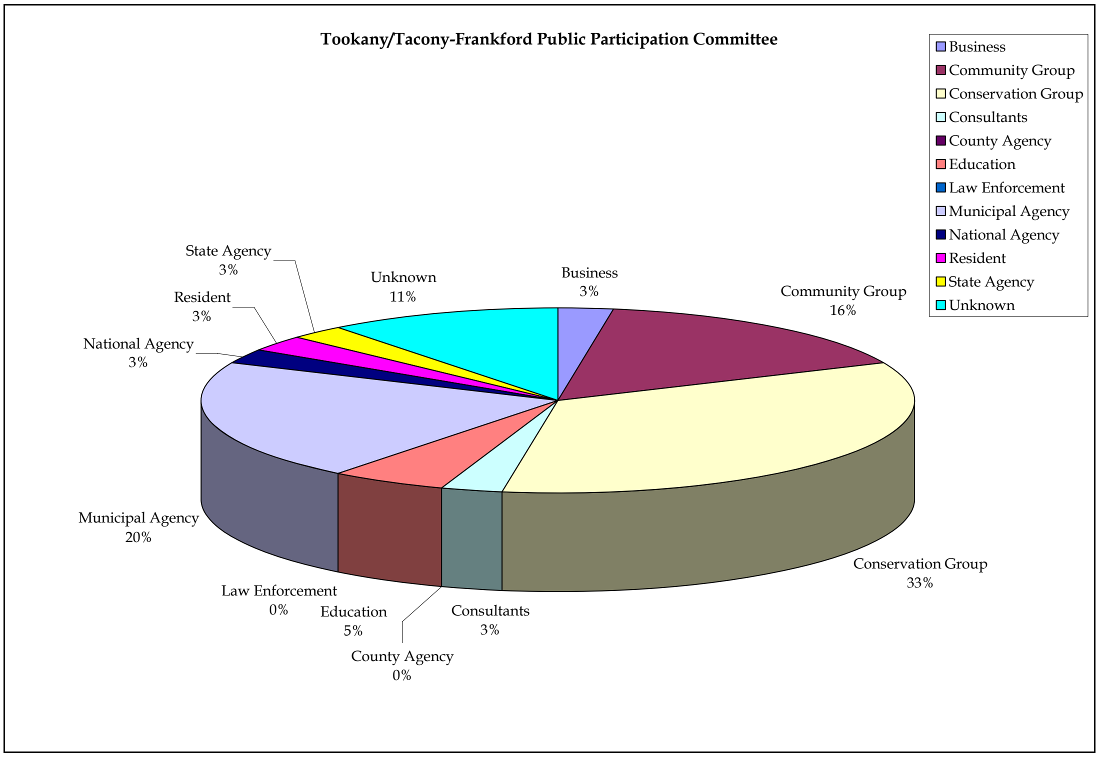
This indicator measures:

- **Breakdown of TTF Partnership committee participation by organization type**

<u>Where We Were</u>:
A historical baseline has not been established for this indicator. Progress will be assessed next time this plan is updated.

<u>Where We Are</u>:
Figure 4.53 illustrates the percentage of representatives of each type of group on the TTF Partnership's Technical and Public Participation Committees. To date, three business representatives have participated in Partnership meetings and events, as illustrated in the below charts. These business representatives included Rohm & Haas Co., Hankin Management, and Cardone Industries. These industries are all located near the creek.

Recently, PWD has developed a partnership with Shop Rite Supermarkets and the Pennsylvania Food Merchants Association (PFMA) to address the removal of shopping carts from local streams. Shop Rite has committed to sponsoring stream side clean-up events with students throughout the watershed.



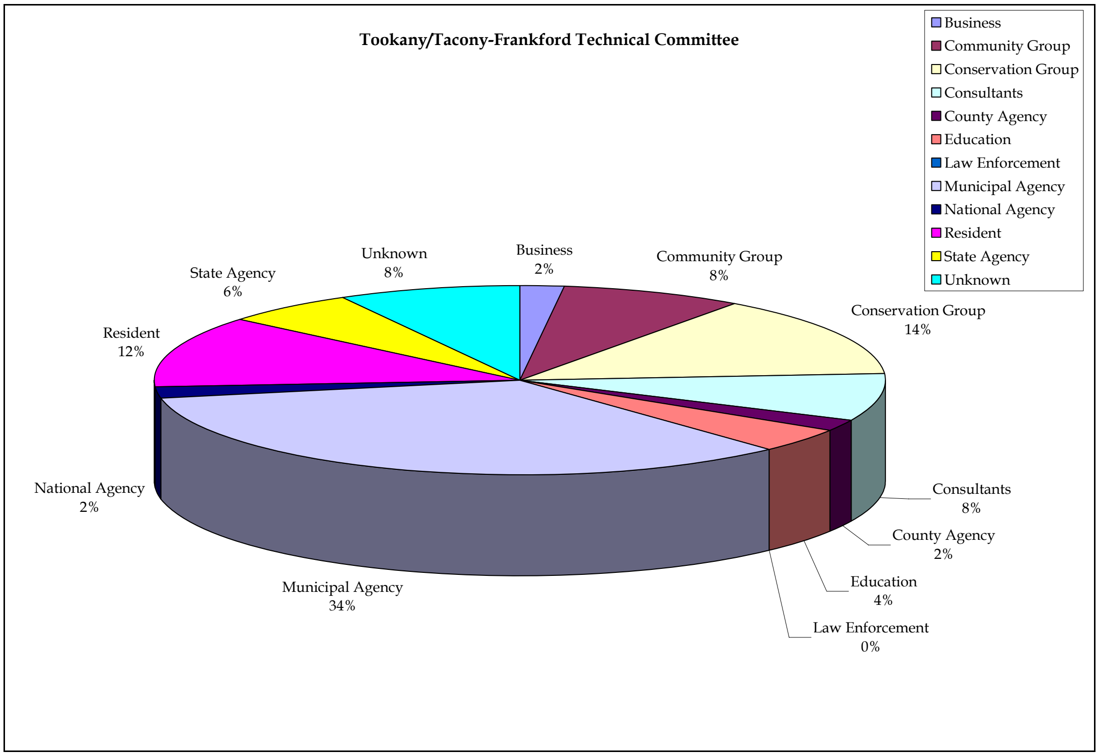


Figure 4.53 Distribution of Partnership Members' Affiliations (2003)

4.6.7 Indicator 21: Cultural and Historic Resources

Waterways have always been cradles of civilization, providing, among many other things, a means of travel and rich floodplain soils in which to cultivate crops. Waterways provided power for mills and fueled the beginnings of the industrial revolution. Consequently, historical and cultural resources are often concentrated in and along waterways. These resources enable us to better understand and appreciate different cultures and traditions, to recognize the struggles endured by our ancestors, and to comprehend the technologies of past generations; and they can be an invaluable tool to inform our understanding of present conditions.

This indicator measures:

- **National Register of Historic Places inventory**
- **National Register of Historic Districts inventory**
- **Number of nonprofit historical/cultural organizations**

Where We Were:
A historical baseline has not been established for this indicator. Progress will be assessed next time this plan is updated.

Where We Are:
Although it is hard to pinpoint the actual number of historic properties located in the watershed, it is approximated that 11 historic properties exist in the municipalities in the Tookany section of the watershed and approximately 46 historic properties exist in the Philadelphia section of the watershed. The Fairmount Park Commission has identified eight historic resources located in Tacony Creek Park. Additionally, six districts are identified as National Register Districts. The four National Register Historic Districts in Philadelphia include Awbury, Germantown, Friends Hospital, and Tulpehocken. The two Districts that exist in Montgomery County include La Mott Historic District with 40 resources, and Wyncote Historic District with 232 resources. The watershed is rich with numerous other historical, cultural, and social amenities throughout both counties, many of which are deemed eligible for listing on the National Registry by the Pennsylvania Historical and Museum Commission. The National Register was authorized by an Act of Congress in 1966 and serves as the nation's official list of cultural resources worthy of protection. The National Register is administered by the National Park Service of the U.S. Department of the Interior.

Furthermore, five nonprofit historical societies or cultural organizations exist to preserve the history and culture of the rich communities of the watershed: Germantown Historical Society, Historical Society of Frankford, Old York Road Historical Society, Ryerss Victorian Mansion, and the Settlement Music School. The City of Philadelphia also has the distinction of being an important destination for fugitive slaves seeking freedom in the North. There are numerous important Underground Railroad sites within the watershed. Two sites that are listed in Charles Blockson's *Hippocrene Guide to the Underground Railroad* are the John Johnson House in Germantown and the Campbell AME Church in Frankford.

Section 5
Problem Definition and Analysis

The watershed "indicators" described in Section 4 are used both to characterize the current state of the TTF Watershed, and to set a baseline for future comparison. Here, Section 5 identifies the wide range of potential problems that have been identified in the watershed, and describes the analysis tools used to define them.

Many of the problems in the TTF Watershed have been identified through the assessments carried out by the project team and others. Other problems were identified through stakeholder participation. Water quality problems were identified by taking samples and comparing results to water quality criteria. Several criteria were relevant to the analysis, many of which provided specific numeric standards with which to comply. Others were less specific, but nonetheless relevant. These are often referred to as narrative standards.

National water quality criteria include aesthetic qualities that protect the quality of streams. The criteria state:

"All waters free from substances attributable to wastewater or other discharges that:

(1) settle to form objectionable deposits;

(2) float as debris, scum, oil, or other matter to form a nuisance;

(3) produce objectionable color, odor, taste, or turbidity;

(4) injure or are toxic or produce adverse physiological responses in humans, animals or plants; and

(5) produce undesirable or nuisance aquatic life." (EPA, Goldbook, 1986)

Also, PA DEP's general water quality criteria state:

> (a) Water may not contain substances attributable to point or non-point source discharges in concentration or amounts sufficient to be inimical or harmful to the water uses to be protected or to human, animal, plant, or aquatic life.
>
> (b) In addition to other substances listed within or addressed by this chapter, specific substances to be controlled include, but are not limited to, floating materials, oil, grease, scum and substances which produce color, tastes, odors, turbidity or settle to form deposits. (PA DEP, Chapter 93 § 93.6.)

Some standards were related to the uses of the creek. The Tookany/Tacony-Frankford Creek's protected uses as designated by PA DEP are:

- Aquatic Life – Warm Water Fishes
- Water Supply – Potable Water Supply
- Recreation and Fish Consumption - Boating, Fishing, Water Contact Sports, and Esthetics

5.1 Visual Stream Assessment (Aesthetics and Narrative Criteria)

The Tacony-Frankford RCP Team and Tookany Creek Watershed Management Plan Steering Committee conducted visual assessments along the major tributaries and mainstem streams. These assessments provided a baseline inventory of the existing conditions along the stream corridor. The method utilized a modified version of the USDA's Visual Streambank Assessment Protocol. Members of these committees and volunteers conducted the visual stream assessments.

The visual assessments assisted in identification of problems and problem locations in the Tookany/Tacony-Frankford Watershed. Generally, the issues found in the watershed included:

- Erosion of creek banks (undercutting, exposed roots).
- Appearance of invasive species – Disturbed areas throughout the watershed are susceptible to invasion by non-native exotic vegetation. Japanese knotweed, kudzu, purple loosestrife, and multiflora rose were identified as issues within the watershed.
- Trash and debris – Along the creeks, there was an abundance of trash and debris.
- Illegal dumping – Dumping of trash, cars, and appliances are an issue for Tacony Creek Park and vacant land. Secluded open areas are especially susceptible to dumping. Sites of abandoned cars often become targets for fire. Illegal dumping ranges from trucks dumping construction materials and appliances to residents throwing trash directly into the creek.
- Illegal recreational activities (e.g., ATVs, swimming) – ATV use is illegal in Tacony Creek Park and has had a detrimental effect on the health of the park. Illegal trails disturb native vegetation and open habitat for invasives while contributing to erosion on slopes of the creek banks.
- Sewage and odors.
- Lack of riparian buffer – The lack of riparian buffer was observed on both public and private property. Native vegetation usually found in the riparian buffer often has been removed or mowed. Sections of the creeks where flooding has been problematic tend not to have riparian buffer areas, coupled with a high percentage of impervious surface.
- Exposed and eroded sewer and stormwater pipes.
- Instream flow obstructions.
- Chemical runoff which may include but is not limited to fertilizers, pesticides, herbicides, oil and grease, antifreeze, and industrial spills.
- Illicit and disconnected sewers.
- Lack of best management practices (BMPs).

Figure 5.1 displays the results of the visual stream assessments, with the locations of problems identified by stream reach.

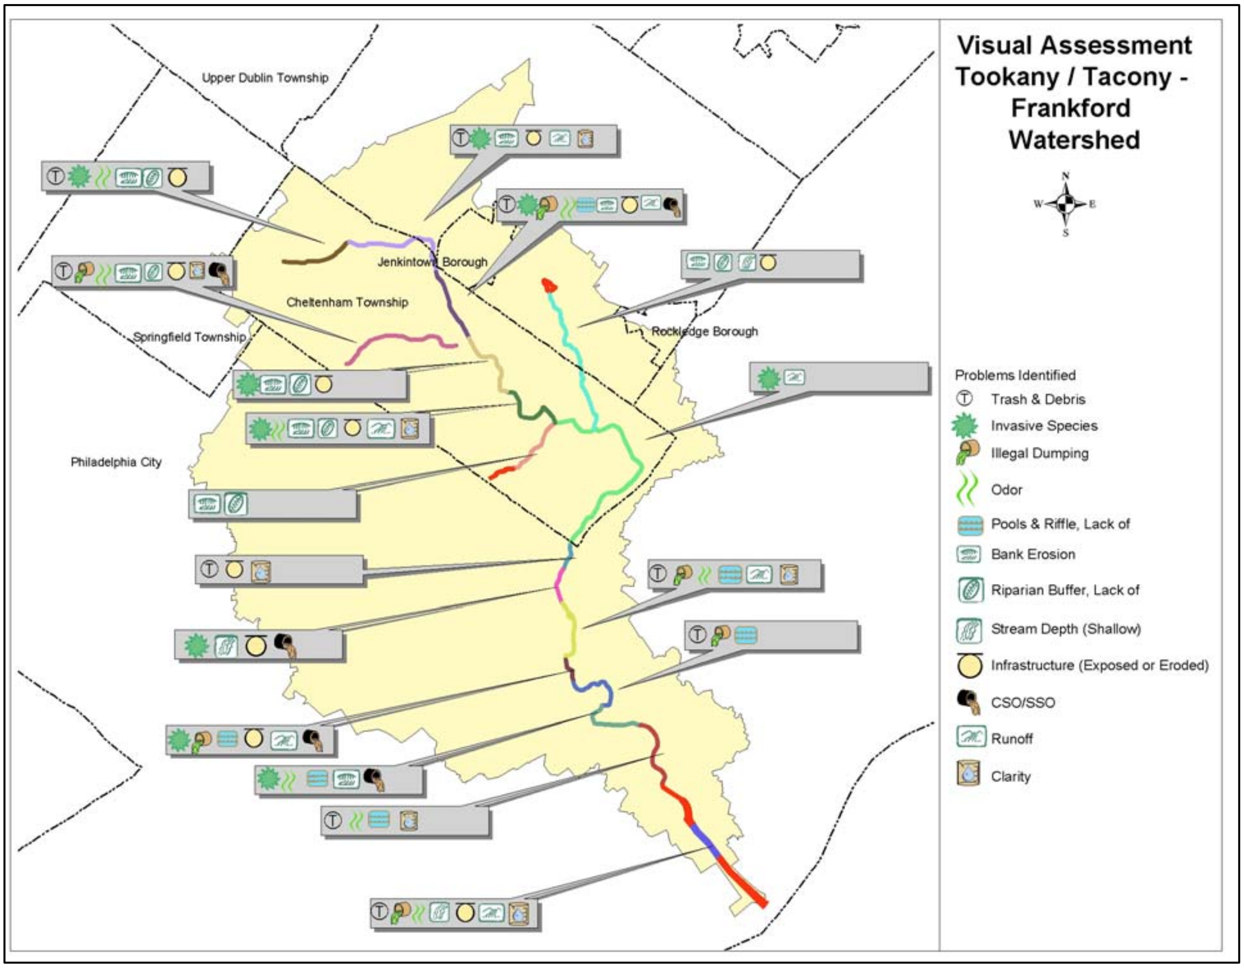

Figure 5.1 Summary of Visual Assessments

Various problems have been identified throughout the watershed. Evidence of streambank erosion was observed at all but one reach of the visually assessed streams. Trash and debris and invasive species were recorded at most reaches. There is no pattern with regards to the location of the reaches, with problems identified both in the city and outside the city.

5.2 Streamflow Analysis

Indicator 2, Streamflow, measures baseflow and runoff to analyze the impact of urbanization on watershed hydrology. As noted previously in Sections 2.2.1 and 4.2.1, the flow records at each of the USGS gauges in the Tookany/Tacony-Frankford Watershed were separated into runoff and baseflow components.

In Table 5.1, the results for Tacony-Frankford Creek are compared with French Creek, a rural stream, and Darby Creek, a stream in a mixed urban and suburban watershed. Results for French Creek are somewhat typical of an undeveloped watershed, with baseflow comprising 64% of mean annual streamflow and stormwater only 17% of annual precipitation.

At the Frankford Creek gauge, representing most of the urbanized Tacony-Frankford watershed, the stormwater component of streamflow is a much greater percentage of total annual streamflow (62%), and baseflow represents a much smaller percentage of total annual streamflow (only 38%). These results are indicative of a highly urbanized stream. The Tacony Creek USGS gauge, representing the headwaters of the Tacony-Frankford Watershed, exhibits a relationship between stormflow and baseflow that is between the two extremes.

Table 5.1 Summary of Hydrograph Separation Results over the Period of Record

USGS Gauge	Period of Record	Baseflow	Baseflow	Stormwater Runoff
		(% of Total Flow)	(% of Precip)	(% of Precip)
Tacony Creek near Jenkintown 01467083	10/1/73 - 9/30/78	56%	27%	21%
Rock Creek 01467084	5/1/71 – 9/30/78	46%	28%	33%
Jenkintown Creek 01467085	5/1/71 – 9/30/78	60%	27%	18%
Tacony Creek at County Line 01467086	10/1/65 - 11/17/88	58%	29%	21%
Frankford Creek at Castor Ave 01467087	7/1/82 - 9/30/03	38%	17%	27%
Frankford Creek at Torresdale Ave 01467089	10/1/65 - 9/30/81, 5/14/82 – 6/29/82	35%	17%	31%
French Creek 01475127	10/1/68 – 9/30/03	64%	31%	17%
Darby Creek 01475510	2/1/64 – 10/3/90	62%	34%	21%
Cobbs Creek 01475550	2/1/64 – 10/3/90	43%	19%	26%

5.3 Water Quality Analysis

As noted above, water uses relevant to the TTF Watershed include the following:

- Aquatic Life – Warm Water Fishes
- Water Supply – Potable Water Supply
- Recreation and Fish Consumption - Boating, Fishing, Water Contact Sports, and Esthetics

As described in Section 2.2.2, an analysis was conducted on the water quality data collected in the Tookany/Tacony-Frankford Watershed. A number of constituents, which are listed in Table 5.2, were used as indicators of watershed health in Section 4.3. Using the data collected from discrete wet and dry weather sampling, comparisons were made to water quality standards. National water quality standards and reference values were used if state water quality standards were not available. The water quality standards or reference values and their sources are also listed in Table 5.2.

The aquatic life criteria for metals were "established to control the toxic portion of a substance in the water column. Depending upon available data, aquatic life criteria for metals are expressed as either dissolved or total recoverable." (PA DEP, Chapter 16)

A color coding is used to indicate problems (red) and potential problems (yellow). Problems are identified if more than 10% of samples exceed the applied water quality standard or criteria. Potential problems are identified if between 2% and 10% of samples exceed the standard or criteria.

Table 5.2 Water Quality Standards and Reference Values

Parameter	Criteria	Water Quality Criteria or Reference Value	Source
Alkalinity	Minimum	20 mg/L	PA DEP
Aluminum	Aquatic Life Chronic Exposure Standard	87 mg/L (pH 6.5-9.0)	53FR33178
Aluminum	Aquatic Life Acute Exposure Standard	750 mg/L	PA DEP
Chlorophyll A	Reference reach frequency distribution approach for Ecoregion IX, subregion 64, 75th percentile	seasonal median: 3 ug/L, (Spectrophotometric)	EPA 822-B-00-019
Dissolved Cadmium	Aquatic Life Acute Exposure Standard	Hardness Dependent	PA DEP
	Aquatic Life Chronic Exposure Standard	Hardness Dependent	PA DEP
	Human Health Standard	10 mg/L	EPA Goldbook
Dissolved Chromium	Aquatic Life Acute Exposure Standard	16 mg/L	PA DEP
	Aquatic Life Chronic Exposure Standard	10 mg/L	PA DEP
Dissolved Copper	Aquatic Life Acute Exposure Standard	Hardness Dependent	PA DEP
	Aquatic Life Chronic Exposure Standard	Hardness Dependent	PA DEP
	Human Health Standard	1000 mg/L	EPA Goldbook
Dissolved Iron	Maximum	0.3 mg/L	PA DEP

Parameter	Criteria	Water Quality Criteria or Reference Value	Source
Dissolved Lead	Aquatic Life Acute Exposure Standard	Hardness Dependent	PA DEP
	Aquatic Life Chronic Exposure Standard	Hardness Dependent	PA DEP
	Human Health Standard	50 mg/L	EPA Goldbook
Dissolved Zinc	Aquatic Life Acute Exposure Standard	Hardness Dependent	PA DEP
	Aquatic Life Chronic Exposure Standard	Hardness Dependent	PA DEP
	Human Health Standard	5000 mg/L	EPA Goldbook
DO	Instantaneous Minimum	4 mg/L	PA DEP
	Average Minimum	5 mg/L	PA DEP
Fecal coliform	Maximum	Geometric Mean of 5 consecutive samples on different days within a 30 day period may not exceed 200/100mL (Summer) or 2000/100mL (Winter)	PA DEP

Based on a comparison of water quality sampling data with standards, criteria, or reference values, the problem and potential problem parameters have been identified and are discussed in this section. The issues have also been identified during wet and dry weather, if applicable.

5.3.1 Water Supply

The state's potable water supply criteria were applied to the Tookany/Tacony-Frankford Watershed. The criteria are listed above in Table 5.2. Comparisons between the water quality data and the criteria for water supply are listed in Table 5.3, which displays observed water quality exceedances of these criteria during dry and wet weather.

Table 5.3 Summary of Water Supply Criteria Exceedances

Parameter	Criteria	Dry			Wet		
		No. Obs.	**No. Exceed**	**% Exceed**	**No. Obs**	**No. Exceed**	**% Exceed**
Dissolved Iron (Fe)	Maximum	64	3	4.69	123	5	4.07
Fluorine (F)	Maximum	61	1	1.64	438	0	0.00
Manganese (Mn)	Maximum	90	0	0.00	461	9	1.95
Ammonia (NH_3)	Maximum	41	0	0.00	144	0	0.00
Nitrate-Nitrite (NO_2+NO_3)	Maximum	62	0	0.00	464	0	0.00
Total Dissolved Solids (TDS)	Maximum	36	0	0.00	144	2	1.39

Green – Parameter is not a problem *Yellow – Potential problem parameter* *Red – Problem parameter*

The results indicate dissolved iron, manganese, and total dissolved solids (TDS) as potential problem parameters. On the pages that follow, Figures 5.2 – 5.4 show the criteria comparison by monitoring location in the Tookany/Tacony-Frankford Watershed. Dissolved iron, prevalent in clay soils, has been identified to exceed the criteria more than 2% of the time in both dry and wet weather. Manganese appears to be a potential wet weather problem, and TDS a potential dry weather problem.

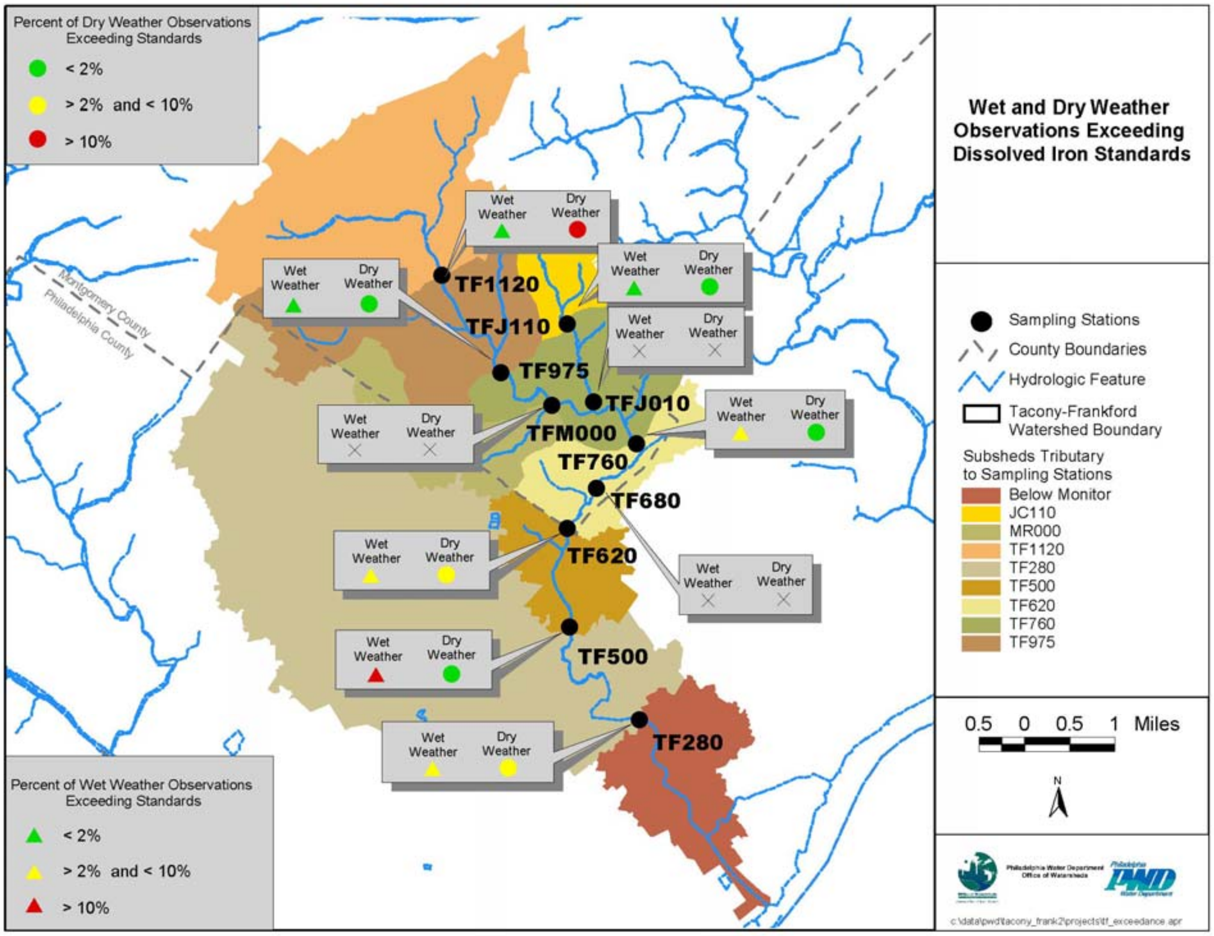

Figure 5.2 Water Supply Criteria for Dissolved Iron

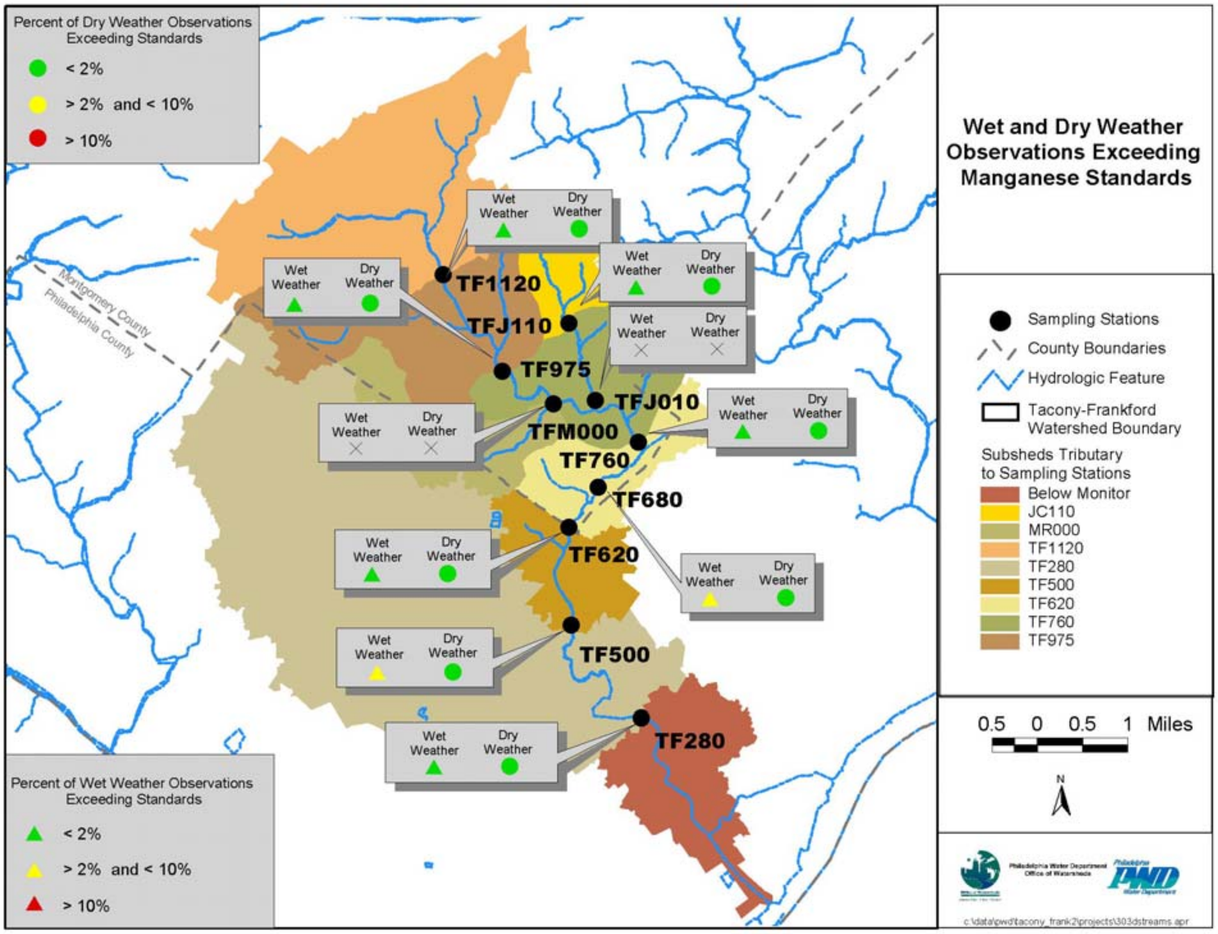

Figure 5.3 Water Supply Criteria for Manganese

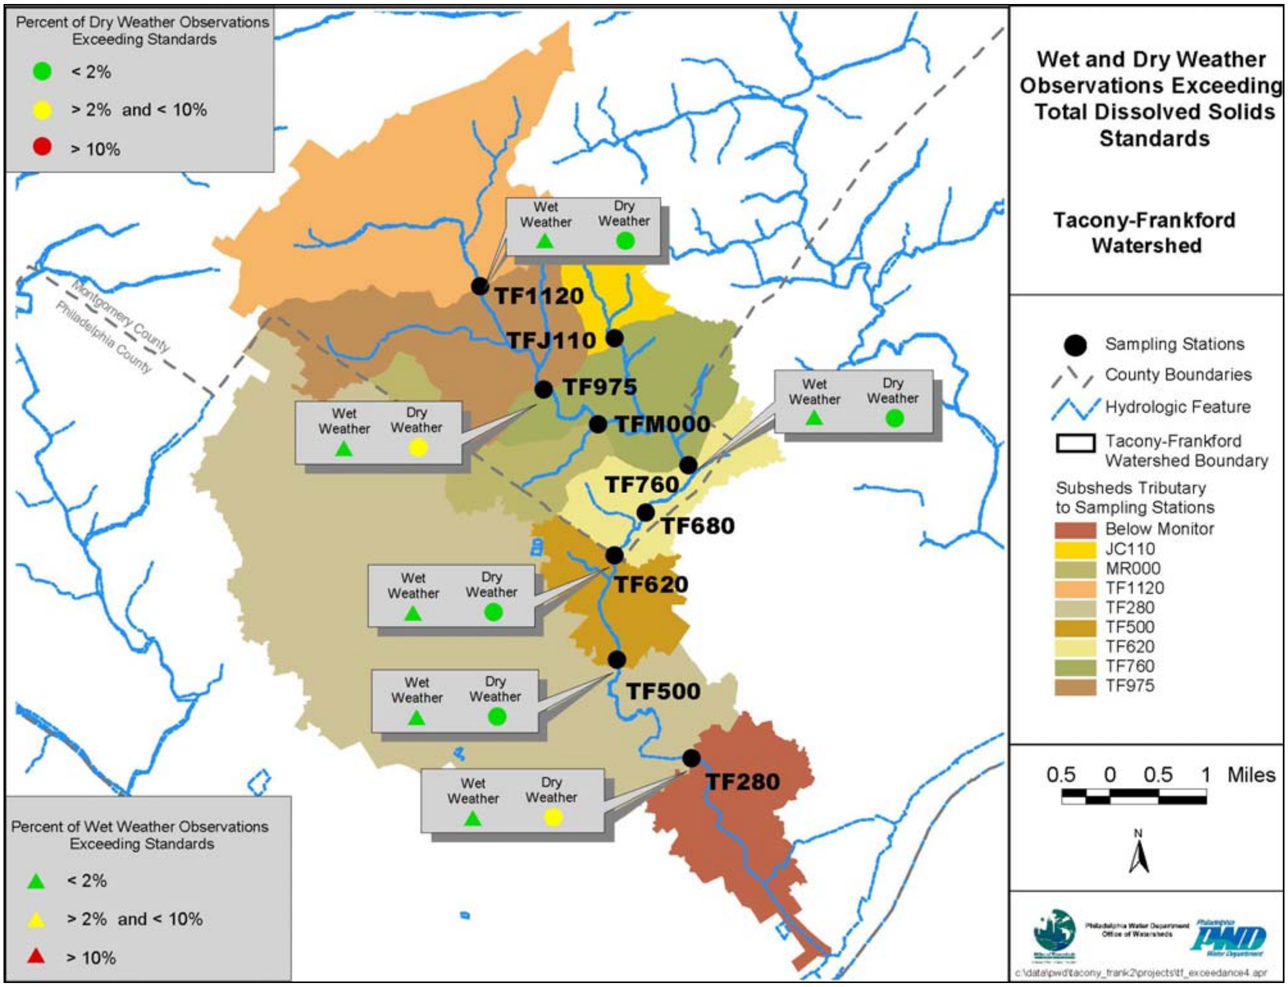

Figure 5.4 Water Supply Criteria for Total Dissolved Solids

5.3.2 Recreation and Fish Consumption

The protected and statewide water use for recreation and fish consumption applicable to the TTF Watershed is water contact sports. The specific water quality criterion for water contact is fecal coliform. Figure 5.5 displays comparisons at the monitoring locations with the criteria throughout the watershed. The data has been compared to the criteria during both swimming and non-swimming seasons. During the swimming season, fecal coliforms are identified as a problem. During the non-swimming season, they are characterized as a potential problem.

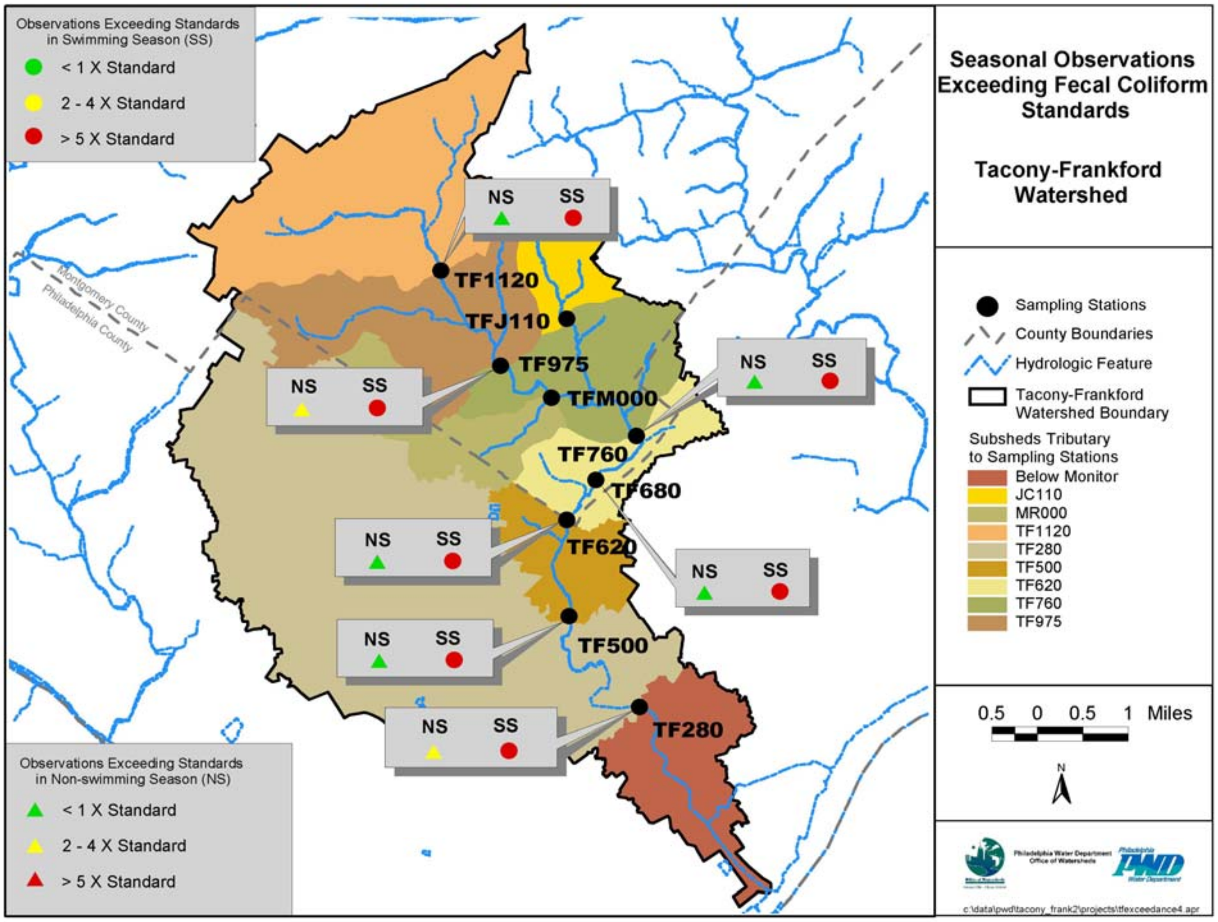

Figure 5.5 Water Contact Criteria for Fecal Coliform

Table 5.4 Summary of Recreation Criteria Exceedances

Season	Site	No. Obs.	No. Exceed	Percent Exc.
Nonswimming	TF500	1	1	100.00
	TF620	7	6	85.71
	TF760	1	0	0.00
	TF975	3	3	100.00
Swimming	TF1120	8	8	100.00
	TF280	7	7	100.00
	TF975	8	8	100.00

5.3.3 Human Health

The relevant human health criteria developed by EPA and PA DEP include exposure to toxic metals from drinking water and fish consumption. No problem parameters were identified among dissolved metals.

Table 5.5 Summary of Human Health Criteria Exceedances

Parameter	Criteria	Dry			Wet		
		No. Obs.	No. Exceed	% Exceed	No. Obs	No. Exceed	% Exceed
Dissolved Cadmium (Cd)	Human Health Maximum	37	0	0.00	118	0	0.00
Dissolved Copper (Cu)	Human Health Maximum	28	0	0.00	5	0	0.00
Dissolved Lead (Pb)	Human Health Maximum	19	0	0.00	N.A.	N.A.	N.A.
Dissolved Zinc (Zn)	Human Health Maximum	27	0	0.00	4	0	0.00
Nitrite (NO_3)	Human Health Maximum	62	0	0.00	464	0	0.00

Green – Parameter is not a problem *Yellow – Potential problem parameter* *Red – Problem parameter*

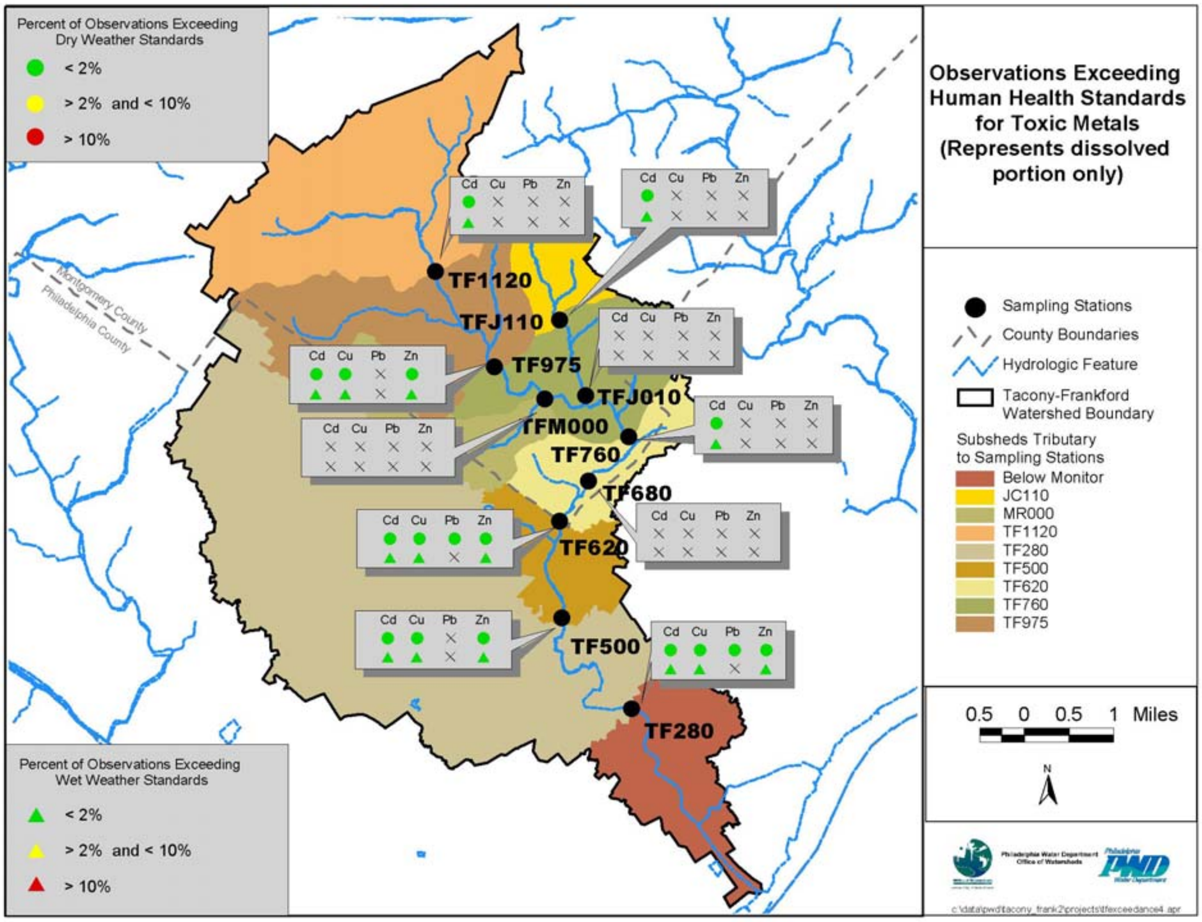

Figure 5.6 Spatial View of Human Health Criteria Exceedances

5.3.4 Aquatic Life

The criteria shown in Table 5.6 are designed to protect reproduction, growth, and survival of aquatic life from acute effects.

Table 5.6 Summary of Aquatic Life Acute Criteria Exceedances

Parameter	Criteria	Dry			Wet		
		No. Obs.	No. Exceed	% Exceed	No. Obs	No. Exceed	% Exceed
Al	Acute Maximum	78	0	0.00	402	77	19.15
Dissolved Cu	Acute Maximum	28	0	0.00	5	3	60.00
DO	Average Minimum (WWF)	59	2	3.39	143	2	1.40
DO	Instantaneous Minimum (WWF)	59	2	3.39	143	0	0.00
Dissolved Iron	Maximum (WWF)	64	3	4.69	123	5	4.07

Green – Parameter is not a problem   Yellow – Potential problem parameter   Red – Problem parameter

The above table suggests that there are a number of problem and potential problem parameters based on water quality criteria related to acute effects on aquatic life.

- During dry weather, only dissolved iron and dissolved oxygen (DO) are flagged as potential problems.
- During wet weather, aluminum and dissolved copper are flagged as problem parameters.
- During wet weather, dissolved iron is flagged as a potential problem.

Table 5.7 lists parameters that have been identified as problems because they exceed aquatic life chronic criteria. Since these are chronic, thus long term, exposure limits, they are not split into dry weather and wet weather results.

Table 5.7 Summary of Aquatic Life Chronic Criteria Exceedances

Parameter	Standard	No. Observations	No. Exceed	% Exceed
Al	Chronic Maximum	480	271	56.46
Dissolved Cd	Chronic Maximum	155	0	0.00
Dissolved Cu	Chronic Maximum	33	5	15.15
Dissolved Pb	Chronic Maximum	19	0	0.00
Dissolved Zn	Chronic Maximum	31	0	0.00

Green – Parameter is not a problem   Yellow – Potential problem parameter   Red – Problem parameter

Table 5.6 (at top of previous page) and Figure 5.7 (below) show the results of dissolved oxygen measurements. Both the figure and table suggest that, in general, dissolved oxygen is not a problem upstream of TF280. Within the tidal portion of the watershed below TF280, insufficient data exists to properly characterize the potentiality of a DO problem.

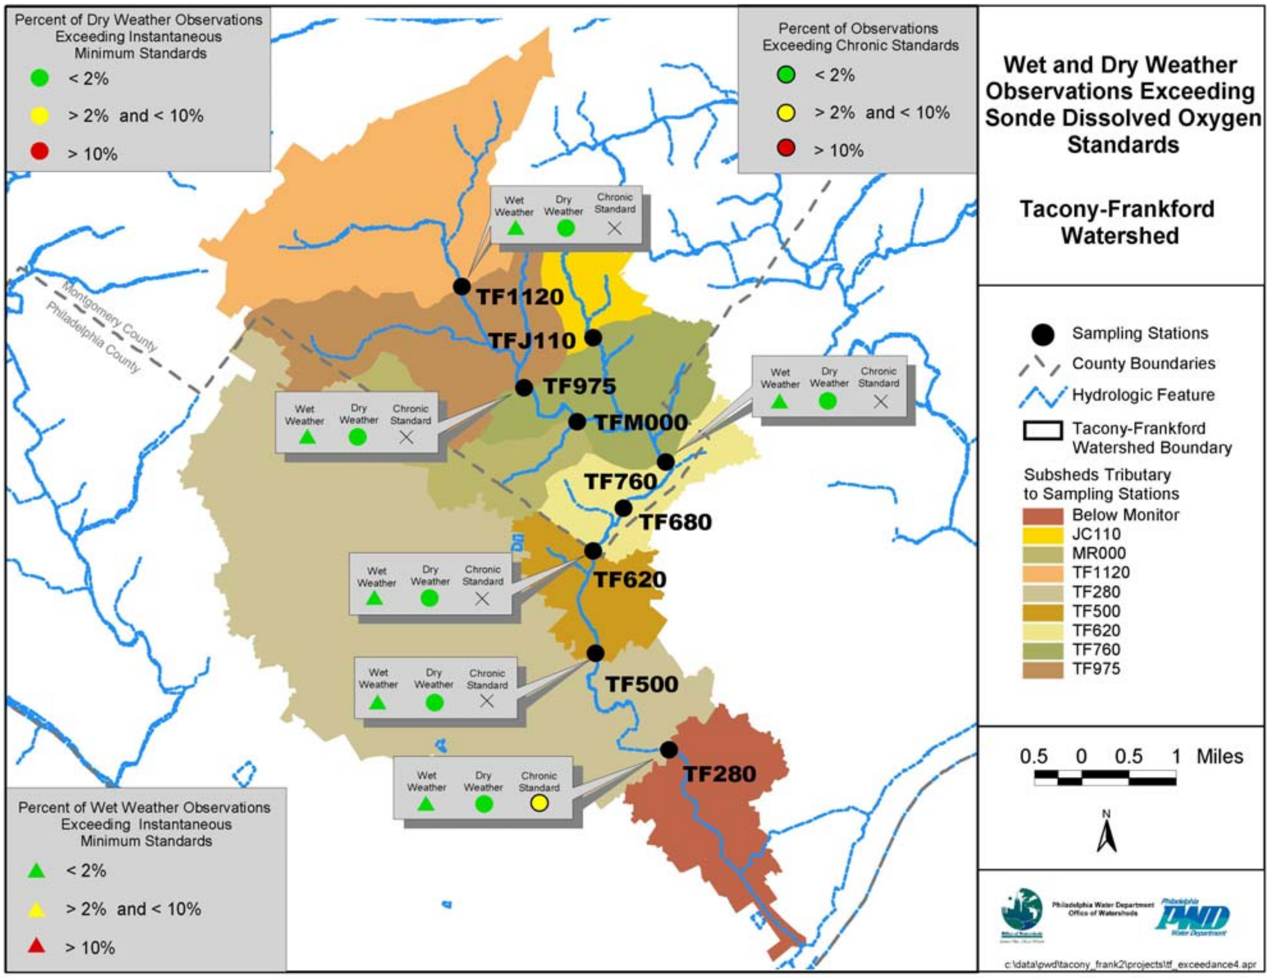

Figure 5.7 Spatial View of Dissolved Oxygen Exceedances in Wet and Dry Weather

Figure 5.8 shows dissolved oxygen measurements taken with one of the Sondes designed to take continuous DO measurements. Although the overall DO levels are adequate in this figure, the figure does point out a rather wide, diurnal fluctuation in DO, in this case over 6 mg/l. This suggests a great deal of biological activity. Although insufficient data exist at this point to indicate the fluctuations in DO are a potential problem, further investigation is important to determine the cause of these unusually wide, short term variations.

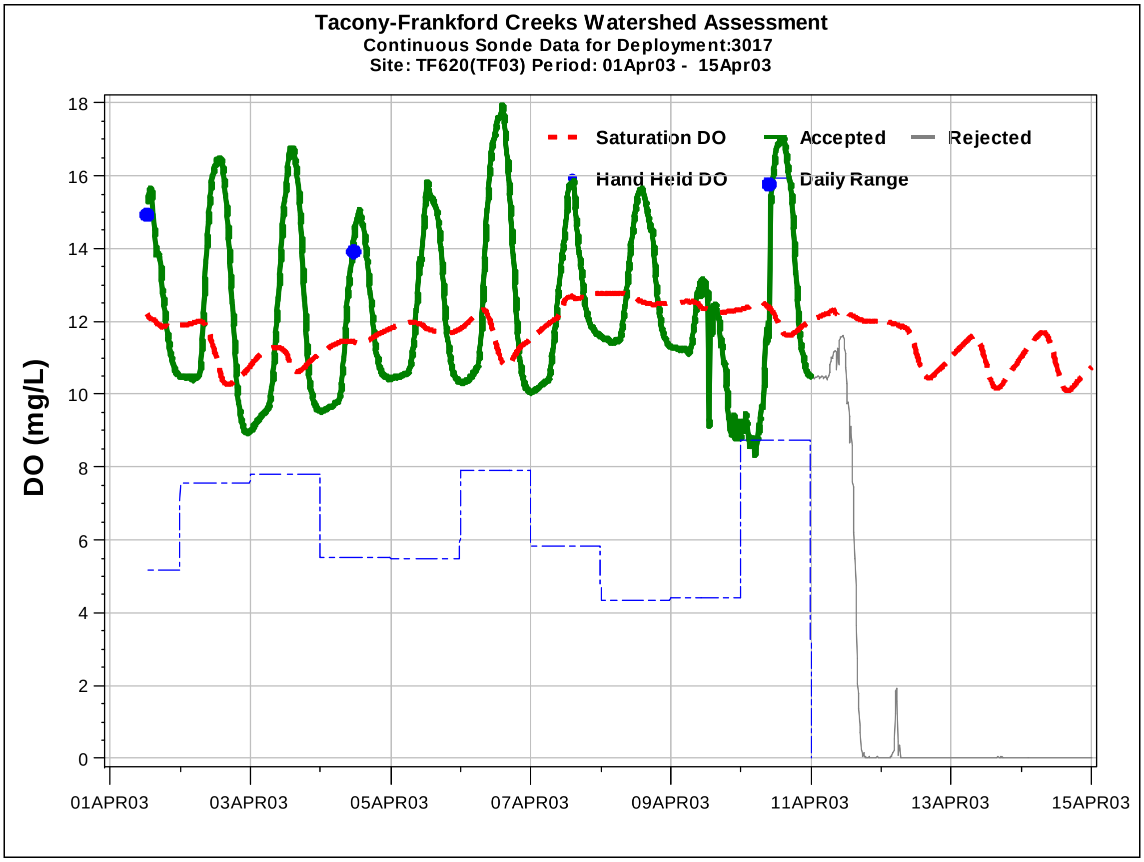

Figure 5.8 Time Series Plot of Dissolved Oxygen Exceedances in Wet and Dry Weather

Finally, Table 5.8 lists several other criteria that are related to aquatic life, but have no set regulatory limits. Criteria were established for this study as "flags of potential problems" using values relating to medians found through the U.S. EPA relevant to Ecoregion IX, subregion 64. As shown in the table, Chlorophyll A is high during both wet and dry weather, and is probably related to the above mentioned problem of large diurnal swings in DO. The nutrients nitrogen and phosphorus are also fairly high, possibly contributing to excessive algal growth. Turbidity and Total Suspended Solids are also quite high during wet weather, suggesting that bank and channel erosion may be occurring, as well as high wash loads of sediments in stormwater during rain events.

Table 5.8 Summary of Aquatic Life Criteria Exceedances

Parameter	Criteria	Dry			Wet		
		No. Obs.	No. Exceeds	% Exceed	No. Obs	No. Exceed	% Exceed

5.4 Potential Problem Parameter Summary

Based on the analysis, the problem and potential problem parameters are summarized below. The problem parameters are those constituents for which more than 10% of the samples exceed the standard. Parameters where the standards (or reference values) were exceeded over 2% of the time for all samples throughout the Tookany/Tacony-Frankford Watershed are listed as potential problems. Also, at the least, over 10% of parameter samples at one sampling location must exceed the standard to be considered a problem parameter.

In Table 5.9, the problem and potential problem parameters are listed by category. They are also broken down as either wet or dry weather problems, if applicable. For the metals, the listing is further broken down for chronic versus acute criteria.

5.5 Stream Ecology

The biological community of the TTF Watershed is heavily impacted by its urban surroundings. The impaired state of the creek is a result of habitat deterioration and water quality degradation. High levels of urbanization and development, and poor stream bank stability and flood control deeply influence the creek itself and the entire watershed. These factors have resulted in creek channelization, further inducing erosion and sedimentation problems. Natural water flows have been redirected to storm sewers and natural land surfaces replaced by block after block of impervious surfaces. Due to the changes in the hydrologic profile of the stream and watershed, storm events result in more concentrated runoff and cause more damage than they once did. Instead of percolating into the ground, stormwater is collected and rushed into an already unstable creek where it scours banks, fills pools, and covers riffles. The rushing water strips soil from the banks and deposits some of it over the embedded cobbles and takes the rest to the Delaware River, all the while holding on to the chemicals and pathogens collected on the city streets and in sewers. Figure 5.9 displays the results of the biological and habitat assessments.

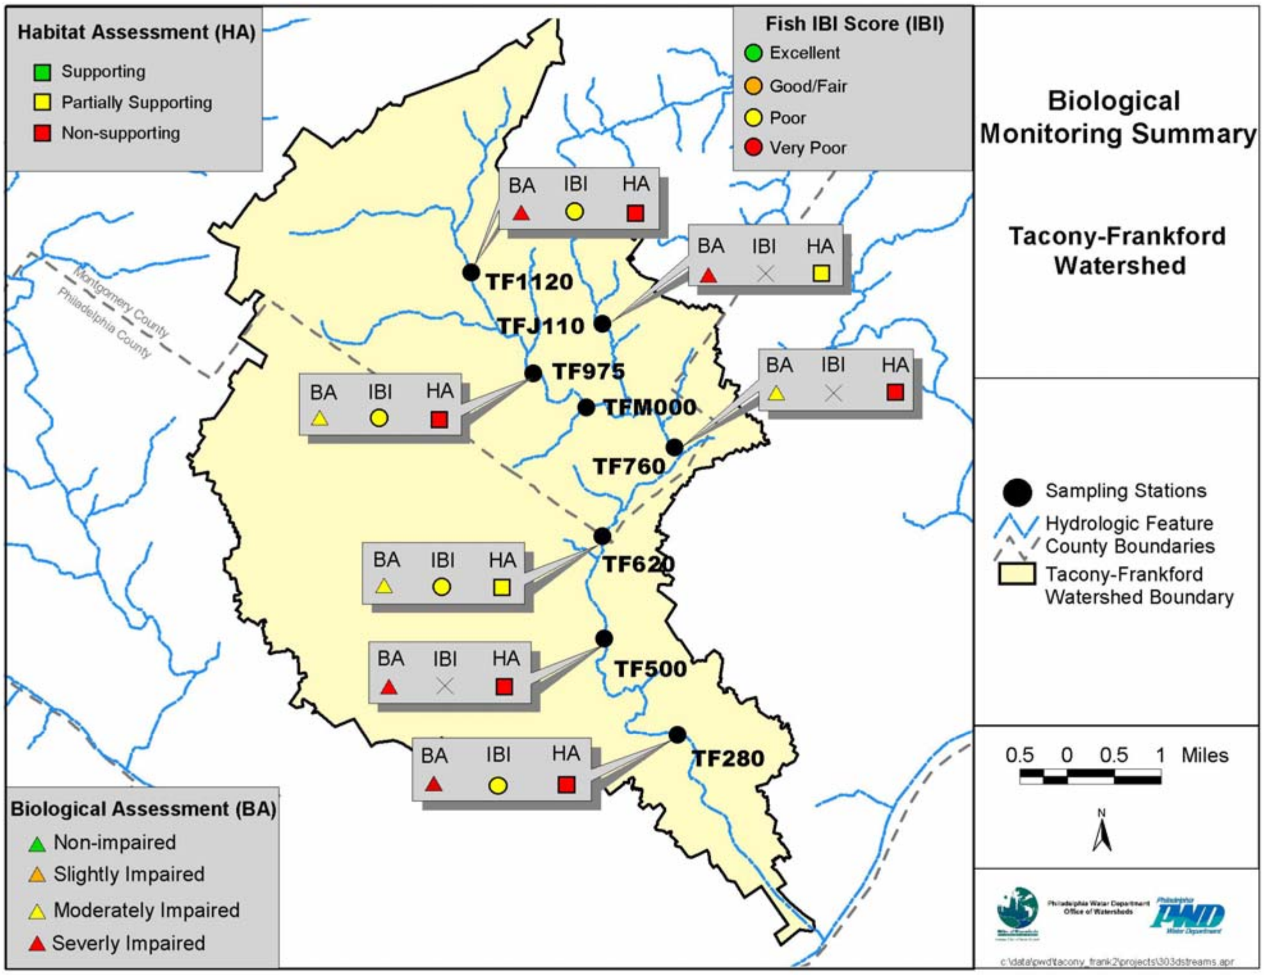

Figure 5.9 Tookany/Tacony-Frankford Biological Monitoring Summary

Biological monitoring indicates that the entire watershed suffers from impaired aquatic habitat and does not meet its designated use as a warm water fishery. As a result, the whole length of the Tacony-Frankford Creek and its tributaries were listed in PA DEP's 303d list of impaired waters in 1999. This impairment is due to severe water flow fluctuations, habitat alteration, point and non-point source (NPS) pollution from urban development, hydro-modification, and combined sewer overflows (CSOs) (PA DEP 2001). The tidal portion of the Frankford Creek remains unassessed because the biological assessment protocol is not applicable to tidal stream segments.

Habitat assessments of the Tacony-Frankford Watershed have determined much of the area to be non-supporting of a biological community. Eight sites within the watershed were assessed based on environmental features such as available vegetation and vegetative cover, riparian zones, stream bank stability, stream flow, riffles, pools, and other factors. Of these eight sites, six were determined to be lacking the attributes needed to support aquatic communities of organisms, while the other two were determined only capable of partially supporting aquatic communities.

Benthic macroinvertebrates rely heavily on stream riffles for at least part of their life cycle. Clinging to life in a riffle requires various adaptations, and most macroinvertebrates are not further prepared for the extreme hydrologic fluctuations that can occur in a channelized creek such as the Tookany/Tacony-Frankford. Increased stream velocities and sediment loads from eroding stream banks disrupt the benthic environment by alternately scouring the stream bottom of appropriately sized cobble substrate and burying those cobbles in sediment. Storm events lead to decreased species richness and evenness, which in turn changes the dynamics of feeding groups within the communities. Specialized feeders are greatly diminished, and generalists such as gatherer/collectors dominate the feeding community. Organisms well adapted to hydrologic extremes and to pollution also begin to dominate the communities. Of the eight sites evaluated for macroinvertebrate life, five were found to be severely impaired, and three were classified as moderately impaired. Only two of the sites were categorized as partially supporting of macroinvertebrate habitats, while the other six are non-supporting.

Like the benthic macroinvertebrate community, fish communities rely heavily on various habitats within a stream reach. An altered hydrologic profile in the stream leads to fewer offspring and decreased diversity in the fish community. The extreme flow conditions disrupt nesting habitats and routines for many species. Fish are also unable to rely on the presence of the calm pools and runs they often inhabit. A fish assessment of the Tookany/Tacony-Frankford Creek collected a total of 14 taxa, all of which being at least moderately tolerant of pollution. One of the sites evaluated had only three species of fish present. The low diversity and species richness is indicative of poor habitat and stream health.

5.6 Wetlands Assessment

As discussed in Section 4.5.2 (Indicator 13), the Philadelphia Water Department conducted an extensive wetlands assessment along the riparian corridor of the Tookany/Tacony-Frankford Watershed. Wetland indicators were used to identify possible wetland locations (e.g., soils, hydrology). Over 100 potential wetland locations were field evaluated, and 24 existing wetlands were identified. These wetlands were characterized using the Oregon Freshwater Wetland Assessment method, which evaluates how effectively a wetland performs the following functions: Wildlife Habitat, Fish Habitat, Water Quality, and Hydrologic Control.

The existing wetlands ranged in size from 0.01 to 2.5 acres. In total, only 15 acres of wetland (excluding open water) remain within the 685 acres that constitute the undeveloped riparian corridor of the Tookany/Tacony-Frankford Watershed, and most of those wetlands exhibit degraded wetland functions as a result of hydrologic disconnection from the waterways, encroachment, and invasive vegetation.

The most significant issues affecting wetlands are:

- Many wetlands have been lost to development;
- Remaining wetlands are not sufficiently inundated because stormwater is piped directly to streams;
- Wetlands are no longer hydrologically connected to the primary waterway;
- Wetlands have suffered encroachment and disturbance from urbanization;
- Wetland vegetative and wildlife diversity has been compromised by disturbance;
- Remaining wetlands are extensively compromised in terms of their water quality improvement function.

The extent of disturbance to the remaining wetlands is indicated by the degree to which the wetland functions have been degraded and the degree of human disturbance. The wetland field investigation produced ratings of the degree to which wetland functions have been compromised and the extent of human disturbance to the wetlands sites. This information is summarized in the tables and figures below.

5.7 Potential Problem Parameters and Planning Implications

Based on the comparisons to water quality criteria, the problem and potential problem parameters have been identified for the Tookany/Tacony-Frankford Watershed. Table 5.12 summarizes these parameters.

The Tookany/Tacony-Frankford Watershed is faced with many challenges. Stormwater outfalls (SWOs) and combined sewer overflows (CSOs) have exacerbated problems within the watershed. Poor water quality and diurnal variations in levels of dissolved oxygen are added stresses on local fauna. Insufficient habitat combined with the highly variable stream flow makes it difficult to establish a diverse and healthy biotic community. An urban watershed must overcome many obstacles to establish meaningful habitat within and alongside a stream.

Table 5.13 (below) lists the indicators that directly link to water quality and aquatic habitat. The water quality sampling locations have been graded according to sampling results and watershed assessments. For most of the Tookany/Tacony-Frankford Watershed, the indicators have been marked as poor or very poor. Dissolved oxygen, important to maintaining aquatic life, has been identified as a potential problem in the downstream portion of the watershed area.

Results of the water quality sampling indicate that the water quality of the Tookany/Tacony-Frankford is impaired, with the problems associated primarily with wet weather conditions. Some problems have been identified during dry weather. Sources of bacterial contamination during dry weather may include inappropriate or illicit discharges from storm or sanitary sewerage systems. Detection of these sources is valuable to the management goals of the Tookany/Tacony-Frankford Watershed. Dry weather concentrations of nutrients may be attributed to treated wastewater effluent, over-watering of lawns and gardens, pet waste, and failing septic tanks.

In wet weather, the model-estimated pollutant loadings have identified contributions from different sources. Estimated annual pollutant contributions for the Tookany/Tacony-Frankford Watershed are discussed in Section 4.4. Permitted industrial and municipal point source discharges make up less than 1% of annual streamflow in both systems. SSOs are thought to occur in both watersheds but have not been well documented to date.

Section 6
Causes of Impairment

This section discusses the causes of the various watershed problems identified through field study, stakeholders input, modeling, and data analysis. It forms the link between the problem analysis presented in Section 5, and the identification of alternative solutions or "management options" presented in Section 7.

There are seven types of primary problems to be addressed. These include:

- Trash and dumping
- Erosion, sediment accumulation, and flow variability
- Instream sewer odors
- Lack of healthy riparian habitat
- Poor instream habitat and biological impairment
- Impaired wetlands
- Water quality concerns (metals, TSS, fecal coliform, DO)

In most cases, field studies and data analysis have identified one or more causes for the problem or impairment. In some cases, particularly regarding dissolved oxygen, further studies will be required before a full understanding of the problem is achieved. The high priority problems and their probable causes are discussed below, with recommendations for additional study where appropriate.

6.1 Trash and Dumping

Cause

The source of litter and dumped material is not hard to establish. Litter reaches the stream through careless behavior resulting from trash and litter accumulation in the streets. If not controlled, this accumulation will wash into the storm sewers or combined sewers and eventually be discharged into the streams. Once in the stream, it can get trapped along banks, or build up near flow obstructions such as bridge supports. In general, littering is not an intentional activity, but results from carelessness or lack of concern for its effect on the environment. Dumping, however, is a more deliberate act, and occurs when people gain access to the stream and dump waste material from the home or business directly into the stream. Dumping is generally done to avoid the costs associated with proper disposal. In either case, the cause of the buildup of litter and trash in the stream is clear, and can only be addressed through education and enforcement to eventually modify the behavior of people living and working in the watershed.

Further Studies

Some further study will be required to identify points along the stream that are most easily accessible by vehicle, and where illegal dumping has been a common practice in the past.

6.2 Erosion, Sediment Accumulation, and Flow Variability

Cause

Erosion of the channel bed and along the streambanks has been identified as a problem in many areas of the watershed. High levels of urbanization and development and poor stream bank stability deeply influence the Tookany/Tacony-Frankford Creek. Natural water flows from some portions of the creek have been redirected to storm sewers and replaced by block after block of impervious surfaces. Due to the changes in the hydrologic profile of the stream and watershed, storm events result in greater amounts of runoff and cause more damage than they once did. Instead of percolating into the ground, stormwater is collected and rushed into an already unstable creek where it scours banks, fills pools, and covers riffles. The rushing water strips soil from the banks and deposits some of it over the embedded cobbles and takes the rest to the Delaware River, all the while holding on to the chemicals and pathogens it collected on the city streets and in the sewers.

The cause of erosion can be traced primarily to the above mentioned flow variability, particularly to bankfull flow conditions that occur more frequently than in more natural watersheds due to the urbanized nature of the Tookany/Tacony-Frankford watershed. Sediment buildup can be caused either by streambed and streambank erosion, or by sediment washing into the creek from stormwater discharges. Note that flow variability has been identified as both a problem in itself, and as the cause of erosion and poor instream habitat (discussed below).

Further Studies

The flow variability is well established and understood, and does not require additional studies. The erosion problem has been generally identified through stream assessments. Further studies will be required, however, to prioritize areas undergoing erosion, and to more exactly identify the cause of erosion or sediment buildup for each reach of the river where erosion or deposition is occurring. These studies will be carried out during conceptual design of stream restoration measures.

6.3 Instream Sewer Odors

Cause

Sewer odors occur during dry weather when sewer lines leak into the stream, or when waste lines from homes or businesses are cross-connected to storm sewers in areas where the sanitary and storm sewer systems are separate. Odors also occur during wet weather, with the cause identified as combined sewer overflows (CSOs), or in areas of separate storm and sanitary sewers, through sanitary sewer overflows (SSOs).

Further Studies

Although the causes are well known, further studies will be required to pinpoint the location and cause of all dry weather sewer discharges in separate sewered areas, and to identify SSOs and opportunities for reduced CSOs during wet weather.

6.4 Lack of Healthy Riparian Habitat

Cause

The entire length of the Tookany/Tacony-Frankford Creek has been assessed, and the existence or absence of riparian buffers noted. The cause is usually obvious: Either development has encroached on the riparian buffer, leaving little or no room for a vegetated buffer, or the riparian area is open but poorly managed.

Further Studies

Additional studies will be required in developing a riparian buffer improvement program. These studies will primarily involve the identification of land ownership of riparian areas.

6.5 Poor Instream Habitat and Biological Impairment

Cause

Poor instream habitat has been identified as both a problem itself, as well as the cause of biological impairment found throughout the watershed. Stream channels in the Tookany/Tacony-Frankford Watershed exhibit many effects of urbanization, including over-widening, erosion, loss of sinuosity, loss of the floodplain, loss of stream connection, channel modification, and loss/degradation of aquatic habitat. Biological monitoring indicates that the whole Tookany/Tacony-Frankford Watershed suffers from impaired aquatic habitat and does not meet its designated use as a warm water fishery. As a result, the whole length of the non-tidal Tookany/Tacony-Frankford Creek and its tributaries were listed in PA DEP's 303d list of impaired waters in 1999. This impairment is due to severe water flow fluctuations, habitat alteration, point and non-point source pollution from urban development, hydromodification, and combined sewer overflows (PA DEP 2001). The tidal portion of the Frankford Creek remains unassessed because the biological assessment protocol is not applicable to tidal stream segments.

The biological community of the Tookany/Tacony-Frankford Watershed is heavily impacted by its urban surroundings. The impaired state of the creek is a result of habitat deterioration due to urbanized stormwater flow patterns and/or water quality degradation.

Benthic macroinvertebrates rely heavily on stream riffles for at least part of their life cycle. Clinging to life in a riffle requires various adaptations, and most macroinvertebrates are not prepared for the extreme hydrologic fluctuations that can occur in a channelized creek such as the Tookany/Tacony-Frankford. Increased stream velocities and sediment loads from eroding stream banks are disrupting the benthic environment by scouring the stream bottom of appropriately sized substrates. The cobble substrate has limited interstitial space, often filled by finer materials, for benthic macroinvertebrates to thrive. Storm events lead to decreased species richness and evenness, which in turn changes the dynamics of feeding groups within the communities. Specialized feeders are greatly diminished, and generalists such as gatherer/collectors dominate the feeding community.

Like the benthic macroinvertebrate community, fish communities rely heavily on various habitats within a stream reach. An altered hydrologic profile in the stream leads to fewer offspring and decreased diversity in the fish community. The extreme flow conditions disrupt nesting habitats and routines for many species. Fish are also unable to rely on the presence of the calm pools and runs they often inhabit.

Further Studies

Additional detailed studies will be required to better understand the degree of impairment and to pinpoint the causes of impairment for each stretch of the stream system. It is also critical to better understand the relative importance of the habitat impairment and the low dissolved oxygen conditions found in the downstream areas of the watershed as it relates to impaired benthic macroinvertebrate and fish communities. These studies must be completed prior to making detailed recommendations on habitat improvement.

6.6 Impaired Wetlands

Cause

Wetland assessments have identified the loss of wetlands and the impairment of remaining wetlands as a problem. The remaining wetlands were evaluated for their value as wildlife and fish habitat, and for their potential to improve water quality (nutrient and toxicant reduction) and temper the hydrologic regime (flood flow). Nearly all wetlands in the watershed exhibit impaired functions that indicate extensive disturbance and deterioration. Urban and suburban development has resulted in the piping of historic streams, destruction of wetlands, and deforestation and modification of historic floodplains. Stormwater is piped directly to waterways rather than flowing overland through vegetation, wetlands, and woodlands. Also, because stormwater runoff frequently flows over impervious surfaces, and is then piped to the streams, the flow and volume of runoff is intensified. Because most stormwater is piped directly to the waterways of the watershed, there is no longer a source of water to maintain many of the wetlands that once existed.

Further Studies

No further studies are anticipated, beyond those associated with the conceptual design of wetland enhancement or wetland creation at specific sites within the watershed.

6.7 Water Quality Concerns (Metals, TSS, Fecal Coliform, DO)

Cause

The primary water quality concerns were identified as elevated concentrations of some metals and Total Suspended Solids (TSS), particularly during wet weather events, high fecal coliform counts, particularly in wet weather, and low dissolved oxygen (DO) in downstream areas of the creek. The primary sources of contaminants are wet weather flows from separate and combined sewers, and some sewage flows during dry weather due to the connection of waste lines to a separate storm sewer, or to leaking combined sewer lines.

Stormwater running off of impervious areas can carry pollutants to the stream through the storm sewers and, during overflow events, through the combined sewer. Stormwater-borne pollutants can include litter, nutrients, metals, fecal coliform from pet wastes, pesticides used on lawns, and sediment. Non-point source pollution poses a threat to the water quality in the Tookany/Tacony–Frankford creek because of the volume of stormwater runoff and the concentrations of pollutants found in the stormwater.

A model was used to estimate runoff quantity and quality in storm, sanitary, and combined sewer systems and from each land use type within the subwatersheds. The list of pollutants simulated using the model included parameters such as nitrate and phosphorus, total suspended solids, heavy metals, and BOD (biological or biochemical oxygen demand). Although the source of pollutants is well established, the model results helped identify areas where stormwater runoff or pollutant loads are particularly high and in need of control.

Using lead and copper to represent metals in the Tookany/Tacony-Frankford watershed, the model-generated stormwater runoff loads are compared with the wet weather exceedance of the standards in Figures 6.1 and 6.2. The results show areas where higher loads are contributing to degraded stream water quality during wet weather, however, the lack of wet weather sampling data does not allow for comparison with runoff loads.

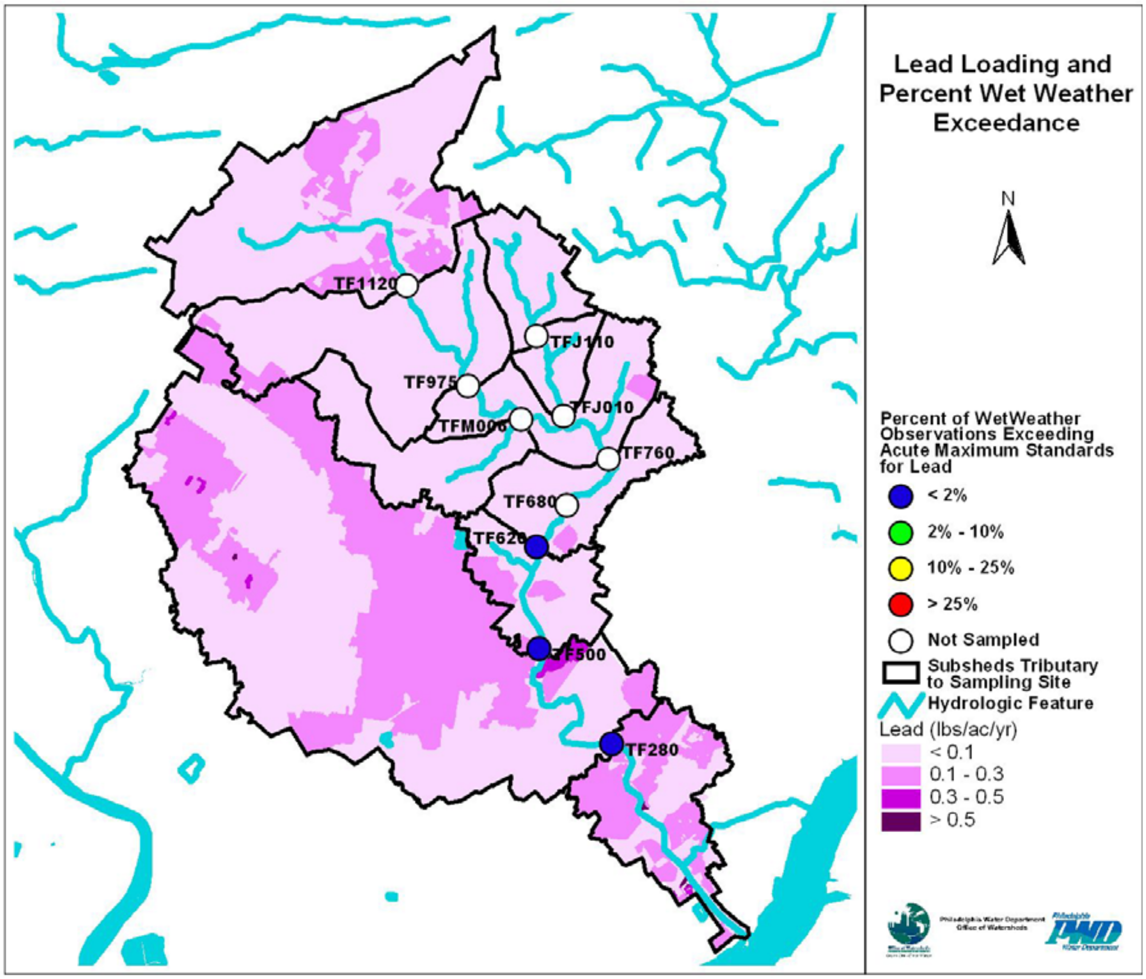

Figure 6.1 Lead Loading

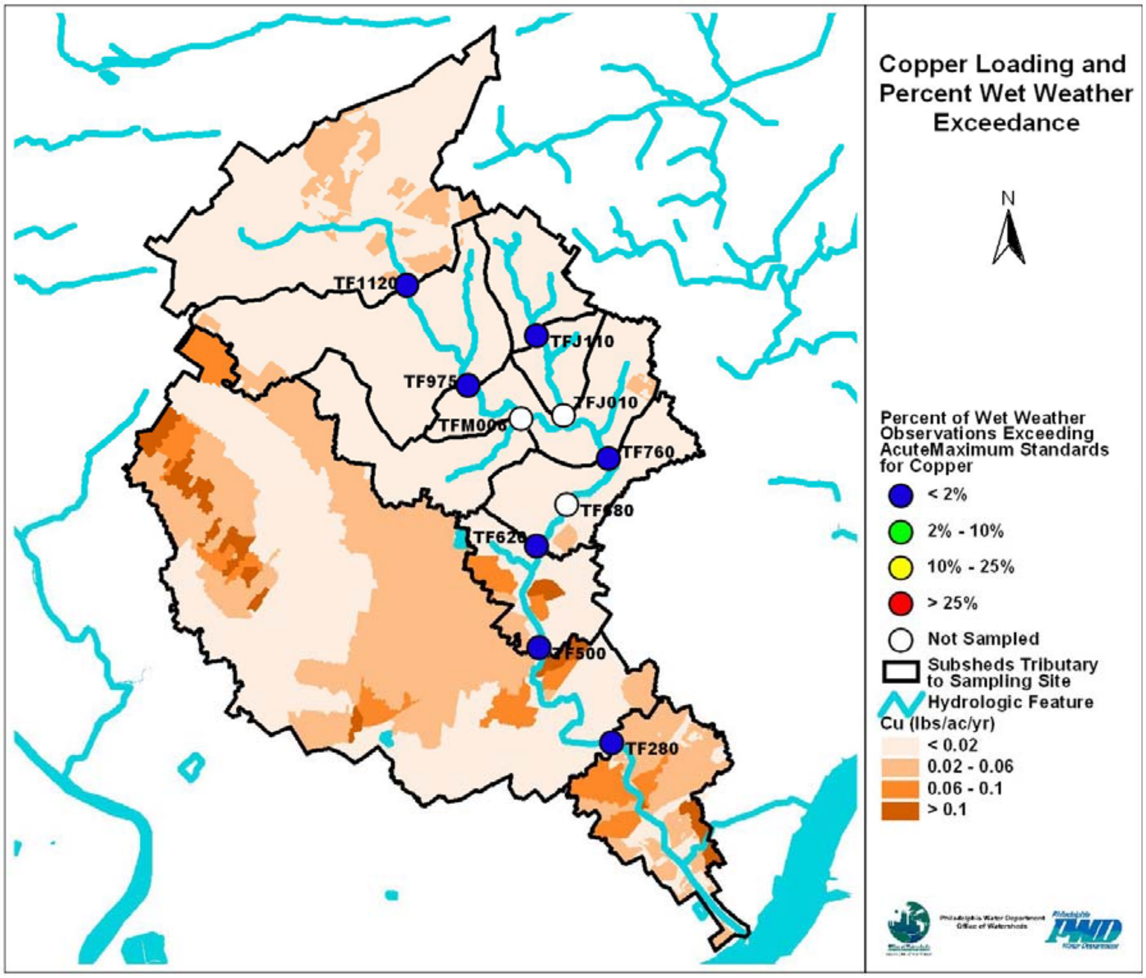

Figure 6.2 Copper Loading

CSO and stormwater discharges are the dominant sources of fecal coliform in the Tookany/Tacony-Frankford Watershed during wet weather. Figure 6.3 displays the spatial distribution of runoff loads for fecal coliform compared with the wet weather water quality. As indicated from the water quality data, fecal coliforms are a problem throughout the watershed.

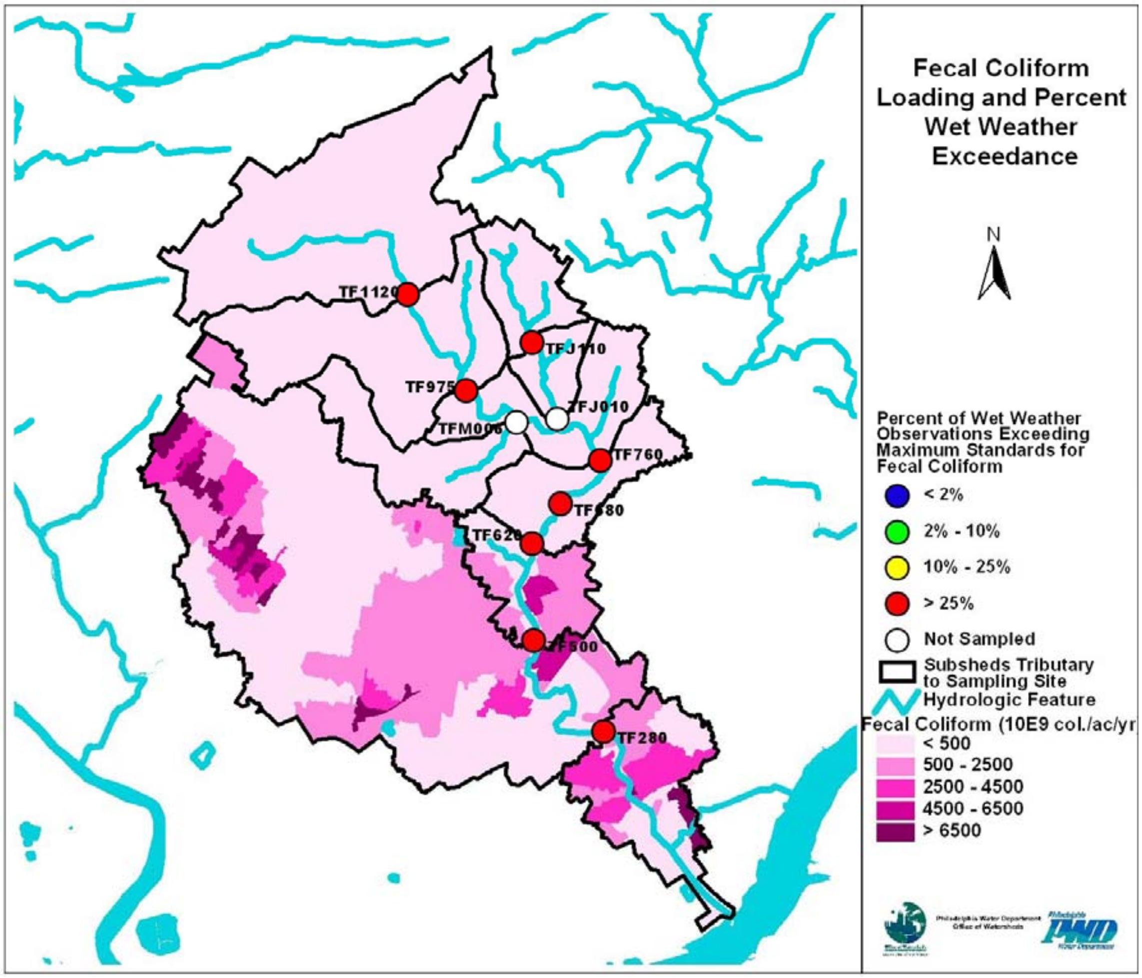

Figure 6.3 Fecal Coliform Loading

Figure 6.4 shows the model-estimated TSS loading and the wet weather sampling results. The pattern of sample results and model-estimated loads is a little less clear for TSS than for some of the other pollutants, with exceedances occurring both upstream and downstream, and loading more heavily weighted toward the urbanized, downstream portion of the watershed. This may indicate that stormwater runoff is not the only source of sediment, and that instream channel and bank erosion may also be a significant source. Additional studies would be necessary to further pinpoint the sources.

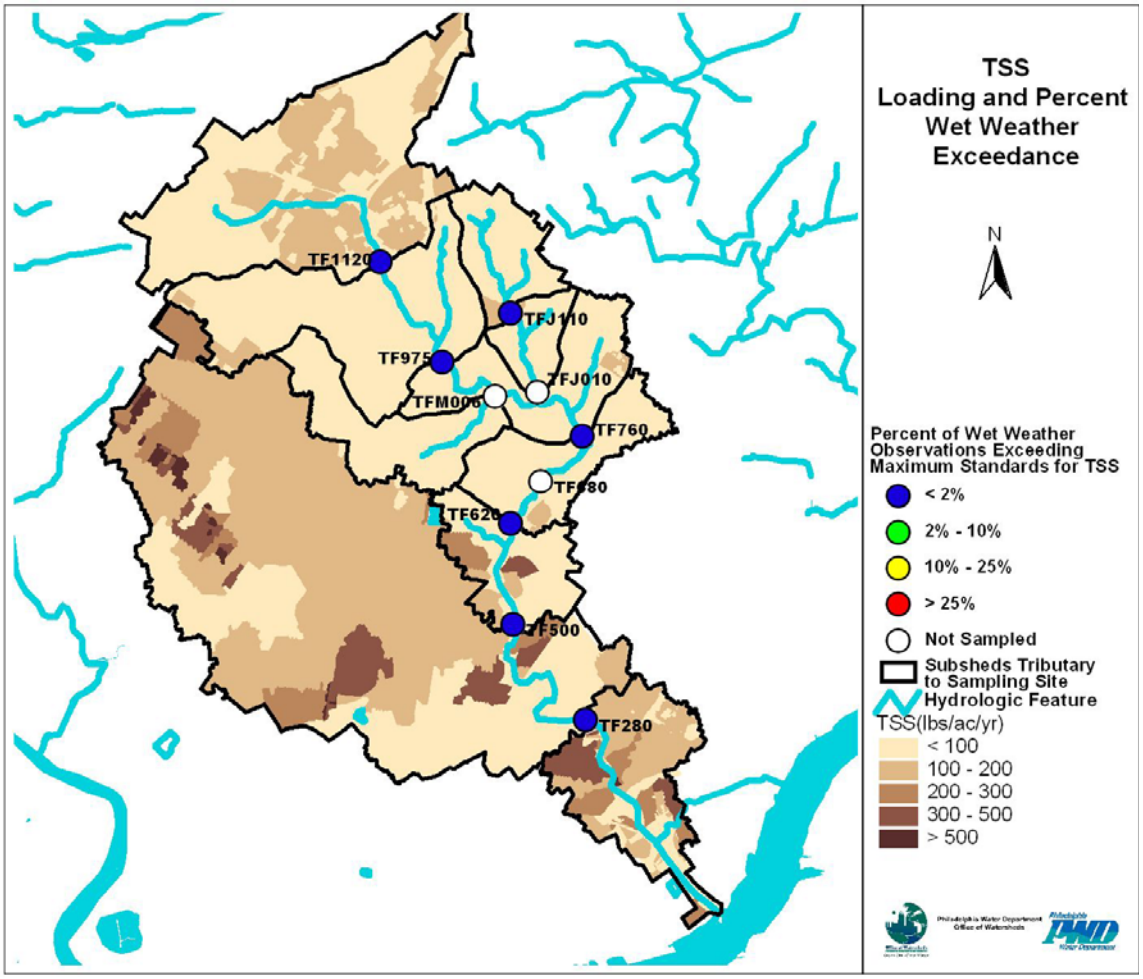

Figure 6.4 Total Suspended Solids Loading

CSOs are the largest source of pollutants associated with urban and suburban runoff, including nutrients such as phosphorus and metals such as lead, copper, and zinc. For the Tookany/ Tacony-Frankford Watershed, stormwater outfalls are a smaller but significant source of these constituents. (Figure 4.20 illustrated the model-estimated contributions for metals and fecal coliforms as percentages of the total estimated load.)

Low dissolved oxygen has been identified as a potential problem in the downstream section of the creek. In addition, unusually high diurnal fluctuations in DO have also been observed in the downstream sections. There are several potential causes of low DO. These include:

- High BOD loading during dry and wet weather;

- The existence of scour pools or pools upstream of dams that do not flush frequently enough, allowing anoxic conditions to occur;
- Excessive growth of attached algae that alternately produce and consume oxygen resulting in large diurnal fluctuations in DO;
- The buildup of organic material in the sediment that exerts high oxygen demand.

BOD (biological or biochemical demand) loading is a concern in the watershed. The BOD load estimates are shown in Figure 6.5. Sediments may store BOD, which may become re-suspended during storms, moving the area of DO deficit further downstream. Generally, the loads carried to the stream by stormwater are highest further downstream in the watershed.

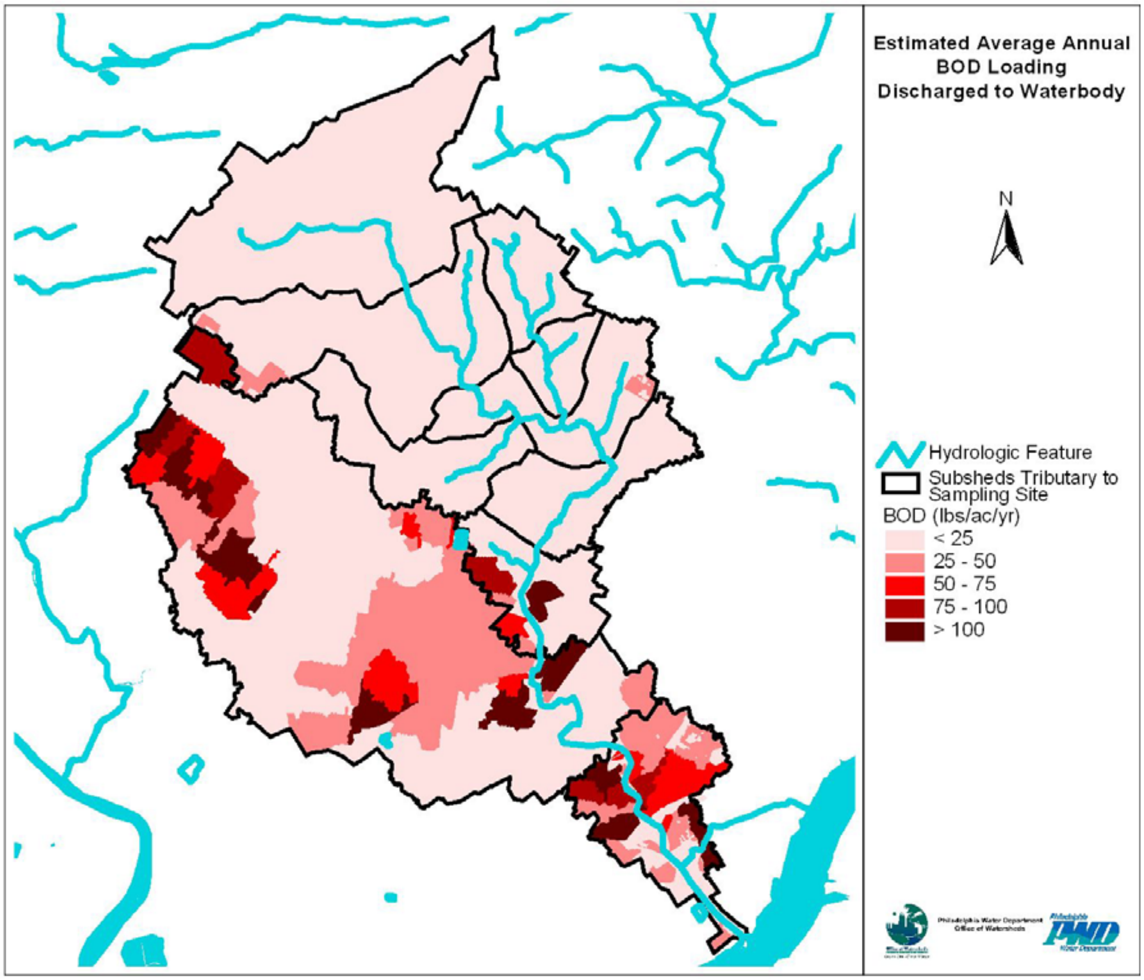

Figure 6.5 Total BOD Loading

Low DO is suspected in the area upstream of the dam at Adams Avenue. This may be caused by a combination of a deep pool that does not flush frequently, and high sediment oxygen demand.

<u>Further Studies</u>

The causes of TSS exceedances have been identified as stormwater discharges, CSOs, and instream erosion. The relative contributions of each, however, have not been adequately characterized. This will require additional analysis once the stream assessment data are available, combined with some additional modeling.

The causes of suspected DO problems in the Tookany/Tacony Frankford Watershed are not yet sufficiently understood, and will require further studies.

Studies should be carried out to:

- better understand the impact of attached algae on DO fluctuations (water quality modeling and field studies);
- identify areas where plunge pools and dams may be the cause of localized occurrences of low DO;
- assess the sediment oxygen demand and the BOD in the water column to better understand the relative contributions of each to low DO; and
- better assess sources of BOD during both dry and wet weather.

Section 7
Development and Screening of Management Options

This section summarizes a comprehensive list of stormwater and watershed corrective measures, or "management options," that the TTF Watershed Partnership judged to be potentially applicable to their watershed. This list serves as the starting point for the screening and evaluation steps (Section 7.2) that lead to the array of recommendations contained in the Implementation Guidelines (Section 8).

7.1 Menu of Options

A large amount of detailed information on these watershed management options is already available from existing sources. Rather than reproducing this information, this section provides references and links to these sources.

The options are grouped under the three targets introduced in Section 2 (with codes listed parenthetically for reference below and in the sections that follow):

Target A: Dry Weather Water Quality and Aesthetics
- Regulatory Approaches (AR1,2)
- Public Education and Volunteer Programs (AP1-3)
- Municipal Measures (AM1-7)
- Enhancing Stream Corridor Recreational and Cultural Resources (AO1)
- Monitoring, Reporting, and Further Study (AMR)

Target B: Healthy Living Resources
- Channel Stability and Aquatic Habitat Restoration (BM1-5)
- Lowland and Upland Restoration and Enhancement (BM6-9)
- Monitoring, Reporting, and Further Study (BMR)

Target C: Wet Weather Water Quality and Quantity
- Regulatory Approaches (CR1-9)
- Public Education and Volunteer Programs (CP1)
- Municipal Measures (CM1-9)
- Stormwater Management:
  - Source Control Measures (CS1-5)
  - Onsite and Regional Stormwater Control Facilities (CS6-16)
- Monitoring, Reporting, and Further Study (CMR)

7.1.1 Target A: Dry Weather Water Quality and Aesthetics

Target A is defined for Tookany/Tacony-Frankford Creek as focusing on trash removal and litter prevention, and the elimination of sources of sewage during dry weather. Streams should be aesthetically appealing (look and smell good), accessible to the public, and be an amenity to the community. Sewer odors occurring from dry weather sewer discharges in both combined and separate sewered areas should be remedied.

Regulatory Approaches

AR1 On-Lot Disposal (Septic System) Management
AR2 Pet Waste, Litter, and Dumping Ordinances

These typical pollution reduction and aesthetic ordinances are already in effect in many locations, and can be effective at controlling diffuse sources of pollutants. They are particularly important in urban watersheds; however, they must be consistently enforced to be effective.

Public Education and Volunteer Programs

AP1 Public Education
AP2 School-Based Education
AP3 Public Participation and Volunteer Programs

Municipal Measures

AM1 Capacity Management Operation and Maintenance (CMOM)
AM2 Inspection and Cleaning of Combined Sewers
AM3 Sanitary Sewer Rehabilitation
AM4 Combined Sewer Rehabilitation
AM5 Illicit Discharge, Detection, and Elimination (IDD&E)
AM6 Stream Cleanup and Maintenance
AM7 Household Hazardous Waste Collection

Enhancing Stream Corridor Recreational and Cultural Resources *(AO1)*

Preservation and enhancement of recreational and cultural resources may be integrated into comprehensive watershed management. These resources are part of the link between the human population and natural resources in a watershed. Strategies to provide access to water resources for recreational purposes encourage appreciation for and stewardship of these areas. Strategies to protect water-based historic structures should be implemented to insure that flooding and other impacts are avoided.

Monitoring, Reporting, and Further Study *(AMR)*

Monitoring and reporting under Target A include monitoring of progress toward achievement of objectives (as measured by indicators introduced in Section 4) and monitoring of implementation of recommended management measures. For example, Indicator 18 measures "tons of trash removed from streams and riparian areas" (a measure of option implementation) and derives a stream accessibility score for individual reaches of the creek (a measure of progress toward an objective).

7.1.2 Target B: Healthy Living Resources

Improving the ability of an urban stream to support viable habitat and fish populations focuses primarily on remediation of the more obvious impacts of urbanization on the stream. These impacts include loss of healthy riparian habitat, eroding and undercut banks, scoured streambed or excessive sediment deposits, channelized and armored stream sections, and invasive species. Encroaching development on the riparian buffer can leave little or no room for a vegetated buffer, while other open riparian areas are often left poorly managed. Biological monitoring indicates that the whole Tookany/Tacony-Frankford Watershed suffers from impaired aquatic habitat and does not meet its designated use as a warm water fishery. This impairment is due to severe water flow fluctuations, habitat alteration, point and non-point source pollution from urban development, hydromodification, and combined sewer overflows (PA DEP 2001).

The primary tool to address these problems is stream restoration. Restoration addresses poor instream habitat and biological impairment, focusing on improving channel stability, improving instream and riparian habitat, providing refuge that allows fish to avoid high velocity conditions during storms, and managing land within the stream corridor. Lowland restoration and enhancement addresses the problem of wetland loss and impairment. Nearly all wetlands in the watershed exhibit impaired functions that indicate extensive disturbance and deterioration.

The wet weather strategy includes both restoration of physical stream habitat and reduction of discharges from stormwater and combined sewage. These measures are complementary; stream restoration provides areas of lower flow where aquatic life can avoid higher flows, and discharge reduction helps limit velocities and protects the long-term investment in the restored stream. Targets B and C are intended to accomplish the restoration of physical stream habitat through control measures involving erosion, sediment accumulation, and flow variability.

Many of the stresses faced by aquatic life in urban streams are the result of alternating extremes of high and low flow, and the resulting sediment scour and deposition. While stormwater BMPs that promote infiltration do help to reduce these extremes, a recent modeling analysis conducted by PWD indicates that impervious cover would have to be reduced by half or more to have a significant effect. This result indicates that stream restoration measures may be a more feasible means of improving the aquatic habitat in the short term. Modern design techniques may create areas of reduced velocity where aquatic life is protected during high flow. Techniques appropriate to our area are summarized in “Guidelines for Natural Stream Channel Design for Pennsylvania Waterways,” by the Alliance for the Chesapeake Bay, March 2003. This publication is available online at http://www.acb-online.org/toolkits.cfm.

Channel Stability and Aquatic Habitat Restoration

BM1	Bed Stabilization and Habitat Restoration
BM2	Bank Stabilization and Habitat Restoration
BM3	Channel Realignment and Relocation
BM4	Plunge Pool Removal
BM5	Improvement of Fish Passage

Lowland and Upland Restoration and Enhancement

BM6	Wetland Improvement
BM7	Invasive Species Management
BM8	Biofiltration
BM9	Reforestation

Monitoring, Reporting, and Further Study ***(BMR)***

Monitoring and reporting under Target B includes monitoring of progress toward achievement of objectives (as measured by indicators introduced in Section 4) and monitoring of implementation of recommended management measures. For example, Indicator 3 measures the channel condition and trend for each reach of the stream. This indicator is both a measure of implementation and a measure of progress toward the goal of reducing streambank and stream channel deposition and scour to protect and restore the natural functions of aquatic habitat and ecosystems, streambanks, and stream channels.

7.1.3 Target C: Wet Weather Water Quality and Quantity

The third target is to restore water quality to meet fishable and swimmable criteria during wet weather. A comprehensive watershed management approach also must address flooding issues. The wet weather strategy includes both restoration of physical stream habitat and reduction of discharges from stormwater and combined sewage. These measures are complementary; stream restoration provides areas of lower flow where aquatic life can avoid higher flows, and discharge reduction helps limit velocities and protects the long-term investment in the restored stream. Targets B and C are intended to attend to restoration of physical stream habitat through control measures involving erosion, sediment accumulation, and flow variability.

Regulatory Approaches

CR1 Requiring Better Site Design in New Development
  - Open Space Preservation Plan
  - Stream Buffer/Corridor Protection Ordinance
  - Wetlands Protection Ordinance
  - Steep Slope Ordinance
  - Cluster Development Ordinance
  - Transfer of Development Rights Ordinance

CR2 Requiring Better Site Design in Redevelopment (may include options in CR1)
CR3 Stormwater and Floodplain Management
CR4 Industrial Stormwater Pollution Prevention
CR5 Construction Stormwater Pollution Prevention
CR6 Post-construction Stormwater Runoff Management
CR7 Pollution Trading
CR8 Use Review and Attainability Analysis
CR9 Watershed-Based Permitting

Following is a brief discussion of each of those nine regulatory approaches toward reaching Target C, as outlined above.

CR1&2 – Requiring Better Site Design in New Development and Redevelopment

The regulatory authority for controlling land use is vested in the municipalities through their ability to develop ordinances that regulate zoning and development practices. In areas that are undergoing development pressures, these ordinances are some of the most effective tools for watershed protection. In fully developed, urban watersheds such as the Tookany/Tacony-Frankford Creek Watershed, they are less effective, and are needed primarily to help improve conditions in areas that are re-developing.

A variety of approaches to environmentally responsible land use controls have been developed in recent years, and some are being implemented in the areas adjacent to Philadelphia that are undergoing rapid development. The Delaware Valley Regional Planning Commission (DVRPC) has collected information on these practices and local applications on their web site at http://www.dvrpc.org/planning/community/protectiontools.htm.

CR3 – Stormwater and Floodplain Management

Ordinances that deal directly with the way that stormwater is handled and floodplains are developed or re-developed are important in both developing and developed areas. Municipal ordinances for stormwater and floodplain management should be consistent with the "Comprehensive Stormwater Management Policy" (Document 392-0300-002) released by PA DEP in September 2002. This policy is intended "to more fully integrate post-construction stormwater planning requirements, emphasizing the use of ground water infiltration and volume and rate control best management practices (BMPs), into the existing NPDES permitting programs and the Stormwater Management Act ('Act 167') Planning Program." The comprehensive policy is available on PA DEP's web site at http://www.dep.state.pa.us/dep/deputate/watermgt/wc/Subjects/StormwaterManagement/GeneralInformation/default.htm.

In late 2004, the municipalities of the Tookany/Tacony Frankford Watershed embarked on the process of developing an Act 167 plan. This will include developing and adopting a model ordinance intended to satisfy the requirements of both the Act 167 and NPDES Phase II programs. This model ordinance may be based on a recently completed model ordinance developed for the Darby-Cobbs Watershed, adapted to meet the needs of the TTF Watershed.

CR4 – Industrial Stormwater Pollution Prevention

Industrial stormwater pollution prevention includes attention to the following measures:

- Good Housekeeping
- Preventive Maintenance
- Visual Inspections
- Spill Prevention and Response
- Employee Training
- Record Keeping and Reporting
- Fueling
- Maintaining Vehicles and Equipment
- Painting Vehicles and Equipment
- Washing Vehicles and Equipment
- Loading and Unloading Materials
- Liquid Storage in Above-Ground Tanks
- Industrial Waste Management and Outside Manufacturing
- Outside Storage of Raw Materials, By-Products, or Finished Products
- Salt Storage
- Flow Diversion
- Exposure Minimization Structures (dikes, drains, etc.)
- Erosion Prevention and Sediment Control
- Infiltration Practices

Detailed guidance on these industrial measures is available in EPA publication 832-R-92-006, "Storm Water Management for Industrial Activities: Developing Pollution Prevention Plans and Best Management Practices", released in September 1992. Municipalities may choose to adopt more stringent controls at the local level, or may work with state authorities to enforce the existing requirements. These measures are also appropriate for commercial and government operations involved in similar activities. The publication mentioned above is available online at http://nepis.epa.gov/pubtitleOW.htm.

CR5 – Construction Stormwater Pollution Prevention

Stormwater pollution prevention during construction activities includes attention to the following measures:

- Sediment and Erosion Control Practices
- Good Housekeeping
- Waste Disposal
- Minimizing Offsite Vehicle Tracking of Sediments
- Sanitary/Septic Disposal
- Material Management
- Spill Response
- Control of Allowable Non-Stormwater Discharges
- Maintenance and Inspection
- Stormwater Management

Detailed guidance on these measures is available in PA DEP publication 363-2134-008, "Erosion and Sediment Pollution Control Program Manual," released in April 2000. Municipalities may choose to adopt more stringent controls at the local level, or may work with state authorities to enforce the existing requirements. These measures are also appropriate for commercial and government operations involved in similar activities. The publication is available online at http://www.dep.state.pa.us/dep/deputate/watermgt/wc/Subjects/StormwaterManagement/GeneralInformation/default.htm.

CR6 – Post-construction Stormwater Runoff Management

Post-construction Stormwater Runoff Management is part of the NPDES Phase 2 stormwater management plan. (Options CR3 and CR6 have substantial overlap.)

CR7 – Pollution Trading

U.S. EPA is exploring market-based measures as a way of reaching targeted overall pollutant load reductions in a watershed. EPA's "Final Water Quality Trading Policy," released in January 2003, may be accessed at http://www.epa.gov/owow/watershed/trading/tradingpolicy.html. As this policy is adopted by the states and incorporated in regulations, it may increase incentives for cooperation and coordination between the municipalities and counties that share a watershed.

CR8 – Use Review and Attainability Analysis

U.S. EPA provides procedures for reviewing the applicability and attainability of designated uses. This process may be appropriate for urban watersheds like the Tookany/Tacony-Frankford. EPA document 833-R-01-002, "Coordinating CSO Long-Term Planning with Water Quality Standards Reviews," provides a framework for the process in areas served by combined sewers. The document is available at http://cfpub.epa.gov/npdes/cso/guidedocs.cfm.

CR9 – Watershed-Based Permitting

A holistic watershed management approach provides a framework for addressing all stressors within a hydrologically defined drainage basin instead of viewing individual sources in isolation. Within a broader watershed management system, the watershed-based permitting approach is a tool that can assist with implementation activities. The utility of this tool relies heavily on a detailed, integrated, and inclusive watershed planning process. Watershed planning includes monitoring and assessment activities that generate the data necessary for clear watershed goals to be established and permits to be designed to specifically address the goals. The policy statement and implementation guidance, "Watershed-Based National Pollutant Discharge Elimination System (NPDES) Permitting Implementation Guidance," finalized in 2004, are available at http://cfpub.epa.gov/npdes/wqbasedpermitting/wspermitting.cfm.

Public Education and Volunteer Programs

CP1 Public Education and Volunteer Programs

Municipal Measures

CM1 Sanitary Sewer Overflow Detection
CM2 Sanitary Sewer Overflow Elimination: Structural Measures
CM3 Reduction of Stormwater Inflow and Infiltration to Sanitary Sewers
CM4 Combined Sewer Overflow (CSO) Control Program
- Nine Minimum Controls
- Long Term CSO Control Plan
- Watershed-Based Planning

CM5 Catch Basin and Storm Inlet Maintenance
CM6 Street Sweeping
CM7 Responsible Landscaping Practices on Public Lands
CM8 Household Hazardous Waste Collection
CM9 Responsible Bridge and Roadway Maintenance

The first three measures above apply primarily to municipalities with separate sanitary sewer systems. The second measure, eliminating sanitary sewer overflow, is believed to be of critical importance in the Tookany/Tacony-Frankford Watershed. Inspection, cleaning, and when necessary, rehabilitation of aging sanitary sewers may be the single most important pollution reduction measure, and should be implemented immediately in this watershed. Reduction of pollutant loads due to stormwater may be of secondary importance if significant loads are being introduced by sanitary sewage.

Structural Stormwater Management Facilities

Detailed information on structural BMPs for stormwater management is available in various existing BMP manuals:

- PA DEP's Comprehensive Stormwater Management Policy (see links in Appendix A): http://www.dep.state.pa.us/dep/deputate/watermgt/wc/Subjects/StormwaterManagement/GeneralInformation/default.htm
- City of Philadelphia Stormwater BMP Manual: http://www.phillyriverinfo.org
- Center for Watershed Protection Stormwater Manager's Resource Center: http://www.stormwatercenter.net/
- Maryland Stormwater Design Manual: http://www.mde.state.md.us/Programs/WaterPrograms/SedimentandStormwater/stormwater_design/index.asp
- New Jersey: Best Management Practices for Control of Nonpoint Source Pollution: http://www.state.nj.us/dep/watershedmgt/bmpmanual.htm

Stormwater Management

Source Control Measures

CS1 Reducing Effective Impervious Cover Through Better Site Design
CS2 Porous Pavement and Subsurface Storage
CS3 Green Rooftops
CS4 Capturing Roof Runoff in Rain Barrels or Cisterns
CS5 Increasing Urban Tree Canopy

The first option above, reducing effective impervious cover, refers to a variety of measures, including encouraging homeowners to reduce the size of paved areas on their properties. Use of porous pavement is an alternative to reduction of paved areas. Rooftops represent a large proportion of the impervious area in highly urbanized watersheds such as the Tookany/Tacony-Frankford; constructing rooftop gardens over public and private buildings can be an effective structural measure to reduce urban runoff. Though this technology is catching on slowly in the United States, there are some examples in Southeastern Pennsylvania to look to as models.

The Tookany/Tacony-Frankford Partnership implemented a rain barrel pilot program. Rain barrels are inexpensive but need to be implemented throughout a watershed and drained between storms to be effective as a runoff reduction measure. It is also important that their owners are properly trained and committed to operate and maintain them. Cisterns are similar to rain barrels in function; they also must be drained on a regular basis to provide effective stormwater control.

Tree planting and urban reforestation programs provide hydrologic benefits in addition to quality of life improvements. Leaf surfaces intercept some rainfall that might otherwise fall on impervious surfaces. The rainfall then either evaporates or is conveyed more slowly to the ground along plant stems and trunks. Trees located over or near impervious cover provide the greatest stormwater control benefits.

Municipalities have the opportunity to provide incentives for private landowners to implement these innovative measures through ordinances, tax incentives, or a stormwater fee linked to impervious cover.

Stormwater Management

Onsite and Regional Stormwater Control Facilities

CS6 Maintaining/Retrofitting Existing Stormwater Structures
CS7 Modifying Catch Basins to Delay Stormwater Inflow
CS8 Retrofitting Existing Sewer Inlets with Dry Wells
CS9 Residential Dry Wells, Seepage Trenches, and Rain Gardens
CS10 Infiltration Basins
CS11 Vegetated Swales and Open Channels
CS12 Bioretention Basins and Porous Media Filtration
CS13 Treatment Wetlands: Onsite and Regional
CS14 Dry Detention Basins
CS15 Wet Retention Basins
CS16 BMPs for Highway Runoff (may include various structural options in this list)

The options listed above (CS6-16) are documented in the state manuals. Most of them may be implemented on the small scale of an individual property. Residential dry wells are an inexpensive way to infiltrate residential roof runoff and provide a benefit distributed over the watershed. Infiltration basins are similar but typically used on a larger scale requiring more land. Porous media filters and bioretention basins are most often used to detain, treat, and infiltrate parking lot runoff. Rain gardens are similar to bioretention and can be implemented in backyards or public land such as school grounds. Proper design and maintenance, along with an effective public relations campaign, can alleviate typical concerns about mosquito control and basement flooding.

Retrofit of existing sewer inlets with dry wells is an innovative option that, while expensive, may be attractive in a completely urbanized area with very little land available for traditional BMPs. Using this technology, existing catch basins are retrofitted to provide some measure of storage and infiltration. With full implementation and favorable soil conditions, the resulting outflows may resemble the pre-development condition. The City of Portland, Oregon, has implemented this approach and has provided some documentation in its Stormwater Management Manual (http://www.portlandonline.com/bes/index.cfm?c=35117).

Dry detention and wet retention basins are traditional BMPs that typically provide detention and treatment functions but only limited infiltration. Their design is extensively documented in the state manuals. Constructed wetlands, either onsite or regional, provide even greater detention and treatment functions; in addition, they may provide a cooling function and removal of some stormwater through evapotranspiration.

Monitoring, Reporting, and Further Study ***(CMR)***

Monitoring and reporting under Target C includes monitoring of progress toward achievement of objectives (as measured by indicators introduced in Section 4) and monitoring of implementation of recommended management measures. For example, Indicator 7 measures the percent of water quality samples where the state fecal coliform standard is met. This indicator is a measure of progress toward the goal of improved water quality in wet weather. Water Quality Concerns such as metals, TSS (total suspended solids), fecal coliform, and DO (dissolved oxygen) require further study to pinpoint sources. However, the problem can still be addressed (as most of the Target C options intend to do).

7.2 Screening of Options

The extensive lists of management options described above were developed to meet each of the goals and objectives established for the Tookany/Tacony-Frankford Watershed. Only those options deemed feasible and practical, however, were considered in the final list of management options. Options were evaluated in three steps:

> **1) Identification of Clearly Applicable Options (Section 7.2.1).** Some options were already being implemented or were mandated by a regulatory program. For some options, the planning team reached an early consensus that they were needed. These options did not require further evaluation.
>
> **2) Screening Based on Watershed Characterization (Section 7.2.2).** The extensive data analyses undertaken to characterize the watershed are summarized in Section 4 (Watershed Indicators: TTF Study Results), Section 5 (Problem Definition and Analysis), and Section 6 (Causes of Impairment). The results were used to evaluate the remaining options.
>
> **3) Detailed Evaluation of Structural Options (Section 7.2.3).** Structural best management practices (BMPs) for stormwater and combined sewage were subjected to a more rigorous modeling analysis. Effects on runoff volume, overflow volume, and pollutant loads were evaluated at various levels of coverage. That analysis is described in Section 7.3.

The table below lists the options chosen for each of those three evaluation steps.

Table 7.1 Options Chosen for Initial Screening and Detailed Evaluation

Option	Clearly Applicable	Screening	Detailed Model Evaluation
Target A	X*		
Target B	X		
Target C – Regulatory Approaches			
CR1 Requiring Better Site Design in New Development		X	
CR2 Requiring Better Site Design in Redevelopment	X

** CSO program in place; model evaluation conducted to quantify benefits.

7.2.1 Clearly Applicable Options: Targets A, B, and C

Some options were already being implemented or were mandated by a regulatory program before preparation of the integrated plan began. For other options, the planning team reached an early consensus that they were needed. These options did not require further evaluation:

- **Virtually all Target A options.** Measures to reduce litter and improve recreational activities along the stream corridor are a clear priority of stakeholders. Due to deteriorating infrastructure and localized areas of low dissolved oxygen that have been identified in the creek, measures to eliminate dry weather sewage discharges are necessary. (Option AM7, Household Hazardous Waste Collection, was eliminated due to results of cost-benefit analysis.)

- **All Target B options.** The results of watershed characterization and experiences in other urban watersheds indicate that some restructuring of the streams and stream corridors will be required to restore designated uses.

- **Selected Target C options.** Regulatory approaches CR2 through CR6 are being addressed by the Pa. Act 167 planning program already underway in the TTF Watershed. Many of these measures are also required under the NPDES program. Public education and volunteer programs (Option CP1) are a critical component of any approach to integrated watershed management. In addition, most of the municipal measures listed under Target C, including the City of Philadelphia's Long Term CSO Control Program, are already being implemented in the watershed. Recommendations for these programs will be to continue or improve upon existing efforts.

7.2.2 Results of Target C Screening Based on Watershed Characterization

CR1 Requiring Better Site Design in New Development

Result: Not Recommended

Discussion:
Based on the analysis of land use and ownership presented in Section 4 (Indicator 1), the potential for new development in the TTF Watershed is limited. Concepts of low impact development may be applied on larger redevelopment sites (Option CR2), but extensive planning for new development is not necessary.

CR7 Pollution Trading

Result: Not Recommended

Discussion:
The Tookany/Tacony-Frankford Creek is currently listed by the PA DEP as impaired for one or more designated uses, not requiring a TMDL. Without a TMDL in place, the "driver" for initiating pollution trading does not exist. If a TMDL were to be enacted, the EPA's "Water Quality Trading Assessment Handbook" (EPA 841-B-04-001) could be used to provide an analytical framework to assess the conditions and water quality problems and determine whether water quality trading (WQT) could be effectively used.

CR8 Use Review and Attainability Analysis

CR9 Watershed Based Permitting

Result: Recommended for Further Study

Discussion:
The U.S. Environmental Protection Agency has endorsed these innovative options for improving the water resources environment in practical, sustainable, and cost-effective ways. Taken together, these three options represent a powerful opportunity for regulatory change in the watershed.

CS6 Maintaining/Retrofitting Existing Stormwater Structures

Result: Recommended

Discussion:
PWD performed an inventory of existing privately owned stormwater control basins in 2000. The results found seven confirmed structures within the Philadelphia portion of the watershed. Retrofit of existing basins, including maintenance and modification of outlet structures, can often increase the benefits from an older structure at minimal cost. This option is recommended and will be discussed in detail in the implementation section.

CS7 Modifying Catch Basins to Delay Stormwater Inflow

Result: Not Recommended

Discussion:
This option delays entry of stormwater runoff into street inlets and catch basins,

providing some level of detention while temporarily storing water on roadways. Based on discussions with stakeholders and local officials, this option is unpopular due to public perception. Other forms of detention are preferred.

CS11 Vegetated Swales and Open Channels

Result: Not Recommended

Discussion:
Vegetated swales and open channels are an attractive option as an alternative to traditional infrastructure in areas with new development. They are generally not applicable on smaller sites or on redevelopment sites. This option is not recommended except in very limited cases to be determined on a site-by-site basis.

CS14 Dry Detention Basins

Result: Not Recommended

Discussion:
Wet retention and infiltration basins are generally recommended over dry detention basins. Wet retention provides more effective water quality treatment in most cases. Dry extended detention ponds have only moderate pollutant removal when compared to other structural stormwater practices, and are ineffective at removing soluble pollutants. If a standing pool is not desired, designing for infiltration is recommended. This option is not recommended except in limited cases to be determined on a site-by-site basis.

CS16 BMPs for Highway Runoff

Result: Not Recommended

Discussion:
Transportation infrastructure in the watershed is dominated by city streets rather than highways. In most cases, there is not sufficient space available on roadway shoulders for significant storage to be created. In some cases, medians and islands in intersections may be appropriate for infiltration. These cases will be discussed under option CS12, Bioretention Basins and Porous Media Filtration.

7.2.3 Detailed Evaluation of Target C Structural Options

Structural options such as best management practices (BMPs) for stormwater and combined sewage were subjected to a rigorous modeling analysis. Effects on runoff volume, overflow volume, and pollutant loads were evaluated at various levels of coverage. In this way, the BMPs could be assessed for their cost-effectiveness when implemented in the TTF Watershed. BMPs that appear to cost-effectively decrease stormwater flows or combined sewer overflows, or significantly reduce pollutant loading during wet weather, were subjected to a series of model runs. BMPs were simulated at various levels of implementation within the watershed, and the results are represented graphically. For the assumed level of implementation, the results in terms of pollutant reduction and amount of stormwater treated were then combined with planning level cost estimates, and the options were subsequently ranked according to their cost effectiveness.

Figure 7.1 compares the effectiveness of the BMPs at volume removal (through infiltration and/or evapotranspiration) at their maximum feasible implementation levels. Two measures are capable of reducing total discharge to the receiving water (the sum of stormwater runoff and CSO) by more than 12%. Porous pavement with subsurface storage removes the volume primarily through infiltration, while real time control (RTC) reduces combined sewer overflow.

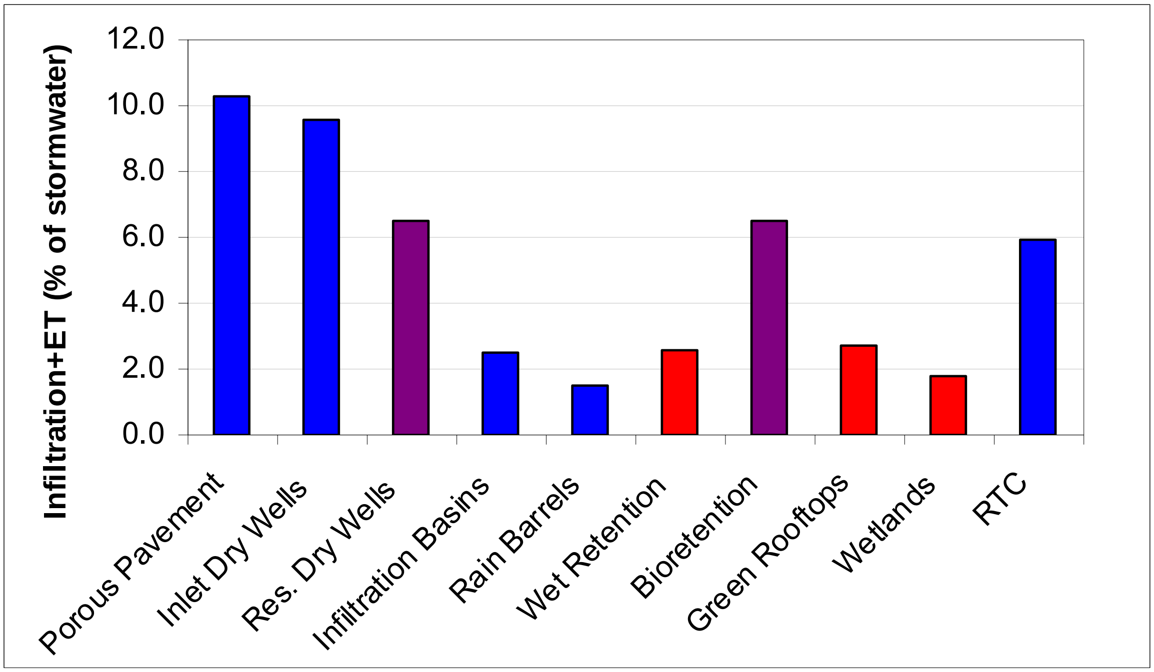

Figure 7.1 Potential Stormwater Volume Removal at Maximum Feasible Coverage

Figure 7.1 represents a range of impervious area draining to BMPs, from existing conditions (46% DCIA, or Directly Connected Impervious Area) to the maximum feasible coverage (varies by BMP). Levels of feasible coverage are chosen to be ambitious but realistic. For example, dry wells may not be technically feasible for all residences due to available space and other site constraints; for planning purposes, the maximum feasible level of coverage for the long term was assumed to be 25% for the TTF Watershed. Table 7.2 ranks the relative ability of each of the

BMPs to store stormwater, treat stormwater, or remove TSS, based on simulations of the maximum feasible level implementation of each of the BMPs. The rankings represent total volume and mass on a watershed basis over the one-year continuous simulation; they are a function of both technical effectiveness and feasible level of coverage. This ranking is independent of cost considerations.

Table 7.2 BMP Performance at Maximum Feasible Coverage

BMP Ranking	Potential Storage	Volume Removed	Load Reduction
Highest	Porous Pavement	Porous Pavement	Porous Pavement
	Wet Retention	Inlet Dry Wells	Res. Dry Wells
	Infiltration Basins	Bioretention	Bioretention
	Bioretention	Res. Dry Wells	Inlet Dry Wells
	Inlet Dry Wells	Real Time Control	Real Time Control
	Res. Dry Wells	Green Rooftops	Wet Retention
	Green Rooftops	Wet Retention	Infiltration Basins
	Wetlands	Infiltration Basins	Green Rooftops
	Rain Barrels	Wetlands	Wetlands
Lowest		Rain Barrels	Rain Barrels

Figure 7.2 shows the amount of storage that could be built in the TTF Watershed given the maximum feasible coverage for each BMP. At the simulated depth of 1 foot, subsurface storage under parking facilities represents approximately 45% of the storage that could feasibly be built. However, rain falling on the parking lot above the storage will not be sufficient to fill the storage. The full storage amount will be active only if additional runoff is directed into it. Infiltration and wet retention basins represent the second largest potential storage volume at approximately 15% of the total. Dry wells intercepting runoff from residential rooftops add 4%.

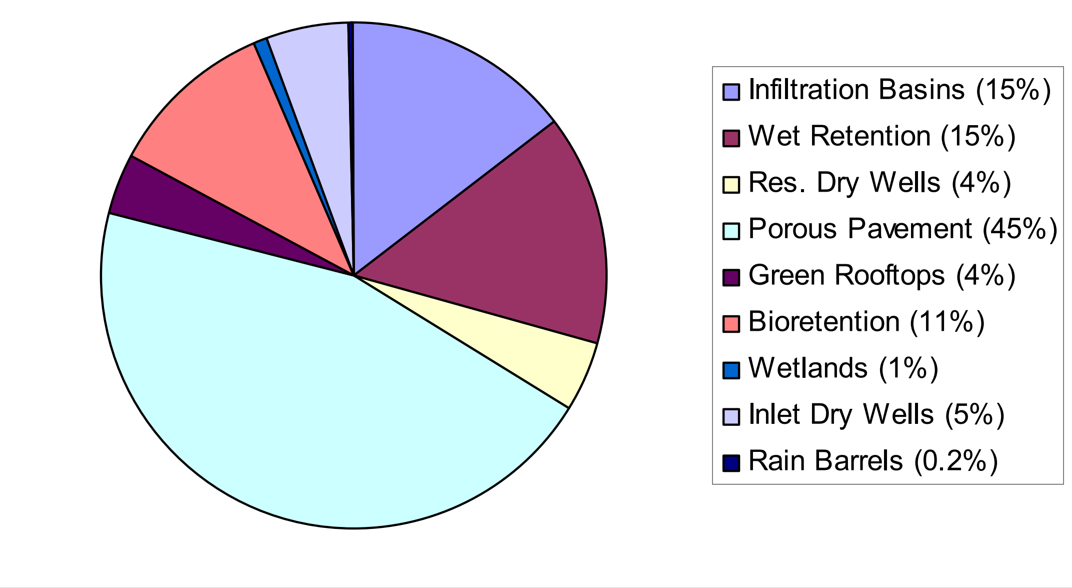

Figure 7.2 Maximum Storage Volume Feasible for Tookany/Tacony-Frankford Watershed

To gain some insight into the cost-effectiveness of various BMPs in the watershed under study, the precise hydraulic modeling results were combined with construction cost estimates. Literature values for costs of some BMPs are available in terms of storage volume. For others, literature values for cost in terms of area or operational unit were combined with model assumptions to obtain approximate costs. Operation and maintenance costs were not included in the current study.

While the hydrologic and hydraulic simulations were performed at a high level of precision, the costs used in this analysis were approximately order-of-magnitude in precision. The purpose of the cost-effectiveness analysis was to identify groups of BMPs that are highly effective, moderately effective, and of limited effectiveness in combined and separate-sewered areas. The values are specific to the climate, development pattern, soil conditions, and sewage systems in the Tookany/Tacony-Frankford Watershed. They are appropriate for long-term planning locally but are not recommended for detailed facilities cost estimating.

Model results were processed to produce relationships between storage volume, discharge reduction, load reduction, and cost. Some BMPs appear to be more efficient at pollutant removal, while others are more efficient at reducing the volume of stormwater reaching the stream; both are objectives of the TTFIWMP. Because the cost-load relationship is approximately linear, it is possible to present the results in the simplified form of approximate cost per gallon of discharge or pound of pollutant eliminated.

Subsurface storage facilities for combined sewage were examined as part of this study, but the cost-discharge and cost-load relationships were found to be nonlinear and could not be presented in the same form as the other results.

The results of the cost-effectiveness analysis are shown in Tables 7.3 and 7.4 (next page). Table 7.3 shows the estimated cost per gallon of stormwater treated and the cost per pound of TSS removed for simulations of feasible levels of implementation for each type of BMP under consideration. The results show that there is a wide range of costs, and that costs differ depending on whether a BMP is implemented in a CSO area or in an area served by separate storm sewers. Table 7.4 shows the list of options, ranked from most cost-effective to least cost-effective, grouped into highly effective, moderately effective, and least effective options.

Table 7.3 Planning-Level Cost-Effectiveness

	WATER QUALITY			WATER QUANTITY		
	TSS Removed			Volume Infiltrated/Evap/Captured		
BMP	Separate ($/lb)	Combined ($/lb)	Watershed ($/lb)	Separate ($/10^3 gal)	Combined ($/10^3 gal)	Watershed ($/10^3 gal)
Wetlands	3.07	1.43	1.80	3.02	1.38	1.75
Wet Retention	19.95	14.39	16.14	27.07	17.78	20.52
Rain Barrels	17.65	3.75	5.41	35.80	2.87	4.47
Inf. Basin	26.21	16.86	19.57	40.29	19.95	24.83
Real Time Control	N/A	5.98	N/A	N/A	4.20	N/A
Residential Dry Wells	19.40	11.47	13.64	44.91	10.38	14.81
Bioretention	42.46	22.09	27.16	60.95	20.86	28.03
Inlet Dry Wells	563.23	37.98	59.60	464.23	26.71	42.17
Green Rooftops	495.50	363.01	405.15	326.32	255.23	278.86
Porous Pavement	146.59	89.75	105.69	97.55	63.60	73.56

The most cost-effective discharge and pollutant reduction strategy is obtained by building the most inexpensive BMP to its maximum feasible level, followed by the next most inexpensive, until wet weather goals are met. Ultimately, other factors (e.g., public vs. private ownership, institutional arrangements for maintenance, degree and length of construction disturbance, feasibility of implementation, socio-political perceptions) must also be considered.

Table 7.4 Cost-Effectiveness of Options (High, Medium, Low)

WATER QUALITY		**WATER QUANTITY**	
TSS Removed		**Volume Infiltrated/Evaporated/Captured**	
Separate	Combined	Separate	Combined
Wetlands	Wetlands	Wetlands	Wetlands
Rain Barrels	Rain Barrels	Wet Retention	Rain Barrels
Residential Dry Wells	Real Time Control	Rain Barrels	Real Time Control
Wet Retention	Residential Dry Wells	Inf. Basin	Residential Dry Wells
Inf. Basin	Wet Retention	Residential Dry Wells	Wet Retention
Bioretention	Inf. Basin	Bioretention	Inf. Basin
Porous Pavement	Bioretention	Porous Pavement	Bioretention
Green Rooftops	Inlet Dry Wells	Green Rooftops	Inlet Dry Wells
Inlet Dry Wells	Porous Pavement	Inlet Dry Wells	Porous Pavement
	Green Rooftops		Green Rooftops

<u>The results of the simulations support a number of general conclusions</u> about the implementation of BMPs in the TTF Watershed. (**Note:** These numbered comments are referenced in summary Table 7.7, at end of Section 7.)

1. The cost of runoff volume reduction is higher in separate-sewered than in combined-sewered areas because temporary storage and release results in additional capture at CSO regulator structures. Larger cost differences between CSO and separate storm sewer

areas occur where evapotranspiration and/or infiltration are minor functions of the BMP (e.g., retrofitting sewer inlets with dry wells).

2. Generally speaking, if pollutant removal is significant for a given BMP, the cost difference between separate and CSO areas is smaller. One example is wetlands, due to water column pollutant attenuation.
3. Traditional BMPs like infiltration basins and wet retention basins can be effective where land is available. These facilities typically have much larger capacities, are regional in nature, and exhibit economies of scale. They are not thought to be practical alternatives for the TTF Watershed, but were included in our modeling simulations for completeness.
4. For the combined-sewered areas, real time control (RTC) is among the most competitive options in terms of both volume and load reduction. The RTC configuration being considered is highly specific to the TTF Watershed, and these results may not hold generally for other watersheds.
5. In highly urbanized areas, storage under parking facilities may be the only practical option to achieve large storage volumes. Porous pavement is one way to direct runoff from the parking lots themselves into the storage facility, while runoff from nearby rooftops can be piped into the facility.

The cost analysis of options in areas of separate storm sewers shows:

6. Wetlands and rain barrels are the most cost effective options for TSS removal on a cost per pound basis. Wetlands and wet retention are the most cost effective on a cost per gallon stormwater removed basis.
7. Dry wells in sewer inlets and green rooftops are particularly expensive for both TSS and discharge reduction. Porous pavement is expensive for TSS removal, but is more cost effective as a volume control measure.

The cost analysis of options in areas of combined sewers shows:

8. Wetlands, rain barrels, residential dry wells, and real time control are all relatively cost-effective options on the basis of cost-per-pound of TSS removed and cost-per-gallon of stormwater removed.
9. Green rooftops are the more expensive choice either on the basis of TSS removal or on the basis of dollars per gallon stormwater treated. Dry wells in sewer inlets are only moderately expensive in combined sewer areas (in contrast with separate sewer areas).
10. It is clear that the most expensive options in combined-sewered areas cost less than the most expensive options in separate-sewered areas. Because hydraulic detention is the most important mechanism in combined-sewered areas, there is less difference in cost-effectiveness between the different types of BMPs.
11. In combined areas, the regulator structures represent an investment already made in pollution reduction. Thus, money spent on stormwater BMPs results in greater load and volume reductions per additional dollar spent than in separate areas without stormwater controls. To meet an overall load reduction target in watersheds with both combined and separate areas, it may be more efficient to focus on the combined areas.

Table 7.5 lists ten measures, a feasible implementation level for each, and discharge and pollutant load reductions that are possible with each. These results may be used as a guide for individual municipalities or a watershed organization to select suitable BMPs.

Table 7.5 Maximum Feasible Discharge and Pollutant Reduction

Target C	Maximum Feasible Implementation	Volume Reduction		Pollutant Reduction
		CSO	Stormwater	
Municipal Measures				
CM4 Combined Sewer Overflow (CSO) Control Program				
● Real Time Control	2 sites	5.9%	N/A	6.1%
Structural Stormwater Management Facilities				
Source Control Measures				
CS1 Reducing Impervious Cover Through Better Site Design	1% reduction in DCIA	0.5%	0.5%	1.0%
CS2 Porous Pavement and Subsurface Storage	50% of parking lots	8.0%	3.3%	11.6%
CS3 Green Rooftops	5% of rooftops	1.8%	0.9%	2.7%
CS4 Capturing Roof Runoff in Rain Barrels or Cisterns	10% of homes	1.4%	0.1%	1.8%
CS5 Increasing Urban Tree Canopy	5% of watershed area	0.3%	0.3%	0.5%
Onsite and Regional Stormwater Control Facilities				
CS8 Retrofitting Existing Sewer Inlets with Dry Wells	100% of inlets	6.9%	0.3%	7.5%
CS9 Residential Dry Wells, Seepage Trenches, Rain Gardens	school grounds; 25% of homes	5.7%	0.8%	10.4%
CS12 Bioretention Basins and Porous Media Filtration	50% of parking lots	6.3%	2.1%	11.6%
CS13 Treatment Wetlands: Onsite and Regional	100% of identified potential	1.4%	0.4%	2.5%

Notes:
1) Volume reductions are % of total discharge (sum of CSO and stormwater).
2) “Maximum Feasible” considers technical feasibility and social acceptance, but not cost.

In spite of its cost, subsurface storage under parking lots is recommended because it is one of the few practical options in the most urban areas. Green rooftops are not recommended as a short-term management strategy due to the high cost and practical constraints they currently impose on private land owners. However, they may become more cost-effective in the future due to economies of scale and increased local availability of materials and expertise. For these reasons, the watershed planning team has recommended that local government implement demonstration projects on public buildings and consider incentives for private land owners. In the near term, the benefit of these projects will be primarily educational rather than technical.

While effectiveness and cost may be the two most important criteria used to assess and choose BMPs, feasibility and sociopolitical factors ultimately play a role. These factors were evaluated using a simpler method. Table 7.6 assigns a rating to assess the effect of each factor on the BMPs studied; the significance of the possible ratings is explained below.

Table 7.6 Evaluation Criteria Applied to Individual BMPs

	Technical Feasibility	Time to Implement	Legal Feasibility	Social/Political Support	Construction Disturbance	Maintenance
Real Time Control	●	●	●	●	●	●
Structural CSO Storage	●	◒	●	◒	○	○
Constructed Wetlands	●	●	○	◒	◒	◒
Rain Barrels	◒	◒	○	●	●	○
Residential Dry Wells	◒	◒	○	○	●	●
Bioretention/Porous Media Filter Systems	●	○	○	●	◒	◒
Green Rooftops	○	○	○	◒	○	○
Porous Pavement	◒	○	○	●	○	◒
Dry Wells in Sewer Inlets	◒	○	○	●	○	●

Legend

Excellent	●
Good/Fair	◒
Poor	○

Technical Feasibility

Excellent ●	The technology has been widely and successfully applied. Several local contractors will have experience with the technology.
Good/Fair ◒	The technology has been successfully applied in other cities or has been successfully demonstrated locally. At least one local contractor will have experience with the technology.
Poor ○	The technology has been applied in only a few pilot or demonstration programs. It may be impossible to find an experienced local contractor.

Length of Time to Implement

Excellent ●	The technology can be implemented in 2 years or less.
Good/Fair ◒	The technology can be implemented in 2 to 5 years.
Poor ○	The technology takes more than 5 years to implement.

Feasibility within the Legal Structure

Excellent ●	Existing laws require or provide an incentive for implementation. For example, measures proposed may overlap with the "six minimum controls" required by NPDES Phase II regulations.
Poor ○	Existing laws do not affect or do provide disincentives for different aspects of the plan. For example, a local ordinance may discourage infiltration.

Social/Political Support

Excellent ●	Overall, the measure proposed will be seen as positive by a majority of stakeholders (citizens, local governments, and non-profits).
Good/Fair ◒	The measure has both positive and negative aspects.
Poor ○	Overall, the measure proposed will be seen as negative by a majority of stakeholders (citizens, local governments, and non-profits).

Construction Disturbance

Excellent ●	Pavement removal is not required or is minimal. Effects on parking, traffic patterns, and noise are minimal. Rain barrels are one example.
Good/Fair ◒	Some pavement removal is required. Effects on parking, traffic patterns, and noise are moderate.
Poor ○	Construction will require removal of large amounts of pavement (streets, parking lots) and/or significantly affect parking, movement of people and vehicles, and the noise level. Examples include porous pavement and installation of dry wells in sewer inlets.

Maintenance – Cost and Institutional Considerations

Excellent ●	Maintenance can be performed through existing programs and existing funding. For example, maintenance of retrofit sewer inlets can be integrated into current sewer maintenance.
Good/Fair ◒	Private land owners will be responsible for minor maintenance chores (e.g., minor landscape maintenance for a bioretention basin that would have been a parking island anyway). Public agencies can handle maintenance with existing staff and budget, and/or will dedicate staff time to outreach, workshops, etc.
Poor ○	Existing public programs, staff, and funding will not cover maintenance, or maintenance will be a large burden on private land owners. Or, frequent maintenance is absolutely critical to BMP effectiveness, as with rain barrels.

7.3 Recommended Options

At the end of this section, Table 7.7 summarizes options recommended for full implementation, options recommended for conditional implementation, and options that are not recommended. Those recommended for conditional implementation include most of the structural stormwater and combined sewage management measures. (Note: Each "Conditional" recommendation in Table 7.7 is accompanied by a numbered reference to one or more of the various conclusions presented in Section 7.2.3, below Table 7.4.)

Target A: Options for Dry Weather Water Quality and Aesthetics

For the Tookany/Tacony-Frankford Creek, the focus of Target A is trash removal, litter prevention, and elimination of sources of sewage during dry weather. Because the options under consideration are aimed at the total elimination of trash and dry weather sources of sewage, no complex analysis was required to help define the program or assess its potential benefits. Virtually all options related to this target are recommended for implementation.

Streams should be aesthetically appealing (i.e., look and smell good), accessible to the public, and an amenity to the community. Access to and interaction with the stream during dry weather have the highest priority, because dry weather flows occur about 60-65% of the time during the course of a year, and is also the time when the public is most likely to be near or in contact with the stream. The water quality of the stream in dry weather, particularly with respect to bacteria, should be similar to background concentrations in groundwater. Many urban streams rarely meet water quality standards for bacteria, and urban streams often have significant BOD (biological or biochemical oxygen demand) problems, even during baseflow or dry weather conditions.

Target B: Options for Healthy Living Resources

Improving the ability of an urban stream to support viable habitat and fish populations focuses primarily on the elimination of the more obvious impacts of urbanization on the stream. These include loss of riparian habitat, eroding and undercut banks, scoured streambed or excessive silt deposits, channelized and armored stream sections, trash buildup, and invasive species. The primary tool to accomplish this is stream and stream corridor restoration. Restoration focuses on improving channel stability, improving instream and riparian habitat, providing refuges for fish from high velocity conditions during storms, and managing land within the stream corridor. Because designated uses in the stream cannot be restored without these options, all options grouped under Target B are recommended for implementation.

Target C: Options for Wet Weather Water Quality and Quantity

Improving water quality and flow conditions during and after storms is the most difficult target to meet in the urban environment. During wet weather, extreme increases in streamflow are common, accompanied by short term changes in water quality. Stormwater generally does not have DO (dissolved oxygen) problems, but sampling data indicate that concentrations of metals (such as copper, lead, and zinc) and bacteria do not meet water quality standards during wet weather. These pollutants are introduced by both stormwater and wet weather sewer overflows (CSOs and SSOs).

Target C options also must address flooding issues. Where water quality and quantity problems both exist, options must be identified that address both. Any BMP that increases infiltration or detains flow will help decrease the frequency of damaging floods; however, the size of such structures may need to be increased in areas where flooding is a major concern. Reductions in the frequency of erosive flows and velocities will also help protect the investment in stream restoration made as part of the implementation of Target B options.

Options recommended for Target C are divided into two groups, as shown in Table 7.7 below. The first group includes options recommended for ***full*** implementation. These options include a range of ordinances and regulatory measures and public education measures related to existing municipal infrastructure, selected source controls, and possibilities for pollution trading and use review. The municipal measures focus on the elimination of sanitary sewer overflows and the causes of overflows such as blockages and excessive infiltration.

The second group of Target C options includes structural measures designed to achieve specific, measurable discharge and pollutant load reductions. These options are recommended on a ***conditional*** basis, based on conclusions of screening and modeling studies. (As noted above, each of the “Conditional” recommendations is linked to one or more of the numbered conclusions listed in Section 7.2.3.)

Table 7.7 Summary of Recommended Options

Option	Recommended	Not Recommended	Conditional
Target A	X*		
Target B	X		
Target C – Regulatory Approaches			
CR1 Requiring Better Site Design in New Development		X	
CR2 Requiring Better Site Design in Redevelopment	X		
CR3 Stormwater and Floodplain Management	X		
CR4 Industrial Stormwater Pollution Prevention	X		
CR5 Construction Stormwater Pollution Prevention	X		
CR6 Post-Construction Stormwater Runoff Management	X		
CR7 Pollution Trading		X	
CR8 Use Review and Attainability Analysis	X		
CR9 Watershed Based Permitting	X		
Target C – Public Education and Volunteer Programs			
CP1 Public Education and Volunteer Programs	X		
Target C – Municipal Measures			
CM1 Sanitary Sewer Overflow Detection	X		
CM2 Sanitary Sewer Overflow Elimination: Structural Measures	X		
CM3 Reduction of Stormwater Inflow / Infiltration to Sanitary Sewers	X		
CM4 Combined Sewer Overflow (CSO) Control Program	X		
CM5 Catch Basin and Storm Inlet Maintenance	X		
CM6 Street Sweeping	X		
CM7 Responsible Landscaping Practices on Public Lands	X		
CM8 Household Hazardous Waste Collection	X		
CM9 Responsible Bridge and Roadway Maintenance	X		
Target C – Monitoring			
CMR Monitoring, Reporting, and Further Study	X		

* All Target A options except Option AM7, Household Hazardous Waste Collection, which was eliminated due to results of cost-benefit analysis.

(Continued on next page)

Table 7.7 Summary of Recommended Options (continued)

Option	Recommended	Not Recommended	Conditional*
Target C – Stormwater Management			
Source Control Measures			
CS1 Reducing Effective Impervious Cover Through Better Site Design	X		
CS2 Porous Pavement and Subsurface Storage			urban areas (5,7)
CS3 Green Rooftops			demonstration projects (7,9)
CS4 Capturing Roof Runoff in Rain Barrels or Cisterns			public relations campaign required (6,8)
CS5 Increasing Urban Tree Canopy	X		
Onsite and Regional Stormwater Control Facilities			
CS6 Maintaining/Retrofitting Existing Stormwater Structures	X		
CS7 Modifying Catch Basins to Delay Stormwater Inflow		X	
CS8 Retrofitting Existing Sewer Inlets With Dry Wells			CSO areas (1,7,9)
CS9 Residential Dry Wells, Seepage Trenches, and Rain Gardens			inexpensive in combined areas (8)
CS10 Infiltration Basins		X**	
CS11 Vegetated Swales and Open Channels		X	
CS12 Bioretention Basins and Porous Media Filtration			inexpensive in combined areas (7)
CS13 Treatment Wetlands: Onsite and Regional			site permitting (2,6,8)
CS14 Dry Detention Basins		X	
CS15 Wet Retention Basins		X**	
CS16 BMPs for Highway Runoff		X	

* **Note:** The parenthetical numbers under the “Conditional” column refer to the numbered conclusions of the BMP simulations, as listed in Section 7.2.3.

** Under the current conditions of the TTF Watershed, these measures are not recommended; however, in the event of large-scale redevelopment within the watershed, these BMPs could be considered.

Section 8
Implementation Guidelines

This section presents guidelines for watershed-wide implementation of the "management options" identified by the Tookany/Tacony-Frankford Watershed Partnership as best meeting the goals and objectives of the TTF Integrated Watershed Management Plan. Following extensive screening and evaluation (described in Section 7), only those options that are likely to be cost-effective and feasible under the specific conditions found in the TTF Watershed are carried over and included in these guidelines. The section begins with tips on how to navigate the information presented.

Navigating Section 8: Summary Tables and Boxes

Following the introductory information below and on the next page, three **summary tables** are presented. These tables categorize the recommended management options according to the agency or level of government responsible for carrying out each recommendation under current regulations: PA DEP, the City of Philadelphia, and the Montgomery County municipalities.

Sections 8.1, 8.2, and 8.3 are then devoted to presenting detailed information about each of those recommended options, grouped under Targets A, B, and C (introduced in Section 2.2.7 and discussed throughout this plan). Most of those options begin with a **summary box** that names (1) "What" the option involves, (2) "Who" is responsible, (3) "Where" the option is to be carried out, and (4) "When." In addition, each summary box lists the numbers of "Related Goals" and "Related Indicators," discussed in Sections 3 and 4, respectively. The summary box is followed by text, figures, and tables that further describe the option and the implementation approach being recommended.

Implementation Guidelines and Five-Year Plans

These guidelines present a long-range vision for implementation over a 20-year horizon, with the intent of meeting both Target A (Dry Weather Water Quality and Aesthetics) and Target B (Healthy Living Resources) within a 15-year planning horizon, while simultaneously proposing step-by-step implementation to meet Target C (Wet Weather Water Quality and Quantity), allowing for adaptive management over time. The guidelines provide information on location and degree to which implementation needs to be accomplished in order to meet the targets. Based upon these recommendations, PWD and the Tookany/Tacony-Frankford Watershed Partnership will prepare detailed, 5-year plans to carry out the recommended projects.

The Implementation Guidelines presented here are intended to offer a long-range vision for implementation over the upcoming 20-year horizon, and to be used as a reference by parties creating actual implementation plans in the future. The implementation plan is to be designed to provide a detailed blueprint for specific implementation tasks during the initial five-year period. Detailed planning for implementation of the TTFIWMP will be broken into four sequential five-year periods to cover the 20-year implementation horizon. The Philadelphia Water Department has created and committed to a detailed five-year Implementation Plan for the portion of the

Tookany/Tacony-Frankford Watershed within the City of Philadelphia (see summary in Appendix E). This plan has been designed to begin in 2006 and run through 2011; though the start date for the implementation period is in 2006, many projects have already been initiated.

The cost estimated for full implementation of the TTFIWMP in the Philadelphia portion of the watershed is roughly $18,000,000, to which PWD has committed staff and resources in the first five years. Detailed comparable costs for the first five years within the Montgomery County portion of the watershed have not yet been derived. A total estimated cost for watershed-wide implementation of this plan for the initial five-year period will be calculated by the Board of the Tookany/Tacony-Frankford Watershed Partnership once budgetary information for municipal implementation is available.

Role of the TTF Watershed Partnership in TTFIWMP Implementation

In the summer of 2005, the Tookany/Tacony-Frankford Watershed Partnership filed official incorporation papers in order to become a 501(c)3 nonprofit watershed organization. As noted in Article 2, Section 2.2 of the TTF Partnership By-Laws:

> *"The primary purposes of the Corporation are to carry out all activities allowable under Section 501(c)(3) of the Internal Revenue Code (or the corresponding section of any future Internal Revenue Law of the United States), including but not limited to: implement the Integrated Watershed Management Plan for the Tookany/Tacony-Frankford Watershed ("TTF Watershed"); improve stream habitat and integrity of aquatic life; reduce the impact of urbanized flow on living resources; improve dry and wet weather stream quality to reduce the effects on public health and aquatic life; protect and restore stream corridors, buffers, floodplains, and natural habitats including wetlands; identify flood prone areas and decrease flooding; enhance community environmental quality of life; foster community stewardship; and improve inter-municipal, inter-county, state-local and stakeholder cooperation and coordination on a watershed wide basis through dedicated public education and outreach."* (See Appendix C for complete By-Laws.)

This organization will strive to help the municipalities and other stakeholders throughout the watershed to realize the vision of a restored and vital Tookany/Tacony-Frankford Watershed.

8.1 Target A: Dry Weather Water Quality and Aesthetics

Below are the recommended options for Target A. As explained in Section 7, virtually all Target A (and all Target B) options were recommended for implementation. These options are described in detail in the pages that follow.

Section 8.1.1 **Regulatory Approaches**

AR1	On-Lot Disposal (Septic System) Management
AR2	Pet Waste, Litter, and Dumping Ordinances

Section 8.1.2 **Public Education and Volunteer Programs**

AP1	Public Education
AP2	School-Based Education
AP3	Public Participation and Volunteer Programs

Section 8.1.3 **Municipal Measures**

AM1	Capacity Management Operation and Maintenance (CMOM)
AM2	Inspection and Cleaning of Combined Sewers
AM3	Sanitary Sewer Rehabilitation
AM4	Combined Sewer Rehabilitation
AM5	Illicit Discharge, Detection, and Elimination (IDD&E)
AM6	Stream Cleanup and Maintenance

Section 8.1.4 **Recreational and Cultural Resources**

AO1	Enhancing Stream Corridor Recreational and Cultural Resources

Section 8.1.5 **Monitoring and Reporting**

AMR	Monitoring, Reporting, and Further Study

8.1.1 Target A Options: Regulatory Approaches

On-Lot Disposal (Septic System) Management (AR1)

Related Goals: 3
Related Indicators: 7, 11, 19, 20

What	Who	Where	When
Septic tank management program required as part of the municipality's Official Act 537 Sewage Facilities Plan.	Municipalities through state certified Sewage Enforcement Officers (SEO). • All Act 537 plans should be updated as necessary.	All areas with septic systems (see Table 8.4).	Within next 5 years.

Septic tank management programs are currently required of all Pennsylvania municipalities as part of their Official Act 537 Sewage Facilities Plans. Keeping these plans up to date, including provisions related to operation and maintenance of on-lot sewage disposal systems (OLDS), is an important means of controlling the release of pathogens and nutrients within the watershed.

The Pennsylvania Sewage Facilities Act (Act 537) requires that all Commonwealth municipalities develop and implement comprehensive official plans that provide for resolution of existing sewage disposal problems, provide for future sewage disposal needs of new land development, and provide for future municipal sewage disposal needs. When a municipality adopts a plan, the plan is submitted for review and approval by the Pennsylvania Department of Environmental Protection. By regulation, the planning process is not final until an Act 537 Plan has been approved by PA DEP. Municipalities are required to revise (unless they are exempt from revising) the "Official Plan" if a new land development project is proposed or if unanticipated conditions or circumstances arise, making the base plan inadequate. There are two basic types of plan changes: "Plan revisions" resulting from new land development are completed using "planning modules" that are specific to individual projects; an "update revision" is used by municipalities to make broad changes to their Official Plan.

Act 537 planning has been a municipal requirement since July 1, 1967. Legally, all municipalities have an Act 537 Plan; however, some plans are newer and more detailed than others. A list of municipalities within the Tookany/Tacony-Frankford Creek Watershed indicating the status of their Act 537 Plans is presented in Table 8.4. Note that most of the plans are quite outdated. The municipalities are shown in Figure 8.1.

Table 8.4 Act 537 Municipal Sewage Facilities Plans

Municipality	County	Plan Approval Date	Status (as of 12/2005)
Abington Township	Montgomery	12/16/99	Plan older than 5 years
Cheltenham Township	Montgomery	1/1/73	Plan older than 30 years
Jenkintown Borough	Montgomery	1/1/73	Plan older than 30 years
Philadelphia	Philadelphia	11/10/93	Plan older than 10 years
Rockledge Borough	Montgomery	1/1/73	Plan older than 30 years

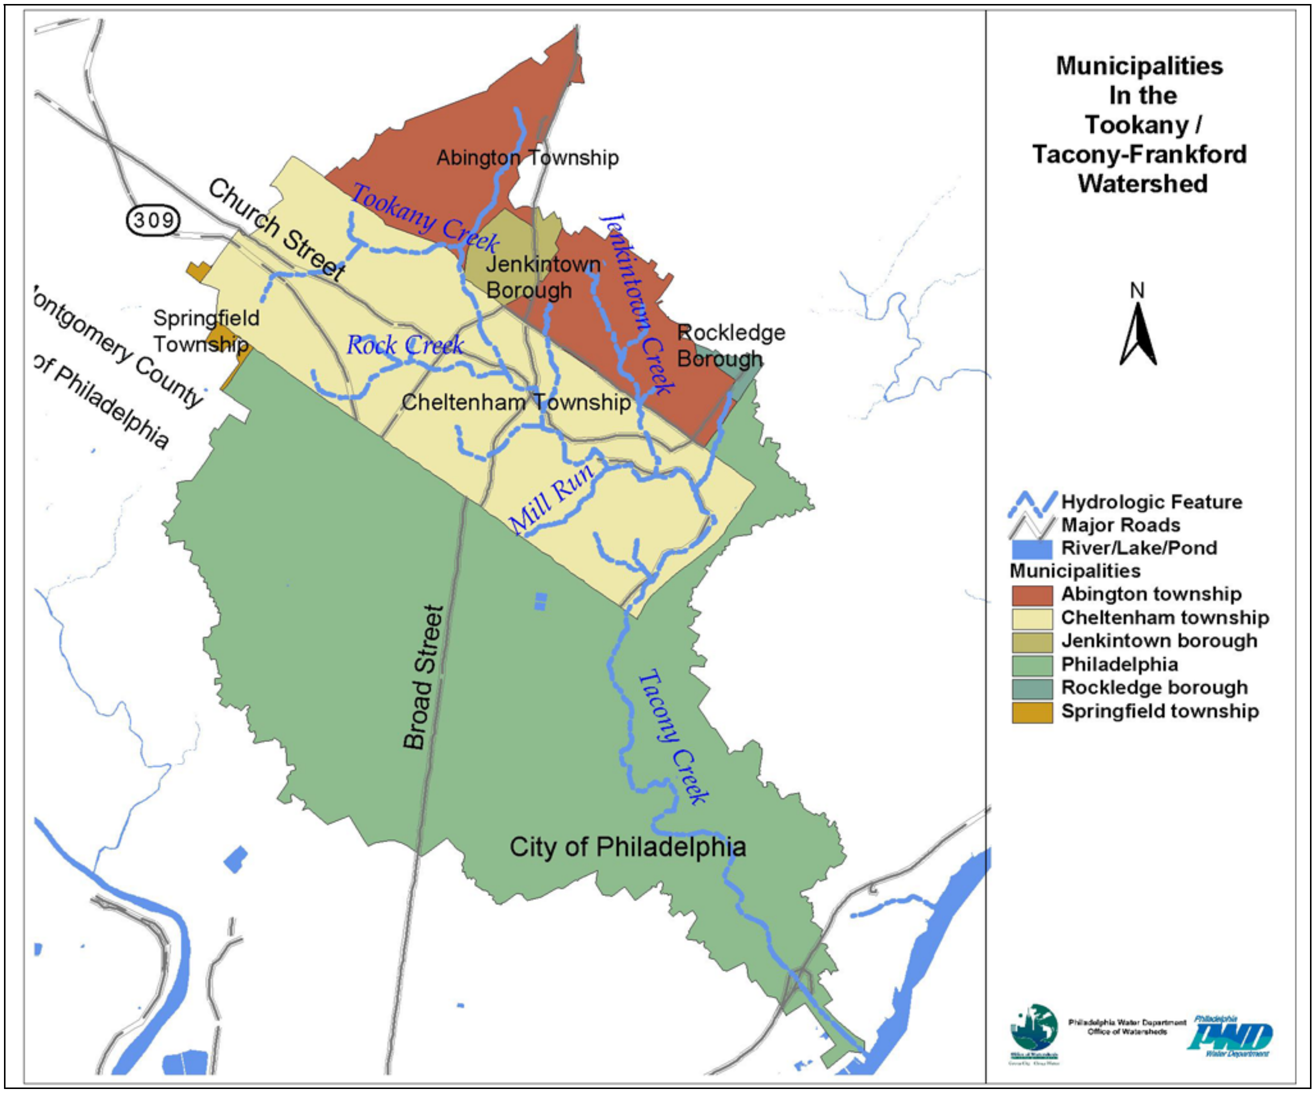

Figure 8.1 Tookany/Tacony-Frankford Watershed Municipalities

<u>**Relevant Provisions of Act 537**</u>

- All municipalities must develop and implement an official sewage plan that addresses their present and future sewage disposal needs. Local agencies are required to employ both primary and alternate Sewage Enforcement Officers (SEO) responsible for overseeing the daily operation of that agency's OLDS permitting program.
- Local agencies, through their SEO, approve or deny permits for construction of on-lot sewage disposal systems prior to system installation. The SEO is responsible for conducting soil profile testing, percolation testing, OLDS design review, and approving or denying OLDS permit applications.
- Local agencies, through their SEO, must manage the permitting program for individual on-lot disposal systems and community on-lot systems with design flows of 10,000 gallons-per-day or less.

- Municipalities are required to assure the proper operation and maintenance of sewage facilities within their borders.

Municipalities should maintain information on the location, type, and operational status of existing sewage facilities, as well as results of sanitary surveys. This information, however, is often incomplete. Septic tank data were included in the U.S. census through 1990, but were believed to be inaccurate and were not included in the 2000 census. County health departments may have information, and assessments have been attempted through voluntary questionnaires submitted by municipalities. These tasks have proven to be difficult but can be completed through perseverance.

Implementation of a Comprehensive Septic Tank Management Program

Each municipality shown in Table 8.4 should update its Act 537 Plan in the coming five-year period, as necessary.

Table 8.5 presents 1990 census sanitary survey results along with the area within the watershed. Better counts and, if appropriate, implementation of septic system management programs should be actively pursued in municipalities that have a large estimated number of septic systems and a high percentage of their total area within the watershed: Philadelphia, and Abington and Cheltenham townships.

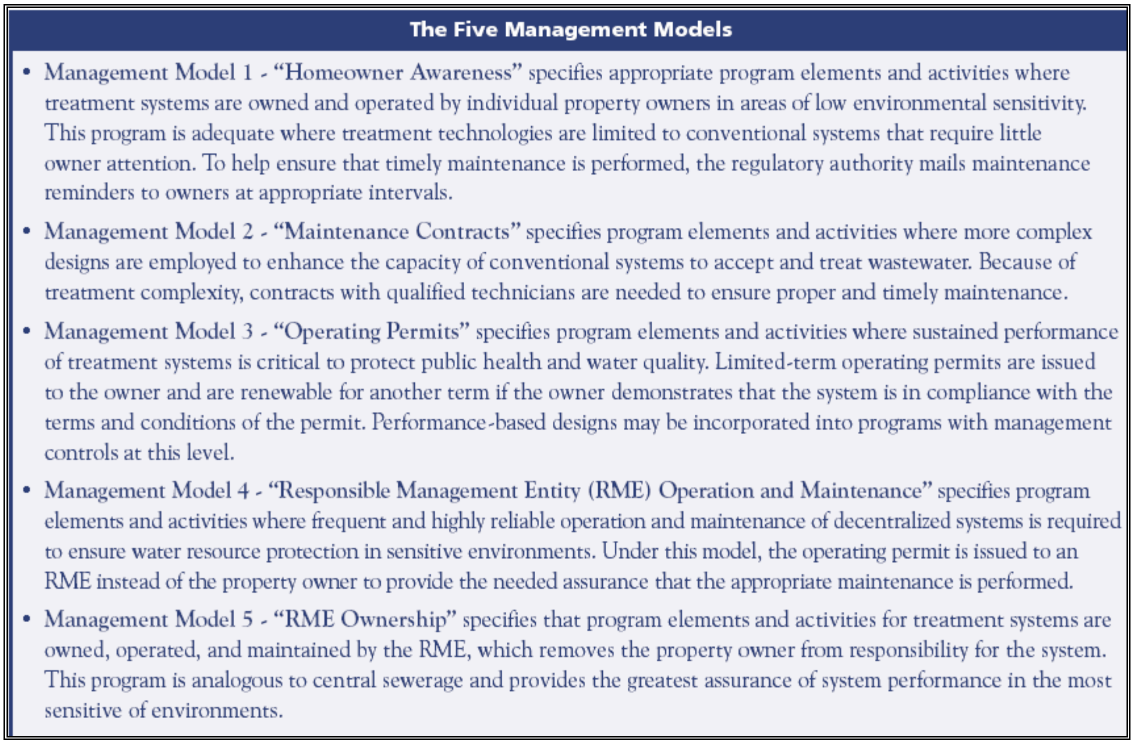
The implementation of comprehensive septic tank management programs in those three municipalities ideally will be consistently designed to provide degrees of protection based on an assessment of the environmental sensitivity of the area.

Table 8.5 Septic System Data from 1990 Census*

Municipality	Area (Acres)	Area in Watershed (Acres)	Percent of Area in Watershed (Acres)	Housing Units with Public Sewer	Housing Units with Septic Systems	Total Housing Units Occupied
Abington Township	9,893	2,712	12.9%	10,717	101	10,818
Cheltenham Township	5,779	5,691	27.0%	14,174	262	14,436
Jenkintown Borough	369	12,178	57.7%	2,072	0	2,072
Philadelphia City	91,287	367	1.7%	134,408	706	135,114
Rockledge Borough	219	81	0.4%	751	0	751
Springfield Township	4,352	65	0.3%	1,186	3	1,189

* Septic data is unavailable for 2000 Census.

The EPA has recently issued Voluntary National Guidelines for Management of Onsite and Clustered Wastewater Treatment Systems (EPA 832-B-03-001), covering all aspects of a comprehensive program, from design, inspection, and enforcement to public education and long-term planning. This document presents several different management models (see below) to choose from; division of responsibility and ownership between private land owners and public agencies varies between the different models. Municipalities should select that approach which best suits their conditions.



The Five Management Models

- Management Model 1 - "Homeowner Awareness" specifies appropriate program elements and activities where treatment systems are owned and operated by individual property owners in areas of low environmental sensitivity. This program is adequate where treatment technologies are limited to conventional systems that require little owner attention. To help ensure that timely maintenance is performed, the regulatory authority mails maintenance reminders to owners at appropriate intervals.
- Management Model 2 - "Maintenance Contracts" specifies program elements and activities where more complex designs are employed to enhance the capacity of conventional systems to accept and treat wastewater. Because of treatment complexity, contracts with qualified technicians are needed to ensure proper and timely maintenance.
- Management Model 3 - "Operating Permits" specifies program elements and activities where sustained performance of treatment systems is critical to protect public health and water quality. Limited-term operating permits are issued to the owner and are renewable for another term if the owner demonstrates that the system is in compliance with the terms and conditions of the permit. Performance-based designs may be incorporated into programs with management controls at this level.
- Management Model 4 - "Responsible Management Entity (RME) Operation and Maintenance" specifies program elements and activities where frequent and highly reliable operation and maintenance of decentralized systems is required to ensure water resource protection in sensitive environments. Under this model, the operating permit is issued to an RME instead of the property owner to provide the needed assurance that the appropriate maintenance is performed.
- Management Model 5 - "RME Ownership" specifies that program elements and activities for treatment systems are owned, operated, and maintained by the RME, which removes the property owner from responsibility for the system. This program is analogous to central sewerage and provides the greatest assurance of system performance in the most sensitive of environments.

Pet Waste, Litter, and Dumping Ordinances (AR2)

Related Goals: 3, 6, 7
Related Indicators: 7, 8, 9, 10, 11, 16, 17, 18, 19, 20

What	Who	Where	When
Adopt and enforce ordinance to require the removal of pet waste by the animal's owner within the municipality. Adopt and enforce ordinance to prohibit littering and dumping within the municipality.	See Table 8.6 (may not identify all municipalities with ordinance).	Entire watershed.	Within 5 years; update as needed.

A study was conducted to identify municipalities in the watershed that have adopted an ordinance to address removal of pet waste by the animal's owner and an ordinance that prohibits littering and dumping. The study verified existing ordinances related to pet waste, litter, and illegal dumping only in the City of Philadelphia; the study is believed to be comprehensive, but it is possible that additional ordinances exist that were not identified by the study. Table 8.6 shows the municipalities in the watershed that are known to have adopted pet waste and littering ordinances.

Table 8.6 Pet Waste and Littering Ordinances in the Tookany/Tacony-Frankford Watershed

Municipality	Pet Waste Ordinance	Littering and Dumping Ordinance
Abington Township		
Cheltenham Township		
Jenkintown Borough		
Philadelphia County	X	X
Rockledge Borough		

Source: www.ordinance.com, Delaware Valley Regional Planning Commission

Municipalities currently without ordinances are strongly encouraged to adopt them within the next two years. As an example of possible ordinance language, excerpts from Philadelphia County appear on the following page.

Pet Waste Ordinance	Littering and Dumping Ordinance
CHAPTER 10-100. Animals §10-105. Animals Committing Nuisances No person, having possession, custody or control of any animal, shall knowingly or negligently permit any dog or other animal to commit any nuisance upon any gutter, street, driveway, alley, curb or sidewalk in the City, or upon the floors or stairways of any building or place frequented by the public or used in common by the tenants, or upon the outside walls, walkways, driveways, alleys, curbs or stairways of any building abutting on a public street or park, or upon the grounds of any public park or public area, or upon any private property, including the property of the owner of such animal.	CHAPTER 10-700. REFUSE AND LITTERING §10-702. Litter in Public Places No person shall place or deposit litter in or upon any street, sidewalk or other public place within the City except in public receptacles or in authorized private receptacles.

Source: http://www.phila.gov/philacode/html/maintoc.htm , *The Philadelphia Code and Charter*

While pet waste and littering ordinances are enacted primarily for aesthetic purposes, reduction of pathogens and debris in stormwater, and thus in the Tookany/Tacony-Frankford Creek, can be reduced through their enforcement. Municipalities can assist residents in abiding by ordinances by placing trash cans in areas with higher pedestrian traffic. Plastic bags should be provided with trash cans in areas heavily used by dog owners, perhaps following the model established by the Partnership for the Delaware Estuary's "Dogi Pots" pet waste control program. Homeowners' associations should also be asked to notify residents of these ordinances and to provide trash cans and plastic bags in those neighborhoods as well.

8.1.2 Target A Options: Public Education and Volunteer Programs

Public Education (AP1) Related Goals: 4, 6, 7 Related Indicators: 16, 17, 18, 19, 20, 21			
What	Who	Where	When
Public Education Plan. Educational Program Implementation.	Municipalities on the Phase II List (see Table 8.7).	All municipalities in the TTF Watershed.	Short-term: first 5 years coinciding with the stormwater permit (see Table 8.8).

Public education about watershed management is an integral part of plan implementation. It will be designed to educate citizens on the importance of the watershed to the community, and on ways that individual behavior can impact water quality and the riparian and aquatic environment associated with Tookany/Tacony-Frankford Creek. In accordance with the TTFIWMP's stated purpose of integrating various existing programs, and to avoid duplication of effort, the recommended implementation plan follows the Stormwater Management Program Protocol to meet the six Minimum Control Measures required of municipal permittees under Phase II NPDES Stormwater Regulations (listed in Section 1.4.1 of this report, and found at 40 CFR § 122.26 – 123.35). In this way, implementation of these public education measures by municipalities will satisfy federal NPDES permit requirements for municipal separate storm sewer systems (MS4s), described in detail at 40 CFR §122.34.

Table 8.7 below lists the municipalities participating in the Phase II program that could work together with the City of Philadelphia on Public Education about watershed management issues. Assuming that a single, watershed-wide public education campaign focusing on all three Targets (A, B, and C) can be implemented, municipalities would meet their regulatory requirements while helping to implement the TTFIWMP, and avoiding the duplication of work with limited resources that would occur if each municipality were to initiate their own outreach campaign.

Table 8.7 Tookany/Tacony-Frankford Creek Municipalities on Phase I or II Stormwater List

Municipality	County	% of Muni. Area Drained by Watershed	% of Watershed within Muni.
Abington Township	Montgomery	27.41%	12.85%
Cheltenham Township	Montgomery	98.48%	26.98%
Jenkintown Borough	Montgomery	99.47%	1.74%
Rockledge Borough	Montgomery	36.89%	0.38%
Springfield Township	Montgomery	1.49%	0.31%

Public Education Plan

PWD and watershed municipalities should jointly develop a public education plan. The public education plan must target three audiences – homeowners, business owners, and developers – focusing on connections between their actions, stormwater runoff, and water quality. By the end of Year 1 of the permit cycle, cooperating municipalities should have a comprehensive plan in place that will help tap into the target audiences' existing communication channels to inform them about improving stormwater quality. During the following permit years, municipalities should monitor the effectiveness of the plan, and update it to ensure information about the target audiences is accurate.

PA DEP has guidelines for a public education plan. The plan should include an approach to collecting information on the three target audience categories. Municipalities should create a comprehensive inventory of the newsletters, newspapers, web sites, meetings, magazines, organizations, associations, etc. used by the target audiences. Cooperation of the municipalities with the assistance of the Tookany/Tacony-Frankford Watershed Partnership in gathering this information should help eliminate redundancy of effort. During the remaining years of the stormwater permit, municipalities are responsible for ensuring that information in the public education plan is accurate and current.

The River Conservation Plans (RCPs) recommend developing a comprehensive educational program for private land owners and businesses. A "do's and don'ts" format is suggested. The RCPs contain additional details and mapping for the following recommendations:

- Holy Sepulchre Cemetery to Ralph Morgan Park: Emphasize effect of land management practices on the creek.
- Washington Lane Underpass to Church Road: Focus on effects of land management on the creek. Target homeowners.
- High School Park to Ashbourne Road along the Tookany Creek Parkway: Emphasize infiltration BMPs.
- Unnamed Tributary in Glenside: Target homeowners, businesses, and SEPTA. Focus on rain barrels and riparian buffer zones.
- Baeder Creek Watershed: Focus on riparian buffer management and native species. Target land owners and apartment complexes.
- Rock Creek Watershed: Emphasize effect of land management practices on the creek.
- Mill Creek Watershed: Emphasize effect of land management practices on the creek.
- Leeches Run Watershed: Emphasize effect of land management practices on the creek. Target religious organizations and land owners.
- Township Line Road near Foxcroft Road to Main Stem: Focus on "no mow" zones, management of lawn waste, bank restoration, and invasive species.
- Township Line Road to Tookany Creek Parkway: Emphasize effect of land management practices on the creek.
- Rising Sun Avenue to Roosevelt Boulevard: Focus on illegal dumping.

- Castor Avenue to Erie Avenue: Emphasize effect of land management practices on the creek. Target local business owners, high school teachers, and students.
- Aramingo Avenue between Wheatsheaf Lane and Church Street: Emphasize effect of land management practices on the creek. Target local business owners, high school teachers, and students.
- Holy Sepulchre Cemetery to Ralph Morgan Park: Work with Bishop McDevitt to implement BMPs to focus on decreasing stormwater runoff from property.
- Wyncote Post Office to Washington Lane Underpass: PECO energy environmental department should be contacted for information regarding the results of studies being done in this area.
- Washington Lane Underpass to Church Road: The township should develop a dialogue and educate SEPTA regarding the needs of the bird sanctuary, the health of the creek, and railroad track safety.
- Eastern Branch of the Baeder Creek: Work with Abington Township School District to develop a land management plan. Focus on increasing on site infiltration.

In addition, other information relevant to watershed management should be included on topics such as:

- Improper Disposal to Storm Drains
- Automobile Maintenance
- Car Washing
- Animal Waste Collection
- Restorative Redevelopment: Public Education Aspects

Public Education Implementation

Once the public education plan is developed, it must be implemented. This means distributing educational materials provided by PA DEP or others that contain messages related to watershed (and stormwater) management. Municipalities can find educational materials needed to implement the educational program on the PA DEP website at http://www.dep.state.pa.us/dep/deputate/watermgt/wc/NPDSMS4/MS4CD/.

To fulfill NPDES stormwater permit requirements, municipalities should implement two phases of educational outreach. During the first stage, the focus is on raising the awareness of target audiences. In the second stage, municipalities should aim to educate the target audiences about the problems and potential solutions. PA DEP presents requirements in the stormwater permit for the "what" and "when" of this minimum measure component, but it does not specify the "how." Municipalities should use their Public Education Plan to determine the most effective means of getting educational materials into the hands of target audiences. Any additional educational activities should show compliance with this Minimum Control Measure. This includes educational activities by watershed groups, and certainly should make use of the existing Tookany/Tacony-Frankford Watershed Partnership activities.

In Year 1, municipalities are required to start raising target audience awareness. Raising awareness can be accomplished by use of PA DEP materials. PA DEP has made available copies of the pamphlet entitled "When It Rains, It Drains" (available on the PA DEP website, http://www.dep.state.pa.us/dep/deputate/watermgt/wc/NPDSMS4/MS4CD/).

This document addresses the issue of pollution related to stormwater runoff and activities that citizens can use to improve stormwater quality. It also provides an overview of a typical stormwater management program. Using the information on distribution channels in the Public Education Plan, municipalities should disseminate these pamphlets to all the target audience categories in the community.

In Year 2, municipalities should begin to educate all the target audiences. This includes distributing fact sheets to developers about their responsibilities under the state and federal stormwater regulations. To meet this requirement, municipalities should distribute the Fact Sheets prepared by PA DEP, and run a "stormwater ad" in local newspapers.

In addition to targeting developers, municipalities may distribute posters to schools, community organizations and institutions, and businesses. Topics such as responsible vehicle maintenance, household hazardous waste disposal, and pet waste are important to stormwater management. PA DEP has developed a series of posters that convey messages about these topics.

Another useful measure is storm drain stenciling. While not required by the Stormwater Management Program Protocol, any stenciling done by outside organizations may contribute to meeting permit requirements for this Minimum Control Measure.

Public education directors should check any links to PA DEP's stormwater website and update the links if necessary.

In Years 3-5, the implementation continues. This consists mainly of continuing with distribution of posters and fact sheets, and running additional ads in local newspapers.

The schedule for developing and implementing the plan to meet Phase II stormwater requirements is shown in Table 8.8.

Table 8.8 Schedule for Implementation of the Public Education Program

PERMIT YEAR	**Education Plan**	**Educational Program**
Year 1	Determine Target Audience. Develop Public Education Plan. Raise Target Audience Awareness.	• Disseminate materials to all target audiences using appropriate distribution channels. • Newspaper advertisement. • Other components of Plan.
Years 2-5	Implement the plan. Revise Plan as needed.	• Disseminate materials to all target audiences using appropriate distribution channels. • Newspaper advertisement. • Other components of Plan.

Source: PA DEP MS4 Stormwater Management Program Protocol, 2003

School-Based Education (AP2) Related Goals: 6, 7 Related Indicators: 17, 18, 21			
What	Who	Where	When
Implement PA Environmental Education Curriculum.	School districts, supported by municipal governments and non-profits.	All schools.	Short-term (within 5 years).

Besides requirements found in the MS4 Stormwater Management Program Protocol, another important aspect of public education is to reach children through school curricula.

School-based watershed education takes many forms, from lesson plans within the classroom, to hands-on activities outside of the classroom such as field trips to Tookany/Tacony-Frankford Creek and nearby nature centers, as well conducting actual restoration projects. Teacher training programs, developed to assist teachers in bringing watershed concepts to their students, are critical. Being engaged in actual restoration projects, whether through service learning, after school clubs, or integrated as a part of lesson plans helps to translate these lessons into actions.

Sources for lesson plans include the following:

- Incorporate the Pennsylvania Environmental Education Curriculum developed by PA DEP into middle school curricula. This curriculum introduces concepts in watersheds, wetlands, stormwater, drinking water, and water and air pollution.

- Use local examples of watershed protection and restoration to enhance the program, work with schools to provide watershed-based educational opportunities, including the Environmental Scholars Program, Tree Survey Project, Urban Watershed Program, Environmental Clubs, Learning Grove/Trail Development Project, Park Management Program, and Teacher Training Program.

The River Conservation Plans (RCPs) suggest that a statewide environmental education curriculum could spark the interest of younger members of the watershed therefore making them aware of the problems at an earlier age. This could include incorporating riparian buffer restoration with some of the mandatory ecology curriculum.

Public Participation and Volunteer Programs (AP3)

Related Goals: 3, 4, 5, 6, 7
Related Indicators: 10, 11, 12, 13, 14, 15, 16, 17, 18, 21

What	Who	Where	When
Public Participation. Volunteer Monitoring and Storm Drain Stenciling.	Municipalities.	All municipalities in the TTF Watershed.	First 5 years coinciding with the stormwater permit.

Public participation is another facet of implementation that must follow the PA DEP Stormwater Management Program Protocol to meet the six Minimum Control Measures required of municipal permittees under the Phase II NPDES Stormwater Regulations (listed in Section 1.4.1 of this report, and found at 40 CFR §§ 122.26 – 123.35). The public must participate in issues related to municipal actions to address stormwater impacts on water quality. This includes new planning initiatives, changes to ordinances and other local regulations. This requirement overlaps the public participation aspects of the watershed management plan, and suggests that a unified and coordinated approach between municipalities would be most efficient. All municipalities in the watershed (listed in Table 8.7) are required to have a public participation program. Again, the Tookany/Tacony-Frankford Watershed Partnership would be able to assist in fostering this coordination and performing public outreach.

Prior to adoption of any ordinance required under the PA DEP Stormwater Protocol, municipalities must provide adequate public notice and opportunities for public review and input, and hold hearings to obtain public feedback. This can be done in conjunction with normal public sessions of the municipal governing body. The notice must be published in a local newspaper of general circulation. Involving citizen groups, watershed organizations, and businesses as much as possible will obtain broad support for stormwater management efforts. The TTF Partnership itself is an obvious example of such inclusion, and can help municipalities to meet this requirement.

Although the actual public participation requirements can be met by following guidelines for Act 167 planning, it is recommended that municipalities go beyond the minimum. Some options for additional public participation are listed below.

- Develop a Public Involvement and Participation Plan: By the end of Year 1, a municipality may want to have a comprehensive plan in place that will guide your efforts to recruit volunteers and obtain participation at public meetings. This could be part of the Public Education Plan discussed above (see Option AP1).

- Produce strategies for recruiting participation from six categories of stakeholders: municipal employees, homeowners, businesses, schools, watershed associations and other volunteer groups, and developers.

- Develop a comprehensive stakeholder mailing list.

- Conduct Public Meetings: PA DEP suggests using a general stormwater public meeting to kick-off public education and participation efforts. This has already been done for the Tookany/Tacony-Frankford Partnership and Steering Committee, and municipalities are encouraged to make use of this. Invite representatives from all six stakeholder categories. It is important that all stakeholder interests have the opportunity to participate. Meeting agendas should include, but not be limited to, the overview presentation on the watershed management and stormwater program and time for questions from the audience.

An important aspect of public participation is the establishment of volunteer programs. There are many types of volunteer programs that can help manage stormwater and improve a community's water quality. The goal of the volunteer program is to obtain and sustain volunteer support that will aid watershed management efforts. To reach this goal, it is important to develop a program that reflects stakeholders' concerns and interests. Examples of volunteer programs are:

- **Volunteer Monitoring Program:** Municipalities should determine which type of assessment the program will undertake and develop a study design using the manual entitled "Designing Your Monitoring Program: A Technical Handbook for Community-Based Monitoring in Pennsylvania" as the basis for planning and implementing your monitoring program (PA DEP, 2001).

- **Storm Drain Stenciling Program:** Municipalities should establish procedures for storm drain stenciling and organize volunteers to carry out the program. PA DEP has provided resource materials in a References and Resources CD-ROM on developing and implementing a storm drain stenciling program.

- **Stream Cleanup and Restoration Activities:** Citizen participation in stream cleanups is a good way to get the community involved in keeping the streams free of trash and debris. In Philadelphia, stream cleanups can be coordinated with PWD's Waterways Restoration Unit. Other participatory activities can include support of riparian plantings during stream restoration activities.

The River Conservation Plans (RCPs) suggest that increased volunteer work will increase the general awareness regarding what citizen can do to keep the watershed free of problems. For example, at the Washington Lane Underpass to Church Road, a group could be organized to adopt the bird sanctuary area.

8.1.3 Target A Options: Municipal Measures

Capacity Management Operation and Maintenance (CMOM) (AM1)

Related Goals: 1, 2, 3
Related Indicators: 7, 9, 11

What	Who	Where	When
Program to manage and maintain sewer systems; plans in place to track SSOs and overflow response plan.	Separate Sewered Municipalities.	Separate Sanitary Sewer Areas.	Medium term: 5+ years.

Capacity, management, operation, and maintenance (CMOM) programs are recommended for all areas with separate sanitary sewer systems and are an important component of Target A because they help prevent dry weather discharges. Recommendations in this section cover both the dry and wet weather aspects of the program; recommendations that are specific to SSO abatement are included here for completeness and are referred to under Target C. The recommendations in this section are adapted from the "Consensus Recommendation of the SSO Federal Advisory Subcommittee," published in October 1999.

1) General Standards

- Properly manage, operate, and maintain, at all times, all parts of collection system. Perform maintenance and inspections using techniques similar to those recommended for combined sewers in Option AM2.
- Provide adequate capacity to convey base flows and peak flows for all parts of the collection system.
- Take all feasible steps to stop, and mitigate the impact of, sanitary sewer overflows in portions of the collection system.
- Provide notification to parties with a reasonable potential for exposure to pollutants associated with the overflow event.
- Develop a written summary of the CMOM program and make it, and the audit under section (5), available to any member of the public upon request.

2) Management Program

Develop a CMOM program to comply with the above general standards. If any element of this section is not appropriate or applicable for the CMOM program in question, it does not need to address the element, but a written summary must explain why that element is not applicable. The management program should consist of the following six components:

1. Goals
The program must identify in detail the major goals of the CMOM program consistent with the general standards identified above.

2. Organization
(A) Identify administrative and maintenance positions responsible for implementing measures in the CMOM program, including lines of authority by organization chart or similar document, and (B) establish the chain of communication for reporting SSOs from receipt of a complaint or other information to the person responsible for reporting to the NPDES authority.

3. Legal Authority
Include legal authority, through sewer use ordinances, service agreements or other legally binding documents, to:

(A) Control infiltration and connections from inflow sources;

(B) Require that sewers and connections be properly designed and constructed;

(C) Ensure proper installation, testing, and inspection of new and rehabilitated sewers (such as new or rehabilitated collector sewers and new or rehabilitated service laterals);

(D) Address flows from satellite municipal collection systems; and

(E) Implement the general and specific prohibitions of the national pretreatment program that you are subject to under 40 CFR 403.5.

4. Measures and Activities
The CMOM program must address the elements listed below that are appropriate and applicable to the sewer system and identify the person or position in the organization responsible for each element.

(A) Maintenance of facilities.

(B) Maintenance of a map of the collection system.

(C) Management of information and use of timely, relevant information to establish and prioritize appropriate CMOM activities, and to identify and illustrate trends in overflows.

(D) Routine preventive operation and maintenance activities.

(E) Assessment of the current capacity of the collection system and treatment facilities.

(F) Identification and prioritization of structural deficiencies and identification and implementation of short-term and long-term rehabilitation actions to address each deficiency.

(G) Appropriate training on a regular basis.

(H) Equipment and replacement parts inventories including identification of critical replacement parts.

5. Design and Performance Provisions
(A) Requirements and standards for the installation of new sewers, pumps, and other appurtenances, and for rehabilitation and repair projects.

(B) Procedures and specifications for inspecting and testing the installation of new sewers, pumps, and other appurtenances, and for rehabilitation and repair projects.

6. Monitoring, Measurement, and Program Modifications

Monitor the implementation and, where appropriate, measure the effectiveness of each element of the CMOM program. Program elements must be updated as appropriate based on monitoring or performance evaluations. The summary of the CMOM program should be modified as appropriate to keep it updated and accurate.

3) Overflow Response Plan

An overflow response plan should be developed and implemented that identifies measures to protect public health and the environment including, but not limited to, mechanisms to:

(i) Ensure that all overflows are made aware of (to the greatest extent possible);

(ii) Ensure that overflows are appropriately responded to, including ensuring that reports of overflows are immediately dispatched to appropriate personnel for investigation and appropriate response;

(iii) Ensure appropriate reporting pursuant to 40 CFR 122.42(e);

(iv) Ensure appropriate notification to the public, health agencies, and other impacted entities (e.g. water suppliers) pursuant to 40 CFR 122.42(h). The CMOM plan should identify the public health and other officials who will receive immediate notification;

(v) Ensure that appropriate personnel are aware of and follow the plan and are appropriately trained; and

(vi) Provide emergency operations.

4) System Evaluation and Capacity Assurance Plan

A plan should be prepared and implemented for system evaluation and capacity assurance if peak flow conditions are contributing to an SSO discharge unless either (1) already taken steps to correct the hydraulic deficiency or (2) the discharge meets the criteria of 122.42(g)(2). At a minimum the plan must include:

(i) *Evaluation:* Steps to evaluate those portions of the collection system which are experiencing or contributing to an SSO discharge caused by hydraulic deficiency or to noncompliance at a treatment plant. The evaluation should provide estimates of peak flows (including flows from SSOs that escape from the system) associated with conditions similar to those causing overflow events, provide estimates of the capacity of key system components, identify hydraulic deficiencies, including components of the system with limiting capacity and identify the major sources that contribute to the peak flows associated with overflow events.

(ii) *Capacity Enhancement Measures:* Establish short- and long-term actions to address each hydraulic deficiency including prioritization, alternative analysis, and a schedule.

(iii) *Plan Updates:* The plan should be updated to describe any significant change in proposed actions and/or implementation schedule. The plan should also be updated to reflect available information on the performance of measures that have been implemented.

5) CMOM Program Audits

As part of the NPDES permit application, an audit should be conducted, appropriate to the size of the system and the number of overflows, and a report submitted of such audit, evaluating the CMOM program and its compliance with this subsection, including its deficiencies and steps to respond to them.

6) Communications

The permittee should communicate on a regular basis with various interested parties on the implementation and performance of its CMOM program. The communication system should allow interested parties to provide input to the permittee as the CMOM program is developed and implemented.

Inspection and Cleaning of Combined Sewers (AM2)

Related Goals: 3, 4, 7
Related Indicators: 11, 19

What	Who	Where	When
Inspection activities, routine maintenance, monitoring activities.	PWD	Combined Sewered Areas (see Figure 8.3).	First 5 years coinciding with the stormwater permit.

Maintenance of sewers includes activities required to keep the system functioning as it was originally designed and constructed. Any reinvestment in the system, including routine maintenance, capital improvements for repair or rehabilitation, inspection activities, and monitoring activities are generally classified as maintenance.

An inspection program is vital to proper maintenance of a wastewater collection system. Without inspections, a maintenance program is difficult to design, since problems cannot be solved if they are not identified. Sewer inspections identify problems such as blocked, broken, or cracked pipes; tree roots growing into the sewer; sections of pipe that settle or shift so that pipe joints no longer match; and sediment and other material building up and causing pipes to break or collapse. The elements of an inspection program include flow monitoring, manhole inspections, smoke/dye testing, closed circuit television inspection, and private sector inspections. Private sector building inspection activities include inspection of area drains, downspouts, cleanouts, sump discharges, and other private sector inflow sources into the system.

In addition to inspection, routine maintenance must also include sewer cleaning, root removal/treatment, cleaning of mainline stoppages, cleaning of house service stoppages, and inspections and servicing of pump stations.

PWD is responsible for implementation of this option in the combined sewer areas of the Tookany/Tacony-Frankford Watershed, but municipalities with separate sewers should have similar permanent and active sewer maintenance programs in place under CMOM (see Option AM1). In Section 4.4.1, Figure 4.19 illustrated the areas where sanitary sewers and combined sewers exist. All municipalities in the watershed are responsible for sewer maintenance.

PWD has combined sewer maintenance responsibilities in the Tookany/Tacony-Frankford Watershed. CSO regulations (including the Nine Minimum Controls discussed in Section 1.4.5) have required that PWD carry out improved sewer maintenance. Some of the activities PWD is carrying out include the review and improvement of ongoing operation and maintenance programs, and comprehensive inspection and monitoring programs to characterize and report overflows and other conditions in the combined sewer system.

Sanitary Sewer Rehabilitation (AM3) Related Goals: 3 Related Indicators: 7, 11			
What	Who	Where	When
Perform major repairs or replacement on sections of sewer determined to be in poor condition.	All municipalities with separate sanitary sewer systems.	All municipalities with separate sanitary sewer systems.	Medium-term.

The CMOM and sewer inspection programs discussed in the two preceding sections may identify segments of sewer that are in poor condition and in need of major repair or replacement. The information in this section is adapted from fact sheets on the EPA web site: http://www.epa.gov/owm/mtb/rehabl.pdf.

Under the traditional method of sewer relief, a replacement or additional parallel sewer line is constructed by digging along the entire length of the existing pipeline. While these traditional methods of sewer rehabilitation require unearthing and replacing the deficient pipe (the dig-and-replace method), trenchless methods of rehabilitation use the existing pipe as a host for a new pipe or liner. Trenchless sewer rehabilitation techniques offer a method of correcting pipe deficiencies that requires less restoration and causes less disturbance and environmental degradation than the traditional dig and-replace method.

Trenchless Sewer Rehabilitation Methods:

- Pipe Bursting, or In-Line Expansion
- Sliplining
- Cured-In-Place Pipe
- Modified Cross Section Liner

These alternative techniques must be fully understood before they are applied. These four sewer rehabilitation methods are described further below:

Pipe Bursting or In-Line Expansion: Pipe bursting, or in-line expansion, is a method by which the existing pipe is forced outward and opened by a bursting tool. The Pipebursting™ method, patented by the British Gas Company in 1980, was successfully applied by the gas pipelines industry before its applicability was identified by other underground utility agencies. Over the last two decades, other methods of in-line expansion have been patented as well. During in-line expansion, the existing pipe is used as a guide for inserting the expansion head (part of the bursting tool). The expansion head, typically pulled by a cable rod and winch, increases the area available for the new pipe by pushing the existing pipe radially outward until it cracks. The bursting device pulls the new pipeline behind itself.

Sliplining: Sliplining is a well-established method of trenchless rehabilitation. During the sliplining process, a new liner of smaller diameter is placed inside the existing pipe. The annular space, or area between the existing pipe and the new pipe, is typically grouted to prevent leaks and to provide structural integrity.

Cured-In-Place Pipe: During the cured-in-place pipe (CIPP) renewal process, a flexible fabric liner, coated with a thermosetting resin, is inserted into the existing pipeline and cured to form a new liner. The liner is typically inserted into the existing pipe through an existing manhole. The fabric tube holds the resin in place until the tube is inserted in the pipe and ready to be cured. Commonly manufactured resins include unsaturated polyester, vinyl ester.

Modified Cross Section Lining: The modified cross section lining methods include deformed and reformed methods, sewagelining™, and rolldown. These methods either modify the pipe's cross sectional profile or reduce its cross sectional area so that the liner can be extruded through the existing pipe. The liner is subsequently expanded to conform to the existing pipe's size. Another method of obtaining a close fit between the new lining and existing pipe is to temporarily compress the new liner before it is drawn through the existing pipeline. The sewagelining™ and rolldown processes use chemical and mechanical means, respectively, to reduce the cross-sectional area of the new liner.

External Sewer Rehabilitation Methods (adapted from EPA/600/R-01/034)

External rehabilitation methods are performed from the above ground surface by excavating adjacent to the pipe, or the external region of the pipe is treated from inside the pipe through the wall. Some of the methods used include:

- External Point Repairs
- Chemical Grouting (Acrylamide Base Gel, Acrylic Base Gel)
- Cement Grouting (Cement, Microfine Cement, Compaction)

Internal Sewer Rehabilitation Methods

The basic internal sewer rehabilitation methods include:

Chemical Grouting: Internal grouting is the most commonly used method for sealing leaking joints in structurally sound sewer pipes. Chemical grouts do not stop leaks by filling cracks; they are forced through cracks and joints, and gel with surrounding soil, forming a waterproof collar around leaking pipes. This method is accomplished by sealing off an area with a "packer," air testing the segment, and pressure injecting a chemical grout for all segments which fail the air test. The three major types of chemical grout are: Acrylic, Acrylate, and Urethane.

Continuous Pipe: Insertion of a continuous pipe through the existing pipe (Polyethylene and Polypropylene).

Segmental: Short segments of new pipe are assembled to form a continuous line, and forced into the host pipe. Generally, this method is used on larger sized pipe and forced into the host pipe. (Polyethylene, Polyvinyl Chloride, Reinforced Plastic Mortar, Fiberglass Reinforced Plastic, Ductile Iron, Steel).

Fold and Form Pipe: This is similar to sliplining, except that the liner pipe is deformed in some manner to aid insertion into the existing pipe. Depending on the specific manufacturer, the liner pipe may be made of PVC or HDPE. One method of deforming the liner is to fold it into a "U" shape before insertion into the existing pipe. The pipe is then returned to its original circular shape using heated air or water, or using a rounded shaping device or mandrel. Ideally, there will be no void between the existing pipe and the liner pipe after expansion of the liner pipe with the shaping device. For the "U" shape liner, the resulting pipe liner is seamless and jointless.

Spiral Wound Pipe: This involves winding strips of PVC in a helical pattern to form a continuous liner on the inside of the existing pipe. The liner is then strengthened and supported with grout that is injected into the annular void between the existing pipe and the liner. A modified spiral method is also available that winds the liner pipe into a smaller diameter than the existing pipe, and then by slippage of the seams, the liner expands outward.

Combined Sewer Rehabilitation (AM4)

Related Goals: 3, 7
Related Indicators: 7, 8, 9, 10, 11, 19, 20

What	Who	Where	When
Perform major repairs or replacement on sections of sewer determined to be in poor condition.	PWD	Combined-Sewered Areas.	Medium-term.

Rehabilitation of combined sewers is conceptually similar to rehabilitation of separate sanitary sewers. Refer to Option AM3 above for information on specific techniques.

Illicit Discharge, Detection, and Elimination (IDD&E) (AM5) Related Goals: 3, 6, 7 Related Indicators: 7, 8, 9, 10, 11, 16, 19, 20			
What	Who	Where	When
IDD&E Program in conformance with Phase II Stormwater Permits and the LTCP for PWD.	All Municipalities required to do Phase II permit (see Table 8.7); PWD in CSO Areas.	All areas with a storm sewer or combined sewer (see Figure 8.3).	5-year program associated with stormwater permit (see Table 8.10).

In accordance with the Tookany/Tacony-Frankford Watershed Plan's stated purpose of integrating various existing programs, and to avoid duplication of effort, the recommended implementation plan follows the PA DEP Stormwater Management Program Protocol to meet the six minimum control measures required of municipal permittees under the Phase II NPDES Stormwater Regulations (listed in Section 1.4.1 of this report, and found at 40 CFR §§ 122.26 – 123.35). One of the six minimum controls is an IDD&E program. The IDD&E program can be summarized as consisting of the following steps:

- Develop map of municipal separate storm sewer system outfalls and receiving water bodies.
- Prohibit illicit discharges via PA DEP-approved ordinance.
- Implement an IDD&E Program that includes 1) field screening program and procedures and 2) elimination of illicit discharges.
- Conduct public awareness and reporting program (see Option AP1, "Public Education," in Section 8.1.2).

A similar approach to controlling dry weather flows is being followed by PWD under the Long Term Control Plan (LTCP) for CSOs.

Each step is explained in more detail below:

Develop an Outfall Map

The federal regulations define an outfall as "a point source as defined by 40 CFR 122.2 at the point where a municipal separate storm sewer discharges to waters of the United States." A "point source" is defined as "any discernable, confined, and discrete conveyance, including but not limited to any pipe, ditch, channel, tunnel, conduit, well, discrete fissure, container, rolling stock, concentrated animal feeding operation, vessel, or other floating craft from which pollutants are or may be discharged."

Many of the outfalls along Tookany/Tacony-Frankford Creek have already been located under the studies performed for the Tookany/Tacony-Frankford Creek RCP. Municipalities should work with PWD to develop a consistent set of outfall maps that meet the specific requirements of the Phase II program.

Illicit Discharge Ordinance

A model ordinance is available from PA DEP and should be used as is. PA DEP discourages changes to the model ordinance, because it has been prepared to meet the MS4 permit requirements. However, some municipalities already have good stormwater ordinances. Municipalities who do not wish to enact the model ordinance in its entirety must get approval from PA DEP to ensure that the MS4 permit requirements are met.

The model ordinance must be enacted in the first year of the permit term, except where a municipality commits to a multi-municipal, watershed-based program following the Stormwater Management Program Protocol, in which case the schedule is delayed one year. Subsequent to completion of the Act 167 Plan (or Plan Update), the ordinance must be modified to reflect Plan requirements. Regardless of the timing of the Act 167 Plan (or Plan Update) an ordinance must be enacted within the first two years of the permit term for all municipalities in the Tookany/Tacony-Frankford Watershed.

IDD&E Program

Following the PA DEP Protocol, the IDD&E Program must consist of the following three elements, which must be implemented according to the schedule shown below:

- Conduct Field Screening.
- Identify Source of Illicit Discharges.
- Develop and Implement a Strategy to Remove or Correct Illicit Discharges.

Field Screening: Field screening is necessary to identify source(s) of actual illicit discharges. Field screening must start in Year 2 of the permit. PA DEP provides a checklist that must be used when conducting field screening. Every outfall in priority areas must be screened two times a year. This activity can be accomplished concurrently with other existing field activities, such as regularly scheduled fire hydrant inspections, road repairs, landscaping activities, other field work conducted during county preparation of the Act 167 stormwater plan, etc.

Using a PA DEP supplied Checklist, the staff designated to conduct field screening collect visual data. The screening should be conducted at least 72 hours since the last precipitation event, and at least 48 hours should pass between the first screening at a particular outfall and the second screening at that outfall. If someone conducting the field screening discovers a dry-weather flow, they (or another designated individual with the proper training) must collect a sample of that flow for analysis. Such a discovery triggers the requirements under the other two program elements, below.

Identify Source of Illicit Discharges: The following IDD&E Program elements apply only if a dry-weather flow is identified during field screening activities in Years 2, 3, 4, and/or 5.

If field inspectors identify a dry-weather flow at an outfall during field screening, they should take two grab samples of the flow and analyze the samples for the characteristics and pollutants listed in the Table 8.9 below.

Table 8.9 Dry-Weather Flow Sampling Analysis Requirements

Characteristic/Pollutant	Method
Color	Visual observation
Odor	Visual observation
Turbidity	Visual observation
Sheen/scum	Visual observation
PH	In-field analysis
Total chlorine	In-field analysis
Total copper	In-field analysis
Total phenol	In-field analysis
Detergents/surfactants	In-field analysis
Flow	In-field measurement
Bacteria	Laboratory analysis

The data obtained from visual, in-field, and laboratory analyses will provide the information necessary to determine the source of the dry-weather flow or floatables. Based on the pollutants contained in the sample, it should be possible to determine if the source is from illegal dumping in a storm drain, a cross-connection, or a leak in a pipe. Potential sources of the dry-weather flow can be located by tracing the flow upstream using storm drain maps and by inspecting upgradient manholes and storm drains. If need be, a more focused test to pinpoint the source can be tried, such as dye testing, smoke testing, and television camera inspection.

Remove or Correct the Illicit Discharge: Once the source has been identified, municipalities need to determine if it is a case of improper dumping or if a property owner has an improper physical connection to the storm sewer system. This will help to select the most appropriate method for correcting or removing the discharge. If it is a case of improper dumping, the only recourse may be to conduct intensified education of residents living in and traveling through that area. If it is a case of an improper physical connection, the appropriate action can be taken to correct the discharge. A plan of action to eliminate illicit connections might include plugging discharge points or disconnecting and reconnecting lines.

If a violation is found, the property owner should be notified of the violation and given a timeframe for removal of the source. After that time has passed, the outfall can be screened to identify the dry weather discharge. The property should be visited a final time to confirm that the property owner removed or corrected the source. The results of all discussions, tests, and screenings should be documented for follow-up purposes. Progress evaluation of the municipal IDD&E program will depend on the ability to tabulate the number of illicit connections corrected and the status of those in the process of being corrected.

All municipalities within the Tookany/Tacony-Frankford Watershed that have a sanitary sewer system are required to carry out this program. Table 8.7 lists the municipalities, and Figure 8.3 shows the location of the sewered areas.

The PA DEP Protocol has laid out a very specific time table for completion of this program by the municipalities. The timing is shown in Table 8.10 below.

Table 8.10 Implementation Schedule for IDD&E Program

PERMIT YEAR	***IMPLEMENTATION SCHEDULE PERMIT REQUIREMENTS AND MEASURABLE GOALS***			
	Mapping	**Ordinance**	**Program**	**Education**
Year 1	Complete map of all outfalls.	Adopt and enact.	Screen Priority Areas. Take corrective actions to remove illicit discharges (as needed).	Presentation on IDD&E. Program and Ordinance during a public meeting. Distribute educational material (see Public Education and Outreach Minimum Measure).
Years 2 - 5	Establish priority areas for 25% of system.	Implement and enforce.	Screen Priority Areas. Take corrective actions to remove illicit discharges (as needed).	Distribute educational material (see Public Education and Outreach Minimum Measure).

The River Conservation Plans (RCPs) noted the following:

- <u>Rising Sun Avenue to Roosevelt Blvd</u>: Investigate exposed pipe at Tabor Road.

Stream Cleanup and Maintenance (AM6)

Related Goals: 1, 3, 4, 6, 7
Related Indicators: 3, 4, 5, 6, 10, 11, 15, 16, 17, 19, 20

What	Who	Where	When
Remove litter and heavy debris. Maintain habitat improvements (fish ladders, FGM, elimination of plunge pools).	PWD Waterways Restoration Unit; Fairmount Park volunteers and other volunteer groups.	Entire creek system.	Begin within 5 years; monthly maintenance schedule to be determined.

Keeping streams free of trash is a continuous activity. Fairmount Park volunteers alone have removed over 2,000 bags of trash from the stream corridor since 1998. Public education should help in reducing trash and debris reaching the streams; however, PWD and municipalities need to put into place a permanent maintenance schedule. PWD has implemented a permanent Waterways Restoration Unit. This team periodically removes trash and large debris from Tookany/Tacony-Frankford Creek on a rotating schedule. For reaches of stream within the City or along the City boundary, the team will focus on removal of litter and heavy debris, and maintenance of instream aquatic habitat improvement projects including fish ladders, fluvial geomorphologic restoration projects, and elimination of outfall plunge pools. For reaches of stream outside the City, municipalities should organize periodic stream cleanups using volunteer groups.

In addition to noting the specific trouble spots listed below, the River Conservation Plans (RCPs) recommend a general cleanup routine be established to conserve both the biological and aesthetical quality of the rivers. Any plans that reduce the amount of trash or illegal dumping would be considered essential. Local township volunteers can be of great assistance in this particular BMP.

- Wyncote Post Office to Washington Lane Underpass: Investigate dumping of construction material.
- Rock Creek Watershed: Monitor commercial areas for illegal dumping.
- Rising Sun Avenue to Roosevelt Boulevard: Erect a barricade to deter illegal dumping.
- Roosevelt Boulevard to Whitaker Avenue: Install a barrier to stop dumping at Whitaker Ave. Bridge.
- Whitaker Avenue to Wyoming Avenue: Erect a barricade to deter illegal dumping.
- Aramingo Avenue between Wheatsheaf Lane and Church Street: Install fence barrier at Aramingo Ave. overpass to stop illegal dumping.
- Holy Sepulchre Cemetery to Ralph Morgan Park: Conduct regular trash removal.
- Ralph Morgan Park to Greenwood Avenue: Clear debris blocking stormwater outlets and ask staff not to dump leaves in the creek.

- Greenwood Avenue to Wyncote Post Office: Routinely clear creek of trash and debris after storms.
- Wyncote Post Office to Washington Lane Underpass: Major cleanup required. SEPTA should be contacted to clean railroad debris.
- Washington Lane Underpass to Church Road: Remove trash, storm debris, and graffiti.
- High School Park to Ashbourne Road along the Tookany Creek Parkway: Conduct regular trash removal.
- Unnamed Tributary in Glenside: Clean up trash and storm debris along Tyson Ave. SEPTA should monitor culverts for blockage.
- Rock Creek Watershed: Continue to improve infrastructure that has a negative impact on water quality. Conduct regular trash removal.
- Abington Country Club to Township Line Road: Clean and maintain channelized portion of the creek on a regular basis.
- Township Line Road near Foxcroft Road to Main Stem (unnamed tributary): Clear entire reach of storm debris.
- Abington Friends School to Township Line Road: Regularly remove trash in the creek area.
- Township Line Road to Tookany Creek Parkway: Conduct regular trash/debris removal.
- Cheltenham Avenue to Adams Avenue: Clear creek of debris. Concentrate on woody debris at bridge. Evaluate trash pick-up schedule with Fairmount Park.
- Crescentville and Adams Avenues to Rising Sun Avenue: Conduct regular trash removal.
- Rising Sun Avenue to Roosevelt Boulevard: Conduct a massive trash removal, concentrating at the F Street site. Clear overgrown vegetation.
- Roosevelt Boulevard to Whitaker Avenue: Conduct massive trash removal of the whole segment.
- Wyoming Avenue to Castor Avenue: Conduct a trash cleanup. Contact Ferko Playground regarding trashcans and regular trash removal.
- Castor Avenue to Erie Avenue: Remove graffiti from walls and secure access areas.
- Aramingo Avenue between Wheatsheaf Lane and Church Street: Clear creek of all debris.
- Rohm & Haas, 5000 Richmond Street: Conduct trash removal at mouth of embankment.
- Intersection of Adams and Newtown Avenue: Investigate illegal dumpsite and install fencing.
- Driveway connecting Adams Ave to Godfrey Ave: Investigate illegal dumpsite and install fencing.
- Castor Avenue near Wyoming Avenue: Investigate illegal dumpsite and install fencing.
- I and Ramona: Investigate illegal dumpsite and install fencing.
- Awbury Arboretum: Investigate illegal dumpsite and install fencing.

8.1.4 Target A Options: Recreational and Cultural Resources

Enhancing Stream Corridor Recreational and Cultural Resources (AO1)

Related Goals: 4, 6, 7
Related Indicators: 16, 17, 18, 19, 20, 21

What	Who	Where	When
Establish and improve trails and greenways using measures recommended in the RCPs and the Fairmount Park Trails Master Plan. Protect historic sites listed in the RCPs.	Outside Philadelphia: partnership of Department of Conservation and Natural Resources (DCNR), county planning departments, and municipalities. Inside Philadelphia: Fairmount Park Commission.	See Figures 8.2.	Medium-term: 5-15 years.

Part of Target A addresses the accessibility of Tookany/Tacony-Frankford Creek. Once dry weather water quality and aesthetics have been improved, the recreational value of the Creek will be enhanced, and better accessibility becomes important. A stream accessibility analysis (Section 4.6.4, Indicator 18) illustrated that much of the headwaters and the downstream portion of the Tookany/Tacony-Frankford are inaccessible. The recommended actions focus primarily on improving access to public lands where recreational potential is greatest.

The River Conservation Plans (RCPs) recommend improving existing stream corridor recreation resources in order for the watershed to gain value as a civic asset. This goal can be achieved through building/repairing trails or by blocking disruptive activities (such as ATV use). Protecting historically significant items is also a recommendation. The RCPs noted in particular:

- Church Road at Chelten Hills Drive to Church Road near Ogontz Field: Remove millstones for historic display at Wall House.
- Rock Creek Watershed: Consider a trail or greenway along township-owned segments.
- Cheltenham Avenue to Adams Avenue: Repair trail erosion at benches. Recommend repair or removal of exercise stations.
- Crescentville and Adams Avenues to Rising Sun Avenue: Research and implement swimming deterrents.
- Whitaker Avenue to Wyoming Avenue: Create barriers to stop ATV use.
- Holy Sepulchre Cemetery to Ralph Morgan Park**:** Create a parks master plan for this area.

Fairmount Park's Natural Lands Restoration and Trails Master Plan contains specific recommendations for creating and enhancing trails in their park system. These are shown in Table 8.11 and Figure 8.2 on the pages that follow.

Table 8.11 Fairmount Park Trails Master Plan Recommendations

- Provide maximum support and development of positive volunteer educational and restoration efforts already in place.
- Eliminate redundant and problematic trails that are contributing to the ecological decline of the natural areas.
- Increase perceived safety by providing better trail sight lines and perimeter lighting.
- Create well-defined trail heads that have good transit and regional connections.
- Provide access points/gateways to adjacent neighborhoods.
- Provide interpretive and educational opportunities for the diverse ecological and cultural settings of the park.
- Provide for adequate parking and controlled access to the trails to eliminate/reduce likelihood of trails as entrance points for motorized vehicles (particularly ATV's and abandoned autos).
- Provide maintenance strategies and restoration solutions for eroded and degraded trails that will continue to be used.

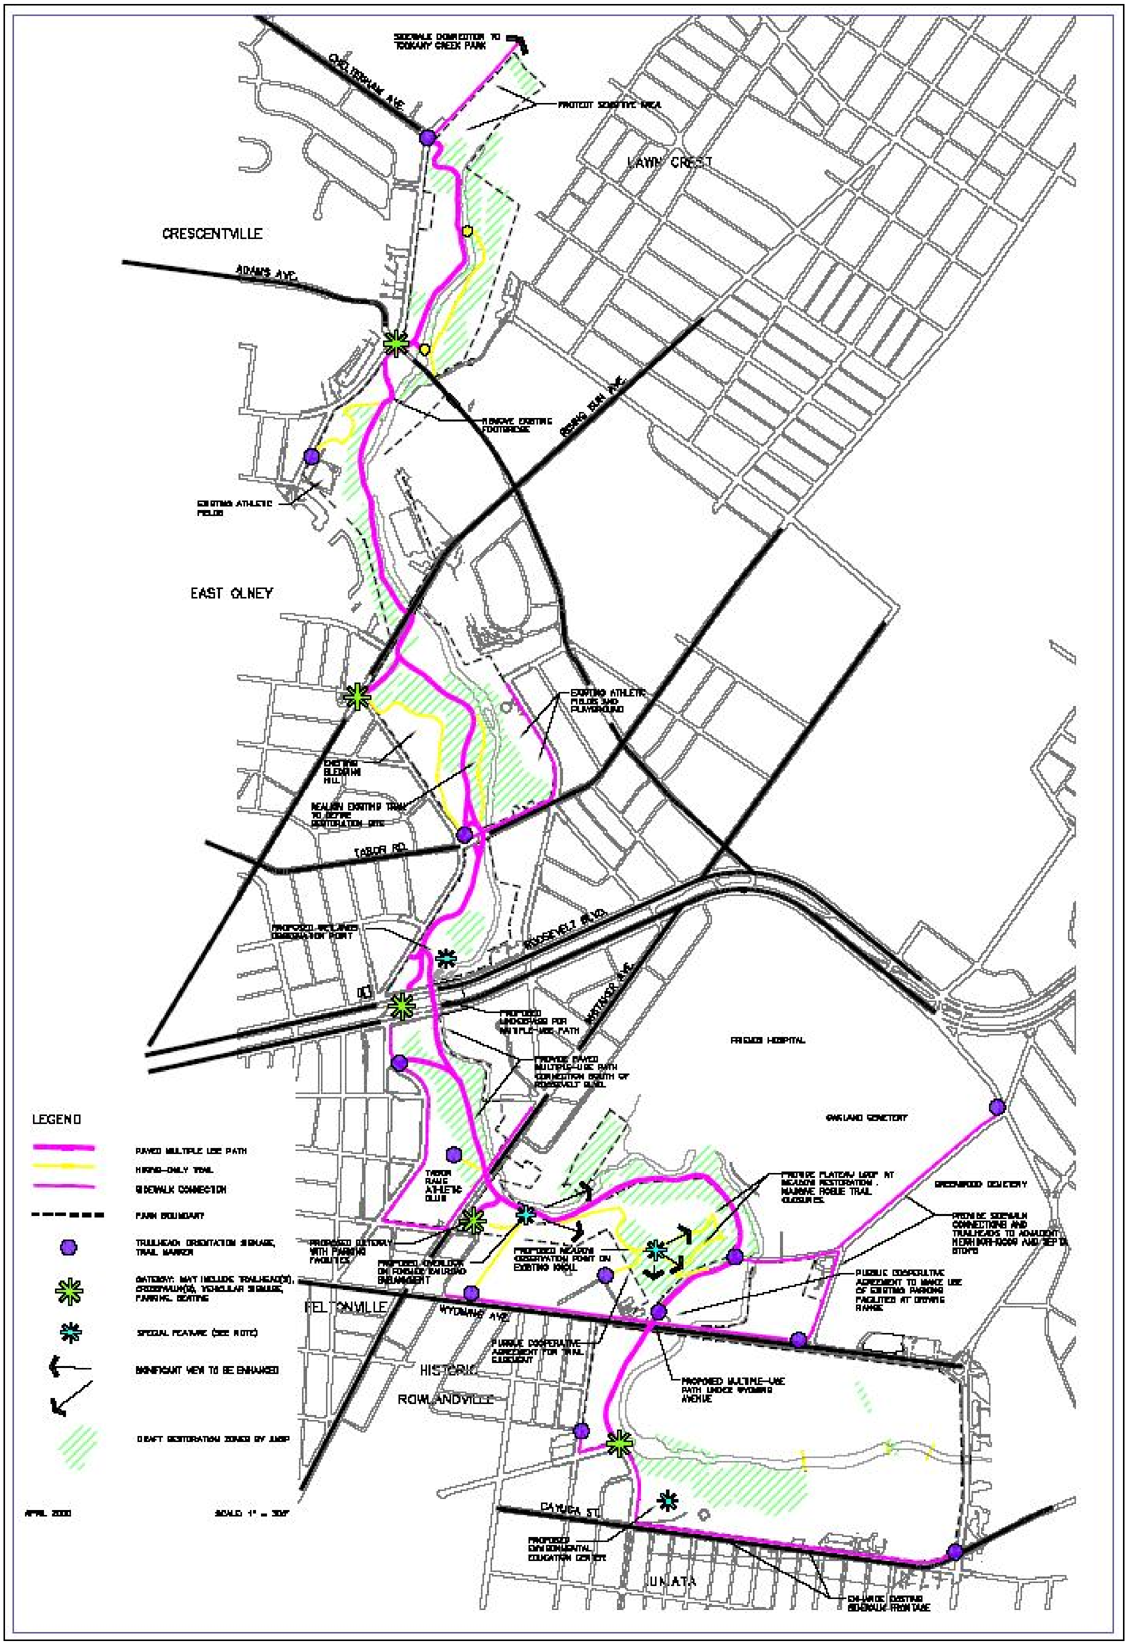


Figure 8.2 Fairmount Park's Proposed Trails Plan for Tookany/Tacony-Frankford Creek

8.1.5 Target A Options: Monitoring and Reporting

Monitoring, Reporting, and Further Study (AMR)

Related Goals:
Related Indicators: 16, 17, 18, 19, 20, 21

What	Who	Where	When
Monitor and collect data in areas where more information is needed to clarify the situation or establish a proper BMP.	PWD in CSO areas; municipal townships in separate sewered areas.	See Figure 8.3.	Short-term: 1-5 years.

The River Conservation Plans (RCPs) recommend monitoring sites where there is an unexpected substance, odor, or bacteria. A comprehensive water quality analysis is also recommended.

- <u>Ralph Morgan Park to Greenwood Avenue</u>: Identify the orange milky substance. Focus on water quality.
- <u>Wyncote Post Office to Washington Lane Underpass</u>: Investigate orange gel-like substance. Township to lead investigation.
- <u>Rock Creek Watershed</u>: Continue to monitor the areas with excessive coliform levels.
- <u>Rising Sun Avenue to Roosevelt Boulevard</u>: Target the cause of sewer odor and rectify.
- <u>Roosevelt Boulevard to Whitaker Avenue</u>: Target outfalls. Investigate possible disconnected sewer line.
- <u>Wyoming Avenue to Castor Avenue</u>: Target outfalls. Investigate sewage smells.
- <u>Aramingo Avenue between Wheatsheaf Lane and Church Street</u>: Investigate discharge from outfall pipe.

In the first five-year implementation plan, additional studies will be recommended to focus on dissolved oxygen, sources of fecal coliform, and the potential causes of large dissolved oxygen swings in the lower portion of the watershed.

8.2 Target B: Healthy Living Resources

Given the historic degradation of the water quality and ecology of Tookany/Tacony-Frankford Creek and its tributaries from urbanization, an interdependent set of corridor improvement actions are recommended. Because of that interdependent nature, this section begins with an overview that addresses various points common to many or all of the recommended Target B options. Following that overview, the individual options – all of which were recommended for implementation (as explained in Section 7) – are described in detail.

Section 8.2.1 **Overview: Stream and Riparian Corridor Improvement**

Section 8.2.2 **Channel Stability and Aquatic Habitat Restoration**

BM1	Bed Stabilization and Habitat Restoration
BM2	Bank Stabilization and Habitat Restoration
BM3	Channel Realignment and Relocation
BM4	Plunge Pool Removal
BM5	Improvement of Fish Passage

Section 8.2.3 **Lowland and Upland Restoration and Enhancement**

BM6	Wetland Creation and Enhancement
BM7	Invasive Species Management
BM8	Biofiltration
BM9	Reforestation

Section 8.2.4 **Monitoring and Reporting**

BMR	Monitoring, Reporting, and Further Study

8.2.1 Overview: Stream and Riparian Corridor Improvement

This Tookany/Tacony-Frankford Integrated Watershed Management Plan proposes a comprehensive stream and riparian corridor restoration strategy. The recommended actions presented throughout Section 8.2 – ranging from conservation of existing open spaces, to stream stabilization actions, to creation of new wetlands and biofiltration areas – together constitute a fully integrated riparian corridor improvement strategy that provides new habitat and water quality improvement. In the Philadelphia portion of the riparian corridor, this approach is intended to complement and expand the Fairmount Park Commission's Environmental Stewardship and Education Program.

These riparian corridor improvement actions, when implemented simultaneously, will result in improvements that span the waterway and riparian corridor. Thus, riparian corridor actions improve the ecology of the Tookany/Tacony-Frankford Creek landscape and optimize the ways in which the limited remaining open space can help improve water quality. The long-term benefits of an integrated riparian strategy significantly outweigh the short-term construction disturbances that are needed to implement the Tookany/Tacony-Frankford Creek riparian corridor improvements.

The riparian corridor is defined here as the land area that borders a stream and which directly affects and is affected by the water quality, including floodplains, shorelines, wetlands, and riparian forest. For the purposes of the Tookany/Tacony-Frankford Creek riparian corridor improvement strategy, the riparian area also includes the stream channel. Thus, the full undeveloped land and waterway area between the existing land development that surrounds the corridor will be considered for ecological improvement and for biofiltration functions that will improve water quality. Listed below are the options recommended for implementation across the corridor, from the lowest point in the landscape (the stream channel) to the highest (upland forest).

The most effective approach to riparian corridor improvement is to perform all the proposed streambed, streambank, wetland, and riparian upland improvements simultaneously along a reach, or stream section, to realize the synergy of the full set of landscape improvements. When one stream segment is completed, work would shift to the next priority location, section by section, for the length of the Tookany/Tacony-Frankford Creek corridor.

Implementing one set of corridor actions, for example, bed stabilization, without complementary actions, such as bank stabilization, will result in only limited success, because the aquatic and streamside land environments must function interactively to provide optimal stability. For this reason, the riparian corridor improvement strategy is both a short-term and long-term plan. Restoration activities in sections of the watershed that are in greatest need of improvement should be implemented early (targeting stream sections that are causing or contributing to water quality or ecological impairment first). For the Tookany/Tacony-Frankford Creek corridor, it is anticipated that significant improvements in water quality and ecology can be realized by addressing high priority locations that are principally upstream during the first 5 years, with sections downstream of Castor Ave. that require further evaluation of water quality issues receiving riparian corridor improvement during a second 10 year period (see Figure 8.4 and Table 8.12). It is important to note that the next step in implementing the riparian corridor improvement strategy is to develop a corridor improvement facilities plan, under which integrated designs are prepared for the full range of corridor improvements (e.g., bed and bank stabilization, and wetland creation and enhancement).

PWD recently performed stream assessments along the entire Tookany/Tacony-Frankford Creek corridor. The results of this study will provide more specific guidance on priority stream sections and recommended improvements.

The River Conservation Plans (RCPs) include the following recommendations for restoring buffer zones and undercut creek banks in an effort to control both stream contamination and flooding:

- Holy Sepulchre Cemetery to Ralph Morgan Park: Initiate plan to study geomorphology and sinuosity. Restore and enforce riparian buffer regulations. Conduct streambank stabilization.
- Ralph Morgan Park to Greenwood Avenue: Restore banks where there is severe undercutting. Plant creek banks to prevent washed out areas. Create "no-mow" zones. Remove a retaining wall, regrade, and plant the bank to facilitate a natural retaining basin. Relocate and replace the macadam walking path with natural material.
- Church Road at Chelten Hills Drive to Church Road near Ogontz Field: Possible relocation of playground equipment away from stream bank to promote healthier buffer zone. Check stability of rip-rap and stacked cement retaining wall. Restore and/or stabilize some of the undercut bank and root exposed trees.
- High School Park to Ashbourne Road along the Tookany Creek Parkway: Initiate plan to study local geomorphology and sinuosity. Conduct streambank stabilization.
- Unnamed Tributary in Glenside: Redesign, regrade, and plant banks along Grove Park. Create "no-mow" zone. Create riparian buffer zone, restore streambank along Waverly Rd. Formally name all unnamed tributaries.
- Baeder Creek Watershed: Consider removal of vertical gabion baskets and concrete wall in place of natural bank slopes. Conduct a hydrological assessment to correct serious flooding and bank instability; much of the creek's geometry has been altered. Conduct biotechnical streambank stabilization in most severe areas.
- Rock Creek Watershed: Restore the riparian buffer.
- Mill Run Watershed: Restore the riparian buffer. Enforce regulations.
- Abington Country Club to Township Line Road: Re-establish riparian buffer, possibly a 20-ft "no-mow" zone.
- Township Line Road near Foxcroft Road to Main Stem (unnamed tributary): Restore and stabilize some of the undercut and eroded banks.
- Abington Friends School to Township Line Road: Consider restoration of natural riparian buffer and channel along residential areas. Repair eroded areas using naturalized approaches such as native plantings.

- Township Line Road to Tookany Creek Parkway: Replant riparian areas and restore riparian buffer. Enforce regulations. Conduct biotechnical streambank stabilization.
- Cheltenham Avenue to Adams Avenue: Restore creek banks where there is severe undercutting.
- Crescentville and Adams Avenues to Rising Sun Avenue: Restore creek banks where there are exposed roots.
- Rising Sun Avenue to Roosevelt Boulevard: Repair undercut streambanks.
- Roosevelt Boulevard to Whitaker Avenue: Restore creek banks where there is severe erosion.
- Whitaker Avenue to Wyoming Avenue: Restore creek banks and repair restoration site.
- Wyoming Avenue to Castor Avenue: Repair undercut and exposed streambank. Repair manmade restoration project.
- Aramingo Avenue between Wheatsheaf Lane and Church Street: Restore creek banks.
- Holy Sepulchre Cemetery to Ralph Morgan Park: Remove fencing crossing stream; it appears to impede normal flow.

8.2.2 Target B Options: Channel Stability and Aquatic Habitat Restoration

Text to be inserted	Placeholder box	Text to be inserted	Placeholder box

Plunge Pool Removal (BM4)

Related Goals: 5, 7
Related Indicators: 3, 15, 19, 20

What	Who	Where	When
Remove plunge pools below stormwater and CSO outfalls.	PWD, and municipalities bordering streams recommended for restoration.	Outfalls shown in Figure 8.3.	Begin within 5 years; monthly maintenance schedule to be determined.

When stormwater and combined sewer outfalls discharge directly to the stream channel, they may create deep, poorly mixed pools. Both types of outfalls discharge along the length of the Tookany/Tacony-Frankford and its tributaries (Figure 8.3). Because these pools are typically near the bank and not in the main flow, they can become poorly mixed during low flow. These pools often have increased odors and reduce the aesthetic quality of the stream. Biological activity in the sediment and water column can reduce dissolved oxygen to low levels, and this low-DO water can be flushed out and affect downstream areas during wet weather. The depression of DO is a function of both pollutant loads from the outfalls and in stream baseflow, and the physical condition of the channel. When DO is in an acceptable range in the well-mixed portion of the channel but not in nearby plunge pools, elimination of the plunge pools can eliminate a water quality condition that might affect the aquatic ecosystem.

When possible, outfalls can discharge further up the bank into a wetland or biofiltration area; these areas provide detention, evaporation, cooling, and treatment of pollutant loads in addition to protecting the integrity of the stream channel. Opportunities for creation of these areas (Options BM6 and BM8, respectively) will be discussed later in this section. Where the only place for an outfall to discharge is directly into the stream channel, the area may be protected using appropriate bed and bank stabilization features (Options BM1 and BM2), as discussed above.

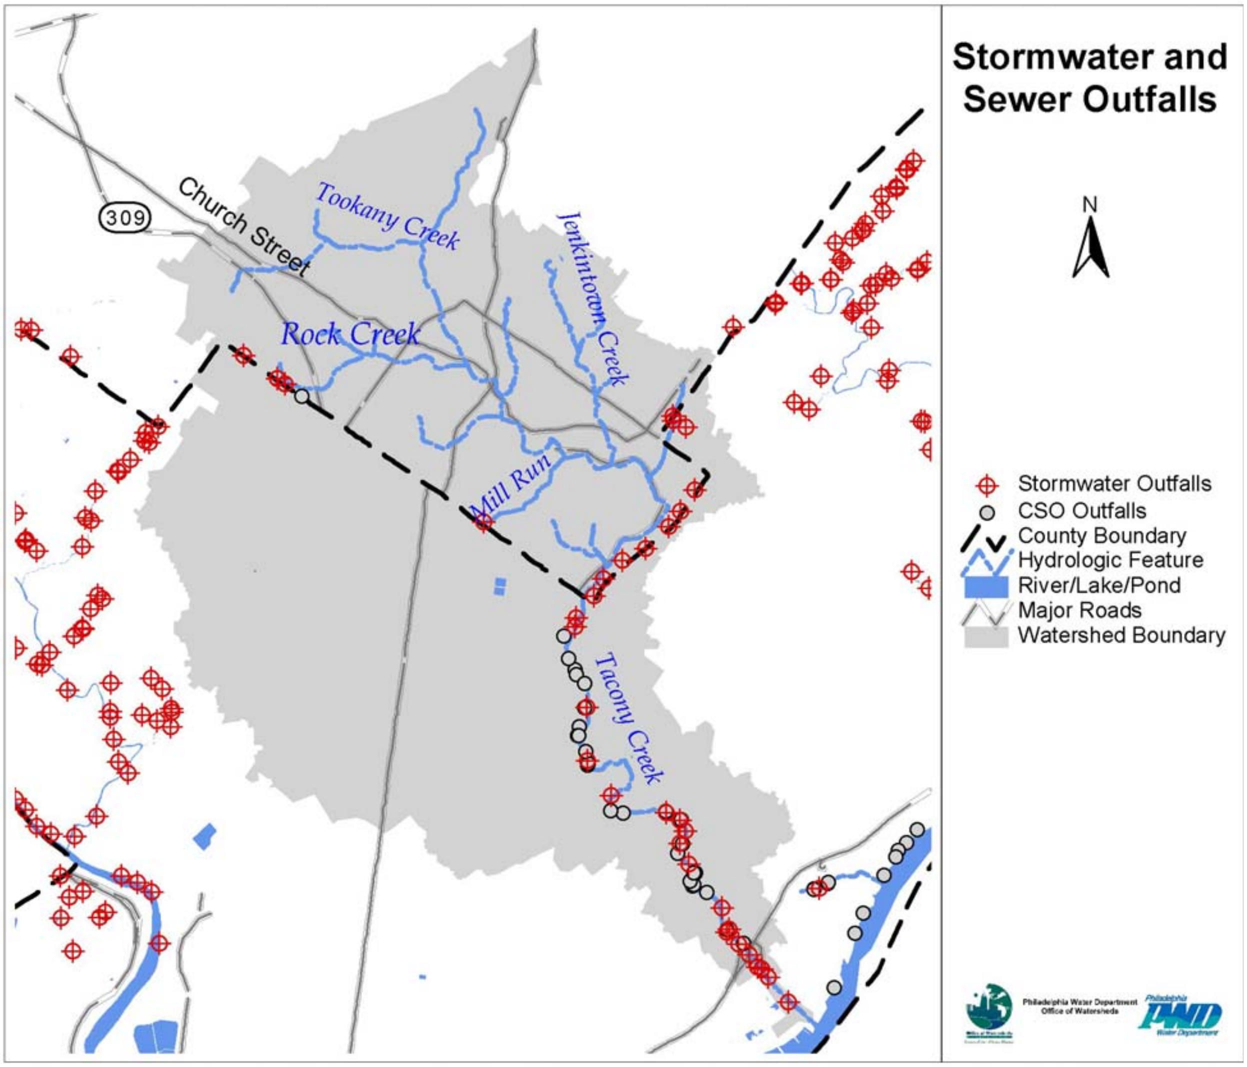

Figure 8.3 Stormwater and CSO Outfalls in the Philadelphia Portion of the Tookany/Tacony-Frankford Watershed

Improvement of Fish Passage (BM5) Related Goals: 1, 6, 7 Related Indicators: 3, 5, 6, 16, 19, 20, 21			
What	Who	Where	When
Assess potential to improve fish migration through dam modification or installation of fish ladders.	PWD; Fairmount Park Commission.	To be determined by future study.	Long-term; after pollutant sources in lower Tacony are addressed.

For the Tookany/Tacony-Frankford Creek, the State-designated aquatic life uses for the non-tidal portion of the creek are Warm Water Fishes (WWF) and Migratory Fishes (MF). The designated recreational water uses also include boating, when surface water flow or impoundment conditions allow; fishing, for recreation and/or consumption; water contact sports; and aesthetics.

Investigation and restoration of fish migration is recommended as a long-term goal. However, areas of low dissolved oxygen (DO) have been identified south of Castor Avenue. Further investigation and remediation of this problem is recommended as a short-term goal; efforts to remove barriers to fish migration will not succeed in restoring populations until water quality conditions are sufficient to support fish.

The River Conservation Plans (RCPs) noted the following:

- Township Line Road to Tookany Creek Parkway: Work with landowner to remove wooden plank to allow fish to pass through.

8.2.3 Target B Options: Lowland and Upland Restoration and Enhancement

Wetland Creation and Enhancement (BM6)

Related Goals: 1, 2, 3, 4, 5, 7
Related Indicators: 1, 2, 3, 4, 7, 8, 9, 15, 19

What	Who	Where	When
Wetland creation and enhancement for flood flow alteration, groundwater recharge, increased habitat, increased plant and animal diversity, and improved water quality.	PWD; Fairmount Park Commission. Municipalities bordering streams recommended for restoration.	Recommended locations for floodplain wetland creation; areas for pocket wetland creation need to be field determined, based on where they are adjacent to lands proposed for stream realignment and bank restoration (see Figure 8.5).	Prototype design and evaluation phase, followed by upstream creation/enhancement in years 1-5; downstream implementation over two 10-year phases.

One high-priority riparian corridor improvement action, from both an ecological and water quality improvement perspective, is creation and enhancement of wetlands along the Tookany/Tacony-Frankford Creek. The Fairmount Park Commission has proposed four vegetation restoration sites along the creek, two of which are wetland sites. The Tookany/Tacony-Frankford Creek subwatersheds were field surveyed in 2002/2003 to assess wetland improvement opportunities for existing wetlands, and wetland creation opportunities for new locations. Existing wetlands were evaluated for their ability to perform important wetland functions (e.g., flood flow alteration, water quality improvement, and habitat), where degraded actions were evaluated to improve compromised functions. Existing wetlands were then assessed to determine if they might be effectively expanded. Finally, locations where new wetlands could be created were identified. New wetland creation opportunities were classified into two groups:

- Wetlands immediately adjacent to the waterway and which would receive flood flows frequently during the year (< one year storm); and
- Pocket wetlands that can be created using checkdams that are higher in the landscape and that would receive stormwater flows from adjacent subwatershed areas, but would receive flood flows only from major storm events.

Wetlands Enhancement

The wetland field investigations for the TTF Watershed rated the opportunity to improve and expand existing wetlands, by evaluating opportunities to reconnect the wetland to the waterway, to receive additional overland flows, to remove sources of encroachment, and to expand the size of the wetlands. Nearly all the 24 existing wetlands exhibited potential for functional improvement through hydrologic improvements, re-vegetation, or reducing historic disturbance. The field analysis indicates significant opportunity for wetland improvement, as shown in Table 8.12 and Figure 8.4.

Table 8.12 Wetland Improvement Potential

Wetland Improvement Potential	
Improvement Rating	*Wetland Areas*
High	15
Moderate	8
Low	1

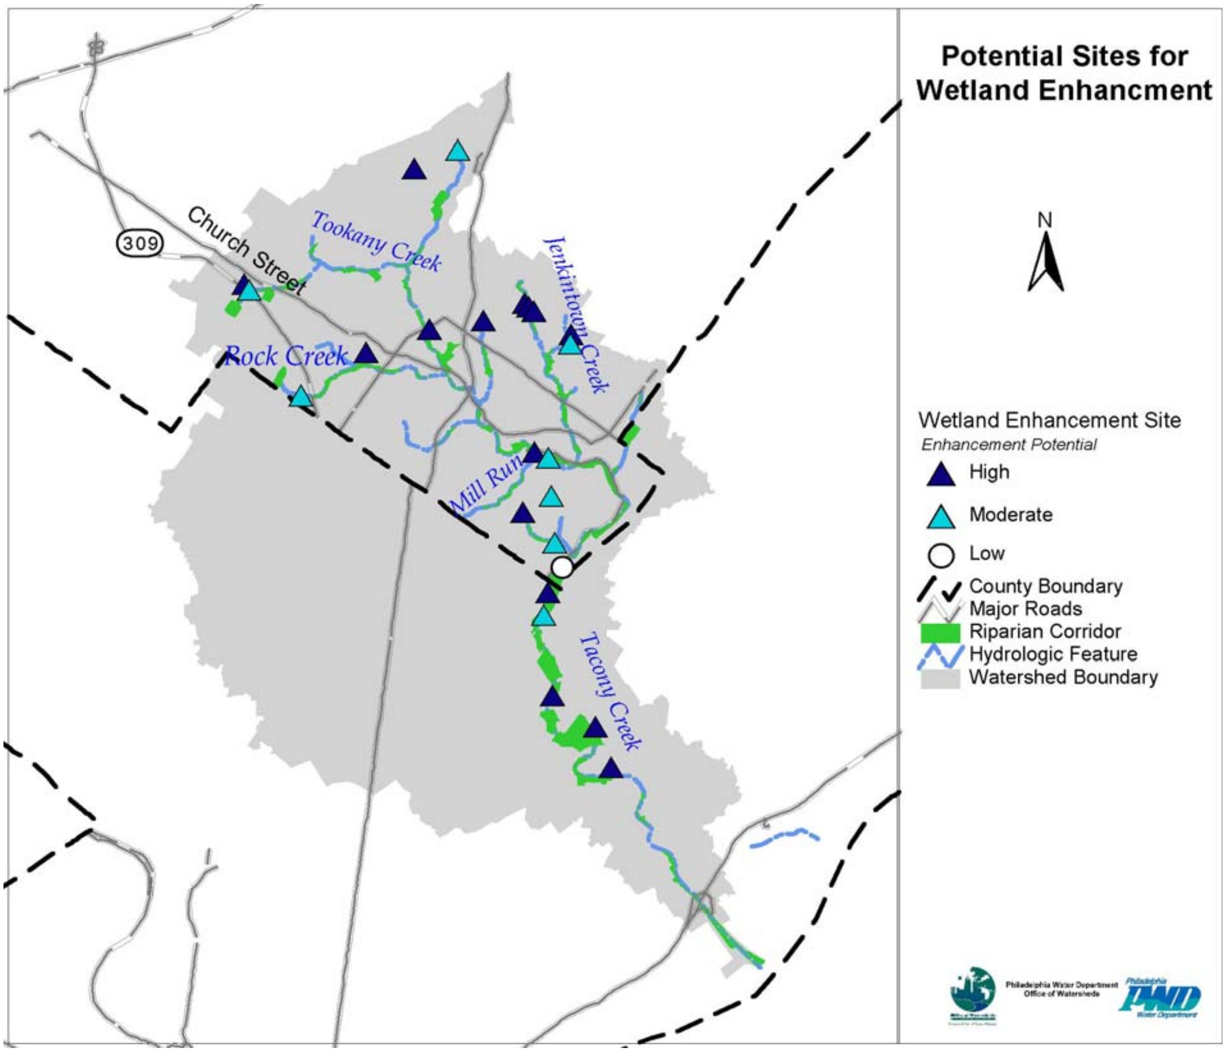

Figure 8.4 Potential Sites for Wetland Improvement

While there are many opportunities for wetland improvement, there is only limited opportunity for wetland expansion. The total potential estimated increase in wetland area for the moderate and high potential wetland sites was limited to less than 3 acres, increasing the existing inventory from about 15 acres to 18 acres. Greater opportunity for increasing wetland acreage is available from wetland creation/re-creation activities.

Wetlands Creation

The wetland field analysis also included an evaluation of potential opportunities for wetland creation along the riparian corridor. The evaluation of wetland creation potential was focused on the physical potential (undeveloped land area present, proximity to waterway, position in landscape) and did not address institutional or ownership factors.

Because stream relocation and realignment typically involve extensive grading and replanting, new runoff patterns and hydrology can be created that are more similar to original riparian conditions, whereby riparian corridor wetlands could receive storm runoff sheet flow from the adjacent landscape. In addition, wetland habitats can be created that allow more diverse habitat. Wetlands are rich habitats that rely on saturated soils and vegetation adapted to these conditions. They could be recreated concurrently with channel realignment, bank restoration, and planting of more diverse native vegetation, including hydrophytic species adapted to saturated soil conditions.

Wetlands must have an adequate input of water, either by flooding or runoff, to maintain the soil and vegetation characteristics that are unique to wetlands. Field investigation of wetlands revealed, however, that several factors constrain the creation of extensive areas of new wetland. These include:

- Extensive urban and suburban encroachment into the riparian corridor;
- Competing active recreational uses along the waterway; and
- Steep slopes adjacent to the waterway limiting potential for floodplain hydrology.

Field estimates indicate that over 24 acres of wetland might be created in 26 separate creation locations. This would result in a more than 150% increase in wetland acreage along the riparian corridor. If wetland expansion potential were also included, the wetland acreage along the riparian corridor could be increased by 175% to about 42 acres. These estimates represent a highly optimistic wetland expansion scenario, but indicate the significant potential to at least double the area of wetland along the riparian corridor. These wetland creation locations are identified in Figure 8.5 below.

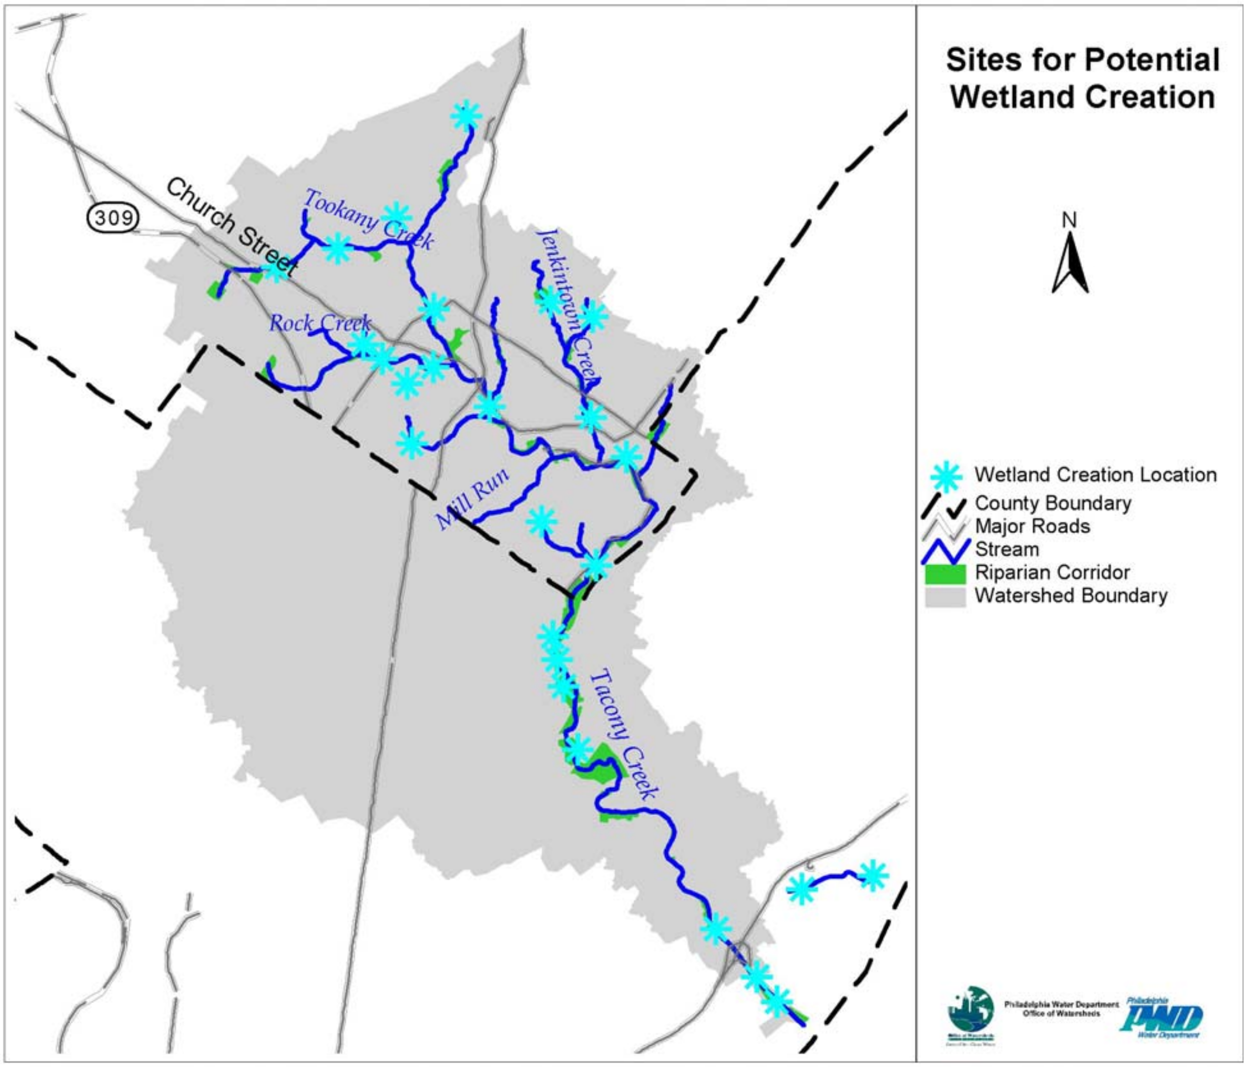

Figure 8.5 Potential Sites for Wetland Creation

In general, priority will be given to wetland creation and improvement over reforestation of uplands because of the greater water quality benefits provided by wetlands.

As noted above, two types of wetland creation are recommended: floodplain wetlands and pocket wetlands. There are numerous opportunities for creation of pocket wetlands throughout the watershed; as stormwater runoff from the adjacent subwatershed is redirected over the riparian landscape, checkdams and piping may be used to spread the runoff over the vegetated riparian land surface. More specific locations for creating pocket wetlands will need to be evaluated in the future as the riparian corridor restoration design is developed during the facilities planning stage. This is because opportunities for creation of pocket wetlands arise from bank restoration, revegetation, and biofiltration actions that will be implemented as part of the integrated riparian corridor improvement strategy for the TTF Watershed.

Both floodplain wetlands and pocket wetlands offer significant opportunity for water quality and ecological improvement along the Tookany/Tacony-Frankford Creek riparian corridor, and both will play a central role as the design of the riparian corridor improvements is developed.

Assuring long term success for wetland creation projects will involve future monitoring to measure integration of the wetland into the riparian landscape and to correct defective conditions, where possible. However, proper design of the wetland to assure adequate input of water (via flooding or runoff), protection from erosion, and maintenance of the diverse planted vegetation is essential to long-term success. Wetland creation projects typically involve monitoring and maintaining the created wetland's hydrology, vegetation (including invasive species, discussed below), and erosion characteristics for a period of three years following creation.

Further investigation of all potential wetland enhancement and creation opportunities should include the following: identification of landowners, rainfall data collection and evaluation, runoff calculations, soils investigation, water budget, native species investigation, and groundwater/soil saturation monitoring.

Invasive Species Management (BM7)

Related Goals: 4
Related Indicators: 12, 13, 14, 19

What	Who	Where	When
Implement an Invasive Species Management Plan (already in effect in Fairmount Park).	PWD; Fairmount Park Commission.	Lowland and upland habitat restoration sites.	Within 5 years.

A plan to control invasive plant species is necessary when restoring or enhancing wetlands and riparian forests. Invasive species provide little value to native animals that depend on native species for habitat and food. Japanese knotweed (*Polygonum cuspidatum*) is one prevalent invasive species that was observed during the field reconnaissance. In many areas, knotweed, due to its aggressive nature, has already out-competed native vegetation. Maintaining a healthy riparian plant community along Tookany/Tacony-Frankford Creek will retain biodiversity and support a healthy stream ecosystem.

The Fairmount Park Commission has implemented an invasive species control program in the Fairmount Park portion of the stream corridor. It is recommended that invasive species control be expanded to the remaining natural areas of the corridor. Implementation of an invasive species management plan would assist natural succession within the riparian buffer and decrease further impacts of invasive species.

Planting plans for all restoration efforts should complement the invasive species management plan by recommending appropriate native planting to supplement areas where invasives have been eliminated. Although invasive species management priority areas are considered those that contain 80% or greater invasive species, the most practical approach is to recommend invasive species management be implemented for all riparian restoration sites. An invasive species management plan will require, at a minimum, a three-year commitment to ensure success.

The River Conservation Plans (RCPs) highly recommend removing invasives and replant native vegetation. The most common invasive was Japanese knotweed. Specific sites noted include:

- Holy Sepulchre Cemetery to Ralph Morgan Park**:** Control invasive plants and replant with natives.
- Ralph Morgan Park to Greenwood Avenue: Remove Japanese Knotweed and replant with natives. Remove invasive vines from trees.
- Greenwood Avenue to Wyncote Post Office: Remove invasive plants from banks and replant with natives.
- Washington Lane Underpass to Church Road: Remove invasive vines from trees and knotweed. Replant native shrubs and groundcover.

- Church Road at Chelten Hills Drive to Church Road near Ogontz Field: Remove knotweed and other invasives. Replant a native buffer zone.
- High School Park to Ashbourne Road along the Tookany Creek Parkway: Eradicate invasive plants and replant with natives.
- Unnamed Tributary in Glenside: Clear knotweed.
- Baeder Creek Watershed: Eradicate invasives and replant natives.
- Rock Creek Watershed: Plant creek banks with natives to prevent invasives from dominating.
- Mill Creek Watershed: Eradicate invasives plants and replant with natives.
- Cheltenham Avenue to Adams Avenue: Remove invasives and replant with natives.
- Crescentville and Adams Avenues to Rising Sun Avenue: Remove invasives and replant with native plants.
- Rising Sun Avenue to Roosevelt Boulevard: Remove invasives and replant with native plants.
- Roosevelt Boulevard to Whitaker Avenue: Remove invasives and replant with native plants.
- Whitaker Avenue to Wyoming Avenue: Remove invasives and replant with native plants.
- Wyoming Avenue to Castor Avenue: Remove invasives and replant with native plants.
- Castor Avenue to Erie Avenue: Remove Japanese knotweed.
- Aramingo Avenue between Wheatsheaf Lane and Church Street: Remove Japanese knotweed.
- Rohm & Haas, 5000 Richmond Street: Remove invasives.

Biofiltration (BM8)

Related Goals: 1, 2, 3, 5, 7
Related Indicators: 1, 2, 3, 4, 15, 19, 20

What	Who	Where	When
Biofiltration involves creating sheet flow over the vegetated landscape to slow the rate of runoff, facilitate groundwater recharge, and remove sediment, nutrients, and toxicants from the runoff.	PWD; Fairmount Park Commission.	Throughout Tookany/Tacony-Frankford riparian corridors; focus on vegetated landscape.	Two 10-year implementation phases (high and medium priority).

The goal of the Tookany/Tacony-Frankford Creek riparian corridor improvement strategy is to identify all opportunities along the riparian corridor for natural landscape designs that achieve water quality improvement. For higher landscape positions at the outer edges of the riparian corridor there are extensive opportunities to implement biofiltration to improve runoff. Biofiltration involves creating sheet flow over the vegetated landscape to slow the rate of runoff, facilitate groundwater recharge, and remove sediment, nutrients, and toxicants from the runoff. Typical biofiltration approaches include installation of stormwater swales and checkdams along natural drainage-ways that spread runoff, creation of bioretention plantings and hydrology, and creation of hydrologic features that allow sheet flow to spread over grassed and shrub/scrub fields to achieve water quality improvement. The advantage of biofiltration is that it is compatible with recreational use of the riparian corridor, because flows are very shallow and are usually present only during rainfall events.

Analysis of the existing stormwater management in the Tookany/Tacony-Frankford Watershed shows that most stormwater outfalls discharge directly to the waterway. However, if the stormwater was redirected over the vegetated landscape higher in the stream valley, it would follow the natural slope and land contour as it traveled down to the stream. There are over 685 acres of undeveloped land along the Tookany/Tacony-Frankford Creek riparian corridor, but almost none of that land carries runoff sheet flow because the stormwater piping system conveys all flows, from storms large and small, directly to the stream. In order to achieve water quality improvement goals, it is important to optimize the ability of this vegetated riparian land to receive overland runoff, rather than piping the runoff directly into the stream.

Biofiltration has an effectiveness range of about 25-60% in removing suspended solids from runoff, and the concept of directing runoff to sheet flow over the vegetated riparian landscape matches fully with the way that such lands function naturally in an undeveloped watershed. Thus, the goal of biofiltration is to restore sheet flow of runoff over the landscape, by using piping and hydraulic controls to spread runoff from smaller storms over the vegetated surface. To avoid erosion, it is essential that the design for biofiltration provide for high velocity flows from major storms to be bypassed.

Reforestation (BM9)

Related Goals: 1, 2, 4, 5, 6, 7
Related Indicators: 1, 2, 4, 12, 13, 16, 18, 19

What	Who	Where	When
Reforestation adjacent to the channel to provide wetland habitat and other associated benefits.	PWD; Fairmount Park Commission. Municipalities bordering streams recommended for restoration.	Priority reforestation sites: lands adjacent to the creek that are not developed and are currently unforested. Potential reforestation sites are existing ball fields, golf courses, hospital grounds, seminaries, and cemeteries located adjacent to the channel. These should also be evaluated.	Begin within 5 years; monthly maintenance schedule to be determined.

The riparian corridor restoration and enhancement plan being proposed in this section covers the width of the stream corridor from developed edge to developed edge, including both lowland and upland forest. Reforestation that occurs adjacent to the channel will provide wetland habitat and other associated benefits. Although priority reforestation areas consist of floodplains, steep slopes, and wetlands, smaller areas such as public rights-of-way, parks, schools, and neighborhoods also provide reforestation opportunities. Benefits of reforestation are numerous: cooler temperatures, rainfall interception, reduced runoff, reduced sediment load, reduced discharge velocities, increased groundwater recharge, increased species diversity and habitat, and improved air quality and aesthetics.

At this time, only the recommendations from the River Conservation Plans (RCPs) are available. These include:

- Washington Lane Underpass to Church Road: Have SEPTA plant low growing shrubs in the areas of the bird sanctuary to develop wildlife habitat.
- Unnamed Tributary in Glenside: Partner with SEPTA to plant native vegetation that is in keeping with their track maintenance requirements in order to reduce NPS pollution and stabilize soil to prevent erosion and downstream sedimentation.

8.2.4 Target B Options: Monitoring and Reporting

Monitoring, Reporting, and Further Study (BMR)

Related Goals: 1, 2, 3, 4, 5, 6, 7
Related Indicators: all indicators relevant to Target B

What	Who	Where	When
Monitoring of implementation and benefits for all Target B options. Creation of a Tookany/Tacony-Frankford Stream Corridor Restoration Master Plan.	PWD; Fairmount Park Commission; municipalities bordering streams.	All implementation sites.	Monitoring and reporting to begin immediately and continue throughout the life of the plan. Master Plan creation within 5 years.

The preceding sections are a first step in identifying proposed projects that can lead to comprehensive stream corridor restoration. However, additional planning is needed to ensure that individual projects do not interfere with one another. For example, realignment of a stream section might eliminate a proposed wetland or reforestation site; or removal of a dam might increase stream velocity and erode restored streambanks or eliminate flow of water to a riparian wetland. Creation of a more detailed Restoration Master Plan for the stream corridor is necessary before individual projects can proceed. This plan will be primarily graphical and will identify boundaries and key elevations for existing features and proposed projects. Detailed designs on individual projects will be required to be consistent with the Master Plan. The plan will show the following on a single map:

- Proposed stream bank stabilization and bed stabilization;
- Proposed stream realignment and relocation;
- Proposed dam modification or fish ladder sites;
- Stream obstructions proposed for further study or removal;
- Existing wetlands; proposed wetland creation and enhancement;
- Existing habitat not to be disturbed, including threatened or endangered species;
- Proposed reforestation and habitat creation areas;
- Existing and proposed upland BMPs (biofiltration); and
- Key recreation and access facilities (trails, parking lots).

Before habitat restoration is recommended, however, water quality problems that might now be the cause of poor fish species diversity must be better investigated, and eventually solved.

8.3 Target C: Wet Weather Water Quality and Quantity

Target C must be approached somewhat differently from the first two targets. Full achievement of this target means meeting all water quality standards during wet weather, as well as eliminating all flooding. Clearly, that will be difficult, particularly with regard to wet weather water quality. It would certainly be extremely expensive, and would require a long-term effort. The only rational approach to full achievement of Target C goals is through stepped implementation with interim targets for reducing wet weather pollutant loads and stormwater flows. During implementation, monitoring must continuously assess the effectiveness of the program. Based on the extensive modeling analysis carried out for Tookany/Tacony-Frankford Creek to date, an initial goal of a 20-25% reduction in stormwater flows and stormwater/CSO related pollutant loads has been identified as a challenging but achievable goal. The stakeholders have identified Mill Creek (also called Mill Run) as a priority area for stormwater control.

It is expected that changes to the approach required to meet Target C, and even to the desired results, will occur as measures are implemented and results are monitored. With most discharge permits of five-year duration, discharge targets and reduction targets must be set and implementation designed in the first five years. Implementation for meeting Target C will begin over the next five years with Targets A and B, while monitoring for effectiveness in order to utilize an adaptive management approach for subsequent years to achieve full implementation of Target C. During the final five-year period, PWD should also work with the regulatory agencies to review water quality standards and determine whether any adjustments to them may be appropriate based on the results of monitoring.

Below are the Target C options that were "recommended" (either fully or conditionally) in Section 7. Most of these options are described in detail in the pages that follow.

8.3.1 Target C Options: Regulatory Approaches

Requiring Better Site Design in Redevelopment (CR2)

Related Goals: 1, 2, 4, 7
Related Indicators: 1, 12, 13, 16, 19, 20

What	Who	Where	When
Adopt or improve ordinances to encourage developers to use low impact methods for new ("greenfield") development and redevelopment of urban areas.	See Table 8.14 (may not identify all municipalities with ordinances).	Entire watershed.	Within 5 years; update as needed.

Environmentally friendly site design, also called low impact development (LID) and conservation site design, encompasses a range of site design elements for developers, and design requirements from municipalities. Some examples of LID design concepts include maintaining stream buffers, designing for open space, reduced street and sidewalk footprints where appropriate, and parking lot designs that reduce runoff and encourage infiltration. Stormwater source controls, infiltration BMPs, and treatment BMPs can be integrated with LID designs. Recommendations for incorporating these features in the Tookany/Tacony-Frankford Watershed are found throughout Target C.

LID is intended to reduce the impact of development on natural resources and water resources. Municipal design requirements are intended to preserve or increase open space, protect sensitive natural resources, and limit impervious cover. The environmental goals of land development and stormwater ordinances are closely related, although the ordinances themselves and mechanisms for enforcing them may be separate.

It appears that some of the municipalities in the Tookany/Tacony-Frankford Watershed encourage several standard low impact development practices through their existing land use ordinances. However, these guidelines tend to focus on clustering housing by allowing higher-density multi-family residential developments with common open spaces. Separate language focusing specifically on the protection of natural resources is recommended. While some municipalities in the watershed have already adopted a steep slope ordinance, Abington and Cheltenham Townships are currently the only municipalities within the watershed with cluster development ordinances and non-binding wetlands protection ordinances in place. Table 8.14 demonstrates that all municipalities located in the watershed have adopted some aspects of low impact development.

Table 8.14 Better Site Design in Existing Ordinances

Municipality	Better Site Design Ordinance (at least one component)	Comments
Abington Township	X	Cluster development for residential zoning districts; max. impervious cover by zoning type; wetlands conservation; steep slope conservation overlay district.
Cheltenham Township	X	Planned cluster development; open space requirements; designated wetlands; steep slope conservation district.
Jenkintown Borough	X	Minimum street, sidewalk widths; maximum grades; non-binding guidelines for density and open space.
Philadelphia County	X	Max. impervious cover requirements; minimum street, driveway widths.
Rockledge Borough	X	Max. impervious cover requirements by zoning type.

Source: www.ordinance.com, *Delaware Valley Regional Planning Commission*

The Delaware Valley Regional Planning Commission (DVRPC) has recently completed the task of reviewing the municipal zoning ordinances of the Delaware Valley's 353 municipalities. Based upon this analysis, DVRPC has created a list of "outstanding sample natural resource and open space protection ordinances." These model ordinances as well as additional information on DVRPC's program are available at these sites:

- DVRPC Natural Resource Protection Information:
  http://www.dvrpc.org/planning/community/ProtectionTools.htm
- Model Ordinances:
  http://www.dvrpc.org/planning/community/ProtectionTools/ordinances.htm

Guidelines for LID in an Urban Setting

Table 8.15 (see below) identifies various zoning ordinances that could be adopted by the municipalities in the Tookany/Tacony-Frankford Watershed. While some municipalities already incorporate elements of these zoning measures within their existing code, it is recommended that ordinances specific to low impact development be adopted to better facilitate future growth and redevelopment. Model ordinances for each of these examples are available on the DVRPC website at the address listed above.

Table 8.15 Selected Components of Low Impact Development Ordinances

Municipal Zoning Ordinance	Description
"Net-Out" of Resources / Site Capacity Calculations	Protect wetlands, floodplains, and riparian buffers by removing them from the area considered for new development and redevelopment. In calculating the developable area, environmentally sensitive areas should be excluded. Some local governments allow increased densities in the remaining developable land area to provide an incentive for protecting sensitive environments. Existing trees should be protected if possible; if not, the land owner may contribute to a mitigation fund for each tree cut down.
Wetlands Management Ordinance	Protects environmentally sensitive wetlands areas. This ordinance usually requires wetlands delineation within the municipality and prohibits any type of development in a delineated wetland area.
Cluster Development Ordinance	Allows developers to build at higher densities on one portion of a site in exchange for preserving another portion as open space. Land preservation percentages and densities vary, but the preferred percentage is for at least 50% of the tract to remain as open space. Achieving a landowner's financial objectives may be a function both of partial development and donation of a conservation easement (and its inherent deductibility under the federal tax code).
Planned Residential Development (PRD)	Facilitates residential development in areas designated by the municipality. Provisions are made for higher housing densities, thereby creating larger contiguous common open spaces, and providing for pedestrian access between residential areas.
Steep Slope Ordinance	Regulates development on areas designated as steep slopes. The minimum gradient classified as steep varies by municipality, but, according to DVRPC, 8% is typical.
Transfer of Development Rights (TDR)	Designates areas of a municipality as "sending" and "receiving" areas. Allows community to preserve open space and natural features while still permitting growth. Development is moved from large tracts of rural land (sending area) to areas designated for higher densities (receiving area).

While the measures above were originally intended for new development, they may be adapted for larger redevelopment projects in urban areas. Older areas often have large areas of vacant and abandoned properties that may be demolished all at once, creating significant open space. Cluster development, for example, could be applied on these larger sites.

In addition to the specific ordinances above, municipalities should require, or provide strong incentives for, innovative site design when urbanized areas are redeveloped. Effective conservation design techniques to consider include the following:

- Review municipal codes for any minimum size requirements for impervious surfaces, such as road and sidewalk widths. Review any stipulation of a minimum size lot that development and stormwater ordinances apply to. In the City of Philadelphia, the ordinance requiring all downspouts to be connected directly to the sewer system is not appropriate in all cases; wherever feasible, infiltration (e.g., using dry wells) should be encouraged over disposal of stormwater to combined or separate storm sewers.

- Depending on the zoning classification, specify a maximum effective impervious cover allowed after construction. Many publications recommend that impervious cover connected directly to the drainage system be limited (see Section 8.3.4, Option CS1, "Reducing Effective Impervious Cover through Better Site Design," for specific recommendations). Developers are then free to choose a combination of methods to meet the requirement: an absolute reduction in impervious cover, directing runoff onto depressed landscaped areas, tree credits, and structural BMPs. Consider incentives in the stormwater control calculations to reduce directly connected impervious surfaces.

- For areas experiencing redevelopment, structural stormwater controls may be tied to the impervious area calculations discussed above. Developers have an incentive to reduce impervious area because it may be more cost effective than installing structural stormwater BMPs. Specific recommendations for stormwater ordinances are discussed below, under Option CR3, "Stormwater and Floodplain Management."

- Promote discussions early in the development review process at the sketch plan/conceptual plan level (before developers have spent large sums of money on design and engineering). A number of municipalities around the U.S. have concluded that sketch/conceptual plans are more important in the planning process than preliminary plans because early intervention and change allows greater opportunity to include innovative low impact development designs. Some municipalities have opted to eliminate the final plan and accept the preliminary plan as the final plan as an incentive to developers to participate.

- After the final plan is submitted, require a pre-construction meeting and a site visit to discuss construction issues and pollution prevention.

- Consider incentives in addition to regulations; for small sites, incentives alone may be sufficient. For example, award density or stormwater control bonuses for reducing impervious cover. Streamline project reviews and waive permit fees when conservation design objectives are met. Tie stormwater fees and/or property taxes to impervious cover and stormwater management practices.

The River Conservation Plans (RCPs) noted the following:

- Church Road at Chelten Hills Drive to Church Road near Ogontz Field: For areas that are redeveloped, landscape architects should design a more natural buffer zone.

Stormwater and Floodplain Management (CR3)

Related Goals: 1, 2, 3, 4, 5, 7
Related Indicators: 1, 2, 12, 13, 15, 19, 20

What	Who	Where	When
Participate in finalization of the watershed-wide Act 167 plan and model ordinance being developed in the watershed. Adopt and enforce the model ordinance.	Counties to adopt plan and ordinance first, followed by all municipalities (see Table 8.16).	Entire watershed.	Begin within 5 years; update as needed.

Table 8.16 identifies the municipalities in the Tookany/Tacony-Frankford Watershed that currently have a floodplain protection or stormwater ordinance in place.

Table 8.16 Floodplain and Stormwater Ordinances in the TTF Watershed

Municipality	Floodplain Ordinance	Stormwater Ordinance	Erosion and Sedimentation Control	Comments
Abington Township	X	X	X	Stormwater design requirements; floodplain conservation district; erosion and sedimentation control plan.
Cheltenham Township	X	X	X	Storm drainage requirements; floodplain conservation district; soil erosion and sediment control (DEP Manual compliance).
Jenkintown Borough	X	X	X	Storm drainage design requirements; floodplain conservation district; erosion and sedimentation control measures required (no description).
Philadelphia County	X	X	X	Stormwater management controls; erosion and sedimentation control measures – engineer required.
Rockledge Borough				No stormwater/floodplain ordinances; all development served by public sewer and public water.

Source: www.ordinance.com, *Delaware Valley Regional Planning Commission*

The majority of municipalities in the watershed have adopted ordinances limiting development in the floodplain or designating a floodplain conservation district. The protection offered varies by municipality, but an effective ordinance should place controls on land development within the 100-year floodplain as well as limit development within riparian corridors. EPA posts a model floodplain preservation ordinance at: www.epa.gov/owow/nps/ordinance/osm1.htm

Philadelphia and Montgomery Counties are cooperating to develop an official Act 167 Stormwater Management Plan and model ordinance. The model ordinance will specify measures that must be undertaken to promote infiltration, improve water quality, reduce streambank erosion rates, and protect against flooding. These requirements will apply to both new (also called "greenfield") development and redevelopment (including brownfields or former industrial sites), and to both separate-sewered and combined-sewered areas. The plan and model ordinance shall be completed with county and municipal input by late 2007.

Adoption and implementation of the model ordinance is a critical step that will allow municipalities to begin implementing many of the wet weather management measures mentioned later under Target C. For example, the ordinance may require a specific storage volume to be created on a developed site and may indicate that it must be a BMP capable of water quality treatment. The developer will then consult a state or local stormwater manual designated by the municipality to determine an appropriate BMP and appropriate design criteria.

While many of the state manuals provide excellent guidance for new development, PWD plans to develop a manual with guidance for redevelopment projects given local conditions. Some preliminary ideas for this BMP manual are listed below.

Commercial/Industrial Land Uses

1. Encourage better site design techniques, impervious cover disconnection, and tree credits to decrease impervious cover directly connected to the drainage system.
2. Directly-Connected Parking Lots:
   - Encourage a bioretention system if sufficient space is available to meet parking needs.
   - In highly urban areas where adding landscaping is not possible, encourage porous pavement (or other drainage mechanism) and subsurface storage if feasible.
3. Directly-Connected Rooftops:
   - If parking lot storage is installed, recommend routing rooftop drainage to the storage.
   - If parking lot storage is not feasible, route rooftop drainage to dry wells. If dry wells are not feasible, route rooftop drainage to rain barrels or tanks.
   - Other approaches may be proposed and considered on a case-by-case basis.

Residential Land Uses

1. Encourage better site design techniques, impervious cover disconnection, and tree credits to decrease impervious cover directly connected to the drainage system.
2. Route roof runoff to dry wells if feasible. If dry wells are not feasible, route rooftop drainage to rain barrels or tanks.
3. Other approaches may be proposed and considered on a case-by-case basis.

The River Conservation Plans (RCPs) recommend the following:

- Holy Sepulchre Cemetery to Ralph Morgan Park: Purchase properties in floodplain to convert land to open space.
- Mill Creek Watershed: Relocate or purchase then demolish structures in the floodplain.
- Church Road at Chelten Hills Drive to Church Road near Ogontz Field**:** Assess upstream issues to see why Shoemaker Road area floods more.

Industrial Stormwater Pollution Prevention (CR4)

Related Goals: 1, 2, 3, 7
Related Indicators: 1, 2, 3, 4, 7, 8, 9, 10, 19, 20

What	Who	Where	When
Enforcement of NPDES requirements for Industrial Stormwater Management. Dissemination of information on spill prevention and pollution prevention plans.	PA DEP is the Designated Authority responsible for issuing, administering, and enforcing NPDES permits. Municipalities are responsible for information dissemination.	All sites contributing stormwater discharges associated with industrial activity within the watershed.	Within 5 years.

Industrial stormwater pollution prevention measures can contribute significantly to achieving the watershed plan's wet weather implementation targets. These measures include monitoring and enforcing existing industrial stormwater permit requirements under Phase I of the NPDES program, as well as Official Industrial Pollution Prevention Plans and Spill Response Actions required by the state. Full implementation of these measures should be monitored and enforced throughout the watershed.

NPDES Industrial Stormwater Permits

All sites contributing stormwater discharges associated with industrial activity, defined in federal regulations (40 CFR §§ 122.26(b)(14)(i)-(xi)), are required to be covered under Phase I of the NPDES stormwater program. This includes discharges from any conveyance that is used for collecting and conveying stormwater and that is directly related to manufacturing, processing, or raw materials storage areas at an industrial plant. This includes, but is not limited to, stormwater discharges from industrial plant yards; immediate access roads and rail lines used or traveled by carriers of raw materials, manufactured products, waste material, or by-products used or created by the facility; material handling sites; refuse sites; sites used for the application or disposal of process waste waters; sites used for the storage and maintenance of material handling equipment; sites used for residual treatment, storage, or disposal; shipping and receiving areas; manufacturing buildings; storage areas (including tank farms) for raw materials, and intermediate and final products; and areas where industrial activity has taken place in the past and significant materials remain and are exposed to stormwater. The term "material handling activities" includes storage, loading and unloading, transportation, or conveyance of any raw material, intermediate product, final product, by-product, or waste product.

The PA DEP is the Designated NPDES Authority responsible for issuing, administering, and enforcing NPDES stormwater permits under the EPA's regulatory provisions set forth in 40 CFR.

Stormwater discharges from most industrial facilities are covered under General Permits when they discharge into municipal separate sanitary sewers. General NPDES permits have a fixed term not to exceed five years. An operator of a stormwater discharge associated with industrial activity which discharges through a large or medium municipal separate storm sewer system shall submit, to the operator of the municipal separate storm sewer system receiving the discharge, the following information: the name of the facility; a contact person and phone number; the location of the discharge; a description, including Standard Industrial Classification, which best reflects the principal products or services provided by each facility; and any existing NPDES permit number.

In addition, the operator of a stormwater discharge associated with industrial activity covered under a general, group, or individual permit, shall provide the following minimum information (40 CFR § 122.26 (c)(i)):

- A site map showing topography, drainage features, buildings, and areas where materials or activities may contribute pollutants to stormwater.
- An estimate of the area of impervious surfaces (including paved areas and building roofs) and the total area drained by each outfall (within a mile radius of the facility) and a narrative description of materials handled or stored as well as measures taken to control pollutants in the runoff.
- A certification that all outfalls that should contain stormwater discharges associated with industrial activity have been tested or evaluated for the presence of non-stormwater discharges which are not covered by a NPDES permit. Tests for such non-stormwater discharges may include smoke tests, fluorometric dye tests, analysis of accurate schematics, as well as other appropriate tests. The certification shall include a description of the method used, the date of any testing, and the onsite drainage points that were directly observed during a test.
- Existing information regarding significant leaks or spills of toxic or hazardous pollutants at the facility that have taken place within the three years prior to the submittal of this application.

Quantitative data based on samples collected during storm events from all outfalls containing a stormwater discharge associated with industrial activity for a number of water quality parameters.

Industrial Pretreatment Requirements

Industrial pretreatment requirements are another area where enforcement can result in lower pollutant concentrations in stormwater. Under PA Code Title 25 § 94.15, the operator of the sewerage facilities in cases where pollutants contributed by industrial users result in interference or pass through, and the violation is likely to recur, must develop and implement specific local limits for industrial users and other users, as appropriate, that together with appropriate sewerage facility or operational changes, are necessary to ensure renewed or continued compliance with the plant’s NPDES permit or sludge use or disposal practices.

Additional Measures

Information on existing pollution prevention plans and spill response requirements should be provided to relevant industries in the watershed as part of the Phase II public education measures.

Industrial Pollution Prevention Plans are one means to prevent spills and accidental releases. Under PA Code Title 25 § 91.34 (Activities Utilizing Pollutants):

- Persons engaged in an activity which includes the impoundment, production, processing, transportation, storage, use, application, or disposal of pollutants shall take necessary measures to prevent the substances from directly or indirectly reaching waters of this Commonwealth, through accident, carelessness, maliciousness, hazards of weather, or from another cause.

- PA DEP may require a person to submit a report or plan setting forth the nature of the activity and the nature of the preventative measures taken. The Department will encourage consideration of the following pollution prevention measures, in descending order of preference, for environmental management of wastes: reuse, recycling, treatment, and disposal.

Spill response is another area that can improve wet weather water quality in Tookany/Tacony-Frankford Creek. Spill response requirements are promulgated under PA Code Title 25 and issued under section 5 of The Clean Streams Law (35 P. S. § 691.5).

Under PA Code Title 25 § 91.33 (Incidents Causing or Threatening Pollution):

- If, because of an accident or other activity or incident, a toxic substance or another substance which would endanger downstream users is discharged, it is the responsibility of the person at the time in charge of the substance to immediately notify PA DEP by telephone of the location and nature of the danger and, if reasonably possible to do so, to notify known downstream users of the waters.

- In addition to the notices, the person shall immediately take steps necessary to prevent injury to property and downstream users, and within 15 days from the incident, remove from the ground the residual substances to prevent further pollution.

The River Conservation Plans (RCPs) noted the following:

- <u>Rising Sun Avenue to Roosevelt Boulevard</u>: Examine car-recycling shop for runoff and determine if it's a legal operation.

Construction Stormwater Pollution Prevention (CR5)

Related Goals: 1, 2, 3, 7
Related Indicators: 1, 2, 3, 4, 7, 8, 9, 10, 19, 20

What	Who	Where	When
Construction Site Stormwater Program in conformance with Phase II Stormwater Permits: • Enact an ordinance. • Review and approve Erosion and Sediment Control Plans. • Distribute educational materials.	All municipalities required to do Phase II permit (see Table 8.7).	N/A	5-year program associated with stormwater permit (see Table 8.17).

In accordance with the TTF Integrated Watershed Management Plan's stated purpose of integrating various existing programs, and to avoid duplication of effort, the recommended implementation plan follows the PA DEP Stormwater Management Program Protocol to meet the six minimum control measures required of municipal permittees under the Phase II NPDES Stormwater Regulations (listed in Section 1.4.1 of this report, and found at 40 CFR §§ 122.26 – 123.35). One of the six minimum controls is a Construction Site Stormwater (CSS) Program.

In Pennsylvania, two programs currently exist that address stormwater runoff from construction activities: 1) the Erosion and Sediment Control Program under 25 Pa. Code Chapter 102, and 2) the NPDES Stormwater Construction Permit Program.

The Erosion and Sediment Control Plan submitted by the developer must contain BMPs appropriate to the site and the surrounding area that might be impacted by the construction activities, as well as for post-construction runoff. Construction activity-related BMPs are available to developers and others through the Erosion and Sediment Pollution Control Program Manual (PA DEP ID: 363-2134-008) at www.dep.state.pa.us (directLINK "stormwater"), as well as at the County Conservation District (CCD).

The CSS program can be summarized as consisting of the following steps:

- Enact, implement, and enforce a stormwater control ordinance using PA DEP model language;

- Coordinate the review and approval of Erosion and Sediment Control Plans with the County Conservation District(s) (CCD) or PA DEP for any earth disturbance of one acre or more causing runoff, or for any earth disturbance of five acres or more. Make approval of the Erosion and Sediment Control Plan a prerequisite for the formal approval of land development and redevelopment plans or the issuance of building permits; and

- Distribute educational materials to land developers with the applications for building permits and other land development/redevelopment.

Municipalities must have an agreement with their local CCD that addresses these reviews and permitting requirements. This agreement ensures the close coordination between the municipality and the CCD on these important issues affecting water quality. Note that a NPDES Stormwater Construction Permit is required for earth disturbance activities where the construction disturbs five acres or more, or where there is a discharge from a site to the MS4 where earth disturbance is one acre or more.

In most cases, the County Conservation District implements these two programs, and PA DEP is responsible for implementing and enforcing these programs in cases where the County does not have this responsibility. By requiring review and approval of Erosion and Sediment Control Plans by the CCD or PA DEP (and proof of NPDES Stormwater Construction Permits where required), and by coordinating building permit and other land development permits or approvals with the CCD (or PA DEP in some cases), municipalities will meet MS4 permit requirements for this component of the Construction Stormwater Runoff Management Minimum Control Measure. Utilizing this existing statewide program, the municipality avoids the need to do a duplicative, independent review of every Erosion and Sediment Control Plan.

All municipalities in the watershed are required to fulfill this aspect of the stormwater regulations. Table 8.17 shows the schedule for implementation.

Table 8.17 Implementation Schedule for Construction Stormwater Pollution Prevention

PERMIT YEAR	***IMPLEMENTATION SCHEDULE***	
	Construction Site Stormwater Program	**Developer Education**
Year 1	**Ordinance:** Enact an ordinance requiring: • the review and approval of Erosion and Sediment Control Plans by the local County Conservation District or PA DEP; • for any earth disturbance one acre or more with runoff to the MS4, or five acres or more regardless of the planned runoff; and • as a prerequisite for the formal approval of land development plans or the issuance of building permit. **Process:** Establish an agreement with the local CCD for the review and approval of Erosion and Sediment Control Plans for all earth disturbance activities equal to or greater than one acre with runoff to the MS4 (or five acres or more regardless of the planned runoff). **Standard:** Require that the Erosion and Sediment Control Plans be developed in accordance with the requirements of Chapters 102 (erosion and sedimentation) of the PA DEP regulations.	Meet permit requirements and measurable goals for Year 1 under Public Education and Outreach MCM.
Years 2-5	Implement the ordinance and agreement for review of Erosion and Sediment Control Plans.	Meet permit requirements and measurable goals for Year 2 under Public Education and Outreach MCM.

Post-Construction Stormwater Runoff Management (CR6)

Related Goals: 1, 2, 3, 7
Related Indicators: 1, 2, 3, 4, 7, 8, 9, 10, 19, 20

What	Who	Where	When
Post-Construction Stormwater Runoff Management in conformance with Phase II Stormwater Permits: • Enact ordinance. • Coordinate review and approval of Plans. Ensure BMP maintenance.	All Municipalities required to do Phase II permit (see Table 8.7).	N/A	5-year program associated with stormwater permit (see Table 8.18).

In accordance with the TTFIWMP's stated purpose of integrating various existing programs, and to avoid duplication of effort, the recommended implementation plan follows the PA DEP Stormwater Management Program Protocol to meets the six minimum control measures required of municipal permittees under the Phase II NPDES Stormwater Regulations (listed in Section 1.4.1 of this report, and found at 40 CFR §§ 122.26 – 123.35). One of the six minimum controls is a Post-Construction Stormwater Runoff Management Program. The program can be summarized as consisting of the following steps:

- Enact, implement, and enforce a stormwater control ordinance using PA DEP model language;
- Coordinate the review and approval of post-construction BMPs simultaneously with the review and approval for construction Erosion and Sediment Control Plans as described in the Construction Minimum Control Measure; and
- Ensure long-term operation and maintenance of the BMPs.

PA DEP links management of post-construction runoff with the Construction Minimum Control Measure component discussed above (see Option CR5). Approvals for construction activities will be dependent on how post-construction issues are addressed. For example, if an applicant's plan for a land development or redevelopment project adequately addresses stormwater issues during construction but does not do so for post-construction impacts, then it must not be approved until the post-construction issues are addressed.

Ordinance

Municipalities must enact, implement, and enforce a stormwater control ordinance using PA DEP model language. The ordinance must address the proper standard for BMPs and operations and maintenance requirements for the BMPs. The ordinance will apply a statewide post-construction requirement until the water quality-based Act 167 Plan is adopted by the County and implemented by the municipality, at which time the municipality will need to amend it to include those requirements.

The ordinance should require that all development and redevelopment activities with earth disturbance one acre or more with runoff to the MS4 (or five acres or more regardless of the planned runoff) be conducted in accordance with the ordinance. No formal approval of land development plans or issuance of building permits should occur without municipal approval of post-construction stormwater controls. A model ordinance is available from PA DEP.

Implement Program

The municipalities must commit resources or establish an agreement with the local County Conservation District (CCD) or other service provider (e.g., municipality's consulting engineer) for coordination of post-construction BMP approvals. There must be a process to review the post-construction controls in conjunction with the review process for construction approval.

Municipalities must ensure that the post-construction controls will meet state water quality requirements. Those requirements depend upon the status of the Act 167 Stormwater Management planning in the watershed. Where a water-quality-based Act 167 plan has been completed (or updated), those local watershed requirements apply. Otherwise, statewide requirements must be implemented.

While it is the municipalities' responsibility to ensure that the BMPs meet the water quality requirements, PA DEP will be reviewing post-construction plans for individual permits, and some County Conservation Districts have the expertise to conduct the reviews under an agreement with the municipality similar to that for the Construction Minimum Control Measure.

Operation and Maintenance of Post-Construction BMPs

It is the municipalities' responsibility to ensure that the post-construction BMPs required and approved pursuant to the program are constructed, operated, and maintained. Many BMPs may be "non-structural," and will require no operation or maintenance. Examples are use of open space and vegetated buffers in development design, minimization of soil disturbance and compaction during construction, and minimization of directly connected impervious areas. Other BMPs – "structural BMPs" – will require proper operation and maintenance. Examples include wet ponds, grassed swales, infiltration basins, and bioretention areas.

Municipalities will need to have a monitoring program that ensures that the post-construction BMPs are constructed, operated, and maintained, within the first permit term of five years. The program must have two elements:

- Implementation: Ensure installation of the BMPs as designed. Coordinate the monitoring with the CCD, especially where a permit has been issued.
- Operation and Maintenance: Some of the structural BMPs will require maintenance over time to be effective. Municipalities must have a system to monitor these BMPs. If any BMPs

are not operated or maintained and are ineffective, municipalities must develop a plan to address them. The PA DEP Model Ordinance provides legal tools to accomplish this.

All municipalities within the Tookany/Tacony-Frankford Watershed must carry out this program (see Table 8.7). The schedule for full implementation is provided, in accordance with the new Phase II rules, in the table below.

Table 8.18 Post-Construction Stormwater Runoff Management: Implementation Schedule

PERMIT YEAR	*IMPLEMENTATION SCHEDULE*	
	Stormwater Management Program	Long Term Operation and Maintenance
Year 1	**Ordinance:** Enact an ordinance requiring: • No formal approval of land development plans or issuance of building permits without municipal approval of post-construction stormwater controls. • Development and redevelopment activities with earth disturbance of one acre or more with runoff to the MS4, or five acres or more regardless of the planned runoff, must be conducted in accordance with the ordinance. **Process:** Rely on PA DEP review of permits where applicable; where no PA DEP review of post-construction controls is conducted, use municipal resources, or establish an agreement with the local CCD or other service provider (e.g., municipal engineer) for coordination of post-construction BMP approvals. **Standard:** Require post-construction structural and non-structural BMPs be designed, constructed, and maintained to meet (1) the requirements of the approved Act 167 plan and the municipal ordinance, or (2) the PA DEP statewide water quality requirements, until such Act 167 Plan is in place.	Ensure that stormwater BMPs are built, operated, and maintained as designed.
Years 2-5	• Implement the ordinance and post-construction BMP approval process.	Ensure that stormwater BMPs are built, operated, and maintained as designed.

Use Review and Attainability Analysis (CR8) Related Goals: 1, 2, 3, 4 Related Indicators: 7, 8, 9, 10, 11			
What	Who	Where	When
Coordinate water quality standards review and revision with PWD's CSO LTCP	EPA and PADEP in partnership with PWD and other permitted dischargers	The Tookany/Tacony-Frankford creek and tributaries	Within 5 years (1 NPDES CSO permit cycle)

The CSO Policy calls for the development of a long-term control plan (LTCP) which includes measures that provide for compliance with the Clean Water Act, including attainment of water quality standards. The CSO Policy provides that "development of the long term plan should be coordinated with the review and appropriate revision of water quality standards (WQS) and implementation procedures on CSO-impacted receiving waters to ensure that the long-term controls will be sufficient to meet water quality standards" (59 FR 18694).

As part of a renewed focus on this commitment, EPA has issued a guidance document, Coordinating CSO Long-Term Planning with Water Quality Standards Reviews (EPA-833-R-01-002). This document lays a strong foundation for integrating water quality standards reviews, implementation of high-priority CSO controls, and development of well-designed and operated LTCPs that support attainment of water quality standards without causing substantial and widespread economic and social impacts. In addition to CSO impacts, many of the processes, procedures and ideas presented can be used to address wet weather issues such as stormwater and other point and nonpoint sources on a watershed basis. An iterative, phased implementation of CSO controls fits well with the watershed approach.

Depending on the impacts, possible water quality standards revisions could include:

1. Re-evaluating recreational uses and applying criteria for bacteria at the point of contact rather than at the end-of-pipe,
2. Segmenting the water body to preserve recreation in areas where it actually occurs, and
3. Revising the use by creating subclasses to recognize intermittent exceedances of bacteriological criteria.

Watershed-Based Permitting (CR9) Related Goals: 2, 3, 4, 5, 7 Related Indicators: 1, 2, 3, 7, 10, 11, 15, 16, 19			
What	Who	Where	When
Explore approaches to developing NPDES permits for multiple point sources located within the watershed	PADEP	Watershed-wide	Long term

Source: Watershed-Based National Pollutant Discharge Elimination System (NPDES) Permitting Implementation Guidance, December 2003 (EPA 833-B-03-004)

Watershed-Based NPDES Permitting
Watershed-based NPDES permitting is an approach to developing NPDES permits for multiple point sources located within a defined geographic area (watershed boundaries) to meet water quality standards. This approach, aimed at achieving new efficiencies and environmental results, provides a process for considering all stressors within a hydrologically defined drainage basin or other geographic area, rather than addressing individual pollutant sources on a discharge-by-discharge basis. This plan provides the first steps in this process. In the long term, a watershed-based permit in the Tookany/Tacony-Frankford system can provide the regulatory framework for implementation of this integrated watershed management plan.

A truly comprehensive watershed management approach should bring together key programs under the Clean Water Act, such as the NPDES Program, the TMDL Program, the Section 319 Nonpoint Source Program, and Section 404 Wetlands Permitting, as well as the Source Water Assessment Program under the Safe Drinking Water Act. Watershed-based NPDES permitting can be another tool to facilitate comprehensive programmatic integration at a watershed level and ensure that permitting activities tie into existing watershed management efforts.

Developing and Implementing a Watershed-Based NPDES Permitting Approach EPA’s suggested process for developing and implementing a watershed-based NPDES permitting approach consists of the following six steps. This integrated watershed management plan fulfills most requirements of the first three steps.

Step One - Select a Watershed and Determine the Boundaries

Step Two - Identify Stakeholders and Facilitate Their Participation

Step Three - Collect and Analyze Data for Permit Development

Step Four - Develop Watershed-Based Permit Conditions and Documentation

Step Five - Issue Watershed-Based NPDES Permit

Step Six - Measure and Report Progress

8.3.2 Target C Options: Public Education and Volunteer Programs

Public Education and Volunteer Programs (CP1) Related Goals: 4, 6, 7 Related Indicators: 16, 17, 18, 19, 20, 21			
What	Who	Where	When
See Public Education and Volunteer Programs under Target A options (Section 8.1.2).	All municipalities.	All municipalities.	Short-term: first 5 years coinciding with the stormwater permit (see Table 8.8).

8.3.3 Target C Options: Municipal Measures

Sanitary Sewer Overflow Detection (CM1)

Related Goals: 3, 7
Related Indicators: 10, 11, 19, 20

What	Who	Where	When
SSO Detection Program.	Municipalities with separate sewer systems in TTF Watershed (see Table 8.7).	See Figure 8.3 (map of separate sewers and responsible authorities).	Permanent ongoing program should be part of each agency's program.

Discharges from sanitary sewers to Tookany/Tacony-Frankford Creek during wet weather are suspected in some areas. Some of the techniques used for inspection of sewer lines can also be used for identifying potential locations of SSOs. Some of the most effective techniques for identifying the location of SSOs are listed below. (Source: Protocols for Identifying Sanitary Sewer Overflows, American Society of Civil Engineers EPA Cooperative Agreement #CX 826097-01-0, June 2000.)

Sewer System Mapping

GIS maps of the sewer system should be developed in all municipalities. These maps serve as the basis for hydraulic modeling, and are key to many of the techniques described below.

Customer and/or Public Complaint

When a basement backup occurs or an SSO occurs in an area exposed to view, it is almost certain that someone will call the sewerage agency and report the incident. The agency should have a plan in place to investigate the reported SSO, find its cause, and take remedial measures to avoid recurrence of the SSO.

Visual Inspections after Overflows

Visual inspections can be used to confirm the occurrence of SSOs at suspected locations. The agency should develop a list of such locations and update it periodically. Immediately following a major storm, an inspection team should be sent to investigate these locations. A visual inspection program can be enhanced by encouraging participation of the public through providing opportunities for the public to become part of the solution.

Scheduled Maintenance Inspection

Municipal sewerage agencies should be performing routine maintenance inspections of their system. While the maintenance crew is performing the inspection, it can also look for signs of SSOs. These are most likely to occur at pumping stations, manholes, stream crossings, and cleanouts.

GIS-Based Analysis of Past SSOs

GIS analysis can answer questions related to location, condition, trends, patterns, and modeling. Listed below are some typical questions that GIS can answer:

- What exists at a given location?
- Where is the location of an object or outcome with a number of specific characteristics?
- What has changed over a given period?
- What is the spatial distribution of areas with a certain attribute?

Sanitary Sewer Management Systems

A Sanitary Sewer Management System (SSMS) can be used to store, organize, and analyze large quantities of data associated with sewer system operation, maintenance, inspection, modeling, and rehabilitation. The SSMS may include the following modules:

- Inventory Module
- Flow Module
- Modeling Module
- Inspection Module
- Maintenance Module
- Rehabilitation (CIP) Module
- Mapping Module

Analysis of the data in the SSMS can reveal many problem areas, trends, and patterns. For example, the database can be searched to develop a list of lines with flat slopes or areas where frequent maintenance is needed. Another application of the SSMS is analysis of historical data.

Flow Monitoring

Flow monitoring at strategic locations may be used to identify potential locations of SSOs. Flow monitors can be installed in open channels and pumping stations to obtain the data necessary for proper system evaluation. In conjunction with flow monitoring, rain gauges should also be installed. Many open channel temporary flowmeters have both velocity and depth measuring sensors. Municipalities should use the existing rain gauge network in the TTF Watershed.

Flow data can be used to determine the average daily flow, the infiltration rate, and the inflow rate. The rain gauge data can be used to determine the recurrence interval or severity of the storm event (for example, 5-year) that caused the inflow. The flow data will also indicate whether a surcharge occurred during the flow monitoring period.

Monitoring of Receiving Stream for Sewage Indicators

This technique may be used for identifying the locations of dry weather SSOs. Samples from a nearby stream are taken at regular intervals along the stream and tested for fecal coliforms. Significant presence of these bacteria could be an indication of sewage leaking from the sewer line into the stream.

Closed Circuit Television (CCTV) Inspection

CCTV inspection has been widely used for inspection of sewer line interiors. The final product of a CCTV inspection is videotape and a field log prepared and narrated by an operator. The videotape provides a visual and audio record of problem areas in the sewer line. Evaluation of the CCTV records help identify structural problems; locate leaking joints and non-structural cracks, blockages, and dropped joints; and identify areas of root intrusion.

Sewer Scanner and Evaluation Technology Surveys (SSET)

The SSET is a new pipeline inspection technology developed in Japan. The equipment consists of a scanner, a CCTV, and a three-axis mechanical gyroscope. The mechanics of placing the SSET in the sewer line are similar to those of CCTV inspection. The images produced by SSET are of higher quality than CCTV images. Interpretation of the results is done in the office by an engineer rather than in the field by a technician. This increases the speed of field operations and reduces the cost.

Surcharge Level Alarms/Remote Monitoring

These devices can be placed at strategic locations in the manholes and pumping stations. Once the flow reaches a certain elevation, the alarm goes off and sends a signal to a control center via a telephone line or SCADA system. The sewerage agency should have a plan in place to respond immediately to such alarms. In addition, the responding agency should also record the event in a database.

Dye Tracing

Dyed water testing consists of dye tracing or flooding, and is done to locate possible sources of inflow such as area drains or catch basins suspected of being connected to the sewer line, or sources of rainfall-induced infiltration/inflow which indirectly contribute to the flow in the sewer line through the soil and pipe cracks. Dye testing is normally used to complement smoke testing of suspect areas. The downstream manhole is monitored to see if the dye water injected into an outside source such as a downspout has found its way into the sewer system. Color CCTV may also be used for locating problem areas after the dye enters the pipeline through the surrounding soil.

Smoke Testing

The purpose of smoke testing is to locate rainfall-dependent I/I (Inflow and Infiltration)sources which could lead to SSOs during a storm events. Public notification is an important and critical element of any smoke testing program. Specific I/I sources detected by smoke testing includes roof, yard, and area drain connections; catch basins; and broken service lines. The testing procedure consists of pumping non-toxic smoke through a manhole into the sewer pipe for distances up to 600 ft. The smoke will surface through open breaks in the pipe connections. All such sources are photographed and documented.

Aerial Monitoring

Aerial monitoring by helicopter may be used to gain a general understanding of conditions along a sewer line which may lead to an SSO. For example, washout may expose a section of pipe, which would then be at risk of damage and subsequent SSO. Examples of features which may be observed during such monitoring include manholes with broken or missing covers and sewer lines exposed by erosion.

Monitoring of Grease Buildup

A significant cause of SSOs during dry weather is sewer stoppages resulting from grease buildup. Such stoppages occur most frequently in downtown areas where restaurants are major sources of flow in the sewer system. A list of locations of grease buildup should be developed and these locations should be regularly inspected. Grease buildup can be prevented by enforcing grease ordinances, by effective pretreatment programs, and by promoting public education. The grease accumulations can be removed using the many available cleaning techniques, such as bucket machines with brushes, power rodders, and high velocity jet cleaners. Bioaugmentation, which involves the addition of bacteria cultures to sewers to speed up the breakdown of grease deposits, can also be effective.

Pump Station Inspection

Pump station failures can lead to significant SSO problems. Such failures can be avoided by regular inspections. The frequency of inspections may vary from once a day to once a month, depending on the size and criticality of the station, and reliance on monitoring by means such as the SCADA system.

Manhole Inspection

Manhole interiors are inspected for physical soundness for evidence surcharging such as high water marks on manhole walls. The observed defects should be compiled into a database that will be used to estimate the I/I attributable to each manhole and to establish manhole maintenance and rehabilitation program.

Line Lamping

Line lamping is done in conjunction with manhole inspection by inspecting the interior of the sewer lines connected to the manhole using an artificial light and a mirror. Lamping helps identify pipe defects and provides a basis for selecting sewers for television inspection.

Building Inspection

Building inspections are conducted to investigate extraneous flow from connections to sump pumps, foundation drains, downspouts, or leaking laterals. Building inspections should include investigation of the causes of basement backups.

Ground Penetrating Radar

Ground penetrating radar uses the transmission and reflection properties of an electromagnetic wave passing through the soil to determine soil properties and the depth and extent of subsurface objects. The speed and amplitude of the electromagnetic wave are dependent on the moisture content of the soil. This principle can be used to detect leaking joints in the line and voids around the pipe, which may be caused by soils being washed out. In such locations, the signal will be delayed because the speed of the wave will be reduced, and the amplitude of the wave will be attenuated.

Soil Moisture and Temperature Monitoring

When the ground is relatively dry, a larger portion of the rainfall will penetrate the soil, which will result in a decrease of groundwater to sanitary sewers. However, as the soil moisture increases, the amount of infiltration to sewers increases. For this reason, the impact of subsequent storm will be more severe: while the system did not overflow during the first storm, it will do so during the second storm, although the second storm of smaller intensity than the first. By monitoring the soil moisture and temperature, it may be possible to develop a measure for assessing the occurrence of SSOs.

Inspections of Stream Crossings and Parallel Lines

Pipes running alongside or crossing streams are often vulnerable to SSOs. If the sewer is buried under the stream bed, the scouring action of the stream bed will eventually expose it, causing the pipe to lose its soil support. The pipe segments may move under the water pressure and joints may open, or the pipe may become exposed as a result of bank erosion. Any such openings admit significant amounts of flow, which may exceed the capacity of the sewer pipe. Stream crossings that include inverted siphons often become clogged with accumulations of silt and debris, which may cause an overflow upstream. The foundations of aerial stream crossing piers are also subject to scouring and may lead to foundation failure of the sewer line.

Sewer pipes that cross or parallel streams should be inspected to ensure that they are not broken or cracked. The manholes on each side of the stream should be checked for excess flow, which would indicate a leaking sewer under the stream. Since these sewers are usually in remote areas, they are vulnerable to vandalism and can overflow undetected for long periods.

All municipalities in the Tookany/Tacony-Frankford Watershed should have a routine and effective SSO detection program. Once SSOs are found and the cause determined, proper measures to eliminate the SSO should be taken.

All municipalities with separate sanitary sewers are responsible for developing an effective SSO detection program.

The River Conservation Plans (RCPs) recommend the following:

- Greenwood Avenue to Wyncote Post Office: Inspect and repair manhole covers as needed.
- Wyncote Post Office to Washington Lane Underpass: Inspect and repair all manhole covers and cement encasements.

Sanitary Sewer Overflow (SSO) Elimination: Structural Measures (CM2)

Related Goals: 3, 7
Related Indicators: 10, 11, 19, 20

What	Who	Where	When
Implement a CMOM program (see Option AM1). Update and implement official Act 537 Sewage Facilities Plans.	Municipalities with separate sewer systems in Tookany/Tacony-Frankford Creek (see Table 8.7).	See Figure 8.3 (map of separate sewers and responsible authorities).	Short-term (within 5 years of SSO detection).

Discharges to U.S. waters from municipal sanitary sewer collection systems are prohibited, unless authorized by an NPDES permit. Permits authorizing discharges from such systems must contain technology-based effluent limitations, based upon secondary treatment and applicable water quality standards. NPDES permits for municipal wastewater treatment plants should require record-keeping and reporting of overflows that result in a discharge. Permits should also contain requirements for operation and maintenance of the sanitary sewer collection system.

The EPA and PA DEP are continuing to address SSO problems with compliance assistance and enforcement in accordance with the Compliance and Enforcement Strategy Addressing Combined Sewer Overflows and Sanitary Sewer Overflows, issued April 27, 2000. In addition to the national policy, Act 537, enacted by the Pennsylvania Legislature in 1966, requires that every municipality in the state develops and maintains an up-to-date sewage facilities plan. The main purpose of a municipality's sewage facilities plan is to ensure that the sewage collection and treatment systems have adequate capacity to convey present and future to sewage flows to a wastewater treatment facility. Official plans contain comprehensive information, including:

- The location of treatment plants, main intercepting lines, pumping stations and force mains, including their size, capacity, point of discharge and drainage basin served (preferably in a GIS format);
- Descriptions of problems with existing sewerage facilities and operation and maintenance requirements; and
- Planning objectives and needs:
  - Physical description of planning area
  - Evaluation of existing wastewater treatment and conveyance systems
  - Evaluation of wastewater conveyance and treatment needs

EPA has developed a comprehensive management framework called Capacity, Management, Operations, and Maintenance (CMOM) to assist municipalities in developing more comprehensive sanitary sewer system management programs. A CMOM program (described in Section 8.1.3, Option AM1) helps to prevent SSOs. Once a recurring SSO is detected using the methods recommended under Option CM1, measures must be taken to eliminate the discharge.

Reduction of Stormwater Inflow and Infiltration (RDII) to Sanitary Sewers (CM3)

Related Goals: 3, 7
Related Indicators: 10, 11, 19, 20

What	Who	Where	When
RDII Reduction Program.	Municipalities with separate sewer systems in TTF Watershed (see Table 8.7).	See Figure 8.3 (map of separate sewers and responsible authorities).	Short-term.

Where significant RDII is detected, measures can be taken to seal the sanitary sewer system to reduce inflow of stormwater and groundwater. These measures are discussed in detail under Option AM3, "Sanitary Sewer Rehabilitation" (in Section 8.1.3).

Combined Sewer Overflow (CSO) Control Program (CM4)

Related Goals: 3, 7
Related Indicators: 7, 8, 9, 10, 11, 19, 20

What	Who	Where	When
Nine Minimum Controls (NMCs). Long Term Control Plan (LTCP) Capital Projects, including real time control (RTC). Watershed Plan development.	PWD	Philadelphia combined sewer system.	NMCs complete and ongoing. RTC short-term (within 5 years).

The fundamental goal of the Philadelphia Water Department's (PWD) combined sewer overflow (CSO) program is to improve and preserve the water environment in the Philadelphia area and to fulfill PWD's obligations under the Clean Water Act and the Pennsylvania Clean Streams Law by implementing technically viable, cost-effective improvements and operational changes.

The PWD's strategy to attain these goals has three primary phases: aggressive implementation of a comprehensive program for Nine Minimum Controls; planning, design, and construction of capital projects that further enhance system performance and reduce CSO volume and frequency; and comprehensive watershed-based planning and analyses that will identify additional, priority actions to further improve water quality in Philadelphia area water bodies.

The implementation of each of these control measures is discussed briefly below.

Nine Minimum Controls

In the first phase of PWD's CSO strategy, and in compliance with its NPDES permits, PWD submitted CSO Documentation: Implementation of Nine Minimum Controls to the PA DEP on September 27, 1995. The nine minimum controls are low-cost actions or measures that can reduce CSO discharges and their effect on receiving waters, do not require significant engineering studies or major construction, and can be implemented in a relatively short time frame. To provide information needed for the development of the Nine Minimum Controls (NMC) program, PWD instituted a $6.5 million project to upgrade its comprehensive system flow monitoring network. This program provides information necessary to identify and eliminate dry weather overflows, monitor system performance and operation, and configure and calibrate computer hydraulic models needed to develop the NMCs and long-term CSO control plans. This information provided the basis for the System Hydraulic Characterization Report that was submitted to the PA DEP in June 1995 and provided the technical basis for the development of the NMC plan.

Extensive data from the PWD's Geographic Information System (GIS), flow monitoring system, the U.S. Army Corps of Engineer's Storage, Treatment, Overflow, Runoff Model (STORM), and the EXTRAN and RUNOFF blocks of the EPA Stormwater Management Model (SWMM) were used to support each phase of the CSO program. These tools were developed to support concept engineering through implementation and post-construction monitoring. The monitoring system, models, and GIS will serve as the basis for planning improvements and enhancing operation of the sewerage system over the long-term.

Using the above tools, the PWD's NMC program includes comprehensive, aggressive measures to maximize water quality improvements through the following nine measures:

1. Review and improvement of ongoing operation and maintenance programs.

CSO Regulator Inspection & Maintenance Program

PWD has committed to demonstrating an improved follow-up response to sites experiencing a dry weather overflow. PWD has instituted a policy of next day follow-up inspection at sites that experience an overflow. PWD will conduct an evaluation of the effectiveness of twice-weekly inspections.

A database has been developed to document the maintenance performed on each CSO site. This system will ensure that proper regulator settings are maintained and system changes are documented. This database can also store scanned plan view and profile view drawings of CSO regulator and hydraulic control point chambers for inclusion in the filed inspection report forms.

Additional components of the O&M program include:

- Pumping Station Maintenance
- Sewer Cleaning Contracts
- Inflow Prevention Program
- Tide Gate Inspection and Maintenance Program
- Emergency Overflow Weir Modification

2. Measures to maximize the use of the collection system for storage.

Use of the collection system for storage has long been recognized as a potentially cost-effective means to mitigate the occurrence and impacts of CSOs. PWD has been implementing in-system storage in Philadelphia's combined sewer system for nearly 20 years, using a variety of technologies:

- Reducing tidal inflows at regulators can reduce CSO overflows to Tookany/Tacony-Frankford Creek by increasing available treatment capacity at the POTW.
- A program to install tide gates or other backflow prevention structures at Tookany/Tacony-Frankford Creek regulators to protect these regulators from potential inundation.
- Another approach that can be implemented to gain additional in-system storage is to raise the overflow elevation by physically modifying the overflow structure (e.g., raising an overflow weir). However, this approach must be implemented cautiously, since raising the overflow elevation also raises the hydraulic grade line in the combined trunk sewer during storm flows, and therefore increases the risk of basement and other structural flooding within the upstream sewer system due to backup or surcharge problems.

3. Review and modification of PWD's industrial pretreatment program.

(Also see Section 8.3.1, Option CR4, "Industrial Stormwater Pollution Prevention.")

- Over the years, PWD has implemented a rigorous industrial pretreatment program. The effectiveness of this program has allowed the City to develop one of the largest and most successful biosolids beneficial reuse programs in the nation. As part of the nine minimum controls effort, PWD is committed to taking actions to encourage industries to better manage their process water discharges to the sewer collection system during wet weather periods.

4. Measures to maximize flow to the wastewater treatment facilities.

As a minimum control, maximizing flow to the publicly owned treatment works (POTW) means making simple modifications to the sewer system and treatment plant to enable as much wet weather flow as possible to reach the treatment plant and receive treatment. The secondary capacity of the treatment plant should be maximized, and all flows exceeding the capacity of secondary treatment should receive a minimum of primary treatment (and disinfection, when necessary). The most effective way to determine the ability of the POTW to operate acceptably at incremental increases in wet weather flow, and to estimate the effect of the POTW's compliance with its permit requirement, is to perform stress testing to determine optimum flows, loads, and operations of the plant's unit processes.

5. Measures to detect and eliminate dry weather overflows.

Relevant measures are discussed in Section 8.1.3, which details various recommended Target A Municipal Measures.

6. Control of the discharge of solid and floatable materials.

Solids are waterborne waste material and debris consisting of sand, gravel, silts, clay, and organic matter. Significant concentrations of solids are not only a visual nuisance, but can affect turbidity and dissolved oxygen, and carry pathogens in the receiving water. In addition, excessive amounts of solids can affect the combined sewer system by decreasing hydraulic capacity, thus increasing the frequency of overflows. Solids can enter the system through domestic and industrial wastewater, and debris washed from streets.

Floatables are waterborne waste material and debris (e.g., plastics, polystyrene, and paper) that float at or below the water surface. Floatables seen in significant quantities are aesthetically undesirable and can cause beach closings, interfere with navigation by fouling propellers and water intake systems, and impact wildlife through entanglement and ingestion.

Floatables and solids control measures consist of non-structural and structural technologies.

Non-structural technologies include combined sewer system maintenance procedures such as sewer flushing, street sweeping, and catch basin cleaning. Public education, land use planning and zoning, and ordinances are also considered non-structural technologies implemented to reduce solids and floatables entering the combined sewer system. (These technologies are discussed elsewhere in Section 8, under various relevant options.)

Structural controls typically consist of abatement devices that would be constructed near the point of discharge. Technologies used for removing solids and floatables from CSOs include: Baffles, Booms, Catch Basin Modifications, Netting Systems, Swirl Concentrators, Screens, and Trash Racks. (Modification of storm and combined sewer inlets for solids control, as well as catch basin and storm inlet maintenance are also discussed elsewhere under Section 8 options.)

Solids and floatables discharged from CSOs may represent a potentially significant impact to Tookany/Tacony-Frankford Creek. PWD currently expends considerable effort to minimize the potential discharge of solids and floatables.

- PWD performs over 50,000 inlet cleanings each year preventing many tons of street surface-related materials from discharging to waterways through CSOs. The significant pipe cleaning and grit removal activities conducted by PWD also remove a great deal of material that otherwise might discharge through CSO outlets during wet weather.
- The continued practice of regularly cleaning and maintaining grit pockets at critical locations in the trunk and interceptor system is an important part of the CSO control strategy. Grit buildup reduces the hydraulic capacity of the interceptor both by constricting its cross sectional area, and by increasing its frictional resistance. For example, quarterly cleaning of the 100-foot deep siphon grit pocket located at the Central Schuylkill wastewater pumping station is a major undertaking requiring specialized equipment and the commitment of significant labor resources. This practice has been shown to reduce the hydraulic grade surface at the siphon, increasing the wet weather flow capacity to the SWWPCP. Prior to the institution of this cleaning practice, the grit pit at this location had not been cleaned regularly in over 40 years.
- Operation condition inspections of regulator chamber and backflow prevention devices are conducted for each structure approximately weekly, resulting in more than 10,000 inspections conducted each year. Additionally, comprehensive structural and preventative maintenance inspections are performed annually.
- A pilot, in-line, floatables netting chamber was constructed as part of a sewer reconstruction project at CSO T-4 Rising Sun Ave. east of Tacony Creek. The construction of the chamber was completed in March 1997 and the netting system continues to operate. The quantity of material collected is weighed with each net change. On an area weighted basis, the inlet cleaning program data suggests that street surface litter dominates the volume of material that can enter the sewer system. The pilot in-line netting system installed at T-4 has been shown to capture debris on the same order as the WPCP influent screens indicating that effective floatables control needs to target street surface litter in order to effectively reduce the quantity of debris likely to cause aesthetic concerns in receiving streams.
- Debris grills are maintained regularly at sites where the tide introduces large floating debris into the outfall conduit. This debris can then become lodged in a tide gate thus causing inflow to occur. Additionally, these debris grills provide entry restriction, and some degree of floatables control. Repair, rehabilitation, and/or expansion of debris grills were performed at outfall F05 during calendar year 2002.

7. Implementation of programs to prevent generation and discharge of pollutants at the source.

Most of the city ordinances related to this minimum control are housekeeping practices that help prohibit litter and debris from being deposited on the streets and within the watershed. These measures include litter ordinances and illegal dumping policies and enforcement (see Section 8.1.1, Option AR2). If such pollutants eventually accumulate within the watershed, practices such as street sweeping and regular maintenance of catch basins can help to reduce the amount of pollutants entering the combined system and ultimately, the receiving water.

8. Measures to inform the public about the occurrence, location, and impacts of CSOs.

PWD has developed and will continue to develop a series of informational brochures and other materials about its CSO discharges and the potential affect on the receiving waters, in addition to information regarding dry weather flows from its stormwater outfalls. The brochures provide phone contacts for additional information. Also, the opportunity to recruit citizen volunteers to check or adopt CSO outfalls in their watersheds (e.g.,, notifying PWD of dry weather overflows, etc.) will be explored through the watershed partnership framework. Brochures and other educational materials discuss the detrimental affects of these overflows and request that the public report these incidences to the department. In addition, the Water Department has enlisted watershed organizations to assist it with this endeavor. PWD continued with this focus in 2002 to raise the level of awareness in its citizens about the function of combined and stormwater outfalls through a variety of educational mediums. The watershed partnerships are important for this kind of public/private effort to protect stream water quality. Lastly, the Department's Waterways Restoration Unit will investigate the feasibility of installing signs that can withstand nature and vandals at PWD outfalls.

9. Comprehensive inspection and monitoring programs to characterize and report overflows and other conditions in the combined sewer system.

Monitoring and characterization of CSO impacts from a combined wastewater collection and treatment system are necessary to document existing conditions and to identify water quality benefits achievable by CSO mitigation measures. Tables are compiled annually to represent average annual CSO overflow statistics as required in the NPDES Permit.

Long Term Control Plan Capital Projects

The second phase of PWD’s CSO strategy is focused on technology-based capital improvements to the City’s sewerage system that will further increase its ability to store and treat combined sewer flow, reduce inflow to the system, eliminate flooding due to system surcharging, decrease CSO volumes, and improve receiving water quality. The recommended capital improvement program is the result of a detailed analysis of a broad range of technology-based control alternatives.

A Real Time Control (RTC) center is being established at PWD’s Fox Street facility. The ultimate goal for this center is to house a centralized RTC system that will allow telemetered commands to be sent to site-specific, automated controls located throughout the collection and treatment facilities. These signals may be transmitted based upon an optimized response to rainfall patterns and are intended to further enhance capture of CSO volume. Establishing a RTC center will enable PWD to provide 24-hour monitoring and, eventually, control of key collection system facilities including automated CSO regulators, pump stations, and inter-district diversions.

Two RTC projects are currently being designed for regulators that discharge to Tacony Creek. The trunk sewer discharging to regulator structure T-14 near Juniata Park and Tacony Creek Park contains excess storage capacity that can be utilized by increasing the overflow elevation during smaller rain events. A dynamic gate is ideal because the original overflow capacity is still needed to provide adequate drainage during very large storms. The project will reduce discharge volume associated pollutants such as bacteria, organic matter, solids, and litter from both untreated stormwater and wastewater.

The trunk sewer discharging to regulator structure T-08, near Nedro Avenue and Hammond Street in Tacony Creek Park, also has excess storage capacity during smaller storms. A similar dynamic gate is being proposed for this location to take advantage of this capacity and increase capture of combined sewage during wet weather. These projects are cost-effective because they modify existing infrastructure rather than requiring construction of new infrastructure. Both areas are in or near parkland used by the public for recreation.

Watershed-Based Planning and Management

The third component of the City's CSO strategy involves a substantial commitment by the City to watershed planning to identify long term improvements throughout the watershed, including possibly additional CSO controls, which will result in further improvements in water quality and, ultimately, the attainment of water quality standards. The need for this watershed initiative is rooted in the fact that, prior to development of the Integrated Watershed Management Plan, insufficient physical, chemical, and biological information existed on the nature and causes of water quality impairments, sources of pollution, and appropriate remedial measures. Because of this deficiency, it was impossible to determine what needed to be done for additional CSO control or control of other wet weather sources throughout the watershed. This deficiency, especially with respect to the effects of wet weather discharges and receiving water dynamics, is increasingly recognized nationwide and has led to a broader recognition of the need for watershed-based planning and management to properly define water quality standards and goals. PWD believes that the National CSO Policy, state and federal permitting and water quality management authorities, cities, environmental groups, and industry, now recognize that effective long-term water quality management can be accomplished only through watershed-based planning. Completion of the Tookany/Tacony-Frankford Integrated Watershed Management Plan represents the realization of this commitment to watershed-based planning.

Catch Basin and Storm Inlet Maintenance (CM5)

Related Goals: 3, 5, 6, 7
Related Indicators: 11, 15, 16, 19, 20

What	Who	Where	When
Regularly inspect catch basins (in combined areas) and storm inlets (in separate areas). Remove sediment as needed.	Sewer owners (PWD and municipalities).	All inlets throughout watershed.	Continue existing programs.

Catch basins and storm inlets that are part of the stormwater collection and conveyance system should be cleaned on a regular basis. Sediment, leaves, grass clippings, pet wastes, litter, and other materials commonly accumulate in catch basins. These materials can contain significant concentrations of nutrients, organics, bacteria, metals, hydrocarbons, and other pollutants. When a storm occurs, runoff entering the basin may dislodge and suspend some of this material. This debris can be conveyed along the storm sewer system and released to a surface water body. Catch basin clean out should be scheduled for the fall and early spring in order to remove leaves and road salt and sand before the spring rains. In general, this is done with vacuum trucks, with disposal of the debris handled as solid waste.

In separate sewered areas of the Tookany/Tacony-Frankford Watershed, each municipality is responsible for an effective storm sewer cleaning program. In Philadelphia, PWD has this responsibility.

Street Sweeping (CM6) Related Goals: 3, 5, 6, 7 Related Indicators: 11, 15, 16, 19, 20			
What	Who	Where	When
Evaluate existing Street Sweeping programs and implement enhanced practices.	All municipalities.	Streets and parking lots in commercial and dense residential areas.	Within next 5 years.

Street and parking lot cleaning performed on a regular basis in urban and dense residential areas can be an effective measure for minimizing stormwater pollutant, sediment, and floatables loading to receiving waters.

Street sweeping programs had largely fallen out of favor as a pollutant removal practice following the 1983 NURP report. Recent improvements in street sweeper technology, however, have enhanced the ability of the machines to pick up the fine grained sediment particles that carry a substantial portion of the stormwater pollutant load, and have led to a recent reevaluation of their effectiveness. New studies show that conventional mechanical broom and vacuum-assisted wet sweepers reduce non-point pollution by 5 to 30 percent and nutrient content by 0 to 15 percent. However, newer dry vacuum sweepers can reduce non-point pollution by 35 to 80 percent and nutrients by 15 to 40 percent for those areas that can be swept (Runoff Report, 1998). A benefit of high-efficiency street sweeping is that by capturing pollutants before they are made soluble by rainwater, the need for structural stormwater control measures might be reduced. Structural controls often require costly added measures, such as adding filters to remove some of these pollutants and requiring regular maintenance to change filters. Street sweepers that can show a significant level of sediment removal efficiency may prove to be more cost-effective than certain structural controls, especially in more urbanized areas with greater areas of pavement.

Computer modeling of pollutant removal in the Pacific Northwest suggests that the optimum sweeping frequency appears to be once every week or two (CWP, 1999). More frequent sweeping operations yielded only a small increment in additional removal (Bannerman, 1999; Claytor, 1999).

The following measures should be implemented toward achieving non-point source reductions in wet weather pollutant loads:

- Evaluate existing street and parking lot sweeping practices by municipalities with urban and dense residential areas contributing stormwater runoff to the watershed.
- Implement enhanced street and parking lot sweeping programs in urban and dense residential areas, prioritizing those not served by existing stormwater BMPs designed to reduce stormwater pollutant, sediment, or floatables loading to the receiving waters.

Responsible Landscaping Practices on Public Lands (CM7)

Related Goals: 1, 2, 3, 4, 6, 7
Related Indicators: 1, 10, 11, 12, 13, 16, 19

What	Who	Where	When
Incorporate integrated pest management (IPM) to reduce chemical use on public lands. Prevent clippings and cuttings from being transported by stormwater, and dispose of them through composting if possible.	Fairmount Park Commission, municipalities. PennDOT for vegetation along state roads.	Parks, golf courses, school and institutional grounds, roadside vegetation.	Short-term (within 5 years).

Common pesticides such as diazinon and chlorpyrifos can be harmful to aquatic life even at very low levels (CWP, 1999; Schueler, 1995). Proper use of these chemicals can be encouraged through public relations campaigns and demonstrated on public lands. Clippings and cuttings carried into the stormwater system and receiving streams can degrade water quality in a variety ways. A related problem exists with the illegal dumping of clippings and cuttings in or near drainage facilities. Recommended controls include:

- Consider an integrated pest management (IPM) program that encourages the use of alternatives to chemical pesticides. An IPM program incorporates preventative practices in combination with non-chemical and chemical pest controls to minimize the use of pesticides and promote natural control of pest species. In those instances when pesticides are required, programs encourage the use of less toxic products such as insecticidal soaps. The development of higher tolerance levels for certain weed species is a central concept of IPM programs for reducing herbicide use. This approach should be balanced with the invasive species control methods discussed in Section 8.2.3, Option BM7.

- Collect clippings and cuttings on slopes and the bottom of stormwater control facilities and near stormwater inlets. Avoid mowing when significant rain events are predicted. Dispose of material through composting when possible.

The River Conservation Plans (RCPs) recommend the following:

- High School Park to Ashbourne Road along the Tookany Creek Parkway: Educate Cheltenham Township Public Works in ecological maintenance practices. Encourage the two golf courses to evaluate fertilizing, mowing regime. Consider Audubon Golf Certification Program.
- Baeder Creek Watershed: Work with Abington Jr. High School to restore riparian buffer. Establish “no-mow” zone 30 feet from creek and plant native plants.

- Rock Creek Watershed: The mowed township-owned park would benefit from a change to a wooded area for both habitat enhancement and increased infiltration.
- Abington Country Club to Township Line Road: The Club greens should be maintained in a way to protect water quality.
- Abington Friends School to Township Line Road: Alter land management practices in the park to the restored pond shoreline including BMPs for the chip and putt course.
- Wyoming Avenue to Castor Avenue: Meet with Juniata golf course to discuss creating a “no mow” zone.

Responsible Bridge and Roadway Maintenance (CM9) Related Goals: 1, 2, 4, 7 Related Indicators: 1, 19			
What	Who	Where	When
Incorporate BMPs into regular repairs and maintenance: Road and bridge resurfacing practices, Deicing chemicals and practices, and Existing bridge drains.	Bridge and roadway owners (municipalities and PennDOT).	Roadways and bridges (Figure 8.6).	Short-term (within 5 years).

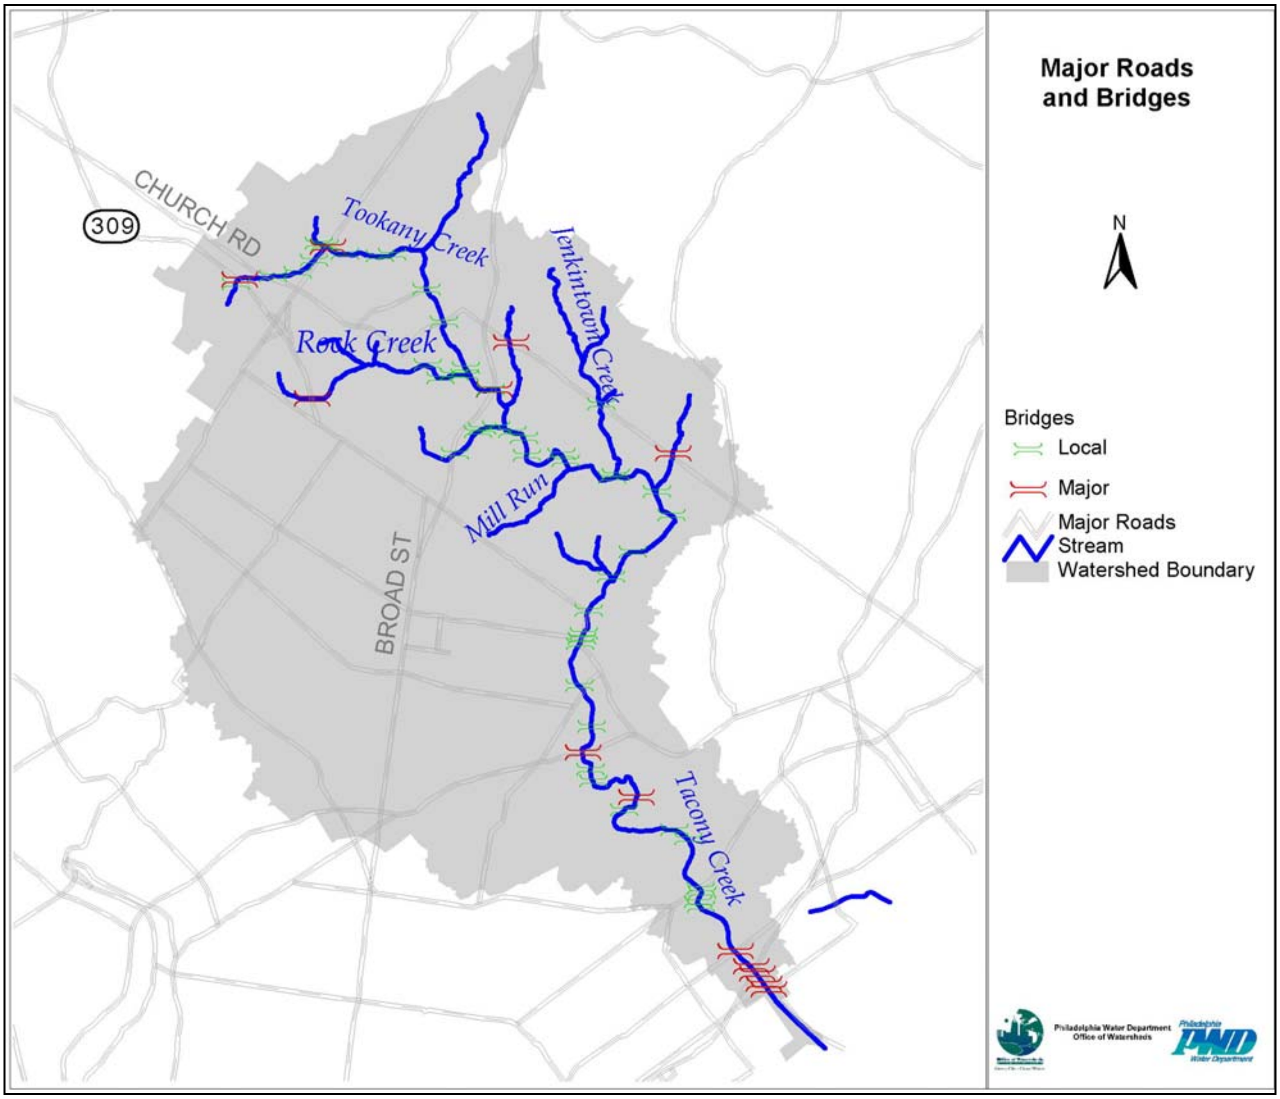

Figure 8.6 Major Roads and Bridges

Sediment and pollutants are generated during daily roadway and bridge use and scheduled repair operations, and these pollutants can impact local water quality by contributing heavy metals, hydrocarbons, sediment, and debris to stormwater runoff. The use of road salt is a public safety and a water quality issue. Aside from contaminating surface and groundwater, high levels of sodium chloride from road salt can kill roadside vegetation, impair aquatic ecosystems, and corrode infrastructure such as bridges, roads, and stormwater management devices.

Recommended techniques are as follows:

- Consider alterations to road and bridge resurfacing practices near the creeks (Figure 8.6). Perform paving operations only under dry conditions. Cover storm drain inlets and manholes during paving operations, use erosion and sediment control measures, and use pollution prevention materials such as drip pans and absorbent material for all paving machines to limit leaks and spills of paving materials and fluids. Finally, consider using porous asphalt for shoulder areas to reduce runoff.

- Consider adjusting the use and application of deicing materials as summarized below.

Table 8.19 Watershed Protection Techniques for Snow and Snowmelt Conditions

Use of De-Icing Compounds:
- Consider alternative de-icing compounds such as $CaCl_2$ and calcium magnesium acetate (CMA).
- Designate salt-free areas on roads adjacent to key streams, wetlands, and resource areas.
- Reduce use of de-icing compounds through better driver training, equipment calibration, and careful application.
- Sweep accumulated salt and grit from roads as soon as practical after surface clears.

Storage of De-Icing Compounds:
- Store compounds on sheltered, impervious pads.
- Locate at least 100 feet away from streams and floodplains.
- Direct internal flow to collection system and route external flow around shelters.

Dump Snow in Pervious Areas Where It Can Infiltrate:
- Stockpile snow in flat areas at least 100 feet from stream or floodplain.
- Plant stockpile areas with salt-tolerant ground cover species.
- Remove sediments and debris from dump areas each spring.
- Choose areas with some soil-filtering capacity.

Blow or Shovel Snow from Curbside to Pervious Areas.
Operate Stormwater Ponds on a Seasonal Mode.
Use Level Spreaders and Berms to Spread Meltwater Over Vegetated Areas.
Intensive Street Cleaning in Early Spring Can Help Remove Particulates on Roads.

- Consider alterations to existing bridge drains. Scupper drains can cause direct discharges to surface waters and have been found to carry relatively high concentrations of pollutants (CDM, 1993). At a minimum, routinely clean existing drains to avoid sediment and debris buildup, and consider retrofitting with catch basins or redirecting runoff to vegetated areas to provide treatment.

Runoff from bridges and roadways can become a serious hazard to water quality when the toxic pollutants from vehicles are taken into consideration.

The River Conservation Plans (RCPs) recommend the following:

- <u>Ralph Morgan Park to Greenwood Avenue</u>: Communicate with SEPTA regarding their maintenance practices of the parking lot.
- <u>Cheltenham Avenue to Adams Avenue</u>: Check railroad area for possible chemical runoff.

8.3.4 Target C Options: Stormwater Management

Source Control Measures

Reducing Effective Impervious Cover through Better Site Design (CS1)

Related Goals: 3, 5, 7
Related Indicators: 1, 15, 16, 19

What	Who	Where	When
Reduce effective impervious cover by approximately 1% through: Downspout disconnection. Pervious landscaping. Sidewalk and driveway width reduction. Vacant lands management.	All municipalities require and/or encourage these measures using regulatory and/or public education options discussed elsewhere in this section.	All areas.	Long term: 15+ years.

Small changes in site design can lead to a gradual reduction in effective impervious cover that becomes significant over time. When applied consistently, the measures above can result in a 5-10% reduction in areas that are redeveloped. Assuming 10% of the watershed might be redeveloped over the planning horizon, a reduction in effective impervious area of 1% is a reasonable goal. Programs to require or encourage these practices are discussed under the regulatory approaches and public education options (Sections 8.3.1 and 8.3.2, respectively).

Downspout disconnection: In highly urbanized areas of the watershed, it is not always possible to direct runoff to pervious areas, and an informal inspection of lower density areas indicates that many properties are already disconnected. However, a further reduction in directly connected roof leaders from just 10% of residences will result in an effective impervious cover reduction of about 5%.

Pervious Landscaping: When repaving parking lots and loading areas, conversion of 10% of the area in half of parking lots to pervious landscaping (a measure required by some municipalities, including Portland, OR) will decrease watershed effective impervious cover by approximately 0.5%.

Sidewalk and Driveway Width Reduction: Reducing sidewalk and driveway widths by one foot will result in a watershed effective impervious cover reduction of approximately 1%.

Vacant Lands Management: Vacant and abandoned lands in Philadelphia are gradually being acquired and demolished by the City. Proper grading of these sites to encourage infiltration, or addition of small, inexpensive BMPs if needed, can eliminate runoff from these sites during all but the largest storms. Similar techniques can be followed for vacant and abandoned lands in the other municipalities.

Porous Pavement and Subsurface Storage (CS2)

Related Goals: 1, 2, 3, 4, 6, 7
Related Indicators: 1, 10, 11, 16, 19, 20

What	Who	Where	When
Install porous pavement and subsurface storage in 10-50% of parking lots; coverage to be chosen by municipality to meet a share of watershed-wide reduction targets. Route runoff from nearby impervious cover to storage when possible.	Public and private parking lot owners.	See Figure 8.7.	Long-term: 15+ years

As discussed in Section 7.2.3, subsurface storage under parking lots is one of the most feasible and effective ways to create storage and promote infiltration in a highly urbanized environment. Porous pavement is an effective way of directing parking lot runoff to storage, but more conventional inlets or grates are also possibilities. The depth of storage is important. Whenever possible, runoff from nearby impervious areas should be routed into the storage under nearby parking lots. When this is not possible, only a few inches of gravel are needed to store a chosen design storm. Storage designs always include an overflow mechanism for very large storms.

The total parking lot area in the TTF Watershed is estimated at 1039 acres in the combined-sewered portion and 623 acres in the separate-sewered portion. Philadelphia has approximately 75% of parking lot area in the watershed. Other municipalities with large parking lot areas are Cheltenham Township (16%), Abington Township (7%), and Jenkintown Borough (2%). Other municipalities have smaller percentages as listed in Figure 8.8.

Because this BMP is believed to be the most important, an ambitious target is proposed. Begin with demonstration projects on public land. Over the long term, convert 10%-50% of parking lots watershed-wide to porous pavement with subsurface gravel storage.

There are a variety of approaches for implementing porous pavement and other structural BMPs. Regulatory and incentive-based approaches were discussed under low-impact redevelopment (see Option CR2, in Section 8.3.1). Distribution of structural BMPs may also be incorporated in a pollution trading program.

- Install demonstration projects in public parking lots.
- Consider requiring all parking lots to be retrofitted with porous pavement (or other drainage mechanisms) and subsurface storage when they are redone. Private land owners cannot be expected to bear the entire cost of this approach; municipalities should consider funding the additional cost of these changes either directly or through tax incentives.

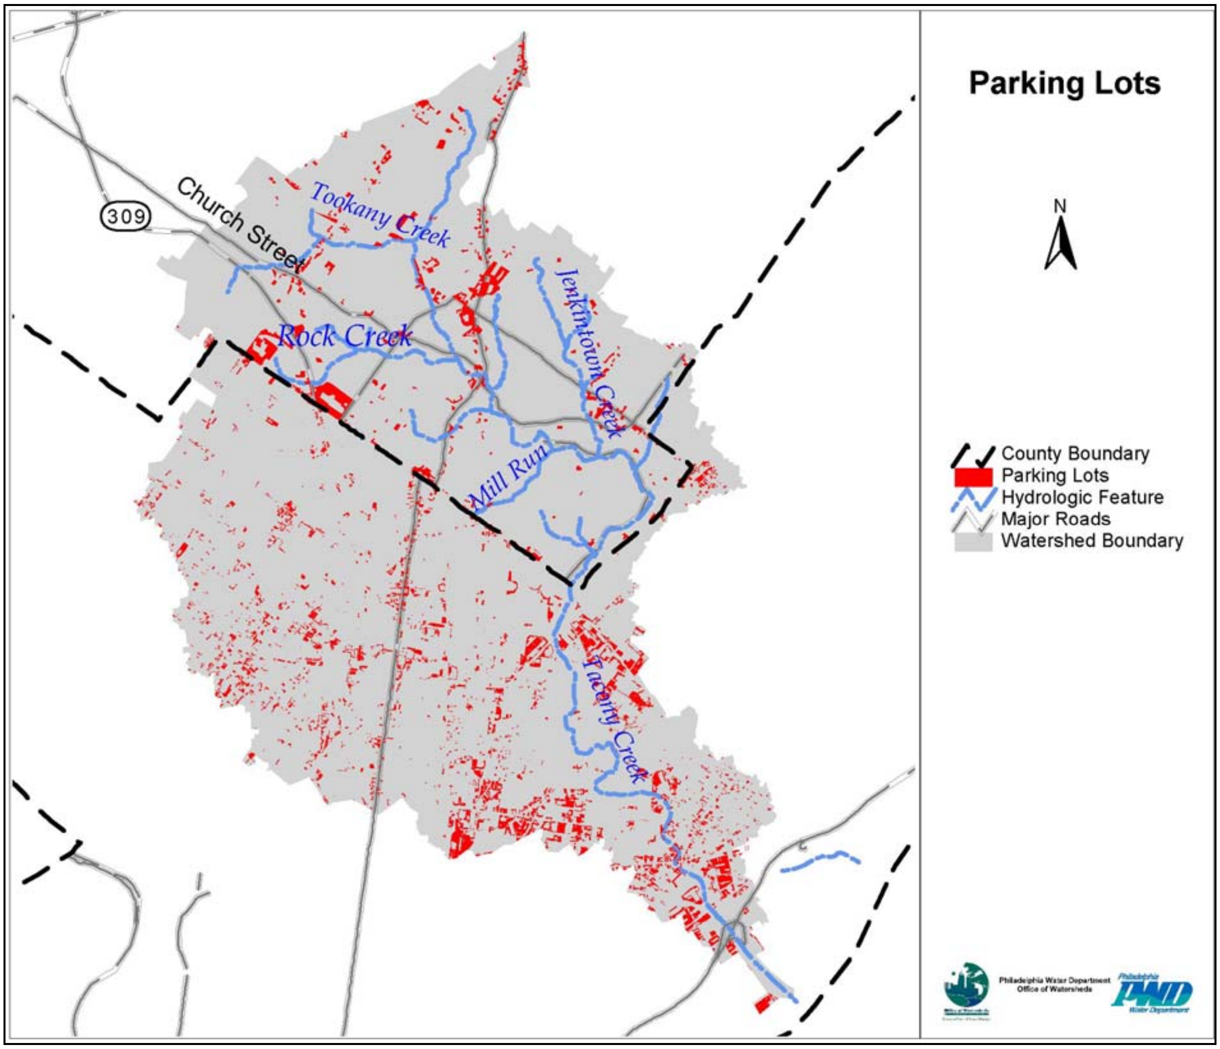

Figure 8.7 Parking Areas in Tookany/Tacony-Frankford Creek Watershed

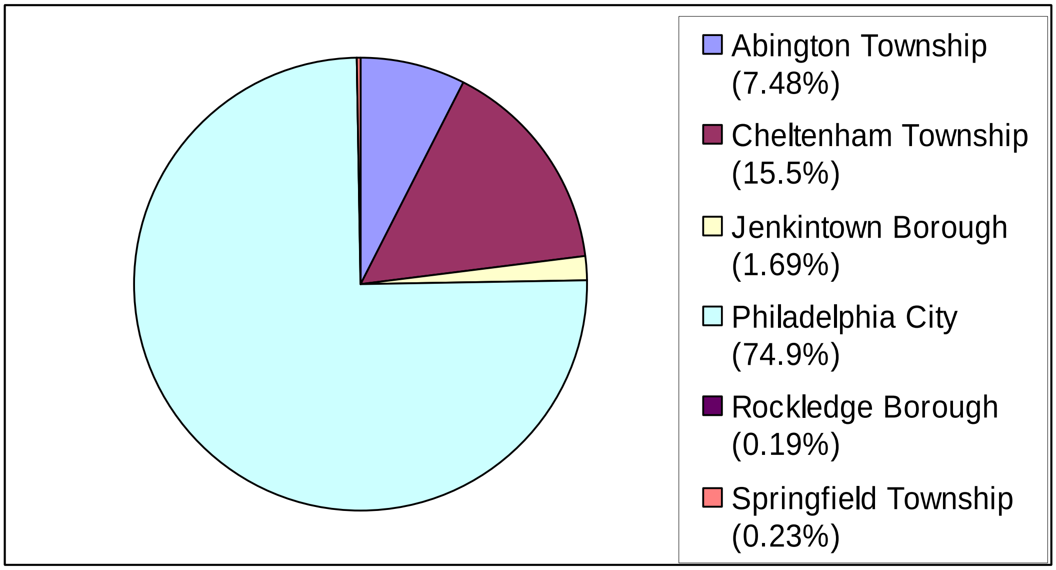

Figure 8.8 Percent of Total Parking Area by Municipality

The River Conservation Plans (RCPs) recommend the following:

- Greenwood Avenue to Wyncote Post Office: If parking lots are renovated, use pervious material to reduce pollutants from washing into creek.

Green Rooftops (CS3)

Related Goals: 1, 2, 4, 6, 7
Related Indicators: 1, 16, 18, 19, 20

What	Who	Where	When
Green rooftop demonstrations. Targeted public information campaign on advantages of green roofs. Feasibility study and green roof implementation plan.	PWD	Appropriate public buildings chosen by PWD.	Medium term: 5-15 years.

The analyses in Section 7.2.3 indicate that green rooftops, while highly effective at detaining and evaporating stormwater, are not currently a cost-effective option for the Tookany/Tacony-Frankford Watershed. However, there is the potential for them to become more cost-effective in the future. As more successful demonstration projects are implemented in the United States, the materials and construction techniques will become more common and the economies of scale will improve. To facilitate this long-term change locally, this plan recommends that Philadelphia take the lead and implement one or more projects on public buildings in the City. Along with this project, we recommend a feasibility study of the potential for a larger-scale green roof program throughout the watershed. The feasibility study will form the basis for future recommendations when this plan is revised. In addition, we recommend a public relations campaign to change the perceptions of citizens, public officials, and contractors.

Capturing Roof Runoff in Rain Barrels or Cisterns (CS4) Related Goals: 1, 2, 4, 6, 7 Related Indicators: 1, 16, 18, 19			
What	Who	Where	When
Install rain barrels on 5 - 25% of homes; coverage to be chosen by municipality to meet a share of watershed-wide reduction targets.	Homeowners through municipal incentive and education programs.	Homes where dry wells are not feasible.	Medium term: 5-15 years.

The Tookany/Tacony-Frankford Watershed Partnership initiated a rain barrel project in 2002, which placed 215 rain barrels at homes throughout the watershed. Rain barrels can be an effective stormwater management tool if they are properly designed and maintained. For detention of residential roof runoff, dry wells are the preferred technique because they have a larger capacity, require no maintenance, and allow more infiltration. Rain barrels are recommended as a secondary technique in areas where dry wells are infeasible. Proper design, including an appropriate slow release, is the responsibility of the municipality or non-profit group leading the rain barrel program. Proper maintenance is accomplished through an intensive public education campaign and series of workshops. An ambitious target is to install rain barrels on 5-25% of homes within a small subshed of "sewershed" area within the watershed in the medium term.

Increasing Urban Tree Canopy (CS5)

Related Goals: 1, 2, 4, 6, 7
Related Indicators: 1, 4, 13, 16, 17, 18, 19, 20

What	Who	Where	When
Increase tree canopy in the watershed from 27% to 32%.	Municipalities (through ordinances, education, and incentive programs affecting land owners).	Private property, parking lots, streets. Parks (riparian corridors under Target B, Section 8.2).	Medium-term (5-15 years).

Tree planting and urban reforestation programs provide hydrologic benefits in addition to quality of life improvements. Leaf surfaces intercept some rainfall that might otherwise fall on impervious surfaces. The rainfall then either evaporates or is conveyed more slowly to the ground along plant stems and trunks. American Forests has assessed tree canopy in the TTF Watershed at 27% (report "Urban Ecosystem Analysis, Delaware Valley Region" available at www.americanforests.org). American Forests recommends the following levels of tree canopy coverage for urban watersheds:

- 40% overall
- 50% in suburban residential zones
- 25% in urban residential zones
- 15% in central business districts

A goal of increasing tree canopy by 5% of the watershed over the medium term was selected as a feasible implementation level. Several regulatory and incentive-based strategies to achieve these goals are listed below. (Also see Option CR2 in Section 8.3.1 on Regulatory Approaches.)

- Requirements to protect existing trees on private property, or creation of "tree banks" to offset loss.
- Tree credits for redevelopers as part of impervious cover requirements or incentives. The City of Portland, Oregon has given developers an impervious cover credit equal to 25% of tree canopy over impervious area.
- Parking lot landscaping or shade requirements.
- Reforestation in parks and along the stream corridor.
- Increases in the number of trees along public streets and on vacant lots. The City of Philadelphia is taking this approach as part of its Green City Strategy.

Tree canopy over an additional 5% of impervious cover will result in an effective impervious cover reduction of approximately 2% over the watershed.

Municipalities with tree related ordinances are shown in Table 8.20.

Table 8.20 Landscape and Tree Related Ordinances

Municipality	Landscaping	Shade Tree/ Street Trees	Wooded Lots*	Tree Advisory Commission	Comments
Abington Township	X	X	X		Buffer areas; tree-planting requirements (streets/parking lots); open space standards/preservation.
Cheltenham Township		X	X	X	Buffer areas; green areas; Tree Commission regulations; Preservation Overlay District.
Jenkintown Borough		X		X	Shade tree-planting desirable along streets; Tree Commission regulations.
Philadelphia County	X	X		X	Fairmount Park Commission regulations; required tree/landscaping ratios in certain residential districts.
Rockledge Borough	X	X			Residential landscaping/buffer area requirements; parking buffer areas for Institutional District; common open space preservation.

Source*:** www.ordinance.com, ***Delaware Valley Regional Planning Commission

* Note: "Wooded Lots" refers to any ordinance directly involving the preservation of open space/undisturbed natural areas. Most of the municipality ordinances included the intention of open space preservation under general goals.

Forming a tree commission is one way of implementing an urban forestry program in Pennsylvania. The powers and responsibilities of a tree commission are based on state statute and are assumed by local government. By forming and empowering a tree commission, a community can empower and motivate volunteers to run an effective urban forestry program. Tree commissions are either advisory or administrative and may have various responsibilities, including the following:

- Advise community leaders and staff on administering the community forest.
- Stimulate and organize tree planting and maintenance.
- Develop and implement urban forest inventories, management plans, and ordinances.
- Lessen liability by arranging to remove hazardous trees and repair damage caused by trees.

In Pennsylvania, a tree commission created by municipal ordinance as a decision-making body has exclusive control over a community's shade trees. No tree can be planted or removed within the public right-of-way except under the auspices of the tree commission. This includes public trees that may be planted or removed in conjunction with subdivisions or approved development plans. Tree commissions can be given additional power within a municipality by a council, including:

- Control over all public trees such as trees within community parks.
- Review and approval of landscaping proposed in development plans.

The formation and empowerment of a tree commission can be a crucial element in developing broad-based support for community trees and ensuring long-term success and continuance of a community forestry program. (For more information, contact the Extension Urban Forestry Program, School of Forest Resources, The Pennsylvania State University, 108 Ferguson, University Park, PA 16802, or call 814-863-7941.)

Onsite and Regional Stormwater Control Facilities

Maintaining/Retrofitting Existing Stormwater Structures (CS6)

Related Goals: 1, 2, 3, 4, 5, 7
Related Indicators: 4, 11, 15, 19

What	Who	Where	When
Inventory structures. Assess potential for increased infiltration.	Municipalities.	Entire watershed.	Short term (within 5 years).

PWD performed an inventory of existing privately owned stormwater control basins in 2000. The results of this study indicate seven confirmed structures within the Philadelphia portion of the watershed. Other municipalities are asked to inventory and inspect existing stormwater control structures. Although this is not an explicit requirement of the Act 167 program, it is a reasonable task to include within the Act 167 framework. Older dry and wet detention basins may have been designed to reduce flood peaks but not to facilitate infiltration; this approach helps prevent property damage but may actually increase stream erosion. In some cases, it may be possible to retrofit these older basins to allow infiltration. Specific guidance on retention times and design recommendations will be included in the Act 167 Plan.

Retrofitting Existing Sewer Inlets with Dry Wells (CS8)

Related Goals: 3, 5, 7
Related Indicators: 11, 15, 19

What	Who	Where	When
Retrofit 5 - 100% of existing stormwater catch basins in the combined sewered area to provide storage and allow infiltration.	PWD	5 - 10% of existing inlets in combined-sewered areas.	Long-term: 15+ years.

As discussed in Section 7 (especially Section 7.2.3), retrofitting existing sewer inlets with dry wells is an expensive but effective measure in combined-sewered areas. Each inlet provides small amounts of storage and detention; distributed over a significant area, these measures reduce the number and duration of overflows.

During the first permit cycle that this plan is in effect, inlets that are being repaired or replaced can be retrofitted at the same time. If, after the first five years, the program is not on track to affect the targeted number of inlets in 15 years, existing inlets in good condition may be retrofitted.

Residential Dry Wells, Seepage Trenches, and Rain Gardens (CS9)

Related Goals: 1, 2, 3, 4, 5, 6, 7
Related Indicators: 1, 11, 15, 16, 17, 19

What	Who	Where	When
Install dry wells in 5-10% of residential yards; coverage to be chosen by municipality to meet a share of watershed-wide reduction targets. Install water gardens on school grounds.	Municipalities. School boards.	Dry wells throughout watershed. Water gardens in school yards with enough space.	Long term: 15+ years.

Routing residential roof runoff to dry wells is recommended as a priority control for the Tookany/Tacony-Frankford Watershed. Dry wells are cost-effective, can potentially affect a large portion of impervious cover, and require virtually no maintenance. They are clearly applicable in the lower density residential areas but can also be installed in some higher density areas; only a small lawn area is necessary. A properly sited and designed dry well will not cause basement flooding. Where soil conditions are insufficient to infiltrate all roof runoff, excess flows can be routed to a combined or sanitary sewer. Because dry wells are a priority control, they are recommended for implementation in the yards of 5%-10% of all homes in the watershed.

Rain gardens are recommended for implementation on school grounds, where they can both promote infiltration and educate students about stormwater management.

The River Conservation Plans (RCPs) recommend the following:

- High School Park to Ashbourne Road along the Tookany Creek Parkway: Incorporate stormwater infiltration devices.
- Rock Creek Watershed: Incorporate stormwater infiltration devices especially in commercial areas.

Bioretention Basins and Porous Media Filtration (CS12)

Related Goals: 1, 2, 3, 4, 5, 7
Related Indicators: 1, 7, 8, 9, 15, 19, 20

What	Who	Where	When
Install bioretention and/or sand filters in 10-50% of parking lots; coverage to be chosen by municipality to meet a share of watershed-wide reduction targets.	Public and private parking lot owners.	Everywhere in watershed.	Long-term: 15+ years. Focus on redevelopment.

The screening and detailed evaluation analyses in Section 7 targeted parking lot runoff for widespread implementation of BMPs. The preferred approach for parking lots is to route runoff to subsurface gravel storage through porous pavement, inlets, or grates. However, there will be cases where that approach is not feasible. The second preferred alternative is to direct parking lot runoff to a bioretention basin and/or a porous media filter. These systems infiltrate smaller storms completely, detain larger storms, and provide effective water quality treatment in separate sewered areas. 10-50% of parking lots are targeted for retrofit with bioretention. Over the long term, it is the goal to retrofit as many parking lots as possible with either subsurface storage or bioretention. However, private land owners should not necessarily be expected to bear the entire cost of this approach; municipalities should consider funding the additional cost of these changes either directly or through tax incentives.

The River Conservation Plans (RCPs) recommend the following:

- <u>Holy Sepulchre Cemetery to Ralph Morgan Park</u>: Incorporate stormwater filtration devices.
- <u>Abington Country Club to Township Line Road</u>: The stormwater management facilities for the parking lots should be examined to see if BMPs are being used to help reduce runoff.

Treatment Wetlands: Onsite and Regional (CS13)

Related Goals: 1, 2, 3, 4, 7
Related Indicators: 1, 10, 11, 13, 19

What	Who	Where	When
Create or enhance wetlands to treat as much runoff as possible in Philadelphia and Montgomery County.	Municipalities.	See Figure 8.4 for proposed sites.	Medium term: 5-15 years.

Wetland creation and enhancement has benefits in terms of habitat, water quality, and water quantity. These benefits as well as proposed sites are discussed extensively under Option BM6, in Section 8.2.3.

8.3.5 Monitoring and Reporting

Monitoring, Reporting, and Further Study (CMR)

Related Goals: 7
Related Indicators: 16, 17, 19

What	Who	Where	When
Monitoring of implementation and benefits for all Target C options.	City of Philadelphia and Municipalities.	Watershed-wide.	Annually beginning after the first year of implementation is initiated

The preceding are a series of implementation options identified as initial measures geared toward meeting Target C. This Target will be more difficult to achieve than Targets A and B as it entails meeting all water quality standards during wet weather, as well as eliminating all flooding. Based on the extensive modeling analysis carried out for Tookany/Tacony-Frankford Creek to date, an initial goal of a 20-25% reduction in stormwater flows and stormwater/CSO related pollutant loads has been identified as a challenging but achievable goal.

The suggested approach to full achievement of Target C goals is through the use of adaptive management while utilizing stepped implementation with interim targets for reducing wet weather pollutant loads and stormwater flows. During implementation, monitoring must continuously assess the effectiveness of the program. Based on monitoring results of each option, recommendations will be made for future implementation. It is expected that changes to the approach, or potentially even to the desired results, will occur as measures are implemented monitored.

Section 9
Cost and Institutional Analysis

This section presents cost estimates for the various recommended "management options," and for the full set of Implementation Guidelines (from Section 8). Those cost estimates are then broken down by county and by municipality within the TTF Watershed. Finally, the section outlines the primary roles and responsibilities for the various levels of stakeholders in the implementation of the TTFIWMP.

9.1 Estimated Cost of Implementation

Planning-level costs have been developed for many of the recommended options. Because costs are highly dependent on site specific conditions as well as the extent to which implementation occurs, costs included in this section are only approximate. These costs are useful, however, in providing order of magnitude funding needs, and also as a comparison to potential costs associated with more traditional approaches to CSO control, such as large scale storage tanks designed to reach the 85% capture goal. Planning level costs are provided for each of the options discussed under the three Targets.

The combination of structural BMPs and implementation percentages in this section are suggested as a feasible plan that will equal or exceed the 20% discharge reduction target. The exact combination of BMPs implemented in each area of the watershed will be determined by local municipalities or by a government or institutional body to be chosen at a later time.

Order-of-magnitude, planning-level cost estimates are shown in Tables 9.1 through 9.4. For structural stormwater BMPs, cost estimates are based on an assumed "feasible implementation" percentage shown in Table 7.5 (in Section 7.2.3) and also Table 8.13 (Section 8.3).

Table 9.1 Planning-Level Cost Estimates for Target A Options

	Total		Philadelphia		Montgomery County	
	Annual Cost	**One-Time**	**Annual Cost**	**One-Time**	**Annual Cost**	**One-Time**
Regulatory Approaches						
AR1 On-Lot Disposal (Septic System) Management	$50,000				$50,000

1 - Estimated cost for ordinance development.

2 - Already in place in most locations, or costs difficult to quantify.

3 - Cost included in options AM1-5.

4 - Includes real time control cost only; other aspects of program included in options AM1-5.

5 - Implementation levels taken from Section 8, Implementation Guidelines.

Table 9.4 Total Watershed Plan Cost

Total		Philadelphia		Montgomery County	
Annual Cost	One-Time	Annual Cost	One-Time	Annual Cost	One-Time
$6,172,000	$148,459,000	$3,532,000	$68,839,000	$2,637,000	$79,625,000
$290/ac	$7,060/ac	$290/ac	$5,650/ac	$300/ac	$9,000/ac

9.2 Distribution of Costs by Political Boundary

In addition to total estimated costs associated with the TTFIWMP, it is useful to express the costs on an annual basis and in the context of acreage and number of households affected. Presenting costs this way allows comparison to existing wastewater infrastructure-related costs supported by users and taxpayers. Those cost estimates are presented by county and by municipality, below.

9.2.1 Distribution of Costs by County

Table 9.5 compares projected costs on a per-acre basis and per-household basis in the City of Philadelphia and outside the City of Philadelphia. The table shows costs on an annual basis, using a 20-year period to pay off the capital costs. Philadelphia pays approximately 50% of the total annual cost (line 3), while representing approximately 60% of the watershed area. On a per-acre basis, costs within Philadelphia are approximately 70% of costs outside the City. This difference occurs because of the greater land area and length of stream outside Philadelphia. (An illustrative distribution of costs among municipalities in the watershed is shown in Section 9.2.2.)

Table 9.5 Affordability Impact by County

	Philadelphia	**Montgomery County**
(1) One-Time Cost (Annualized)	$3,338,000	$3,875,000
(2) Annual Cost	$2,598,733	$2,268,386
(3) Total Annual Cost Associated with WMP	$5,936,733	$6,143,386
(4) Cost per acre in watershed	$487	$694
(5) 2000 Median Household Income	$30,746	$59,621
(6) Estimated Annual Sewer User Charge*	$343	$250
(7) WMP cost per household in watershed (in entire municipalities)	$52.53 ($10.06)	$258.93 ($157.00)
(8) WMP cost as % of mean household income in watershed (in entire municipalities)	0.17% (0.03%)	0.43% (0.26%)
(9) Existing sewer cost + WMP cost in watershed (entire municipalities)	1.59% (1.15%)	0.62% (0.46%)

* *The sewer user charge in Philadelphia includes a stormwater collection and treatment fee. Stormwater-related charges outside Philadelphia were not investigated.*

In addition to showing costs per unit area, it is useful to express costs on a per-household basis. Line 7 in Table 9.5 expresses cost per household, assuming only households inside the watershed boundaries would be required to pay. This comparison is made because improvements occur, and citizens benefit, primarily within the watershed boundaries. Expressed in this manner, the cost is greater for households outside Philadelphia (line 7, outside parentheses); because of greater population density within the urban watershed, there are more households to distribute the cost among inside the City. Line 8 of Table 9.5 expresses the per-household cost inside the watershed boundary as a percentage of mean household income (line 8, outside parentheses).

While expressing costs in terms of households inside the watershed boundary allows direct comparison between communities, it is also useful to express costs on the basis of all households within the boundaries of municipalities that intersect the watershed. Currently, most funding and institutional mechanisms occur on a municipal basis. For example, a given township may use a percentage of all water and sewer bills paid to finance improvements related to the TTFIWMP, including bills paid by households outside the TTF watershed boundary.

The numbers in parentheses on lines 7 through 9 of Table 9.5 present the costs in terms of all residents of municipalities intersecting the watershed. These costs are lowest in Philadelphia because it has the greatest number of households; all households paying sewer bills will pay approximately 0.03% of household income to support the TTFIWMP, compared to 0.26% for the remaining communities. Compared to the other municipalities, Philadelphia has many more households to spread the cost of the TTFIWMP over, but will ultimately have additional watersheds that will require management activities. Over time and on a regional basis, watershed management costs are expected to approach 0.3% to 0.5% of mean household income within affected communities.

The costs associated with the TTFIWMP are generally incremental to existing maintenance and management activities associated with water-related infrastructure. Therefore, it is useful to add the TTFIWMP cost to current wastewater charges paid by households to obtain an approximate measure of the total annual cost of watershed and water-related infrastructure management. These costs, shown in the final line of Table 9.5, range from approximately 0.6% to 1.6% of mean household income regionally.

9.2.2 Distribution of Costs by Municipality

Tables 9.6 and 9.7, below, provide data to assist communities in placing projected TTFIWMP costs in a local context. Table 9.6 expresses estimated costs for communities per acre and per household inside the watershed boundaries; Table 9.7 presents costs within the boundaries of all municipalities that intersect the watershed. For the purposes of this illustrative example of cost distribution, general, watershed-related costs for communities outside of Philadelphia are apportioned according to the percentage of the watershed area within each municipality's jurisdiction.

These cost tables are but one illustration of a possible cost distribution, and are provided to aid municipalities in deciding what funding and institutional mechanisms may be most appropriate given local conditions.

Table 9.6 Affordability Impact by Municipality – Rate Payers in TTF Watershed

	Abington	Cheltenham	Jenkintown	Philadelphia	Rockledge
Municipality area in watershed (ac)	2,712	5,691	367	12,178	81
Area of municipality in watershed (% of municipality total)	27%	98%	99%	13%	37%
Households in municipality and watershed	7,147	14,218	2,013	113,022	348
Annual cost associated with TTFWMP	$807,899	$1,695,749	$109,277	$3,532,000	$24,075
Cost per acre (within watershed)	$297.95	$297.95	$297.95	$290.03	$297.95
Cost per household (within watershed)	$113.04	$119.27	$54.29	$31.25	$69.18
Median household income ($/year)	$59,921	$61,713	$47,743	$30,746	$47,958
Cost per household (% of MHI)	0.19%	0.19%	0.11%	0.10%	0.14%

Table 9.7 Affordability Impact by Municipality – All Rate Payers in Municipality

	Abington	Cheltenham	Jenkintown	Philadelphia	Rockledge
Municipality area (ac)	9,893	5,779	369	91,287	219
Watershed area in municipality (ac)	2,712	5,691	367	12,178	81
Watershed area in municipality (% of watershed total)	12.9%	27.1%	1.7%	57.9%	0.4%
Households in municipality	21,690	14,346	2,035	590,071	1,060
Annual cost associated with TTFIWMP	$807,899	$1,695,749	$109,277	$3,532,000	$24,075
Cost per acre (whole municipality)	$81.66	$293.42	$296.36	$38.69	$109.91
Cost per household (whole municipality)	$37.25	$118.20	$53.70	$5.99	$22.71
Median household income ($/year)	$59,921	$61,713	$47,743	$30,746	$47,958
Cost per household (% of MHI)	0.06%	0.19%	0.11%	0.02%	0.05%

9.3 Institutional Analysis

The primary purpose of Section 9 of this plan is to provide recommendations and guidance to stakeholders - primarily state, county, and other government agencies, municipalities, non-government organizations, land owners, and individuals - on ways to better manage the water resources of Tookany/Tacony-Frankford Creek. Everyone in the watershed communities can contribute in numerous ways to the protection of water resources.

Both government and non-government organizations will play a role in the successful implementation of the Tookany/Tacony-Frankford Integrated Watershed Management Plan. The primary roles are outlined below.

9.3.1 PA DEP Role

Two agencies of the Commonwealth of Pennsylvania are directly and indirectly involved in watershed planning in the TTF Watershed: the Department of Environmental Protection (PA DEP) and the Department of Conservation and Natural Resources (DCNR). Achievement of Watershed Plan goals through local implementation will require continued support through funding and integration of the various existing state level stormwater management and runoff related programs. Particular attention should be paid to the following programs:

- Act 167 Plans
- Phase II Stormwater permits
- Act 537 / CMOM Plans
- Construction Stormwater Pollution Prevention
- Industrial Stormwater Pollution Prevention
- Watershed monitoring and performance reporting
- Watershed permitting opportunities

A critical PA DEP role will be activities required under Section 303(d) of the Clean Water Act and the EPA's Water Quality Planning and Management Regulations (40 CFR Part 130). PA DEP will need to actively administer the water quality standards process for portions of the Tookany/Tacony-Frankford Creek in the near future. PA DEP should be active in encouraging municipalities to carry out the requirements of Phase II stormwater permits and Act 167 requirements. This plan provides the blueprint for effectively integrating both programs, and addressing water quantity and quality goals.

9.3.2 PWD Role

PWD, as the primary author of this plan, plays a central role in its implementation, as well as in continued monitoring to chart improvements to water quality. PWD will take a lead role in implementing a variety of the recommendations, including;

- Stream restoration
- Improvement of fish passage
- CSO Control

- Green rooftop demonstrations
- Stormwater BMP installation
- Organization of stakeholder participation
- Monitoring

9.3.3 Municipal Role

Municipalities can play a key role in the implementation of recommendations through the incorporation of water resource strategies into their land use planning and governance functions. Because of the authorities contained in the Pennsylvania Municipalities Planning Code (MPC), municipalities are one of the two main foci of implementation efforts (PWD being the other). Enabled by the MPC, municipalities are the focal point to address runoff from redeveloped and existing developed lands, to address problems associated with sanitary sewer collection systems, to enhance recreational opportunities, and to protect natural resources from the effects of land disturbance.

The most fundamental roles recommended for municipalities are to consider undertaking a comprehensive review of their existing land use regulations, policies, and requirements to identify where they may be unnecessarily causing impacts to water resources, and to undertake the necessary actions needed to eliminate SSOs and sanitary sewer leaks.

The primary actions recommended for municipalities include: encouraging disconnection of roof leaders from storm sewers, reduction of expansive paved (impervious) parking lot requirements and replacement of asphalt with porous paving surfaces or the installation of bioretention structures to handle parking lot stormwater runoff, repair and maintenance of leaking sanitary sewers, and the elimination of SSOs. Municipalities also might consider creating an Environmental Advisory Council (EAC), which is possible under Pennsylvania General Assembly enabling legislation - Act 148 of 1973. The EAC could then participate in the implementation of the plan, and help to coordinate the approach among all the municipalities within the watershed.

9.3.4 County Role

An important role of Montgomery County is to conduct the necessary comprehensive stormwater management studies to:

- Complete an Act 167 stormwater plan that is consistent with and furthers the achievement of the goals and objectives of the TTFIWMP.
- Work with municipalities to update Act 537 plans.

In addition, the Montgomery County Conservation District has several important responsibilities within the watershed, including:

- Chapter 102 Erosion Control: Administer the State's program to control sediment pollution from earth disturbance activities.
- National Pollution Discharge Elimination System (NPDES): Process applications and seek compliance towards stormwater discharge permits for Construction Activities.

- Chapter 105 Waterways and Wetlands General Permitting: Assist applicants with permit information. Process general permits for work within wetlands and streams.

These are important elements in coordinating Act 167 planning requirements with Phase II of the NPDES Stormwater Program.

9.3.5 Non-Government Organization Role

The Tookany/Tacony-Frankford Watershed Partnership will be critical to the successful implementation of the TTFIWMP. As noted in the introduction to Section 9, this newly incorporated watershed organization has formed with the purpose of implementing the recommendations of the TTFIWMP. With representatives of the two counties, several municipalities, and various non-profit organizations making up the Board of Directors of this organization, the vehicle for coordination and collaboration now exists.

Some of the primary functions of the newly formed organization could include:

- Creating a watershed-wide implementation plan and receiving approval from watershed municipalities. This approval includes obtaining signatures from municipalities followed by a letter of support from PA DEP.
- Overseeing the continued implementation of basic, essential services required of all municipalities by stormwater permits (e.g., sewer system maintenance).
- Overseeing continued monitoring, sampling, data analysis, and reporting on both the water quality and biology of the system using the established indicators.
- Providing public participation and public education opportunities (both workshops and other types of participatory programs).
- Exploring innovative solutions to long-term operation and maintenance of stormwater management facilities.
- Requiring that projects within the watershed area applying for state funding (Growing Greener, DCNR) must be reviewed and shown to be consistent with the TTFIWMP. The organization would review all submitted projects and apply a rating scale for consistency with the plan.
- Encouraging the idea of applying for federal funding for regional projects (e.g., stream restoration, regional wetlands); however, most smaller-scale projects would be funded locally. Public funding for major infrastructure projects on private land could be explored.

Another role for the new organization would be created if the State sets up a watershed-based permitting experiment in the watershed. The organization could then function as a Watershed Compliance Association (WCA). A WCA is a Commonwealth-created non-profit entity comprised of public and private entities that hold individual NPDES permits or General Permits to discharge to the creeks. A WCA is specifically created to implement watershed based permitting. The WCA would constitute a point of contact between PA DEP and its co-permittee members on issues related to the group permit for the parameter(s) of concern, once a TMDL is established in the watershed. If the WCA exceeds its parameter limit (load) for the year, the

Association would be out of compliance, and any co-permittee member that exceeds its individual load limit would also be out of compliance and subject to enforcement action. Through the group approach, however, pollution trading can be easily implemented.

9.3.6 Land Owners' Role

Voluntary watershed stewardship by all land owners can contribute significantly toward the protection and restoration of the Tookany/Tacony-Frankford Watershed while simultaneously minimizing the need for additional regulatory controls. Recommended roles for land owners include:

- Implementing "watershed stewardship" practices in their landscape and outdoor housekeeping practices.
- Disconnecting roof leaders and installing rain barrels or dry wells.
- Considering pervious solutions for driveways.
- Joining and supporting the activities of the TTF Watershed Partnership.

Appendix A: Glossary of Terms

Acute	Describing an effect or response, such as toxicity, that is measured or occurs over a relatively short amount of time; not chronic.
Adaptive management	Process of continually monitoring progress and adjusting the approach.
Algae	Any of a number of several groups of single-celled or multi-cellular organisms, all of which lack leaves, roots, flowers, and other organ structures that characterize higher plants.
Ammonia/ Ammonium	A Nitrogen-containing molecule that exists naturally in both gaseous (NH3) and ionized (NH_4+) forms. The gaseous form is corrosive and toxic, while the ionized form is a usable source of nitrogen for plant growth. Ammonia may be produced by decomposition of nitrogen-containing molecules such as proteins.
Anthropogenic	Man-made or human in origin; influenced by mankind.
Aquatic	Relating to water, particularly freshwater.
Aquifer	An underground geologic feature containing water.
Autotroph/ Autotrophic	Describing organisms that can produce their own food, such as plants, algae or certain specialized bacteria.
Bankfull discharge	The high flow stage of a fluvial system distinguished by the highest stage elevation a stream can reach before spilling over.
Baseflow	Flow in a stream that is not influenced by precipitation.
Basic	Alkaline; containing oxide or hydroxyl ions; not acidic.
Benthic	Used to describe aquatic organisms living at the bottom of a body of water.
Benthic macroinvertebrates	Aquatic insect larvae that live on stream bottom. Because of a short lifespan and relative immobility, they reflect the chemical and physical characteristics of a stream and chronic sources of pollution.
Bioassessment	An evaluation technique that uses measures of the structure, condition, or distribution of biological communities.
Bioindicator	An organism that exhibits sensitivity or tolerance of environmental conditions and may be used in assessing an environmental condition, such as water pollution.

Biotic	Living, relating to life or biology.
BMP	Best Management Practice – Also called a "management option," a BMP is a technique, measure, or structural control that addresses one or more objectives (e.g., a detention basin that gets built, an ordinance that gets passed, and an educational program that gets implemented).
BOD	Biological or biochemical oxygen demand, an empirical test procedure that measures the ability of a water sample to deplete oxygen.
Cadmium (Cd)	A toxic heavy metal element.
Calcium (Ca)	A metallic element found in limestone and numerous naturally occurring compounds.
$CaCO_3$	Calcium carbonate
CCD	County Conservation District
CCTV	Closed Circuit Television
Channelization	The process of modifying the natural course of a stream in order to make it flow into or along a restricted path.
Chlorophyll	Any of a group of green pigments necessary for photosynthesis, concentrations of which are used as a surrogate measurement of producer biomass.
Chl-*a*	Chlorophyll-α, a form of chlorophyll that is found universally in autotrophic organisms.
Chromium (Cr)	A heavy metal element, occurring naturally in trivalent [CrIII] and hexavalent [CrIV] forms. The latter form is highly toxic.
Chronic	Describing an effect or response, such as toxicity, that occurs or can be measured over a relatively long period of time; not acute.
Clay	Inorganic sediment particles smaller than 0.002 mm.
CO_3^{2-}	Carbonate ion
Cobble	A stream particle with diameter between 64 and 256 mm.
Coliform	Of or relating to the bacilli (bacteria) that inhabit the intestines of warm-blooded animals.
Conductance/ Conductivity	A measure of the ability of a water sample to conduct an electric current; a measure of dissolved ionic strength.

Copper	An essential metallic nutrient that can be toxic in relatively small concentrations.
Criterion	An established standard, such as concentration of a pollutant, that is limited or regulated by law.
CSO	Combined Sewer Overflow
CSS	Combined Sewer System
Culvert	A metal, concrete, or plastic pipe that allows water to flow under a road or any other obstruction.
CWA	Clean Water Act – Federal Amendment that authorizes EPA to implement pollution control programs and set water quality standards for all contaminants in surface waters. "The Act made it unlawful for any person to discharge any pollutant from a point source into navigable waters, unless a permit was obtained under its provisions. It also funded the construction of sewage treatment plants under the construction grants program and recognized the need for planning to address the critical problems posed by nonpoint source pollution." (EPA website)
CWA Section 104(b)(3) Program	Promotes the coordination and acceleration of research, investigations, experiments, training, demonstrations, surveys, and studies relating to the causes, effects, extent, prevention, reduction and elimination of pollution.
CWA Section 208 Wastewater Planning	Intended to encourage and facilitate the development and implementation of area-wide waste treatment management plans.
CWA Section 319(b) Non-point Source Management Program	Designed to address mine drainage, agricultural runoff, construction/urban runoff, hydrologic and habitat modifications, on-lot wastewater systems, and silviculture.
DCIA	Directly Connected Impervious Area
Decomposition	Decay; process through which a complex substance, such as dead organic matter, is broken down into smaller molecules.
Defective lateral	A plumbing problem in which a lateral pipe is damaged, potentially leading to sanitary waste in a storm sewer and the receiving water body.
Designation/ Designated Use	Describing the uses a waterbody is intended to support, such as stocking trout for recreational fishing.

Diatom	Single-celled algae of the class bacillariophyceae, having a cell wall composed of silica. Diatoms are primary producers in streams and lakes.
Diffusion	Spontaneous, random movement of molecules that tends to result in equalization of concentrations over time as net movement occurs from areas of greater concentration to areas of lower concentration.
Diluent/Dilutant	A thinning agent, such as water, which reduces the concentration of a solution. Pollution may be diluted by streamwater.
Dilute/Dilution	The process through which a solution is made less concentrated through the addition of a diluent/dilutant.
Discharge	Flow; a measure of the volume of water flowing through a defined area in a given time. Discharge is often abbreviated as Q, and measured in cubic feet per second (cfs).
Dissolve	Cause to pass into solution. In laboratory testing, substances may be considered dissolved if they pass through a 0.45 μm filter.
Diurnal	Relating to or occurring in a 24-hour period; daily.
DO	Dissolved Oxygen
Drainage area	The area of land that drains to a particular body of water or site on a waterbody.
DRBC	Delaware River Basin Commission
DVRPC	Delaware Valley Regional Planning Commission
DWO	Dry-Weather Outlet - connector pipe between a CSO regulator and interceptor sewer.
Dynamic	Relating to conditions that change or are in motion; not static.
E. coli	A common rod-shaped bacterium that is found in the intestinal tract of warm blooded animals. Used as an indicator of contamination by feces/sewage.
EACs	Environmental Advisory Councils
Ecoregion	A relatively large area of land characterized by a unique set of communities, physical, and climatological characteristics.
Ecosystem	A collection of living things and their environment.
Effluent	Outflow of liquid waste, such as discharge from a sewage treatment plant.

Empirical	Of or related to direct observation; not theoretical.
Encapsulated	Enclosed or covered, such a stream that has been built into a sewer.
Endogenous	Coming from or produced wholly from within, such as an enzyme produced by bacteria.
EPA	U.S. Environmental Protection Agency
Epifaunal	Of or relating to stream surfaces upon which attached algae and other living things may grow or find shelter.
Equilibrium	A steady state or condition in which opposing influences balance one another out.
Erosion	The process by which soil particles are removed or displaced, usually by wind or water.
Estuary	A body of water intermediate between an ocean and river, usually tidal and highly productive.
Eutrophic	Characterized by abundant or overabundant life, such as a stream or river that is nutrient enriched and has dense growth of algae or aquatic vegetation.
Eutrophication	The process through which a waterbody comes to have an overabundance of life, usually caused by nutrient enrichment.
FGM	Fluvial Geomorphology is the study of a stream's interactions with the local climate, geology, topography, vegetation, and land use; the study of how a river carves its channel within its landscape.
Fluvial	Of or relating to flowing waters, especially rivers.
Floatables	Waterborne waste material and debris (e.g., plastics, polystyrene, paper) that float at or below the water surface.
GIS	Geographic Information Systems
H_2CO_3	Carbonic acid
Hardness	A measure of the concentration of calcium and magnesium ions in water.
HCO_3-	Bicarbonate ion
Heterotrophic	Describes organisms that cannot synthesize their own food through photosynthesis or other chemical means.
Hilsenhoff Biotic	A biological index of stream health that employs a scale of sensitivity of

Index (HBI)	macroinvertebrates to organic pollution.
HNO_3	Nitric acid, a source of atmospheric nitrogen pollution and acid rain.
Hydraulic	Of or relating to forces exerted by a fluid, often water, under pressure.
Hydrograph	A graphical representation of the change in stage or discharge of a stream as a function of time.
Hydrolysis	A chemical reaction in which water reacts with another molecule, often resulting in new compounds. The breakdown of urea is a hydrolytic reaction.
IDD&E	Illicit Discharge, Detection, and Elimination – one of the six minimum control measures required of permittees under the Phase II NPDES Stormwater Regulations. Program steps include developing maps of municipal separate storm sewer system outfalls and receiving waterbodies; prohibiting illicit discharges via PA DEP-approved ordinance; implementing an IDD&E Program that includes a field screening program and procedures, and elimination of illicit discharges; conducting public awareness and reporting program. A similar program is being followed by PWD in the Long Term Control Plan (LTCP) for CSOs.
Illicit connection	An illegal sewer connection, particularly connection of a sanitary sewer, household or industrial waste pipe to a storm sewer. Illicit connections may result in sewage or other pollution inputs to receiving waterbodies.
Impairment	Weakening, damage, or instability, such as the effects caused by pollution.
Impervious	Incapable of being penetrated, such as a surface that does not absorb water.
Index/Indices	A number, ratio, or value on a scale of measurement that can reveal differences between observations or reveal changes over time. Numerous indices are used to assess the health of aquatic communities, such as the Hilsenhoff Biotic Index or HBI.
Infrastructure	The basic system of utilities and services needed to support a society. Structures such as culverts, pipes, bridges, dams, and flood control measures can cause instability of streams and affect aquatic habitats.
Insoluble	Unable to pass into solution.
Instantaneous	Immediate; occurring, such as a change, quickly. Some continuous water quality parameters are observed instantaneously.

Invertebrates	Animals, such as insects and crustaceans, that lack backbones (vertebrae).
IPM	Integrated Pest Management
Iron (Fe)	A common metallic element; an essential nutrient that may be toxic in relatively large concentrations. Iron can cause problems with taste and color of drinking water.
Kjeldahl nitrogen test	A laboratory procedure for determining the concentration of ammonia and organically-bound nitrogen in a water sample.
Larva/larvae	Immature life stage of an invertebrate, such as a beetle or fly. Many insects that have aquatic larval stages are used as bioindicators of water pollution.
LID	Low-Impact Development (similar to "better site design" and "conservation site design").
LTCP	Long-Term CSO Control Plan – part of the EPA's CSO Control Policy for regulation of CSOs under NPDES that guides municipalities, state, and federal permitting agencies in reaching full compliance with the CWA.
Macroinvertebrates	Macroinvertebrates are invertebrate animals that can be seen without the aid of a microscope.
Macronutrient	A nutrient, such as nitrogen or phosphorus, needed in relatively large amounts for biological growth.
Magnesium (Mg)	A common cation that contributes to hardness in water.
Mainstem	The main flow or central channel of a stream drainage network into which tributaries flow.
Manganese (Mn)	A relatively common metallic element; an essential nutrient that may be toxic in relatively large concentrations.
Mean/ Arithmetic mean	Average; a measure of the central tendency of a set of numbers equal to the sum of all members of a set divided by the number of members of the set.
Median	In descriptive statistics, the value in a set of numbers for which half the members of the set are greater and half are smaller. In some instances, the median value may be more informative than the arithmetic mean if a small number of extreme values tends to skew the mean.
Metabolism	All the biochemical processes exhibited by a living organism.

Model	A useful representation, such as a computer simulation, that can be used to simplify and study systems and processes.
MPC	Municipalities Planning Code
MS4	Municipal Separate Storm Sewer System
NH_3	Ammonia (gaseous, un-ionized)
NH_4+	Ammonium ion
Nitrate (NO_3)	An oxidized form of nitrogen; an essential plant nutrient. Elevated nitrate concentration may result in eutrophication of water bodies and in very great concentrations may be toxic (see methemoglobinemia).
Nitrification	The process of converting ammonia to nitrite and nitrate in the presence of oxygen, especially by the action of naturally occurring bacteria.
Nitrite (NO_2-)	An oxidized ion of nitrogen; an intermediate form in the reaction that converts ammonia to nitrate. Nitrite is usually not available for plant growth.
Nitrogen	A macronutrient needed for biological growth. Inert nitrogen gas makes up a large portion of the Earth's atmosphere.
NOAA	National Oceanic and Atmospheric Administration
Nonferrous	Not containing iron; especially metals and alloys that do not contain iron.
Nonparametric statistics	A collection of statistical analysis tools, used when the data to be analyzed do not meet the assumptions of parametric statistics, such as homogeneity of variances.
Non-point source pollution	Pollution that comes from a diffuse source such as atmospheric deposition, stormwater runoff from pasture and crop land, or individual on-lot domestic sewage systems discharging through shallow groundwater.
Non-structural BMPs	These BMPs will require no operation or maintenance. Examples are use of open space and vegetated buffers in development design, minimization of soil disturbance and compaction during construction, and minimization of directly-connected impervious areas.
NPDES	National Pollutant Discharge Elimination System
NPDES Phase I	The stormwater management component of the NPDES program instituted in 1990, which addressed the storm runoff sources most threatening to water quality. Under this phase, industrial activity, and construction sites within large communities (population 100,000 or more) are required to obtain permits for the stormwater leaving the site.

NPDES Phase II	Additional stormwater management regulations enacted in 1999, applying to smaller communities and construction sites.
NRCS	Natural Resource Conservation Service
NTU	Nephelometric turbidity units; a unit of measure describing the light scattering properties of a water sample.
Nutrient	An element or molecule needed for biological growth. When nutrients such as phosphorus are present in great concentrations, biological growth (algae in particular) can become overabundant, causing problems for aquatic ecosystems.
OLDS	On-Lot sewage Disposal Systems
O&M	Operations and Maintenance
OOW	PWD's Office of Watersheds
Orthophosphate (OPO_4)	A dissolved, inorganic form of phosphorus, available as a nutrient for plant growth; soluble reactive phosphorus.
Outfall	A pipe or other structure that discharges flow, such as treated sewage effluent or stormwater, to receiving waters.
Oxidation	Chemical process in which a molecule or atom reacts with oxygen or generally, a reaction in which an atom loses electrons and increases in valence state; the opposite of a reduction reaction.
Oxygen	An element, common in Earth's atmosphere and dissolved in water, necessary for most forms of complex animal and plant life.
PA Act 167	Stormwater Management Act
PA Act 537	Sewage Facilities Planning Act
PA DCNR	Pennsylvania Department of Conservation and Natural Resources
PA DEP	Pennsylvania Department of Environmental Protection
Parameter	A chemical constituent or physical characteristic of water quality (e.g., dissolved oxygen is a chemical constituent, temperature is a physical characteristic).
Parametric statistics	A collection of powerful statistical tools that assume certain qualities of the data being analyzed, such as homogeneity of variances.

Parasite	A functional feeding group of aquatic organisms characterized by feeding usually upon bodily fluids of other organisms, rather than direct predation and consumption. The organism that is fed upon need not die due to the effects of feeding
PEC	Pennsylvania Environmental Council
PFBC	Pennsylvania Fish and Boat Commission
Phosphate	An oxidized form of phosphorus, which may be organic or inorganic. Inorganic phosphates are generally more likely to be available as nutrients for biological growth.
Photosynthesis	A set of chemical reactions in which plants and other organisms, such as blue-green algae, can synthesize their own food using light and inorganic carbon. Photosynthetic activity in water increases dissolved oxygen concentration during daylight hours.
Physicochemical	Physical and chemical properties of water; a term used to group water quality parameters of interest.
Phytoplankton	Collectively, algae suspended in water; a group or growth form of algae defined by passive or active suspension in the water column.
PO_4	Phosphate
Point source	Pollution discharged from a single point, defined in the CWA as “any discernable, confined and discrete conveyance, including but not limited to any pipe, ditch, channel, tunnel, conduit, well, discrete fissure, container, rolling stock, concentrated animal feeding operation, vessel, or other floating craft from which pollutants are or may be discharged.”
Potassium (K)	An elemental macronutrient required for biological growth.
POTW	Publicly Owned Treatment Works
PRD	Planned Residential Development
Predator	A functional feeding group of aquatic organisms characterized by actively feeding upon captured prey.
Productivity	A measure of the amount of biological growth that occurs in an ecosystem.
PWD	Philadelphia Water Department
QA/QC	Quality Assurance/Quality Control

RBP	(Rapid Bioassessment Protocol) A standard method developed by the EPA to assess aquatic health through fish and macroinvertebrate diversity (EPA website).
RBPIII	(Rapid Bioassessment Protocol III) EPA approved technique for evaluating macroinvertebrate communities of a river or stream.
RBPV	(Rapid Bioassessment Protocol V) EPA approved technique for evaluating the fish communities of a river or stream.
RCP	PA DCNR's Rivers Conservation Planning Program.
Reach	A segment of a stream as defined by the study being undertaken.
Reference	A condition or value used for comparison. Many types of biological assessment techniques require comparison to references.
Regulator	In sewer infrastructure, a physical gate, valve, or other control structure that routes flow between two or more receiving pipes, usually one of which terminates in a CSO.
Respiration	Biological metabolic process in which a large molecule is broken into smaller pieces to yield usable energy. Aerobic respiration, the efficient respiration reaction favored by complex living things, requires oxygen.
Riffle	A reach of stream that is characterized by shallow, fast moving water broken by the presence of rocks and boulders.
Riparian	Related to, within, or near a river or its banks.
Riparian corridor	The area of land along the bank or shoreline of a body of water (EPA website).
Riparian woodlands	Woodlands that grow within the riparian corridor.
RTC	Real Time Control - a dynamic system of hydraulic controls to provide additional storage and reduce overflows from a combined sewer system.
Run	A reach of stream that is characterized by smooth flowing water.
Runoff	Generally, precipitation that is not absorbed by surfaces or evaporated, but allowed to flow over the surface to a receiving body of water.
Sediment	Particles, especially inorganic soil particles, that settle upon stream surfaces.
SEO	Sewage Enforcement Officers (designated by PA DEP).

Sinuosity	A measure of the degree to which a stream, viewed from above, deviates from a linear path, expressed as the ratio of stream length between two points divided by the valley length, or point-to-point distance between the same two points.
Significant	When describing the results of scientific or experimental study, describes a comparison or relationship that has been determined to be more likely real than related to randomness or chance to a stated degree of confidence.
Silt/Siltation	Inorganic sediment particles between 3.9 and 62.5 µm in diameter. also the process of being covered by or embedded in silt.
Soluble/Solubility	The quality or state of being able to pass into solution. In water chemistry analysis, a substance may be considered soluble or dissolved if it passes through a 0.45 µm filter.
Sonde	A continuous water quality monitoring instrument.
Species	The level of biological taxonomic classification at which living things are separated from one another by the ability to reproduce yielding fertile offspring.
SSA	Separate-Sewered Area stormwater runoff
SSO	Sanitary Sewer Overflow
STORET	U.S. EPA's water quality database (STOrage and RETrieval).
Stormwater Management Program Protocol ("Protocol")	PA DEP guidance for implementing the requirements of the NPDES Phase II stormwater regulations.
Structural BMPs	These BMPs will require proper operation and maintenance. Examples include wet ponds, grassed swales, infiltration basins and bioretention areas.
SWMM	Storm Water Management Model
TDR	Transfer of Development Rights
Temporal	Of or relating to time, such as a change observed over time.
TIGER	Topologically Integrated Geographic Encoding and Referencing (U.S. Census database).
TMDL program	Total Maximum Daily Load program - EPA/PA DEP program for limiting and allocating discharges of a pollutant within a watershed.

Toxic/toxicity	Describing a substance that is harmful, able to cause injury or death; also the concentration at which a substance may cause injury or death.
Transpiration	The process by which water vapor passes through the membrane or pores of plants to the atmosphere.
Trophic	Describing or relating to food, food type, or the process through which a living thing acquires food.
TSS	Total Suspended Solids
TTFIWMP	The Tookany/Tacony-Frankford Integrated Watershed Management Plan.
Turbidity	A measure of the light scattering properties of water.
UA	Urban Areas
UAA	Use Attainability Analysis
Unimpaired	Natural, unmolested; describing an unaltered or undisturbed state.
USDA	United States Department of Agriculture
USGS	United States Geological Survey
Velocity	A vector quantity that describes speed in a stated direction or along an axis.
Vertebrate	A complex living thing having a backbone (vertebrae).
Violation	An instance or time period during which a regulated water quality parameter was exceeded.
Watershed	The area of land draining to a stream, river, or other water body. Watershed boundaries are established where any precipitation falling within the boundary will drain to a single water body. Precipitation falling outside the boundary will drain to a different watershed. These boundaries are typically formed on high elevation ridges. The water bodies formed from the watershed drainage are usually at the lowest elevation in the watershed. Watersheds can also be called drainage basins.
WLA	Waste Load Allocation
WMP	Watershed Management Plan
WQS	Water Quality Standards
WRAS	PA DEP's Watershed Restoration Action Strategy

Public Survey

Tacony-Frankford River Conservation Plan

Philadelphia Residents: Do you live within the boundaries of the **Tacony-Frankford Watershed?** (see map below). If yes, please fill out and return this survey. Thank you!

A **watershed** is all the land that drains rain into a specific body of water, such as a creek.

Philadelphia Neighborhoods in the Tacony-Frankford Watershed:

OPPORTUNITIES FOR YOUR INVOLVEMENT

16. Would you like to participate in any of the following activities? Check those that interest you.

___Monitor water quality in the creek.
___Volunteer in the parks to plant trees, pick up trash, or fix trails.
___Participate in planning meetings.
___Educate others about watershed issues.
___Take a guided walk along the creek.

17. If you checked any lines above, or if you would like to stay informed about future watershed-related events, please provide the following information.

The Tacony-Frankford River Conservation Plan is a collaborative project of Philadelphia citizens, community groups, and public agencies. Key organizers of the plan include the Philadelphia Water Department, Frankford Group Ministry, Fairmount Park Commission, Heritage Conservancy, and the Pennsylvania Environmental Council, with funding provided by the Pennsylvania Department of Conservation & Natural Resources.

Upstream of the Tacony-Frankford Creek, Montgomery County citizens and officials are creating a conservation plan for the **Tookany Creek.**

Together, these river conservation plans will provide a community-based vision for improving the entire Tookany-Tacony-Frankford Watershed. To learn more about how you can participate in the **Tookany/Tacony-Frankford Watershed Partnership**, contact the Pennsylvania Environmental Council at 215-563-0250, or visit www.phillywater.org (Go to "Watershed Partnerships" link).

Mailing Instructions: Please fold along lines, tape closed, and mail by June 30, 2002. Postage is prepaid for your convenience, or use a stamp to help cut costs.

Tacony-Frankford Public Survey

BACKGROUND INFORMATION

Philadelphia Neighborhood: ____________________

Zip code:______________ Age:______

Type of dwelling:	Length of residency there:
A. Detached house	A. 0 to 1 year
B. Twin	B. 1 to 5 years
C. Rowhouse	C. 5 to 10 years
D. Apartment	D. 10 to 20 years
	E. > 20 years

YOUR WATERSHED AWARENESS

1. Before reading the cover of this brochure, did you know what a watershed was? (Circle one)
   A. Yes.
   B. No.
   C. I was aware of the term but not entirely sure what it meant.

2. Do you ever think of yourself as a resident of the Tacony-Frankford Watershed?
   A. No, I never thought of myself as a resident of any watershed.
   B. No, I knew that I live in a watershed, but I wasn't sure which one.
   C. Yes.

3. When it rains, where does most of the water drain to from your roof?
   A. Into my driveway/street and down a storm drain.
   B. Into my yard where it absorbs in the soil.
   C. Into the downspout and directly underground to the city sewer system.
   D. Other ____________________________
   E. I don't know.

4. In your neighborhood, when water goes into storm drains on the street, where does it go?
   A. Wastewater treatment plant. C. Into the ground.
   B. Directly to a stream. D. I don't know.

5. During a heavy rain storm, do you ever see flooding in these places? (Circle each place that floods.)
   A. My street. D. My basement.
   B. My driveway. E. Other ______________
   C. My yard. F. No flooding problems.

TACONY-FRANKFORD WATERSHED

6. How close do you live to Tacony-Frankford Creek?
   A. The creek flows next to my property.
   B. Less than 4 blocks away.
   C. More than 4 blocks away.
   D. I don't know.

7. Do you or anyone in your family spend time along Tacony-Frankford Creek? How often?
   A. At least 2-3 times per week.
   B. Once a week.
   C. Once a month.
   D. Several times a year.
   E. Rarely or never (Go to question #9)

8. What activities do you and/or your family do there? (Circle all that apply)
   A. Fishing. D. Picnic.
   B. Nature exploration. E. Walking.
   C. Outdoor sports. F. Other _______________

9. How clean do you think the water is in Tacony-Frankford Creek?
   A. High quality. I would wade or swim in the water.
   B. Moderate quality. I might wade occasionally.
   C. Poor quality. I would never wade or swim.

10. Of all the possible sources of pollution from the entire Tookany/Tacony-Frankford Watershed, which of these sources do you think are a problem? Circle one option for each. 1=major problem, 2=occasional problem, 3=not a problem, ?= don't know.

1 2 3 ? Pollution discharge from factories.
1 2 3 ? Sewage from homes or commercial buildings.
1 2 3 ? Trash and litter from careless people.
1 2 3 ? Stormwater runoff from streets/parking lots.
1 2 3 ? Animal waste from dogs, geese, etc.
1 2 3 ? Lawn fertilizers and herbicides.
1 2 3 ? Sediment from eroding creek banks.
1 2 3 ? Illegal dumping.
1 2 3 ? Other ___________________________

11. If money were used to enhance or improve Tacony-Frankford Creek and its surrounding communities, which of these changes would you recommend as important? Circle one number for each. 1= very important, 2=somewhat important, 3=not important.

1 2 3 Less litter.
1 2 3 Cleaner water.
1 2 3 Less flooding.
1 2 3 Better trails along the creek.
1 2 3 More recreational facilities (ballfields, play grounds, etc.)
1 2 3 More native trees and shrubs on stream banks.
1 2 3 Increased safety and security in parks.
1 2 3 More environmental education programs.
1 2 3 Preservation of historic buildings.
1 2 3 More public art near or about the creek.
1 2 3 More cultural events along the creek.
1 2 3 Other ______________________

ACTIONS IN YOUR NEIGHBORHOOD

12. All of the following actions can harm water quality in streams. Put a check next to actions you have observed in your neighborhood.

___Leaving dog waste on lawns/streets.
___Car-washing with detergents that go into streets.
___Leaky motor oil or antifreeze from cars.
___Dumping fluids or trash into storm drains.
___Over-use of lawn fertilizers or herbicides.
___Riding ATVs in the parks, tearing up soil/plants.
___Dumping tires or other trash into vacant lots/parks.
___Dumping leaves or grass clippings in the creek.
___Other ______________________

13. Do you think *most* people in your neighborhood know these actions pollute streams? YES NO

14. Do you know where to report illegal dumping? YES NO

(You can report to the Philadelphia Police Environmental Response Unit, 215-685-3097, *or* the PA Department of Environmental Protection, 610-832-6014.)

15. Have you ever helped with any watershed protection activities? If so, what? (for example, picking up trash, planting trees, putting "no dumping" signs on storm drains, etc.)

Appendix C

TOOKANY/TACONY-FRANKFORD WATERSHED PARTNERSHIP CORPORATE BYLAWS

ARTICLE 1
NAME; PRINCIPAL OFFICE

1.1. **Name**. The name of the nonprofit corporation is Tookany/Tacony-Frankford Watershed Partnership ("Corporation").

1.2. **Principal Office**. The principal office of the Corporation shall be c/o the Pennsylvania Environmental Council (PEC) at 123 Chestnut Street, Suite 401, Philadelphia, PA 19106. The Corporation may also have offices at other places as the Directors may from time to time see fit or the activities of the Corporation may require.

ARTICLE 2
PURPOSES

2.1. **General Purposes.** The Corporation is established in compliance with the Nonprofit Corporation Law of 1988 (the "Act"). The Corporation is established exclusively for charitable, educational and scientific purposes as set forth in the Articles of Incorporation. In pursuing such purposes, the Corporation shall not act so as to impair its eligibility for exemption under Section 501(c) (3) of the Internal Revenue Code of 1986, as amended.

2.2. **Specific Purposes.** The primary purposes of the Corporation are to carry out all activities allowable under Section 501(c)(3) of the Internal Revenue Code (or the corresponding section of any future Internal Revenue Law of the United States), including but not limited to: implement the Integrated Watershed Management Plan for the Tookany/Tacony-Frankford Watershed ("TTF Watershed"); improve stream habitat and integrity of aquatic life; reduce the impact of urbanized flow on living resources; improve dry and wet weather stream quality to reduce the effects on public health and aquatic life; protect and restore stream corridors, buffers, floodplains, and natural habitats including wetlands; identify flood prone areas and decrease flooding; enhance community environmental quality of life; foster community stewardship; and improve inter-municipal, inter-county, state-local and stakeholder cooperation and coordination on a watershed wide basis through dedicated public education and outreach.

ARTICLE 3
MEMBERS

3.1. **Membership Corporation.** The Corporation shall have no members.

3.2. **Honorary Titles.** The Directors may create such classes of membership, such as contributing members or honorary members, as the Directors see fit, but such persons shall not have the rights of members under the Act.

ARTICLE 4
DIRECTORS

4.1. **Powers.** The activities, property, and affairs of the Corporation shall be managed by the Board of Directors ("Board"). Each Director shall possess all powers and undertake duties required for the conduct and management of the business and affairs of the Corporation except as otherwise required by law, these Bylaws, or a resolution duly adopted by the Board. The Board may adopt such rules and regulations as may be required by regulatory authorities.

4.2. **Categories of Board Membership.**

(a) The Board of Directors shall consist of not less than eleven (11) and not more than twenty-four (24) persons. Board members shall represent a specific Board category as defined herein.

(b) *Appointed Board Members:*

Each of the following entities ("Eligible Appointing Entities") shall be entitled to appoint one member of the Board of Directors: Montgomery County Board of Commissioners, Abington Township, Cheltenham Township, Jenkintown Borough, Rockledge Borough, Philadelphia Water Department, Fairmount Park Commission, Philadelphia City Planning Commission, the Mayor's Office of the City of Philadelphia, and the Office of the President of City Council (Philadelphia).

(c) *Elected Board Members*:

The *Elected Directors* shall be elected by the Board in accordance with procedures established in these Bylaws. The *Elected Directors* shall, whenever possible, represent the following constituencies: non-profit organizations, large businesses, small businesses, universities, civic organizations, and individuals who are stakeholders of TTF Watershed.

4.3. **Term of Office.**

(a) The members of the initial Board of Directors shall include both *Appointed Directors* and *Elected Directors*. *Appointed Directors* shall be appointed by their respective Eligible Appointing Entities; *Elected Directors* shall be appointed by the Incorporator at the First Organizational Meeting of the Board. The initial Directors shall be assigned an initial Board term of one (1) year, two (2) years, or three (3) years.

(b) Thereafter, as the initial terms of the initial Board Directors conclude, Directors shall be appointed or elected to the Board at the Corporation's Annual Meeting. Directors shall be appointed or elected to fill specific categories of Board membership in accordance with these Bylaws.

(c) Upon the conclusion of the initial terms as described in Section 4.3(a), all Directors shall serve a three-year term. The terms of the Directors shall be fixed so that the term of one-third of such Directors shall expire at each Annual Meeting of the Corporation.

(d) No Director may serve more than six consecutive years (not including the initial term).

4.4. **Appointment of the *Appointed Directors*.**

(a) Not less than thirty (30) days before the First Organizational Meeting, the Eligible Appointing Entities shall submit to the Incorporator their respective appointments for Directors ("*Appointed Directors*"). Eligible Appointing Entities shall only appoint professionals or staff of the Eligible Appointing Entities, or those who provide professional services to the jurisdiction of the Eligible Appointing Entities. During the First Organizational Meeting, the Incorporator shall announce and seat the *Appointed Directors*.

(b) Thereafter, not less than thirty (30) days before each Annual Meeting, the Eligible Appointing Entities shall appoint the number of nominees equal to the number of directorships that are vacant or will become vacant at the time of the Annual Meeting. These Eligible Appointing Entities shall submit to the Secretary of the Board their appointments for *Appointed Directors*. The Secretary shall immediately inform the Board of Directors of these appointments. During the Annual Meeting, the Board of Directors shall announce and seat the *Appointed Directors*.

4.5. **Nomination and Election of the *Elected Directors*.**

(a) During the First Organizational Meeting, the Incorporator shall announce and seat the first *Elected Directors*.

(b) Thereafter, not less than sixty (60) days prior to each Annual Meeting, the President shall send written notice to the members of the Board announcing the number of Directors to be elected, declaring that the nominations of candidates for election as Director are open, and calling for nominations. Nominations will be directed though a Nominations Committee appointed by the Board President.

Not less than thirty (30) days before the Annual Meeting, the Nominations Committee shall submit to the Secretary of the Board its nominations. After nominations have been made, the President shall declare the nominations closed, and thereafter no further nominations may be made.

(c) During the Annual Meeting, the voting procedure followed shall be such that a separate vote is taken for each directorship to be filled. Each directorship shall be filled by majority vote of the Directors voting (a quorum must be present).

d) Upon demand of any three Directors in attendance, elections shall be conducted by written ballot; otherwise all ballots will be cast by voice vote only.

4.6. **Removal.**

(a) The Board, by a majority vote, may make a recommendation for removal of an *Appointed Director*. After a lawfully conducted vote to recommend removal is affirmed, the President shall contact the Eligible Appointing Entity that appointed this Director and discuss matters concerning removal of this Director and appointment of a new Director by the Eligible Appointing Entity. The Eligible Appointing Entity shall make the final decision concerning the removal of this *Appointed Director*.

(b) Any *Elected Director* may be removed from office, without the assignment of any cause, by a majority vote of the Board, whenever in the judgment of the Board the best interest of the Corporation will be served.

(c) Votes in accordance with the above Section 4.6 (a) and (b) shall be conducted at a duly convened meeting of the Board. The written notice of the intention to consider removal of such Director shall be included in the notice of the meeting. No Director shall be removed without having the opportunity to be heard at such meeting, but no formal hearing procedure need be followed.

4.7 **Vacancies.**

(a) When a directorship of an *Appointed Director* becomes vacant during the period between Annual Meetings of the Corporation, the President shall inform the affected Eligible Appointing Entity to appoint a new Director to fill such vacancy until the next Annual Meeting.

(b) When any directorship of an *Elected Director* becomes vacant during the period between Annual Meetings of the Corporation, the Board may elect a new Director to fill such vacancy until the next Annual Meeting. The vacancy shall be filled with a Director from the same type of organization, business, civic interest, or individual interests as set forth in Section 4.2 (c).

4.8. **Resignation**. Any Director may resign at any time by giving written notice to the Corporation. The resignation shall be effective upon receipt by the President (or in the case that the President elects to resign or is not available, receipt by the Board of Directors), or at such subsequent time as may be specified in the notice of resignation.

4.9. **Director Compensation.** Directors shall not be compensated for their service on the Board, although they may be reimbursed for reasonable and necessary expenses incurred for the benefit of the Corporation. Reimbursement shall require the submission of expense vouchers and receipts.

4.10. **Conflict of Interest.**

(a) No contract or transaction between the Corporation and its Directors or Officers or between the Corporation and any other corporation, partnership, association, organization, or governmental agency in which one or more of its Directors or Officers have a financial interest shall be void or voidable if:

(1) the material facts as to the relationship or interest and as to the contract or transaction are disclosed to the Board of Directors, and are authorized in good faith by the affirmative vote of a majority of disinterested Directors; and

(2) the contract or transaction is fair to the Corporation as of the time it is authorized by the Board of Directors.

(b) In making the above determination, the affected Director or Officer shall withdraw from the meeting in which this matter is discussed for as long as this matter remains under consideration. Should the matter be brought to a vote, the affected Director shall neither be present nor cast a vote.

ARTICLE 5

MEETINGS

5.1. **Annual Meetings.**

(a) The Annual Meeting of the Directors shall be held during the month of May of each year at the offices of one of the Directors or at such other location as agreed upon by the Directors at least two (2) weeks prior to the Annual Meeting. If all of the Directors agree, the Annual Meeting may be held during a month other than May as determined at least two (2) weeks prior to the Annual Meeting.

(b) At the Annual Meeting, the Board shall be organized for the succeeding year, including the official recognition of appointment of the *Appointed Directors* and the election of the *Elected Directors* by vote of the remaining Directors, to fill the positions of those whose terms expire at that time, as well as review and adoption of the annual budget, and consideration of such other matters as may properly come before the Board.

5.2. **Regular Meetings.** The Board of Directors shall meet according to a schedule it determines, provided that it meets at least four times a year, and without an interval of more than four months between any two meetings. Each Director shall receive timely advance notice of meetings, in accordance with these Bylaws.

5.3. **Special Meetings.** Special meetings may be called by the President or by any five Directors calling for the meeting by contacting the President.

5.4. **Telephone Communication.** Members of the Board of Directors may participate in any meeting of the Board through the use of conference telephone or similar communication equipment that enables all participants in the meeting to hear each other at the same time. Such participation shall constitute presence in person at the meeting.

5.5. **Quorum and Voting**.

(a) Two-thirds of the Directors seated shall constitute a quorum for amendment of the Articles of Incorporation or the Bylaws; issues relating to the sale, lease, or purchase of real estate; and removal or suspension of any Officer at any Board meeting, whether annual, regular, or special. For matters mentioned above, if a quorum is present, the act of two-thirds of Directors voting shall be an act of the Board of Directors.

(b) For all other matters, unless specifically stated by resolution of the Board, a majority of the Directors seated shall constitute a quorum. If a quorum is present, the act of a majority of Directors voting shall be an act of the Board of Directors, except as otherwise expressly provided in these Bylaws or required by law.

5.6. **Notice**. Notice shall be given in writing to each Director of each Annual, regular, or special meeting of the Directors. Such notice shall be delivered by hand, by mail, or by facsimile or electronic mail at least ten (10) days before the day named for the Annual, regular or special meeting. The notice shall state the date, time, place, and purpose of the meeting, including the agenda, if one has been established or required by these Bylaws.

5.7. **Waiver of Notice.** A written waiver signed by a Director, or attendance by a Director at any Annual, regular, or special meeting, shall be deemed equivalent to appropriate notice and shall be considered consent to the holding of the meeting.

5.8. **Proxy Votes**. A Director is allowed to vote by proxy, if necessary. Every proxy shall be executed in writing by the Director or by his or her duly authorized representative and filed with the Secretary of the Corporation. A proxy statement shall indicate the specific matters on which the proxy is authorized to vote. A Director’s proxy who is entitled to vote at the meeting shall vote only in the matters specified in the proxy statement executed by the Director and only for that specific meeting. A vote by proxy that exceeds the authority specified in the proxy statement is invalid. A proxy shall be revocable at will, notwithstanding any other agreement or any provision in the proxy to the contrary, but the revocation of a proxy shall not be effective until notice thereof has been given to the Secretary of the Corporation. A proxy shall not be revoked by the death or incapacity of the maker unless before the vote is counted or the authority is exercised, written notice of such death or incapacity is given to the Secretary of the Corporation.

ARTICLE 6
OFFICERS

6.1. **Officers.** The officers of the Corporation shall be a President, Vice-President, Treasurer, Secretary, and an Executive Director, and such other officers as the Board of Directors may from time to time elect. The duties of the officers of the Corporation shall be as provided in the Bylaws, except as modified from time to time by the Board.

6.2. **Election and Term.** Officers may be elected for more than one office and serve for consecutive terms. The Officers (except for Executive Director) shall be elected by a majority vote of the Board at the Annual Meeting of Directors and shall serve for a term of one (1) year and until their successors are elected and qualified, or until death, resignation, or removal.

6.3. **Qualification of Officers.** The President, Vice-President, Secretary, and Treasurer must be at least 18 years of age and shall be members of the Board of the Corporation.

6.4. **President.** The President shall preside at meetings of the Board, shall have general responsibility for dealing with questions of policy related to the Corporation's affairs, and shall be responsible for calling meetings of the Board and for assuring adequate communication between the operating staff of the Corporation and the Board on matters of policy and financial concerns.

6.5. **Vice-President.** The Vice-President shall perform such duties as may from time to time be assigned by the Board of Directors or designated by the President. In the case of the death, disability, or absence of the President, the Vice-President shall fulfill all the duties and be vested with all powers and responsibilities of the President.

6.6. **Secretary.** The Secretary shall keep a book of minutes of all meetings of the Board, shall direct the issue of all notices required by law or requested from time to time by the Board of Directors or by the President, and shall perform such other duties as are incident to the office of Secretary. The Secretary shall be the custodian of the seal of this Corporation and all books, records, and papers of this Corporation, except those documents in the charge of the Treasurer, or of some other person authorized to have custody and possession thereof by a resolution of the Board of Directors.

6.7. **Treasurer.** The Treasurer serves as the principal financial advisor to the Board of Directors in planning, directing, and appraising the effectiveness of the Corporation's fiscal operations. The Treasurer shall ensure full and accurate accountability and control of the receipts and disbursements of the Corporation's assets. The Treasurer shall perform such other duties as may be assigned by the Board of Directors or as are incidental to the office. The Treasurer shall agree to be bonded as deemed necessary by the Board of Directors.

6.8. **Executive Director.** The position of Executive Director is a paid position within the Corporation. The Executive Director shall be appointed or dismissed by the Board of Directors, on such terms and conditions as the Board of Directors deems appropriate. The Executive Director shall be an ex-officio member of the Board of Directors, shall direct all operations of the Corporation, shall supervise all personnel, and shall have control and management of its business and affairs, all subject to the direction of the Board of Directors. The Board shall evaluate the performance of the Executive Director annually, against a set of written, agreed upon goals and objectives.

ARTICLE 7
COMMITTEES

7.1. **Establishment.**

(a) The Board of Directors may, if set forth in these Bylaws or by resolution, establish one or more committees and give them such powers and authority as the Board shall deem appropriate.

(b) Committees shall have and shall exercise authority as prescribed by the Board of Directors. The creation of a committee shall not operate to relieve the Board of Directors, or any individual Director, of the responsibility imposed by law. No committee shall have the authority of the Board to conduct any of the following:

(1) The filling of vacancies of the Board;
(2) The adoption, amendment, or repeal of the Bylaws;
(3) The amendment or repeal of any resolution of the Board; and
(4) Action on matters committed by the Bylaws or by resolution of the Board to another committee of the Board, or to the full Board.

7.2. **Executive Committee**.

(a) The members of the Executive Committee shall be the Officers who are elected by the Board at the Annual Meeting. This shall include the President (who shall serve as chair of the Committee), Vice-President, Secretary, and Treasurer. In addition, the Executive Committee shall include one additional Director. Such additional member shall be elected to the Executive Committee at each Annual Meeting following the election of Directors and Officers, and shall serve for one year or until his/her successor is seated to this Committee.

(b) The Executive Committee shall have power and authority to take actions on behalf of the Board of Directors for emergencies and other urgent business matters that occur between meetings of the Board. The Executive Committee shall not be authorized to conduct the standard and usual business of the Board. All actions taken by the Executive Committee shall be reported at the next meeting of the Board and shall be binding on the Board only when approved by formal vote of the Board or when so authorized previously by the Board and delegated to the Executive Committee.

ARTICLE 8
DISSOLUTION

8.1. **Distribution of Assets.** Upon dissolution of the Corporation, the Board of Directors shall, after paying or making provision for the payment of all the liabilities of the Corporation, dispose of all of the assets of the Corporation exclusively for the purpose of the Corporation in such manner, or to such organization or organizations organized and operated exclusively for charitable, educational, or scientific purposes as shall at the time qualify as an exempt organization or organizations under Section 501(c)(3) of the Internal Revenue Code of 1986 (or the corresponding provision of any future United State Internal Revenue Law), as the Board of Directors shall determine. Any such assets not so disposed of shall be disposed of by a Court of competent jurisdiction of the County in which the principal office of the Corporation is then located, exclusively for such purposes or to such organization or organizations, as said Court shall determine, which are organized and operated exclusively for such purposes.

ARTICLE 9
AMENDMENTS

9.1. **Amendments.**

(a) The Directors may, by a two-thirds vote of those present in person at any duly called meeting at which a quorum is present as set forth in Article 5.5(a) of these Bylaws, alter, amend, or repeal the Articles of Incorporation or these Bylaws or any portion thereof. Provided, however, that no such alteration, amendment, or repeal should impair the Corporation's eligibility for exemption under Section 501(c) (3) of the Internal Revenue Code of 1986.

(b) Written notice as to the substance and effect of any proposed amendment to the Articles of Incorporation or these Bylaws shall be given or mailed to each Director not less than ten (10) days prior to the meeting of the Board at which such proposed amendment is submitted to a vote.

ARTICLE 10
OPERATIONS

10.1. **Execution of Documents.** Except as otherwise provided by law or resolution of the Board of Directors, checks, drafts, promissory notes, orders for payment of money, other evidences of indebtedness of this Corporation, contracts, leases, or other instruments executed in the name of and on behalf of the Corporation may be signed by any Officer or any Director. If the amount of indebtedness or obligation on any single document mentioned in this Article is two thousand dollars ($2,000) or above, such document shall be executed by two people who have authority to sign (Officer or Director) in order to be binding on the Corporation.

10.2. **Corporate Seal.** The Corporation may have a corporate seal containing the name of the Corporation, the year of incorporation, and such other details as may be approved by the Board of Directors.

10.3. **Books and Records.** The Corporation shall keep correct and complete books and records of account, and will also keep minutes of the proceedings of its Board of Directors and Committees. The Corporation will keep at its registered office the original or a copy of its Articles of Incorporation as filed with the Secretary of State of the Commonwealth of Pennsylvania, and the original or a copy of these Bylaws, including amendments, certified by the Secretary of the Corporation

10.4. **Fiscal Year.** The fiscal year of the Corporation shall begin on July 1 and end on June 30 of each year.

ARTICLE 11
LIABILITY AND INDEMNIFICATION

11.1. **Liability.** General Rule. A Director shall not be personally liable for monetary damages as a Director for any action taken, or any failure to take action, unless:

(a) the Director has breached or failed to perform the duties of Director in accordance with the standard of conduct contained in section 5712 of the Act, “Standard of care and justifiable reliance”; and

(b) The breach or failure to perform constitutes self-dealing, willful misconduct, or recklessness.

Provided, however, the foregoing provision shall not apply to (1) the responsibility or liability of a Director pursuant to any criminal statute or (2) the liability of a Director for the payments of taxes pursuant to local, state, or federal law.

11.2. **Insurance.** The Corporation may purchase and maintain insurance on behalf of any person who is or was a Director, Officer, or employee of the Corporation or is or was serving at the request of the Corporation as a representative of another domestic or foreign corporation for profit or not-for-profit, partnership, joint venture, trust, governmental agency, or other enterprise against any liability asserted against him or her and incurred by him or her in any such capacity, or arising out of his or her status as such, whether or not the Corporation would have the power to indemnify him or her against that liability under the Act.

11.3. **Indemnification.**

(a) The Corporation shall reimburse any Director, Officer, or other representative of the Corporation (each, a “Representative”) for any expenses that are actually and reasonably incurred by him or her in connection with any lawsuit or action in which the performance of his or her duties as a Representative is in question (“Reimbursable Costs”) if he or she is successful in defending himself or herself against the lawsuit or action as demonstrated by a judgment in his or her favor on the merits of the claim.

(b) Subject to paragraph (c) below, the Board has discretion to decide, by a unanimous vote, whether to reimburse a Representative for Reimbursable Costs in those instances where a judgment in his or her favor on the merits of the claim is not reached and, therefore, he or she is not entitled to mandatory indemnification pursuant to paragraph (a) above, but where the Representative acted in good faith and in a manner he or she reasonably believed to be in, or not opposed to, the best interests of the Corporation or, with respect to a criminal proceeding, had no reasonable cause to believe that his or her conduct was unlawful. The Corporation may only reimburse the Reimbursable Costs up to the limit amount that its insurance covers.

(c) Under no circumstances may the Corporation reimburse a Representative for Reimbursable Costs if a court determines that his or her behavior in connection with the lawsuit or action at issue constituted willful misconduct or recklessness.

ADOPTED BY THE BOARD OF DIRECTORS ON ____________________.

Appendix D: Potential Sources of Funding

SOURCE OF ASSISTANCE	PROGRAM NAME	CONTACT NUMBER	BRIEF DESCRIPTION OF PROGRAM
DCED	Communities of Opportunity		Provides grants to municipalities, redevelopment authorities and housing authorities for community revitalization, economic development, and low-income housing development and rehabilitation.
DCED & Governor's Office	Community Revitalization Program		Very broad grant program. Officially intended to promote community stability, increase tax bases and improve quality of life. Applications may be made by municipalities, authorities, economic development organizations and non-profit corporations. Public/non-profit/profit partnerships are encouraged. Generally can be used for infrastructure, community revitalization, building rehabilitation, demolition of blighted structures, public safety, and crime prevention.
DCED in cooperation with PA DEP	Industrial Sites Reuse Program, PA ("Brownfields")		Provides grants of up to 75% and low interest loans for assessment of environmental contamination and remediation work at former industrial sites. Available to private companies, non-profit economic development agencies or authorities that own the land. Mainly targeted towards cities. Financing is not available to the company that caused the contamination.
DCED	Intermunicipal Projects Grants		Promotes cooperation between neighboring municipalities so as to foster increased efficiency and effectiveness in the delivery of municipal services at the local level.
DCED	Land Use Planning and Technical Assistance Program		Assists local governments and counties to prepare comprehensive plans, downtown plans, special community development studies and development regulations. Typically provides 50% of the eligible costs.
DCED	Shared Municipal Services		Provides modest-sized 50/50 matching grants to promote cooperation among municipalities, in order to increase the efficiency of public services. Two or more municipalities may apply, or a council of governments.
DCNR	Community Conservation Partnership Grant Program		Funds a wide variety of recreation, greenway, rivers conservation and open space preservation activities with 50% matching grants. Four main categories of grants are: Planning and Technical Assistance, Acquisition Projects, Development Projects, Federally Funded Projects

SOURCE OF ASSISTANCE	PROGRAM NAME	CONTACT NUMBER	BRIEF DESCRIPTION OF PROGRAM
DCNR	Conservation Corps, PA.		Provides funding for work crews for community projects, such as trail improvements.
DCNR	Keystone Rec., Park & Cons. Program - Land Trust Grants		Grants to well-established non-profit land trusts and conservancies to plan for and acquire critical natural areas. Land that is acquired must be open to the public.
DCNR	Keystone Rec., Park & Cons. Program - Community Grants		Provides 50% matching grants to municipalities to fund: overall planning for park and recreation, master plans for individual parks, acquisition of parkland and nature preserves, countywide natural area inventories, and rehabilitation and improvements to public recreation areas. Grants up to $20,000, without a local match, are available for material and design costs in small municipalities.
DCNR	Pennsylvania Forest Stewardship/Stream ReLeaf Program	717-787-2106	Cost-Share (75%) assistance for riparian zone protection or improvement projects: streambank restoration, fencing and crossings.
DCNR	Rivers Conservation Program	717-787-2316	Conserve and enhance river resources by offering planning grants, technical assistance, implementation grants, development grants, and acquisition grants.
DCNR	Urban Forestry Grants		Provides grants for tree planting projects. Is also a Federal "America the Beautiful" grant program for tree planting.
DEP	Coastal Zone Management Program	717-787-5259	Grants for planning and construction in the Lake Erie and the Delaware Estuary Coastal Zones.
DEP	Environmental Stewardship and Watershed Protection Grant Program	717-787-5259	Grants focus on nonpoint source pollution and watersheds: acid mine drainage abatement, mine cleanup efforts, well plugging, planning and implementing local watershed-based conservation efforts (formerly WRAP+WRPA).
DEP Bureau of Waterways Engineering	Flood Protection Program, PA		Offers design and construction of flood protection projects. The project must be deemed economically justifiable under the state capital budget process.
DEP	Nonpoint Source Management (EPA 319) Program	717-787-5259	Grants for planning and nonpoint source pollution control projects.
DEP	PA Environmental Education Grants Program	717-772-1828	Provides financial support for projects that design, demonstrate or disseminate environmental education practices, methods or techniques.

SOURCE OF ASSISTANCE	PROGRAM NAME	CONTACT NUMBER	BRIEF DESCRIPTION OF PROGRAM
DEP	Pennsylvania Wetland Replacement Project	717-787-6827	Grants for restoring wetlands, riparian corridors and other aquatic systems within the Commonwealth.
DEP	Sewage Facility Planning Grants		Grants to pay up to 50% of the costs to prepare a new sewage facilities plan or update an existing plan, under State Act 537 of 1966.
DEP	Stormwater Management Program	717-772-4048	Watershed planning for stormwater control (counties) and implementation of programs at local levels (municipalities).
DEP	Stream Bank Fencing Program	717-783-7577	To improve water quality and reduce soil erosion by constructing one or two strand fences to limit livestock access streams.
DEP	Stream Improvement Program (SIP)	717-787-3411	Assistance through the construction of small projects to prevent flooding, restore natural stream channels and to stabilize banks.
Federal Emergency Management Agency	Flood Hazard Mitigation Grant Program		Provides 75% funding to relieve imminent hazards from flooding, such as voluntary buy-outs and demolitions of highly flood-prone properties.
National Fish and Wildlife Foundation	Chesapeake Bay Small Watershed Grants Program	202-857-0166	This program supports communities undertaking small-scale watershed projects. Grants range from $1,000 to $35,000 to local governments and community groups for education and demonstration projects to protect watersheds.
National Park Service	Rivers, Trails and Conservation Assistance Program	215-597-1581	The National Park Service works with communities to conserve land and river resources and provides funding for various projects dealing with the conservation of these resources including the development of trails and greenways.
PACD	Nonpoint Source Pollution Education Mini Project Grant	717-238-7223	Small grants for Pennsylvania-based, grassroots educational projects that address nonpoint source watershed concepts.

SOURCE OF ASSISTANCE	**PROGRAM NAME**	**CONTACT NUMBER**	**BRIEF DESCRIPTION OF PROGRAM**
PA Infrastructure Investment Authority and PA DEP Bureau of Water Supply Management--Involves both U.S. EPA and State funds	PENNVEST		Offers low interest loans for construction and improvement of drinking water and wastewater systems. Outright grants may be available for highly distressed communities. Mainly intended for public systems, but some private systems may be approved. Water projects are funded through the Drinking Water Revolving Loan Fund. Sewage projects are funded through the Clean Water Revolving Fund. In addition, PennVest is authorized to provide loans for projects to control existing stormwater problems, such as separating stormwater from sanitary sewage. The "Advance Funding Program" provides low-interest loans for feasibility studies and engineering of systems if the utility cannot fund such work itself.
Pennsylvania Department of Community and Economic Development		888-223-6837	Financial assistance may include: preparing environmental protection or physical development strategies or special studies that will support comprehensive land use planning. The application of advanced technology such as Geographic Information Systems (GIS).
The William Penn Foundation Philadelphia, PA		215-988-1830	Grants to preserve natural areas, including environmental education and planning within the foundation's geographic area (primarily southeastern Pennsylvania).
U.S Department of the Interior U.S. Fish and Wildlife Service North America Waterfowl and Wetlands Office (NAWWO)		703-358-1784	The North American Wetlands Conservation Act of 1989 provides matching grants to carry out wetlands conservation projects in the United States, Canada, and Mexico. Both the Standard and Small Grants Programs help deliver funding to on-the-ground projects through protection, restoration, or enhancement of an array of wetland habitats.
U.S. Environmental Protection Agency Office of Wetlands, Oceans, and Watersheds		202-260-4538	EPA establishes a cooperative agreement with one or more nonprofit organization(s) or other eligible entities to support watershed partnership organizational development and long-term effectiveness. Funding supports organizational development and capacity building for watershed partnerships with diverse membership.

SOURCE OF ASSISTANCE	PROGRAM NAME	CONTACT NUMBER	BRIEF DESCRIPTION OF PROGRAM
U.S. Environmental Protection Agency Office of Wetlands, Oceans, and Watersheds		202-260-8076	This Five-Star Program seeks to support restoration projects in 500 watersheds by 2005, a key action of the Clean Water Action Plan. Competitive projects will have a strong on-the-ground habitat restoration component that provides long-term ecological, educational, and/or socioeconomic benefits to the people and their community.
U.S. EPA	Brownfields Program		Grants for a very limited number of pilot demonstration projects for cleanup of contaminated underused industrial sites.
U.S. EPA	Sustainable Development Challenge Grants (SDCG)	206-553-2634	Grants to support communities in establishing partnerships to encourage environmentally and economically sustainable practices.

Tookany/Tacony-Frankford Integrated Watershed Management Plan (TTFIWMP)

5-Year Implementation Plan 2006 – 2011

PWD commitment $18,000,000

This Implementation Plan (IP) builds upon an already significant body of work developed by the Philadelphia Water Department in cooperation with the Tookany/Tacony-Frankford Watershed Partnership. The Tookany/Tacony-Frankford Integrated Watershed Management Plan (TTFIWMP) was completed in the winter of 2005. This planning effort incorporated both regulatory and non-regulatory programs including the Phase I and Phase II stormwater regulations, the PA Act 537 sewage facilities planning program, the PA Act 167 stormwater management program, EPA's Combined Sewer Overflow (CSO) Control Policy and PA DCNR's River Conservation Planning program while also combining the ideas and concerns of watershed stakeholders in order to create a comprehensive vision for restoring this region.

The TTFIWMP included guidelines for implementing the management options identified by our watershed partners for areas outside the City of Philadelphia over the upcoming 20 year planning horizon. Implementation projects and initiatives within the guidelines have undergone intensive screening to determine that they are both cost-effective and feasible under the specific conditions found in the Tookany/Tacony-Frankford Creek watershed.

This implementation plan is designed to provide a more detailed blueprint for implementation of projects within the City of Philadelphia during the initial five-year period (2006-2011), though many projects have already been initiated. This plan represents the first steps in the simultaneous implementation of projects related to Targets A, B, and C. These environmental targets were established to guide the overall implementation strategies while always keeping our eyes on the long-term goals of the program.

Note that each project being implemented will require a feasibility study, followed by conceptual, preliminary, and final design reports that will provide successively more detail.

Planning, Outreach & Reporting

PWD Commitment: $1,000,000

It is imperative that the existing Tookany/Tacony-Frankford Watershed Partnership not only continue to function as a driving force within the watershed, but that it also evolve into an implementation oriented entity to take on the responsibility of executing many of the projects identified during the integrated planning process. These projects have been identified for implementation over a 20 year period, broken into five-year increments. Progress must be tracked and reported in order to illustrate progression as implementation moves forward.

P-1. Maintain Watershed Partnership

In the summer of 2005, the Tookany/Tacony-Frankford Watershed Partnership filed incorporation papers with the federal government in order to evolve its organizational structure from that of a loose alliance of stakeholders into a formal, 501(c)3 non-profit organization. The Partnership has a mission focused on implementation of the plan, and is now structurally aligned to do so. PWD will take part in the new organization, as well as move forward with its own implementation plan. PWD will support the newly formed organization in developing and carrying out future implementation efforts.

Priority Tasks	**Projected Timeline:**
1. Establish Permanent 501c3 Watershed Organization:	End of 2005
2. Develop and secure funding for project implementation: PWD will assist the TTF Partnership in the pursuit of funding for individual project implementation	Begin in 2006
3. Identify and incorporate high-priority/"Marketing" messages from the TTFIWMP Produce a document containing a short list of high-priority messages (e.g., litter and dumping, good housekeeping practices for homes and businesses, etc.) to be included in all community relations work to help support the goals of the plan. (Should include a plan for distribution of the messages, including targeted groups and means of distribution)	2006
4. Incorporate high-priority/"Marketing" messages in all outreach activities: Work interdepartmentally with PWD to incorporate messages in outreach materials. Additionally work with TTF Partnership to achieve the goals for distribution	2006 - 2011

P-2. Track WMP programs and progress

Develop and maintain a performance tracking system for plan progress. This system would track projects and monitored improvements using the indicators from the TTFIWMP.

Priority Tasks	Projected Timeline:
1. Inventory all TTF projects and initiatives related to TTFIWMP implementation, create database of information:	Begin in 2006
2. Utilize database as the clearinghouse for implementation project related information (budget, lead contact, status etc.):	2006-2011
3. Utilize for annual reporting purposes:	Begin in 2007

P-3. Annual report

CDM and OOW staff will collaborate to produce an annual report at the end of each fiscal year.

Priority Tasks	Projected Timeline:
1. Update status of each task proposed in this implementation plan:	Annually, begin 2007
(a) Write recommendations for moving each task forward in the following year:	Annually, begin 2007
2. Initiate Watershed Indicator Status Update:	Biannually, begin 2008
(a) Evaluate all 21 Watershed Indicators, document any changes:	Biannually, begin 2008
(b) Write memo documenting status changes for sharing with watershed partners:	Biannually, begin 2008
3. Update the list of projects proposed, in progress, or completed in the given year:	Annually, begin 2007
4. Monitor status and results for any projects that have been completed within the given year:	Annually, begin 2007

P-4. Update WMP and supporting technical documentation

The TTFIWMP will be updated at the end of the permit cycle. Information in the annual reports will be consolidated, progress will be assessed, and a new 5-year implementation plan will be produced.

Priority Tasks	Projected Timeline:
1. Evaluate Biological Monitoring Data collected in 2010: PWD Biological monitoring program is scheduled to be updated every five years. (Last program update was 2005)	2011
2. Evaluate accomplishments and recommendations of each Annual Report:	2010 - 2011
3. Evaluate Watershed Indicators, update with new information:	Biannually, begin 2008
4. Update TTFIWMP with new information:	2011

Target A

PWD Commitment: $9,100,000

This target is designed to help achieve water quality standards in the stream during dry weather periods. The focus is on the elimination of sources of sewage discharge during dry weather, as well as trash removal and litter prevention.

A-1. Sewer Rehabilitation and Maintenance

Sewers must be assessed to identify segments in need of rehabilitation, particularly where leakage is directly flowing into the stream. In separate sewered areas, a detection program for potential cross-connections is needed in order to eliminate dry weather flows.

Maintenance of sewers includes activities required to keep the system functioning as it was originally designed and constructed. Any reinvestment in the system, including routine maintenance, capital improvements for repair or rehabilitation, inspection activities, and monitoring activities are generally classified as maintenance.

Priority Tasks	**Projected Timeline:**
1. Continue PWD Sewer Inspection and Cleaning Program: a. Identify Sewers in need of Rehabilitation: b. Initiate Sewer repairs: c. Create a memorandum with map showing all problem areas identified: d. Provide information from the stream assessment regarding exposed and/or leaking sewers to sewer maintenance: e. Track and document sewer repairs:	2006 – 2011

A-2. Source Controls

Runoff pollution has severely impacted the stream. Ordinances must be evaluated, updated and enforced in order to ensure the reduction of pollutant sources such as pet waste and dumping. Street sweeping, inlet maintenance and additional NPDES related measures must be enforced.

Priority Tasks	Projected Timeline:
1. Implement 6 Minimum Control Measures for NPDES Stormwater Phase II:	2006 - 2011
2. Continue PWD Inlet Cleaning & Maintenance Program:	2006 - 2011
(a) Work with Inlet Maintenance team to develop an ongoing schedule of maintenance for this watershed area:	
3. Continue City of Philadelphia Street Sweeping Program:	2006 - 2011
(a) Meet with Philadelphia Streets Department to gather information regarding current street sweeping programs and scheduling:	
(b) Work with the Philadelphia Streets Department to develop a city-wide schedule of sweeping:	
4. Review Enforcement of City of Philadelphia Pet Waste Disposal and Litter/Dumping Related Ordinances:	Mid-2006
(a) Develop recommendations for improvement:	2007
(b) Discuss changes with implementing agencies:	Mid-2007
(c) Identify access points with the Fairmount Park Commission:	2007
(d) Monitor progress:	2008 - 2011
5. Continue and expand upon outreach and assistance programs to other municipalities:	2006 – 2011
(a) Outreach to municipalities regarding status of plan implementation:	
(b) Workshops and programs to share information about Stormwater BMPs:	
6. Continue the efforts of the Philadelphia Inter-Governmental Scrap and Tire Yard Task Force:	2006 – 2011
Program response to complaints about operation of scrap metal and auto salvage businesses operating in violation of regulations	

A-3. Stream Clean-up

Target A is also associated with improving the esthetic quality of the stream so that it can be viewed and treasured as a resource. Stream clean-ups are a way to achieve this while also involving residents and volunteers in the process.

The Waterways Restoration Unit was created in order to assist with the removal of litter and heavy debris from streams, maintain habitat improvements (fish ladders, FGM, elimination of plunge pools).

Priority Tasks	**Projected Timeline:**
1. Continue the efforts of the Waterways Restoration Unit: (a) Inspect and assess the condition of sewerage infrastructure along streams: (b) Identify, prioritize, & maintain a list of obstructions, aesthetic nuisances, and debris removal needs: (c) Develop and maintain a corrective action plan: (d) Investigate ROW complaints and update action plan:	2006 - 2011

Target B

PWD Commitment: $2,300,000

This target is focused on improving the in-stream conditions of the Tookany/Tacony-Frankford Creek. Implementation projects are aimed at habitat improvements as well as measures to provide the opportunity for organisms to avoid high velocities during storms. Improvements to the number, health, and diversity of the benthic invertebrate and fish species are anticipated as a result of these measures.

B-1. Stream Restoration

A high priority is placed on the creation of a restoration master plan for the Tookany/Tacony-Frankford Watershed. The plan will include recommendations from the wetland assessment program, information from the stream assessments, WRU activities, and input from the Fairmount Park Commission. The resulting document could be as simple as a large map showing outlines and key elevations for all the projects together – which would then become a check list for the creation of a detailed design for a given reach. A schedule should be outlined for high priority locations in stream restoration.

Priority Tasks	Projected Timeline:
1. Develop an FGM-based stream restoration master plan:	Mid-2006 through 2007
(a) Demonstration Project #1 – Mill Run at 7th and Cheltenham: Include bank revetment and channel modifications to the stormwater outfall. The goal is to clear the concrete pad at the outfall and re-grade 90 linear feet of the natural channel bottom and stabilize the stream banks.	2006
(b) Demonstration Project #2 – Awbury Arboretum: This multi-phased project includes; riparian buffer restoration , wetland restoration, meadow enhancement, stream daylighting, and stormwater diversion	2005-2007
(c) Demonstration Project #3 – Whitaker Ave: Include stream bank stabilization using soil bioengineering, and natural channel design measures that protect infrastructure and the environment	2006-2008
(d) Develop specific projects for large-scale restoration: Conceptual design of large scale stream restoration should be developed based on recommendations of FGM study	2008 - 2011

B-2. Wetlands Restoration and Construction

There are currently several large projects taking place (Riverfront development along the Delaware River, and the Airport expansion) that will require significant mitigation of wetlands and open water. Stream restoration provides an ideal opportunity to provide projects that serve as mitigation for the planned development projects, and that fit within the overall goals of the watershed plan.

Priority Tasks	**Projected Timeline:**
1. Complete Wetland Master Plan – including prioritization of restoration opportunities: (a) Initiate Demonstration Project #1: i. Design Demonstration Project #1: ii. Construct Demonstration Project #1:	2006 - 2011

B-3. Protect & Enhance Riparian Corridors

It is imperative that PWD and the TTF Watershed Partnership continue to work closely with the Fairmount Park Commission in order to meet the mutual goal of protecting and enhancing the riparian corridor along the Tookany/Tacony-Frankford Creek.

Priority Tasks	**Projected Timeline:**
1. Assist Fairmount Park Commission with Restoration Projects: PWD can offer assistance through project prioritization with the FGM and wetlands assessment data, project design and pursuit of funding	2006 - 2011
2. Invasive species controls: The FPC ES&ED has implemented invasive species control program in Fairmount Park portion of the stream corridor; recommended that initiative be expanded to the remaining natural areas of the corridor.	2006 - 2011
3. Assist Fairmount Park Commission with volunteer clean-up programs: Work with TTF Partnership to support clean-up efforts	2006 - 2011

Target C

PWD Commitment: $5,600,000

This target is designed to improve water quality standards in the stream during wet weather periods. These projects are designed to reduce and improve the quality of storm water discharges and to reduce CSOs.

C-1. CSO Controls

The use of Real Time Control is designed to utilize the maximum in-system storage capacity of the sewer system by using a computer controlled CSO outfall/regulator gate that uses level monitors to control the position of the dry-weather outlet (DWO) gate and tide gate at each location. This allows the capture and delivery to the treatment works of flow at the maximum rate at which it can be treated.

Priority Tasks	Projected Timeline:
1. Real Time Control Implementation	2006 - 2011

C-2. Stormwater Management Regulations

Act 167 Stormwater Management Planning is currently underway within this watershed area. The resulting model ordinance will allow for watershed-wide management of stormwater runoff. The city of Philadelphia must implement and enforce regulations city-wide to reflect the ordinance adopted by their Montgomery County counterparts in the watershed.

Priority Tasks	Projected Timeline:
1. Work with Montgomery County on completion of Act 167 Stormwater Management Planning and creation of model ordinance for the TTF Watershed:	2006 - 2008
2. Enforce new city-wide stormwater regulations:	2006 - 2011
3. Establish review procedures and staff for implementation of Urban Stormwater BMP manual:	2006
4. Complete SW Rate Structure Review and make Recommendations: (Cost of stormwater management should be fully reflected in rates charged to homeowners, businesses, and land owners in the form of stormwater fees.)	2006 - 2010
5. Begin implementing city-wide SW Rate Structure Improvements:	2010

C-3. Stormwater BMP Projects

"Model" Stormwater BMP demonstration projects will be designed and constructed illustrating the various types of on-site stormwater management techniques that can be applied in urban areas. The goal is to provide local examples of BMPs recommended under the new stormwater regulations that reduce the volume of runoff entering the sewer system as well as reduce the pollutant loads within the runoff whenever possible.

Initial load reduction targets for parameters such as stormwater flow, metals, total suspended solids, and bacteria have been set at 20%, with the goal of continuous reassessment of the load reduction target as projects are implemented.

Priority Tasks	**Projected Timeline:**
1. Complete BMP implementation plan, site list & prioritization of projects:	2006 - 2008
2. Demonstration Projects:	
(a) Martin Luther King Jr. High School: Will result in detaining and/or infiltrating first 1.5 inches of runoff from parking lots, thus diverting nearly 2.5 million gallons of runoff from combined sewer system each year	2006 - 2011
(b) Bureau of Laboratory Services Low Impact Development (LID) Retrofit Project: This retrofit could include the implementation of multiple BMPs, including an infiltration trench, cisterns, a green roof, and a bioretention system.	2006 - 2011
(c) Implement Demonstration Project #3: Demonstration projects will include the implementation of BMPs such as median infiltration, porous pavement or green roof technology.	2006 - 2011
(d) Implement Demonstration Project #4:	2006 - 2011
(e) Implement Demonstration Project #5:	2006 - 2011
(f) Implement inlet & roof leader disconnect project (Located at Awbury Arboretum):	2006 - 2011
(g) Initiate a Targeted Rain Barrel Program PWD and the TTF Partnership have already conducted a Rain Barrel Pilot Project. Based upon successes and lessons learned, a second program would be targeted to an individual sewershed and monitored for the reduction of stormwater contribution.	2006 - 2011

Priority Tasks	**Projected Timeline:**
(h) Initiate and/or invigorate TreeVitalize program in the TTF Watershed	2006 - 2007
i. Set 5 year goals for tree planting	2007 - 2008
ii. Plant trees	2008 - 2011
3. Initiate incentive grant programs for stormwater BMP implementation city-wide	2007 - 2010

Section 10: Discussion and Analysis

Section 1 Introduction

To meet the regulatory requirements and long-term goals of its CSO, stormwater, and drinking water source protection programs, The Philadelphia Water Department (PWD) has embraced a comprehensive watershed characterization, planning, and management program. Watershed management fosters the coordinated implementation of programs to control sources of pollution, reduce polluted runoff, and foster managed growth in the city and surrounding areas, while protecting the region's drinking water supplies, fishing and other recreational activities, and preserving sensitive natural resources such as parks and streams. PWD has helped form watershed partnerships including surrounding urban and suburban communities to explore regional cooperation based on an understanding of the impact of land use and human activities on water quality.

Coordination of these different programs has been greatly facilitated by PWD's recent creation of the Office of Watersheds (OOW). This newly formed organization is composed of staff from the PWD's planning and research, CSO, collector systems, laboratory services, and other key functional groups, allowing the newly established organization to combine resources to realize the common goal of watershed protection. OOW is responsible for characterization and analysis of existing conditions in local watersheds to provide a basis for long-term watershed planning and management.

OOW is developing a series of watershed management programs on each of its watersheds. Cobbs Creek is the first watershed to complete a management plan. This report contains a series of technical documents that form the technical basis for the Cobbs Creek Integrated Watershed Management Plan (CCIWMP), released in 2004. The report characterizes the land use, geology, soils, topography, demographics, meteorology, hydrology, water quality, ecology, fluvial geomorphology, and pollutant loads found in the Darby-Cobbs Creek watershed. It presents and discusses data collected through the end of 2002. The report is not intended as a single, comprehensive document, but rather a compilation of background documents that can be periodically updated as additional field work or data analysis is completed. The sections of the report were written at different times by a variety of groups, and no attempt at consistency in style or formatting has been made. Some sections of the report, including wetlands and fluvial geomorphology, are incorporated by reference to other reports.

Section 2 Characterization of the Study Area

2.1 Watershed Description and Demographics

The Darby-Cobbs watershed is defined as the land area that drains to the mouth of Darby Creek at the Delaware Estuary, encompassing approximately 80 square miles in southeastern Pennsylvania. This area includes portions of Chester, Delaware, Montgomery, and Philadelphia Counties. The watershed may be subdivided into the Cobbs Creek, Darby Creek, and Tinicum subwatersheds. Figures 2-1 and 2-2 include the watershed boundaries, hydrologic features, and political boundaries. Much of the information is based on the U.S. Census Bureau's TIGER (Topologically Integrated Geographic Encoding and Referencing) database.

Cobbs Creek drains approximately 14,500 acres or 27% of the total watershed area. The upper portions and headwaters of Cobbs Creek, including East and West Branch Indian Creek, include portions of Philadelphia, Montgomery, and Delaware Counties. The lower portion of Cobbs Creek watershed, including the lower mainstem and Naylors Run, drains parts of Philadelphia and Delaware Counties. Cobbs Creek discharges to Darby Creek.

The Darby Creek watershed drains approximately 29,000 acres or 55% of the total study area. The watershed is located primarily in Delaware County. The northwest corner of the watershed, including the headwaters of the mainstem, is located in Chester County. Darby Creek has a number of small tributaries, including Little Darby Creek, Ithan Creek, and Foxes Run.

The Darby-Cobbs watershed discharges to the Delaware River through the wetlands of the Tinicum Refuge. The Tinicum watershed includes portions of Philadelphia and Delaware Counties and totals 9800 acres or 18% of the total. Much of the area consists of low-lying wetlands, including the John Heinz National Wildlife Refuge. Named streams in the subwatershed include Hermesprota, Muckinipattis, and Stony Creeks.

In a relatively undisturbed watershed, watershed boundaries follow topographic high points or contours. The U.S. Geological Survey (USGS) has further subdivided the Darby-Cobbs watershed based on topography, as shown in Figure 2-3. These USGS subwatersheds are determined from the land area draining to a particular point of interest, such as a stream confluence or gauging site. These boundaries allow initial determinations of drainage areas and modeling elements. However, it is important in the urban environment to include the effects of man-made changes to natural drainage patterns.

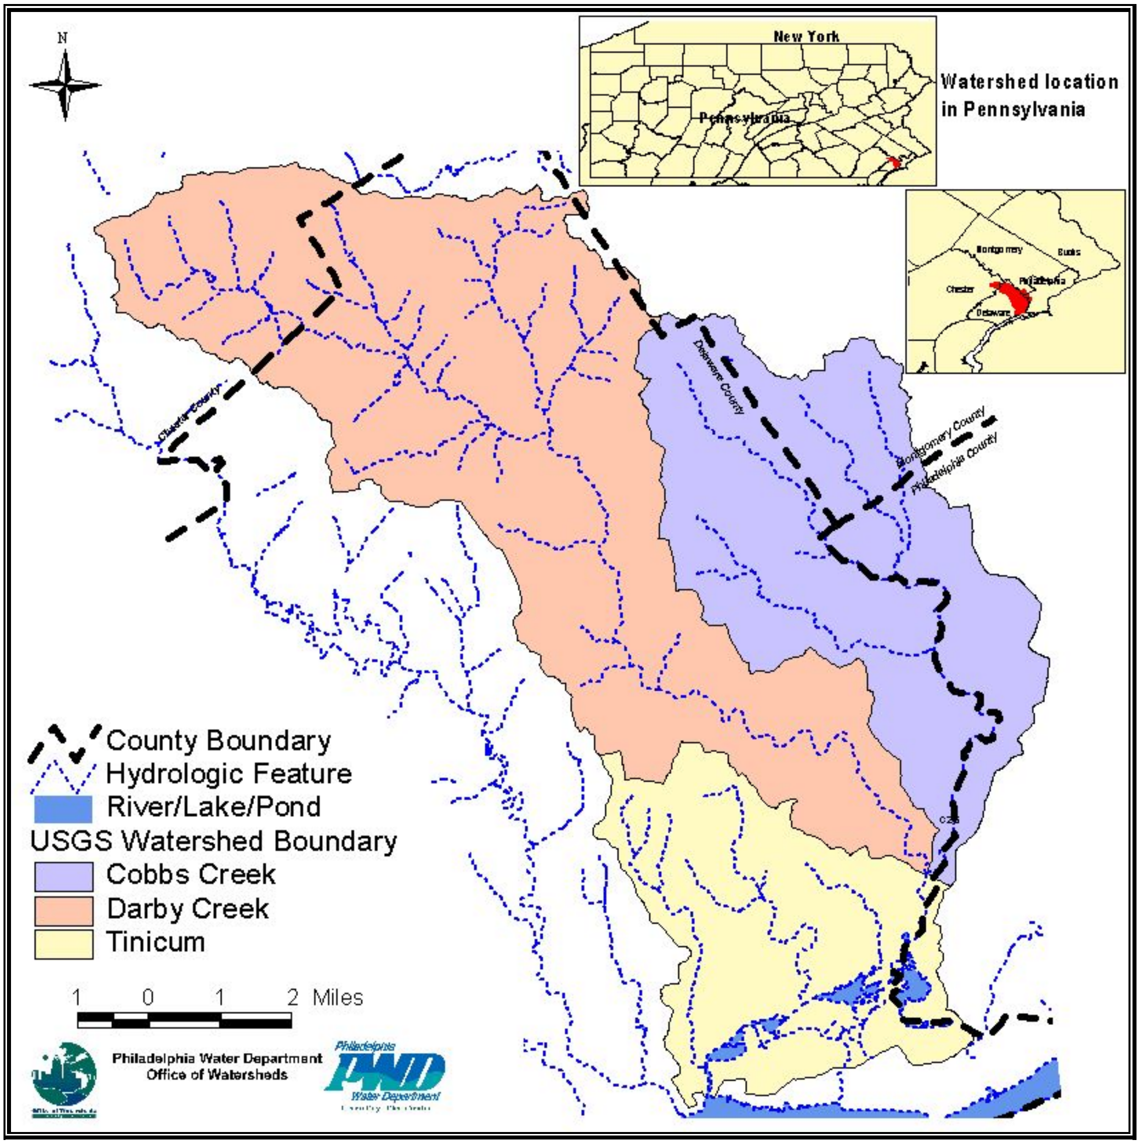

Figure 2-1 Darby-Cobbs Study Watershed

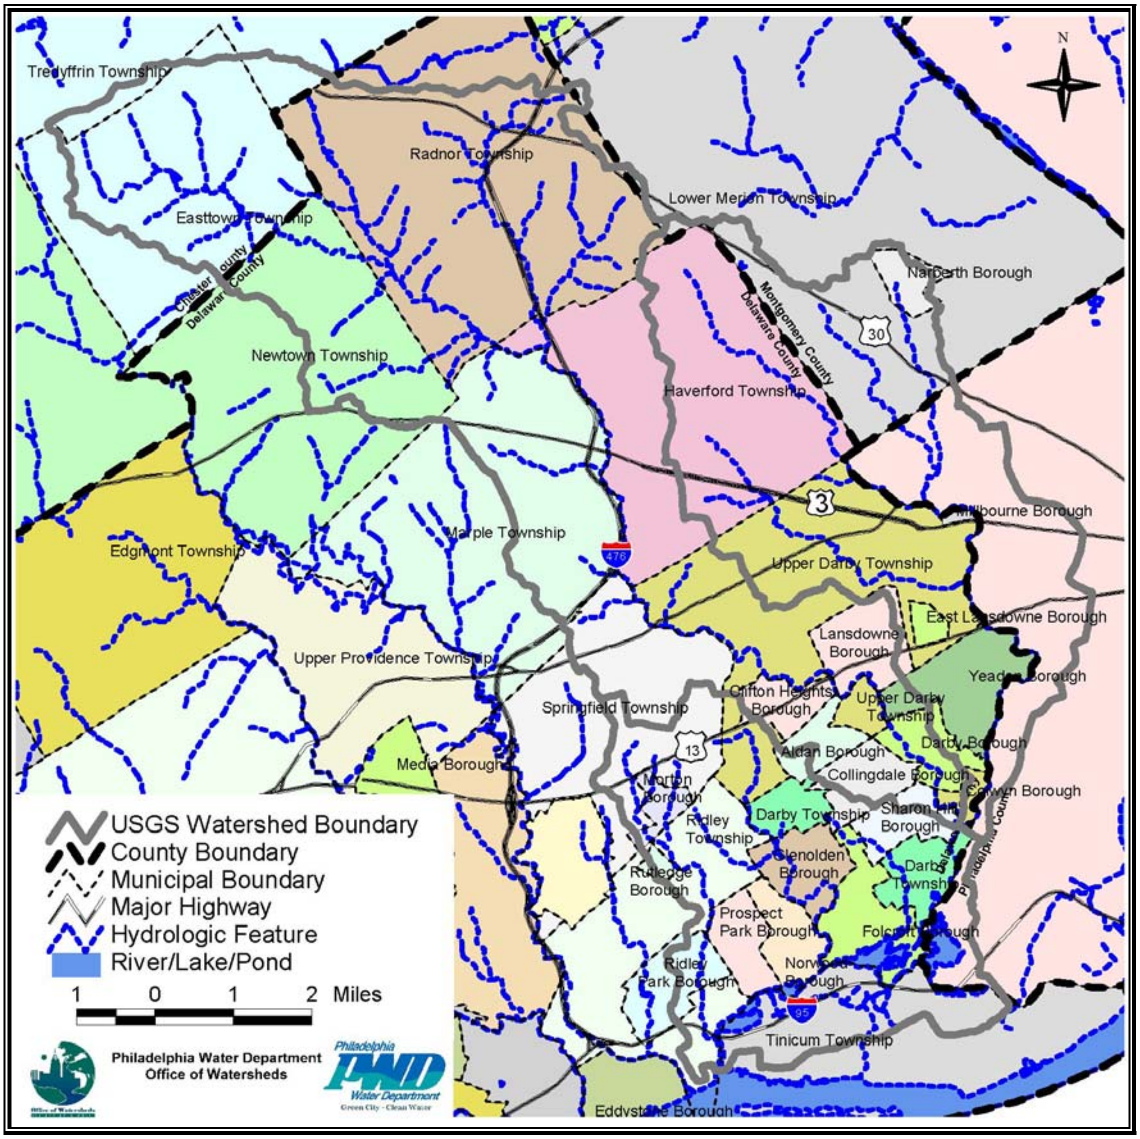

Figure 2-2 Darby-Cobbs Study Area

Geology and Soils

Geology and soils play a role in the hydrology, water quality, and ecology of a watershed. The Darby-Cobbs watershed falls within the Coastal Plain and Piedmont physiographic provinces. Geologic formations on the surface in the area include gneiss, schist, and serpentine formations in most of the watershed (Piedmont) and layers of sediment in the downstream reaches (Coastal Plain) as shown in Figure 2-4. Soils in the upper portions of the Darby Creek subwatershed include loams and silty loams, as shown in Figure 2-5. Soil in much of the rest of the watershed is classified as urban or made land and is not representative of the original undisturbed soil. Wetland soils are present in the Tinicum area.

Demographic Information

Population density and other demographic information in the watershed are available from the results of the 2000 census. Approximately 500,000 people live within the drainage area of the Darby and Cobbs Creeks. Figure 2-6 shows the population density in the watershed at the census block level. Spatial trends in population correspond closely to land use, with multi-family row homes displaying the greatest population density of 20 people per acre or more, single-family homes displaying a lower density, and other land use types displaying the lowest density. In addition to population data, the U.S. Census Bureau provides a range of socioeconomic data that are often useful in watershed planning and general planning studies. Median household income and mean home value (Figures 2-7 and 2-8) are two of the many sample datasets provided.

Figure 2-3 USGS Topographic Subwatersheds

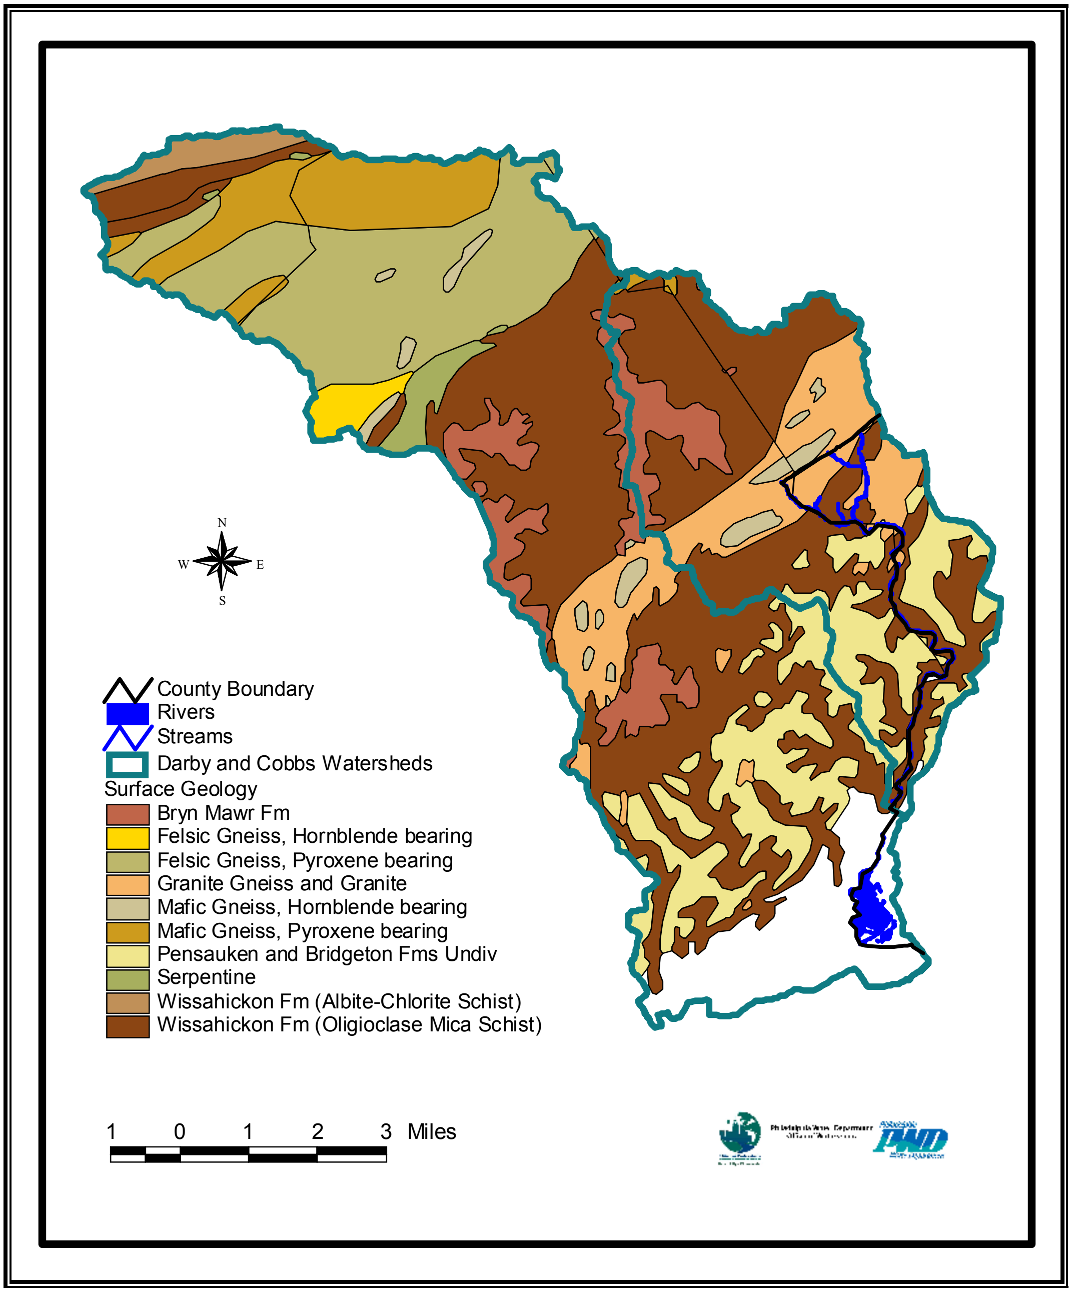

Figure 2-4 Surface Geologic Formations

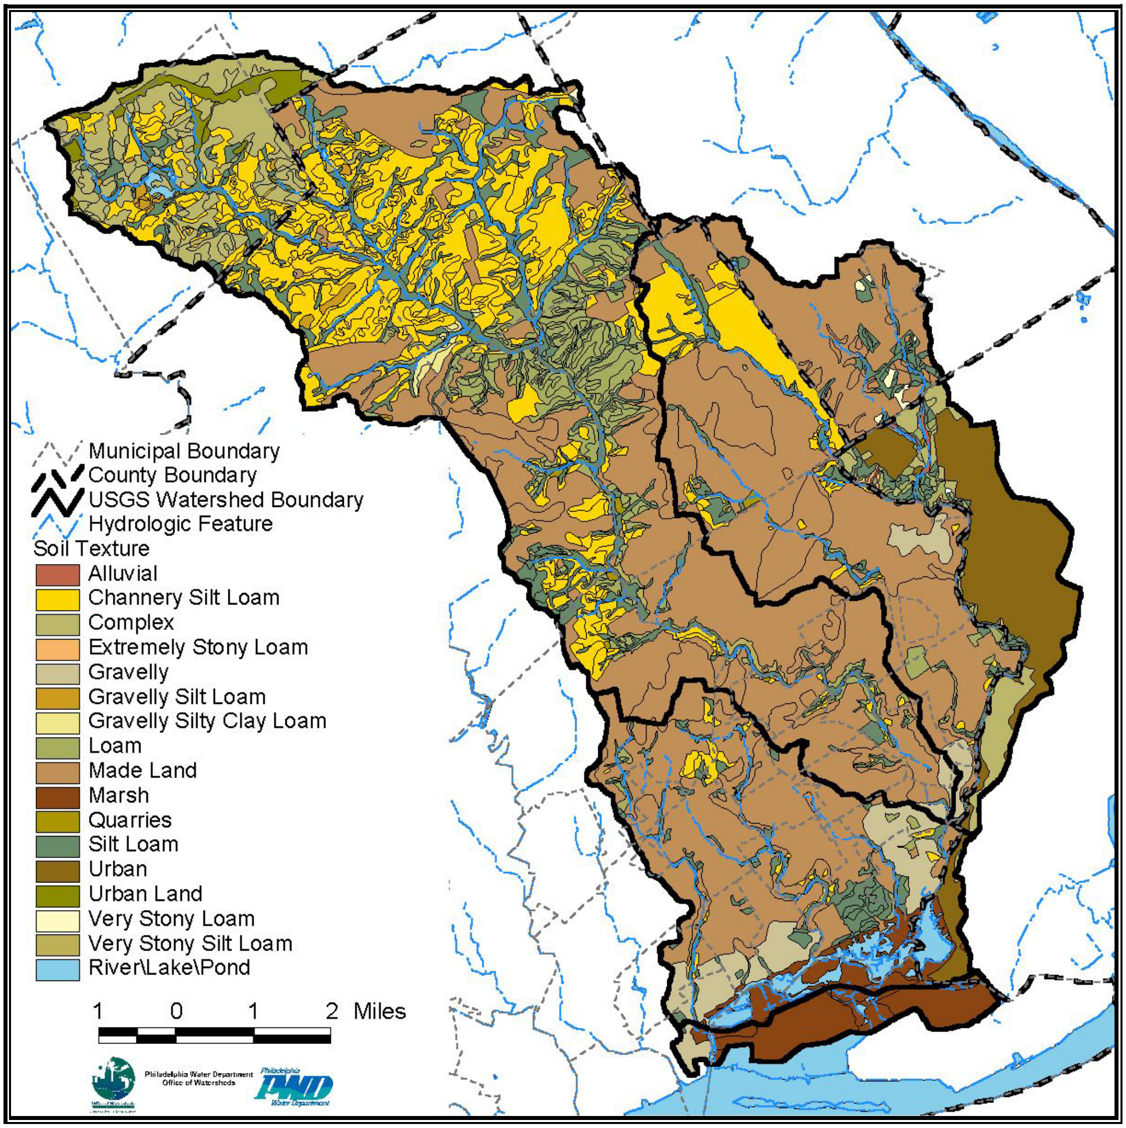

Figure 2-5 Soil Types in the Darby-Cobbs Watershed

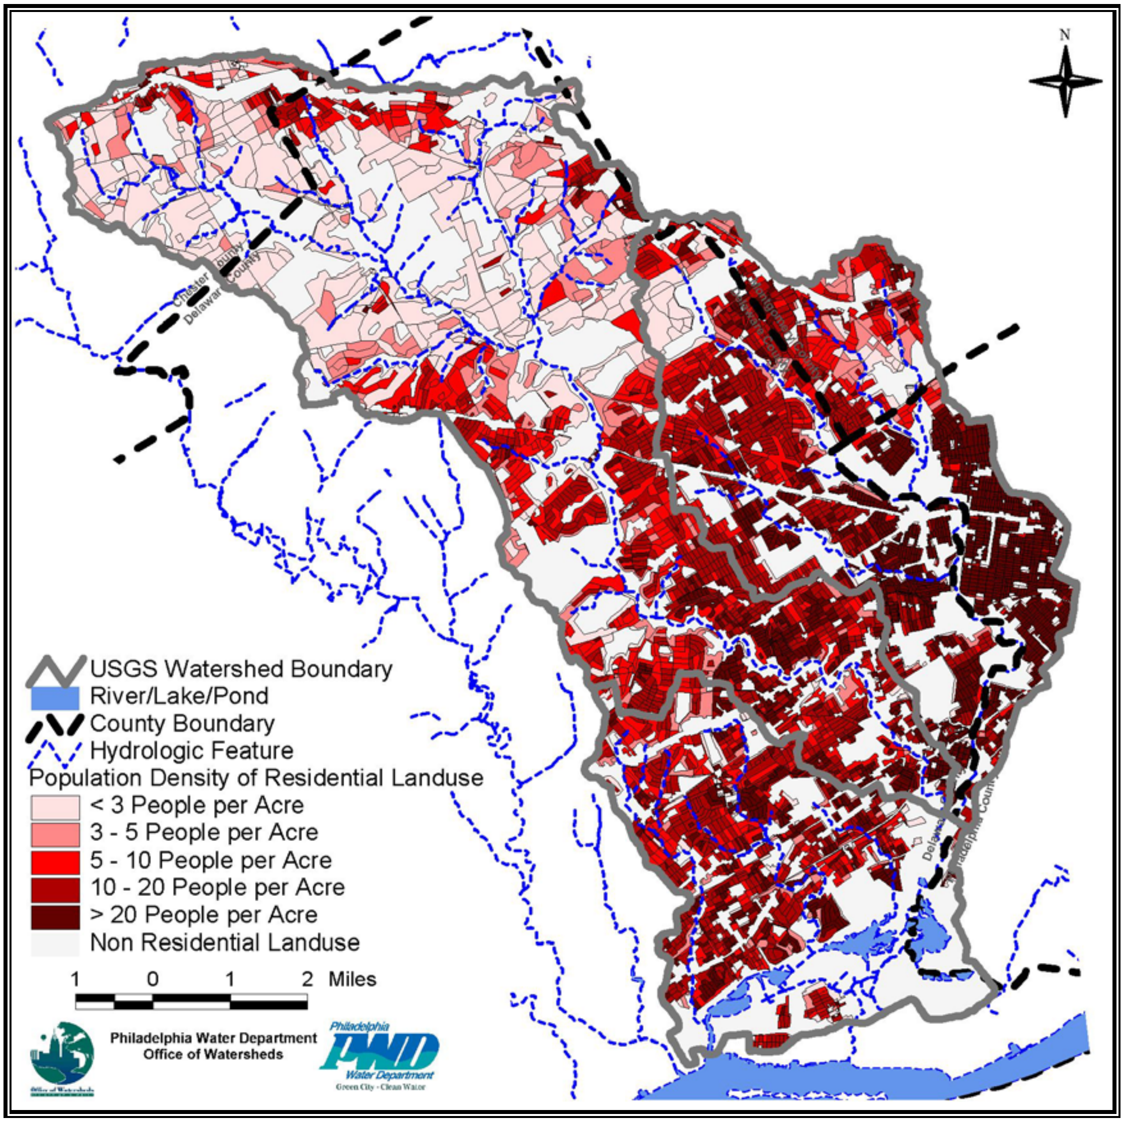

Figure 2-6 Population Density Based on 2000 Census Data

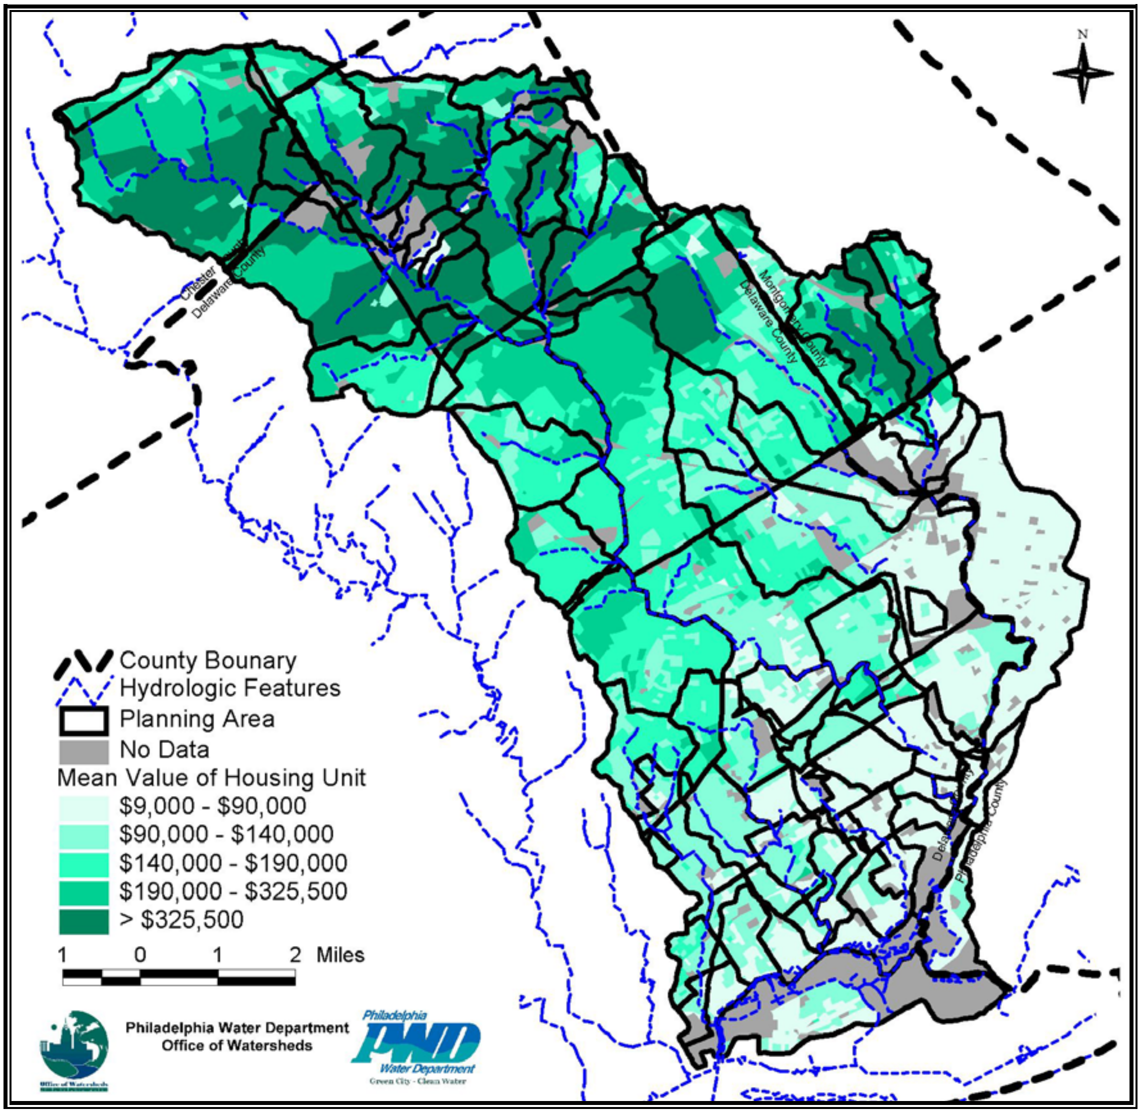

Figure 2-7 Mean Home Value

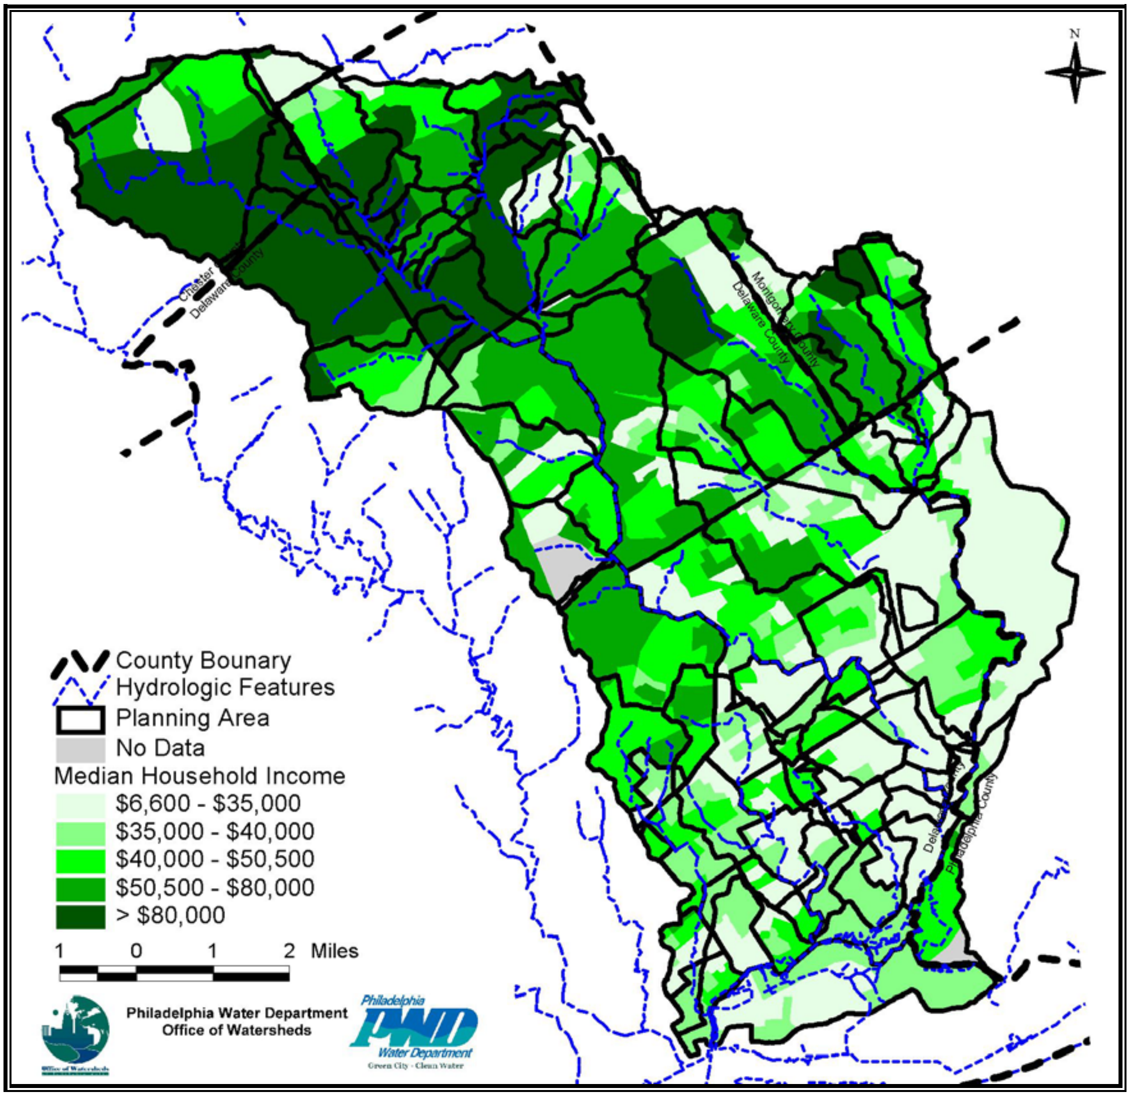

Figure 2-8 Mean Household Income

2.2 Land Use

Land use information for the Darby and Cobbs Creeks Watershed was obtained from the Delaware Valley Regional Planning Commission (DVRPC). Figure 2-9 is the current land use map for the study area. The upper reaches and headwaters of the Cobbs Creek watershed are characterized primarily by a mix of multiple-family and detached single-family residential areas. The lower portions of the Cobbs Creek watershed are primarily high-density residential areas in the City of Philadelphia and a mix of high- and low-density residential areas in the Delaware County portion, with commercial areas along highway corridors. Riparian lands within the City consist mainly of relatively undisturbed parkland.

Land uses in the Darby Creek watershed consist primarily of single- and multiple-family residential areas in the lower portions and a combination of single-family residential, commercial, park land, and golf course uses in the upper reaches. A large commercial area is located along the northern edge of the watershed in Chester and Delaware Counties. The Tinicum watershed consists of residential and commercial development to the northwest and undeveloped wetlands and marshes to the southeast.

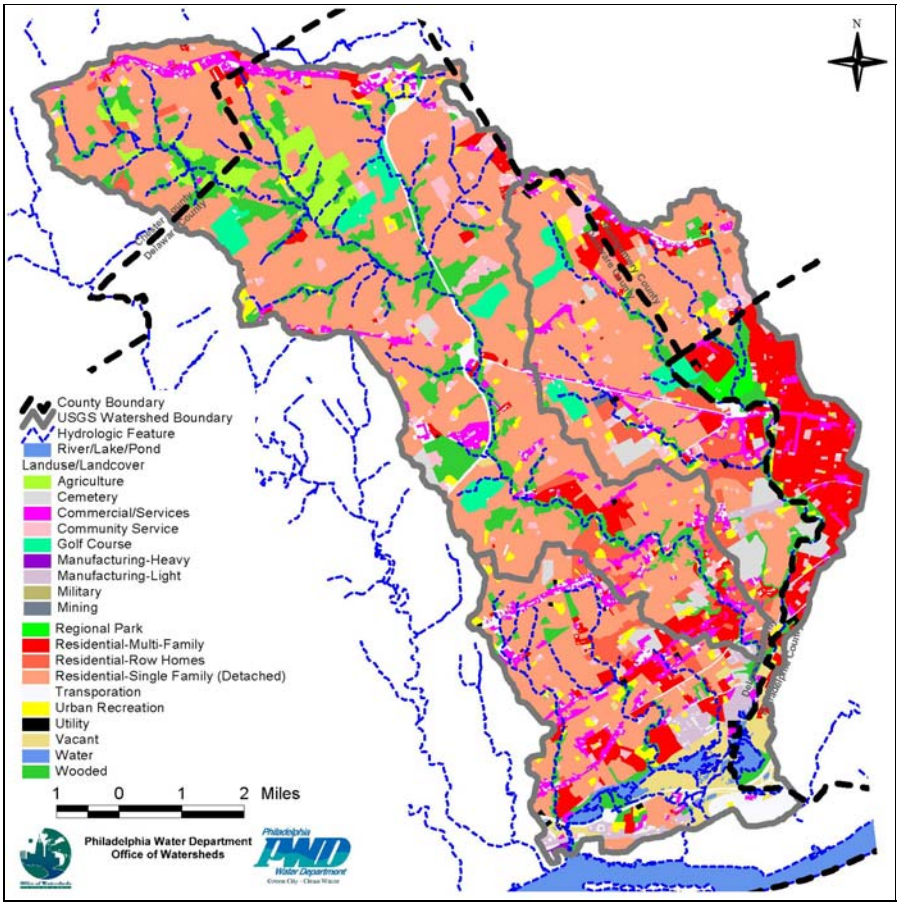

Figure 2-9 Land Use

One of the primary indicators of watershed "health" is the percent of impervious cover in the watershed. Based on numerous research efforts, studies and observations, a general categorization of watersheds has been widely applied to watershed management based on percent impervious cover (Schueler 1995). These are summarized in Table 2-1. Table 2-2 shows that the entire watershed is above 25% impervious cover, placing it in the "Non-Supporting" category of stream health.

Table 2-1 Impervious Cover as an Indicator of Stream Health (Schueler 1995)

Characteristic	Sensitive	Degrading	Non-Supporting
Percent Impervious Cover	0% to 10%	11% to 25%	26% to 100%
Channel Stability	Stable	Unstable	Highly Unstable
Water Quality	Good to Excellent	Fair to Good	Fair to Poor
Stream Biodiversity	Good to Excellent	Fair to Good	Poor
Pollutants of Concern	Sediment and temperature only	Also nutrients and metals	Also bacteria

Table 2-2 Estimated Total Impervious Cover

Watershed	County	Area (ac)	% Impervious
Cobbs	Delaware	8,041	46.7%
Cobbs	Montgomery	2,644	40.6%
Cobbs	Philadelphia	3,562	60.2%
Darby	Chester	4,217	25.7%
Darby	Delaware	24,503	38.7%
Darby	Montgomery	70	44.2%
Darby	Philadelphia	558	66.7%
Tinicum	Delaware	5,811	49.4%

Table 2-3 summarizes several of the impacts of traditional development on streams and watersheds, most of which are created by the addition of impervious cover across the portions of the land surface. Figures 2-10 and 2-11 illustrate the changes to the volume and duration of runoff as well as the physical stream channel before and after development. Figure 2-10 also illustrates the benefits of using various BMP's and low impervious techniques to manage stormwater. As Figure 2-11 depicts, traditional development within a watershed may raise the elevation of the floodplain limit and reduce summer low flows when compared to predevelopment conditions.

Table 2-3 Impacts of Traditional Development on Watershed Resources (Schueler 1995)

Changes in Stream Hydrology	Changes in Stream Morphology
▪ Increased magnitude/frequency of severe floods ▪ Increased frequency of erosive bankfull and sub-bankfull floods ▪ Reduced ground water recharge ▪ Higher flow velocities during storm events	▪ Channel widening and downcutting ▪ Streambank erosion ▪ Channel scour ▪ Shifting bars of coarse sediments ▪ Imbedding of stream substrate ▪ Loss of pool/riffle structure ▪ Stream enclosure or channelization

Changes in Stream Water Quality	Changes in Stream Ecology
▪ Instream pulse of sediment during construction ▪ Nutrient loads promote stream and lake algae growth ▪ Bacteria contamination during dry and wet weather ▪ Higher loads of organic matter ▪ Higher concentrations of metals, hydrocarbons, and priority pollutants ▪ Stream warming ▪ Trash and debris jams	▪ Reduced or eliminated riparian buffer ▪ Shift in external production to internal production ▪ Reduced diversity of aquatic insects ▪ Reduced diversity of fish ▪ Creation of barriers to fish migration ▪ Degradation of wetlands, riparian zones and springs ▪ Decline in amphibian populations

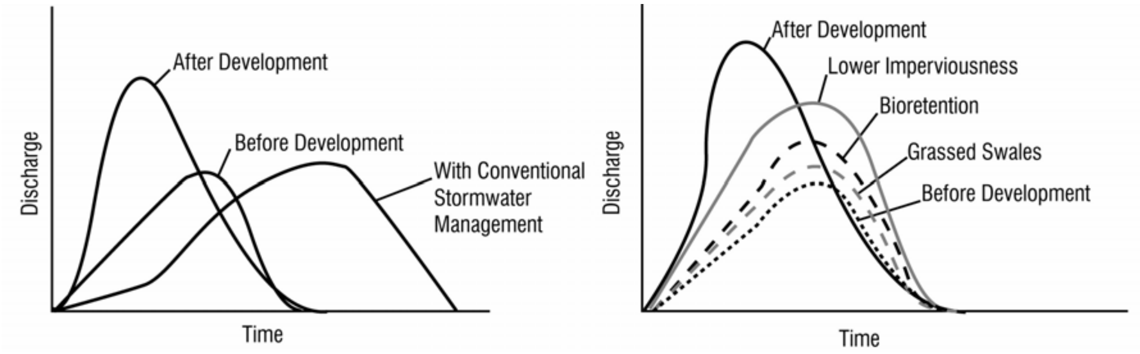

Figure 2-10: Comparison of volume and duration of stormwater runoff before and after land development, and reductions in runoff from BMP’s. (Prince George’s County Department of Environmental Resources et. al., undated)

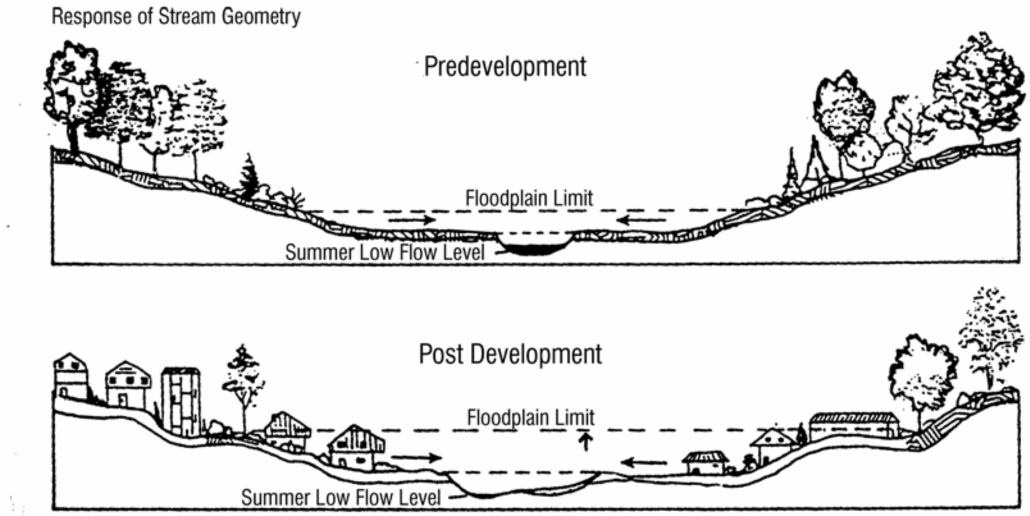

Figure 2-11: Potential impacts of development on stream flow and flooding. (Schueler 1995(a), and Schueler 1987)

Section 3 Sampling and Monitoring Program

Background

PWD's Office of Watersheds (OOW) has carried out an extensive sampling and monitoring program to characterize conditions in the Darby and Cobbs Creeks watershed. The program is designed to document the condition of aquatic resources and to provide information for the planning process needed to meet regulatory requirements imposed by EPA and PADEP. The program includes hydrologic, water quality, biological, habitat, and fluvial geomorphological aspects. OOW is well suited to carry out the program because it merges the goals of the city's stormwater, combined sewer overflow, and source water protection programs into a single unit dedicated to watershed-wide characterization and planning.

Under the provisions of the Clean Water Act, the National Pollutant Discharge Elimination System (NPDES) program requires permits for point sources that discharge to waters of the United States. In the Darby and Cobbs Creeks watershed, stormwater outfalls, wet weather sewer overflow points, and wastewater treatment plant discharges to surface waters are classified as point sources and are regulated by NPDES.

EPA's Combined Sewer Overflow Control Policy, published in 1994, provides the national framework for regulation of CSOs under NPDES. The Policy guides municipalities and state and Federal permitting agencies in meeting the pollution control goals of the CWA in as flexible and cost-effective a manner as possible. As part of the program, communities serviced by combined sewer systems are required to develop long-term CSO control plans (LTCPs) that will result in full compliance with the CWA in the long term, including attainment of water quality standards. PWD completed its LTCP in 1997 and is currently implementing its provisions. The strong focus of the National CSO Policy on meeting water quality standards is a main driver behind PWD's water quality sampling and monitoring program.

Regulation of stormwater outfalls under the NPDES program requires operators of medium and large municipal stormwater systems or MS4s, such as the separate-sewered portions of the Darby and Cobbs Creeks watershed, to obtain a permit for discharges and to develop a stormwater management plan to minimize pollution loads in runoff over the long term. Partially in administration of this program, PADEP assigns designated uses to water bodies in the state and performs ongoing assessment of the condition of the water bodies to determine whether the uses are met and to document any improvement or degradation. These assessments are performed primarily with biological assessments based on the EPA's Rapid Biomonitoring Protocols (RBPs) for benthic invertebrates and fish. Water bodies that do not meet their designated uses are classified as unattained and are included on the state listing of impaired waters under section 303(d) of the CWA.

Cobbs Creek and its tributaries are designated warm water fisheries. Darby Creek is designated a cold water fishery above PA Route 3 and a trout stocking fishery below Route 3. Muckinipattis and Stony Creeks in the Tinicum subwatershed are designated warm water fisheries. All of the Cobbs watershed and the lower portions of the Darby watershed are classified as unattained by PADEP. For this reason, the stormwater permit for the City of Philadelphia specifies that the state of the aquatic resource must be evaluated periodically. Because PADEP has endorsed biomonitoring as a means of determining attainment of uses, PWD periodically performs RBPs in the Cobbs watershed and has assisted PADEP on assessments in the Darby watershed.

OOW is responsible for characterization and analysis of existing conditions in local watersheds to provide a basis for long-term watershed planning and management. The extensive sampling and monitoring program described in this section is designed to provide the data needed for the long-term planning process.

Summary of Sampling and Monitoring

PWD’s Office of Watersheds (OOW) and Bureau of Laboratory Services (BLS) have planned and carried out an extensive sampling and monitoring program to characterize conditions in the Darby and Cobbs Creeks watershed. The program includes hydrologic, water quality, biological, habitat, and fluvial geomorphological aspects. OOW is well suited to administer the program because it merges the goals of the city’s stormwater, combined sewer overflow, and source water protection in a single unit dedicated to watershed-wide characterization and planning.

Sampling and monitoring follow the Quality Assurance Project Plan (QAPP) and Standard Operating Protocols (SOPs) prepared by BLS. These documents cover the elements of quality assurance, including field and laboratory procedures, chain of custody, holding times, collection of blanks and duplicates, and health and safety. They are intended to help the program achieve a level of quality assurance and control that is acceptable to regulatory agencies.

Tables 3-1 and 3-2 summarize the types, amounts, and dates of recent sampling and monitoring performed by PWD, PADEP, and USGS. A river mile-based naming convention is followed for sampling and monitoring sites located along waterways in the watershed. The naming convention includes three letters and three or more numbers which denote the watershed, stream, and distance from the mouth of the stream. For example, site DCC-110 is located as follows:

- “DC” stands for the Darby-Cobbs watershed.
- “C” stands for Cobbs Creek.
- “110” places the site 1.10 miles upstream of the mouth of Cobbs Creek, where it flows into Darby Creek.

Hydrologic and Outfall Monitoring

Hydrologic monitoring includes a system of precipitation gauges and measurement of flows at outfall points. Characterization of hydrologic and hydraulic data is presented in Section 4.

Precipitation data are available from the National Oceanography and Atmospheric Administration (NOAA) and from local gauges operated by PWD and other organizations. NOAA's gauge at the Philadelphia International Airport, located in southeastern Philadelphia, has over 100 years of hourly precipitation data; the period of record runs from January 3, 1902 through the present. Additional precipitation data can be obtained from PWD's network of 23 rain gauges throughout the city; these data are available in 15-minute increments from the early 1990's to the present. Five of the City gauges are located in or near the Darby and Cobbs Creeks watershed, as shown in Figure 3-1.

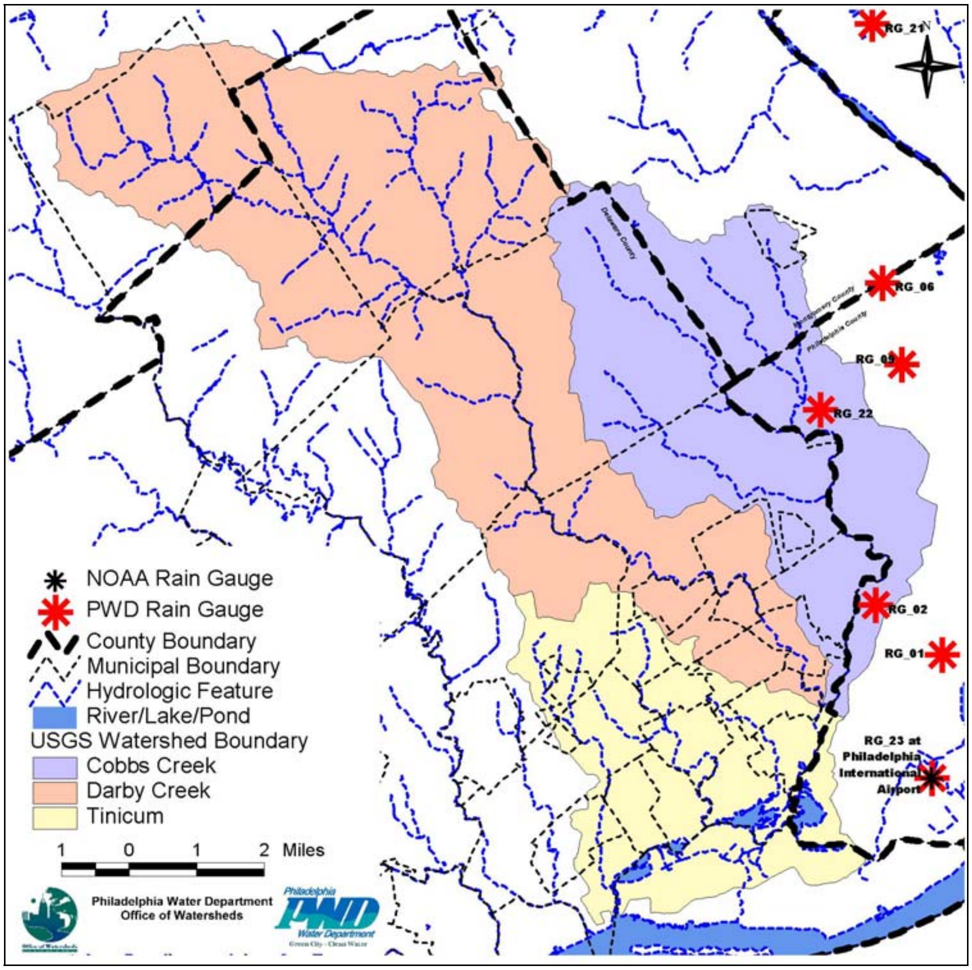

Figure 3-1 City Rain Gauges In or Near the Watershed

PWD maintains real-time sewer monitors in the Cobbs Creek system. At these points, monitors are typically present in the trunk sewer just above the regulator and in the outfall pipe itself. The magnitude and quality of discharges from the city's CSO outfalls are determined by a combination of this monitored data and calibrated computer models.

Water Quality Sampling and Monitoring

A range of water quality samples were collected between 1999 and 2001 at eleven sites in the watershed. The sites are listed in Table 3-3 and are shown on Figure 3-2. Three different types of sampling were performed as discussed below. Parameters were chosen because state water quality criteria apply to them or because they are known or suspected to be important in urban watersheds. The parameters sampled during each type of sampling are listed in Table 3-4. Water quality in each reach and section of the watershed is characterized in Section 5.

The sampling and analysis program meets AMSA (2002) et al. recommendations for the minimum criteria that should form the basis for impairment listings:

- Data collected during the previous five years may be considered to represent current conditions.
- At least ten temporally independent samples should be collected and analyzed for a given parameter.
- "A two-year minimum data set is recommended to account for inter-year variation, and the sample set should be distributed over a minimum of two seasons to account for inter-seasonal variation."
- "No more than two-thirds of the samples should be collected in any one year."
- "Samples collected fewer than four days apart at the same riverine location should be considered one sample event."
- "Samples collected within 200 meters [about 0.1 miles] of each other will be considered the same station or location." This convention was followed except where two sampling sites were chosen to represent conditions upstream and downstream of a modification such as a dam.

Discrete Sampling. Discrete samples were collected at 11 sites in both wet and dry weather at an interval of two weeks to one month. During discrete sampling, each sampling site along a stream is sampled once during the course of a few hours. The purpose of discrete sampling is initial characterization of water quality under both dry and wet conditions and identification of parameters of possible concern. Discrete sampling follows the Standard Operating Protocol "Field Procedures for Grab Sampling".

Wet Weather Event Sampling. At three sites, a series of samples was collected over the course of several wet weather events. During wet weather sampling, several discrete samples are collected just before and during the course of a wet weather event. The data allow characterization of water quality responses to stormwater runoff and wet weather sewer overflows.

Continuous Measurement. Continuous data were collected at six sites for a total of over 12,900 hours. During continuous sampling, data for selected parameters are collected at 15-minute increments by a submerged instrument (YSI Sonde 6600) over approximately two weeks. The instrument measures parameters using voltage and diffusion-based probes rather than physically collecting samples. Parameters measured include stage, dissolved oxygen, temperature, pH, turbidity. To the author's knowledge, this type of equipment has not been employed extensively in urban streams in the past. This method produces 96 measurements per parameter every 24 hours, but cost and quality control are more challenging compared to discrete sampling. The SOP for continuous sampling describes the extensive quality control and assurance procedures applied to the data.

Biological and Habitat Monitoring

Benthic invertebrate, fish, and habitat assessments were carried out by PWD in the Cobbs Creek watershed between December 1999 and April 2000. Bioassessment procedures are summarized below. The results of the bioassessments are presented in Section 6.

Fish Sampling. Five sampling stations were chosen on Cobbs Creek; three on the main stem and two sites on the smaller tributaries, West Branch Indian Creek and Naylor's Run. Prior to the main stem analysis, the Academy of Natural Sciences (ANS) completed their assessment on the three tributaries and were interested in completing a watershed analysis on Cobbs Creek. Data from these sites were provided to the Philadelphia Water Department and the Pennsylvania Department Of Environmental Protection (PADEP). Using EPA protocols for rapid bioassessment, a reach was measured using a graduated tape and both upstream and downstream portions were blocked off using standard seining nets. Two Coffelt backpack electro-shockers were operated at 50-75 watts direct current (DC). Fish were collected using D-frame dip nets, identified to species and total length of each individual was obtained.

Benthic Invertebrate Sampling. On December 6th-7th, 1999, the Pennsylvania Department of Environmental Protection (PADEP), Office of Watersheds and the Bureau of Laboratory Services conducted Rapid Bioassessment Protocols (RBP III) on seven sites (Figure 3.2) in the Cobbs Creek watershed. Using EPA guidelines, macroinvertebrates were collected by placing a standard D-frame dipnet at the downstream portion of a riffle. The substrate was then kicked and scraped manually one meter from the net aperture to remove all benthic species. This procedure was repeated at another riffle location with less flow. Specimens were then preserved in 95% ETOH (ethyl alcohol) and returned to the laboratory in polyethylene containers. In the laboratory, samples were placed in a 11″ x 14″ gridded (numbered) pan and random "plugs" were examined until 100 individuals were collected. Macroinvertebrates were identified to genus and population estimates were calculated.

Habitat Assessment. Prior to the benthic procedures, habitat assessments at the seven sites were completed based on the Stream Classification Guidelines for Wisconsin (Ball, 1982) and Methods of Evaluating Stream, Riparian, and Biotic Conditions (Platts et al., 1983). Reference conditions were used to normalize the assessment to the "best attainable" situation. Habitat parameters are separated into primary, secondary, and tertiary parameters. Primary parameters are those that characterize the stream "microscale" habitat and have the greatest direct influence on the structure of the indigenous communities. Secondary parameters measure the "macroscale" habitat such as channel morphology characteristics. Tertiary parameters evaluate riparian and bank structure and comprise three categories: (1) bank vegetative protection, (2) grazing or other disruptive pressure, and (3) and riparian vegetative zone width. Additional habitat assessment was also carried out by the fluvial geomorphological study team using customized parameters from the Rapid Steam Assessment Technique (RSAT, Washington Metropolitan council of Governments) and the Qualitative Habitat Evaluation Index (Ohio).

Fluvial Geomorphological Monitoring

Assessment of fluvial geomorphological conditions in the watershed was performed to support future stream channel, streambank, and habitat restoration initiatives. The results of the assessments are presented in Section 8.

Approximately eleven miles of stream cross sections and banks were assessed within the study area. A team of three environmental scientists walked the length of Cobbs Creek and Indian Creek and characterized channel morphology, disturbance, stability, and habitat parameters. The team surveyed cross sections of Cobbs Creek and Indian Creek to characterize the morphological features of the channel, provide a template for hydrologic and hydraulic modeling, and serve as a baseline for assessing channel bank and bed changes (erosion and sediment accretion). Features surveyed included breaks in slope, bankfull stage, water surface and thalweg. A permanent bench mark was established on one side of the cross section to mark the location and relative elevation.

The assessment team installed bank pins and scour chains, providing PWD the opportunity to measure and quantify stream bank erosion and streambed degradation/aggradation. As the bank begins to erode, the pins protrude further and further into the steam. After a storm event, technicians can locate the pins and measure the distance they protrude and compare that to the previous distance. This 'depth' of erosion can then by multiplied by the length and height of the eroded bank to quantify the cubic yards of sediment being deposited into the channel. Over time these measurements can be correlated to different storm events to estimate the rate and quantity of sediment being deposited into the system. Similarly, scour chains are placed into the bed of the stream and allow one to measure the amount of bed scour or sediment accretion occurring during each storm event. Both the bank erosion pins and the bed scour chains are easy to maintain and measure and provide solid data that can be used to estimate degradation and prioritize capital improvement projects.

Section 4 Characterization of Hydrology

This section examines the components of the hydrologic cycle for the Darby-Cobbs watershed. The hydrologic cycle includes precipitation, evaporation, infiltration into soil, stormwater runoff over the land surface and in the sewer system, surface water flow in streams, and groundwater. The different types of sewer systems that serve the area are discussed in this section because they are an important part of the hydrologic cycle in the urban environment.

4.1 Components of the Urban Hydrologic Cycle

One way to develop an understanding of the hydrologic cycle is to develop a water balance. The balance tries to characterize the flow of water into and out of the "system" by assigning estimated rates of flow for all of the components of the cycle. It is also important to understand that the natural water cycle components of precipitation, evapotranspiration (ET), infiltration, stream baseflow, and stormwater runoff must be supplemented by the many artificial interventions related to urban water, wastewater, and stormwater systems.

The first step in developing a water balance for the urban hydrologic cycle is to identify the system boundaries and the pathways that allow water to cross those boundaries. For the Darby and Cobbs Creeks watershed, the system includes the land surface within the watershed boundaries, structures and vegetation on the surface, and the subsurface beneath the watershed. Inputs to the system are precipitation and outside sources of potable water. Outflows from the system include streamflow through the system outlet, evaporation and transpiration losses to the atmosphere, and flows of wastewater to the system outlet. In addition, it is possible for subsurface exchanges to occur across the boundary.

Precipitation that falls on the land surface may evaporate, be taken up by plants and lost through transpiration, flow directly to a water body over land or through a storm sewer system, or enter a combined sewer system. In combined sewer systems, a portion of flow is captured by the sanitary sewer system and a portion reaches surface water. Flow in streams consists of stormwater runoff, combined sewer overflow, delayed wet weather inputs through shallow groundwater, and a baseflow component due to the discharge of groundwater to the creek during dry weather. A portion of potable water pumped in from outside the watershed enters the sanitary sewer system and is sent to outside treatment plants, and a portion is lost to consumptive uses.

The system inflows and outflows can be split into a number of components. These are shown below as a simple, input equals output water balance with the many natural and anthropogenic components of a typical urban water cycle.

Inflows: P + OPW + WW/IND Rech + EDR + WW Disch

Outflows: RO + SWW+ GWW + EDW + BF + OWD + ET where:

P is the average precipitation at the Philadelphia gage

OPW is the outside potable water brought in

WW/IND Rech is the wastewater and industrial discharge back to groundwater

EDR is the estimated domestic recharge from private septic systems

WW Disch is the discharge of water to creeks from larger wastewater plants or industrial facilities

RO is the surface water runoff component of precipitation

SWW is the withdrawal of water from creek, primarily for public water supply and industrial use

GWW is the groundwater withdrawal from public water supply or industrial wells

EDW is the estimated domestic withdrawal of groundwater from private wells

BF is the median baseflow of streams

OWD is the discharge of wastewater to outside plant

ET is the evaporation and transpiration of water (including error)

4.1.1 Precipitation

P + OPW + WW/IND Rech + EDR + WW Disch = RO + SWW+ GWW + EDW + BF + OWD + ET

Precipitation is the primary, natural inflow to the hydrologic system. Precipitation data used to estimate this component are available from the National Oceanography and Atmospheric Administration (NOAA) and from local gauges operated by PWD and other organizations. NOAA's gauge at the Philadelphia International Airport, located in southeastern Philadelphia, has over 100 years of hourly precipitation data covering a period of record from January 3, 1902 through the present. The average annual rainfall in the Philadelphia area based upon the airport gauge is 41 inches. Most months have average precipitation totals of 3-4 inches. The driest season is late fall, and the wettest is late summer when thunderstorms are common (Table 4-1). Average temperatures during the winter months are above the freezing point during the day and below the freezing point at night. Snow and snowmelt events occur, but it is rare for a snow pack to accumulate and last through the season.

Additional precipitation data can be obtained from PWD's network of 23 rain gauges throughout the city; these data are available in 15-minute increments from the early 1990's to the present. Five of the City gauges are located in or near the Darby and Cobbs Creeks watershed, as shown in Figure 4-1. Data from these gauges provide precipitation at a higher level of spatial and temporal detail.

Table 4-1 Average Monthly Precipitation, Temperature, and Potential Evaporation

		Average Temperature		
Month	Average Precipitation (in)	High (°F)	Low (°F)	Potential Evaporation (in/month)
January	3.3	39.2	24.4	2.1*
February	2.9	42.1	26.1	2.1*
March	3.6	50.9	33.1	2.1
April	3.4	63	42.6	4.5
May	3.5	73.2	52.9	5.4
June	3.6	81.9	61.7	6.3
July	4.1	86.4	67.5	6.6
August	4.3	84.6	66.2	5.7
September	3.4	77.4	58.6	4.2
October	2.8	66.6	46.9	2.7
November	3.0	55	37.6	2.1
December	3.3	43.5	28.6	2.1*

* estimated

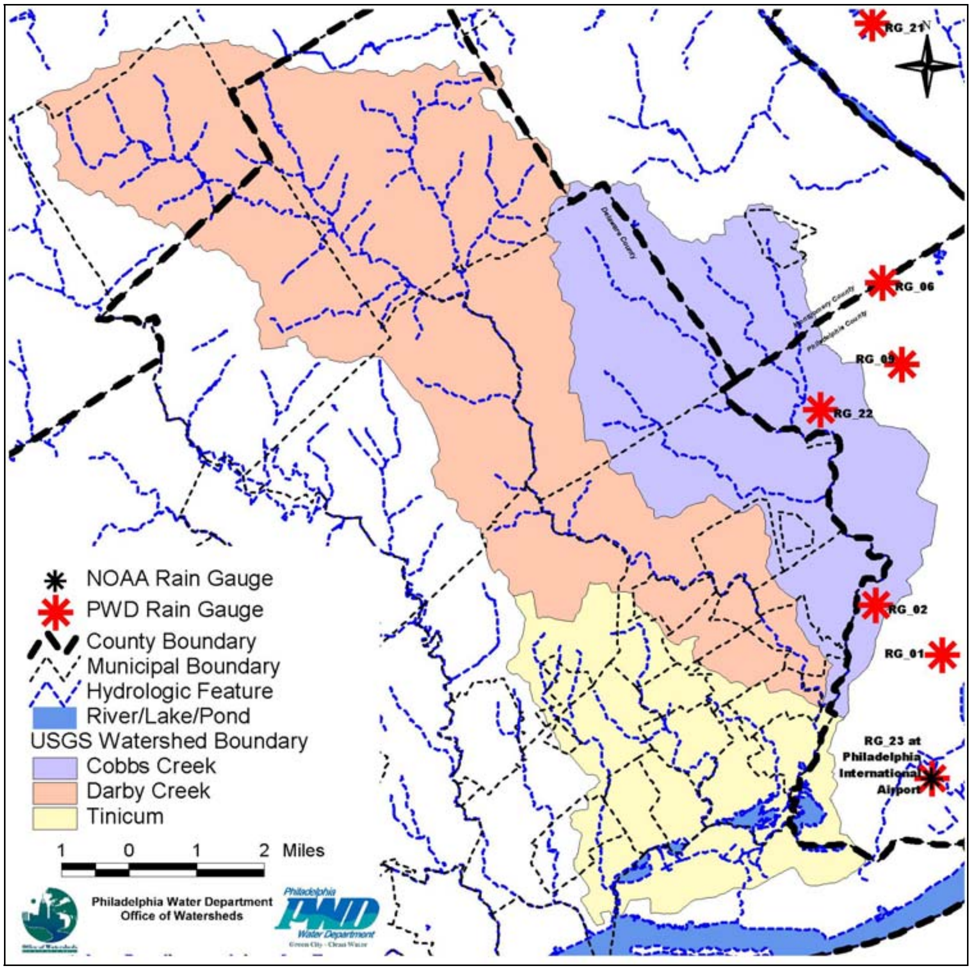

Figure 4-1 City Rain Gauges In or Near the Watershed

4.1.2 Outside Potable Water

P + OPW + WW/IND Rech + EDR + WW Disch = RO + SWW+ GWW + EDW + BF + OWD + ET

The watershed is generally supplied with drinking water from sources of water outside the watershed. For the Philadelphia portion of the watershed, water is "imported" into the watershed through the drinking water distribution system from raw water drawn from the Schuylkill and Delaware Rivers. For the outside communities, most of the water is supplied by Aqua America (formerly Philadelphia Suburban) and Pennsylvania American from Crum and Ridley Creeks.

For the Darby-Cobbs watershed, most of this water never leaves the urban infrastructure used to transmit drinking water to and convey wastewater from homes to wastewater treatment plants outside the watershed. In this sense, this component of the watershed water balance is not critical to the development of the watershed management plan.

4.1.3 Wastewater and Industrial Recharge to Groundwater

P + OPW + WW/IND Rech + EDR + WW Disch = RO + SWW+ GWW + EDW + BF + OWD + ET

This component represents water that has been used in homes or industry, has been treated, and is subsequently discharged back to the groundwater, thus making it an "inflow" component. Available data suggest that there are no such discharges within the watershed. For this reason, this component is not included in the table of estimated flows for components of the hydrologic cycle.

4.1.4 Estimated Domestic Recharge

P + OPW + WW/IND Rech + EDR + WW Disch = RO + SWW+ GWW + EDW + BF + OWD + ET

This component represents water that has been used in homes and is subsequently discharged to septic systems. In this way, it represents an inflow component to the groundwater portion of the hydrologic cycle. Although there are some septic system areas in the watershed, most of the population is served by sanitary sewers, making this a very small component of the water cycle. Counts of septic systems are based on 1990 U.S. census data and are highly uncertain. Based on this information and an estimate of 50 gallons of sewage per person per day discharged to septic systems, this component represents 56,000 gallons per day in the Cobbs watershed and 205,000 gallons per day in the Darby watershed upstream of the confluence. These flows may also be expressed as 0.05 inches per year for the Cobbs and 0.11 inches per year for the Darby.

4.1.5 Wastewater Discharges to the Stream

P + OPW + WW/IND Rech + EDR + WW Disch = RO + SWW+ GWW + EDW + BF + OWD + ET

This component represents water that has been used in homes or industry, has been treated, and is subsequently discharged back into the stream, thus making it an "inflow" component. Available data suggest that there are no discharges to Cobbs Creek, and only a few, very small permitted discharges on the Darby Creek. For this reason, this component can be considered insignificantly small in comparison to the main inflow components and is not included in the table of estimated flows for components of the hydrologic cycle.

4.1.6 Runoff

P + OPW + WW/IND Rech + EDR + WW Disch = RO + SWW+ GWW + EDW + BF + OWD + ET

Precipitation is the primary natural inflow component of the water cycle. This inflow component generally results in three, natural outflow components: evapotranspiration (ET), runoff, and infiltration into the groundwater. Thus runoff is one of the major, natural outflow components to be estimated.

The amount of stormwater runoff depends on a variety of factors, including rainfall intensity, surface ponding of rain, ground slope, and, most importantly, the imperviousness of the ground surface. The amount of impervious cover follows patterns of land use and population density because manmade structures and pavement are the cause of impervious surface. Estimates of imperviousness can be further refined by examining the relative proportion of impervious surfaces on the USGS quadrangles and in aerial photos. Because of the urbanized nature of the watershed, runoff is almost always collected into a sewer system. Depending on the location within the watershed, it can either be discharged through storm sewers or through combined sewers. Therefore, this component is further discussed under the Runoff/Outside Wastewater Discharge component below.

4.1.7 Surface Water Withdrawals

P + OPW + WW/IND Rech + EDR + WW Disch = RO + SWW+ GWW + EDW + BF + OWD + ET

This outflow component represents intakes for water withdrawal for drinking water or industrial use. For the Darby-Cobbs watershed, no permitted withdrawals exist on either river, and this component can be left out of the water balance table.

4.1.8 Groundwater Withdrawals

P + OPW + WW/IND Rech + EDR + WW Disch = RO + SWW+ GWW + EDW + BF + OWD + ET

This outflow component represents groundwater pumping for industrial use or public water supply. There are no public supply or industrial wells of significance in the watershed, and this component can be left out of the water balance table.

4.1.9 Estimated Domestic Withdrawals

P + OPW + WW/IND Rech + EDR + WW Disch = RO + SWW+ GWW + EDW + BF + OWD + ET

The entire watershed is served by a public water supply distribution system. There are no areas where domestic wells form a significant source of supply, and groundwater pumping can be ignored as a significant component of the water balance.

4.1.10 Baseflow

P + OPW + WW/IND Rech + EDR + WW Disch = RO + SWW+ GWW + EDW + BF + OWD + ET

Precipitation results in three, natural outflow components: evapotranspiration (ET), runoff, and infiltration into the groundwater. In most shallow groundwater systems, the surface watershed generally corresponds to the recharge and discharge area of the groundwater system. This means that infiltration enters the groundwater aquifer, and flows underground to the stream for eventual discharge as stream baseflow. This allows us to equate infiltration with stream baseflow, making it possible to estimate infiltration through baseflow separation techniques at stream gauges.

In pervious areas, the amount of water that infiltrates the soil, and thus reappears as stream baseflow, depends on soil properties. At the beginning of a storm, when soil pores are usually not saturated, the moisture content of the soil determines the amount of infiltration that can occur. Capillary suction forces caused by surface tension in the pores also affect the infiltration rate. The size, shape, and distribution of soil pores determine the rate at which a soil can transmit flow in both the unsaturated and saturated states. The infiltration rate decreases as soil pores become filled with water during the course of the storm. When the pores become completely saturated, the water transmission rate reaches an equilibrium and is referred to as the saturated hydraulic conductivity or soil permeability. Sandy soils allow the highest infiltration rates, while soils with high clay content allow very slow infiltration; loams and mixtures of different soil types fall between the two extremes. Table 4-2 lists typical values for saturated hydraulic conductivity, capillary suction, and initial moisture deficit for a range of NRCS soil textures (Handbook of Hydrology, D.R. Maidment, Editor in Chief, McGraw-Hill, Inc., 1993, pp 5.1-5.39.) Soil textures found in the watershed were discussed in Section 1. It is important to remember that in urbanized areas, the original soils have often been disturbed, compacted, or replaced by fill material that may have different hydraulic characteristics from the undisturbed state.

Table 4-2 Typical Hydraulic Properties of Different NRCS Soil Textures

	Saturated Hydraulic Conductivity (in/hr)	Capillary Suction (in)	Initial Moisture Deficit (fraction)
Sand	9.3	2.0	0.35
Loamy Sand	2.4	2.4	0.31
Sandy Loam	0.86	4.3	0.25
Loam	0.52	3.5	0.19
Silt Loam	0.27	6.6	0.17
Sandy Clay Loam	0.12	8.6	0.14
Clay Loam	0.08	8.2	0.15
Silty Clay Loam	0.08	10.8	0.11
Sandy Clay	0.05	9.4	0.091
Silty Clay	0.04	11.5	0.092
Clay	0.02	12.5	0.079

The simplest way to compute infiltration, which is generally difficult to measure and/or model, is to perform baseflow separation on streamflow. In this way, if baseflow is assumed to equal infiltration, then the infiltration component can be directly balanced by the baseflow component. For the Darby-Cobbs watershed, this approach results in an annual infiltration/baseflow component of 8.1 inches per year in Cobbs Creek and 14.4 inches per year Darby. This difference is a good indication of the more impervious nature of the Cobbs Creek watershed when compared to the Darby Creek watershed.

Table 4-3 Summary of Hydrograph Separation Results Over the Period of Record

Gauge	Mean Total Flow (in/yr)	Mean Baseflow (in/yr)	Mean Runoff (in/yr)	Baseflow (% of Total Flow)	Runoff (% of Rainfall)
French Creek 01475127	20.3	12.9	7.4	64	18
Cobbs Creek 01475550	18.8	8.1	10.7	43	26
Darby Creek D/S 01475510	23.3	14.5	8.9	62	21
Darby Creek U/S 01475300	23.7	15.6	8.1	66	20

4.1.11 Runoff and Outside Wastewater Discharges

P + OPW + WW/IND Rech + EDR + WW Disch = RO + SWW+ GWW + EDW + BF + OWD + ET

Almost the entire watershed is served by sewers. Depending on the area of the watershed, stormwater may either enter surface water directly, enter a combined sewer, or enter a separate storm sewer system. Unsewered areas, where runoff flows overland to the stream system, make up approximately 5-10% of the Darby and Cobbs Creeks watershed. These areas serve mainly natural areas located along the stream corridor, such as Cobbs Creek Park, where storm sewers are not necessary. Some areas in western Delaware County are also unsewered.

Sewered areas within the watershed are served by two types of sewer systems. In areas served by combined sanitary and storm sewers, the sewer system conveys flows to an interceptor sewer and later to a wastewater treatment plant under dry weather conditions. During larger wet weather events, a combined flow regulator structure diverts a portion of the flow to a receiving stream. Portions of Philadelphia County, including 20% of the Cobbs Creek subwatershed, are serviced by combined sewers. The City of Philadelphia has 38 regulator structures within the watershed, as shown in Figure 4-2. 25 of these structures are instrumented with continuous flow monitors.

Except for park lands (about 5% of the Cobbs watershed), the rest of the watershed area is serviced by separate sanitary and storm sewer systems. In these areas, the storm sewer system conveys most surface runoff directly to a receiving stream. A portion of stormwater, known as infiltration and inflow, enters the sanitary sewer system during wet weather. The occurrence of CSO and the categorization of sampling periods as wet or dry are discussed later in the section.

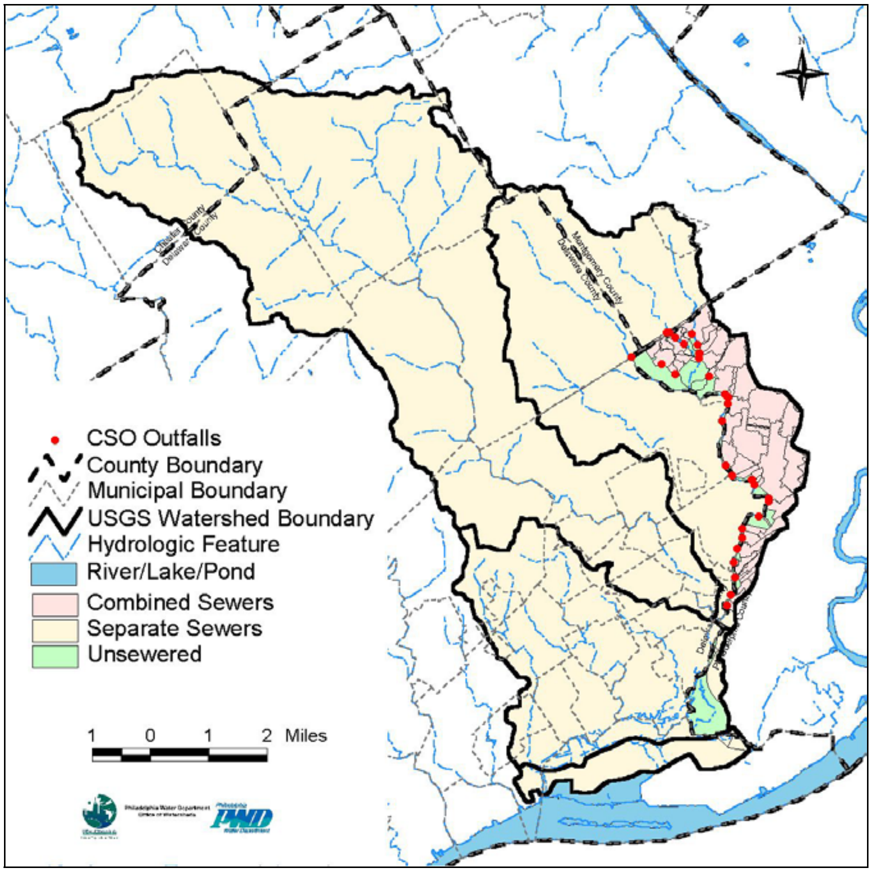

Figure 4-2 Types of Sewer Service and Locations of Regulator Structures

Hydrologic and Hydraulic Modeling

Estimates of the volume, frequency, and duration of combined sewer overflows are based on results from calibrated hydrologic and hydraulic models. Model calibration depends on data from PWD's extensive rainfall gauge network and sewer monitoring program.

The hydraulic and hydrologic model development process focused the greatest detail on the interceptor sewer system, using the USEPA Storm Water Management Model (SWMM) Extended Transport (EXTRAN) module. The EXTRAN module of SWMM was chosen as the most appropriate tool for the interceptor model. This model is the most widely used and accepted model for interceptor and CSO modeling (Roesner et al., 1988). It accurately simulates complex hydraulic conditions that occur in combined sewer interceptors, including unsteady flow, surcharging, branched and looped pipe networks, pumps, orifices, and weirs.

To estimate the treatment rates of the combined sewer regulator structures, or the maximum flow that can pass through the regulator's connector pipe to the interceptor in wet weather, the initial sewershed hydrologic representation is in the form of ramp-function hydrographs loaded directly to EXTRAN. Later in the process, the combined sewersheds are modeled in the United States Army Corps of Engineers (USACOE)

Storage, Treatment, Overflow, Runoff Model (STORM), providing a more detailed characterization of the hydrologic response of the system with an algorithm for the computation of rainfall excess. STORM thereby provides a wet weather characterization that is useful for assessment of impacts and for planning-level alternatives screening used to establish the direction for detailed facility planning and design.

STORM is run in continuous simulation mode using a long-term rainfall record. There is general agreement in the modeling community that single event or design storm simulations are not sufficient for the generation of long-term CSO statistics, including average annual frequency and volume (EPA, 1993). Continuous simulation more thoroughly accounts for antecedent conditions and inter-event conditions within the system.

Discharge Monitoring Report and Annual Report Generation

The EXTRAN model is used for the hydraulic characterization of interceptors and regulators to a fine level of detail. The model supports estimates of sewer system overflow characteristics using STORM. This characterization of the combined sewersheds and trunk sewer system is at the correct level of detail for the hydrologic and hydraulic characterization requirements of NPDES permits for CSO and sanitary sewer facilities and for the alternatives analyses required for long term CSO control planning.

Quarterly discharge monitoring reports (DMR's) are required under the NPDES permit system. In addition, the results of the SWMM/NetSTORM model are used to prepare the CSO Annual Report required under Philadelphia's LTCP and Chapter 94 of the Pennsylvania Code. This report details progress on the three phases of the LTCP: implementation of the Nine Minimum Controls, construction of capital projects, and watershed-based planning. The report also summarizes CSO volume, frequency, and capture statistics for the year.

Annual CSO Frequency and Volume Stats

Table 4-4 lists estimated capture percentages for regulator structures in the Cobbs Creek watershed, based on the modeling results listed in the CSO Annual Reports. A capture percentage is defined as the percentage of combined sewage (mixed sanitary sewage and stormwater) that is "captured" and sent to a treatment plant during rainfall events over the course of a year. 85% capture is considered to be an ultimate goal for many communities as they implement CSO long term control plans. Based on Table 4-4, capture percentages are generally in the range 50-60% for the Cobbs Creek High Level sewer system (32 regulator structures draining 2180 acres) and 70-80% for the Cobbs Creek Low Level sewer system (12 regulator structures draining 390 acres). It is important to note that percent capture for a given year is strongly dependent on the frequency and magnitude of rainfall events during that year. The seven years of data listed in Table 4-4 are not sufficient to determine whether an increasing or decreasing trend has taken place. However, as the amount of data increases throughout implementation of the Long Term Control Plan, it will ultimately be possible to evaluate the effectiveness of the control measures.

Table 4-4 Estimated Annual Combined Sewage Capture Percentages

Year	Precipitation (in)	Capture (%) – Lowest and Highest Structure	
		Cobbs Creek High Level	Cobbs Creek Low Level
2001	31.1	61 – 62	84 – 85
2000	43.2	51 – 52	74 – 75
1999	48.6	49 – 50	73 – 74
1998	30.7	65 - 67	87 - 88
1997	32.0	59 – 63	88 – 92
1996	53.2	30 – 31	63 – 65
1995	31.6	74 – 75	76 – 78

4.1.12 Evapo-Transpiration

P + OPW + WW/IND Rech + EDR + WW Disch = RO + SWW+ GWW + EDW + BF + OWD + ET

Once precipitation reaches the earth's surface, it may take a variety of paths. Typically, a portion enters soil pores through infiltration, a portion returns to the atmosphere through evaporation, and a portion runs off over the land surface (or often into a sewer in urbanized areas). A portion may also be stored temporarily in puddles, in plant parts, through freezing, or in manmade structures designed to detain stormwater; this portion then infiltrates, evaporates, or runs off at a later time.

One of the largest "outflows" of water from the system is evaporation and transpiration. Evapotranspiration includes evaporation, or loss of water to the atmosphere as water vapor, and transpiration, or loss of water to the atmosphere through plants. Evapotranspiration rates depend on temperature, wind speed, solar radiation, type of surface, type and abundance of plant species, and the growing season. Because of these factors, estimated evapotranspiration rates for the Philadelphia region vary seasonally. Neither the Philadelphia Airport nor the Wilmington Airport records evaporation data. One site in New Castle County, Delaware was located which has recorded daily evaporation data from 1956 through 1994. Average daily evaporation rates from this site were developed and are listed in Table 4-1 (City of Philadelphia Combined Sewer Overflow Program: System Hydraulic Characterization).

4.2 Cobbs Creek Water Cycle Component Tables

The relevant components of the urban water cycle have been estimated for the Darby-Cobbs watershed. Outside Potable Water is assumed to balance Outside Wastewater Discharges, with stormwater and CSO's considered as part of the Runoff component of the water cylde. Tables 4-5 and 4-6 show the results of the analysis, first in inches per year, then in million of gallons per day. The inches per year figure simply takes all the flows over an average year, and divides by the area of the watershed. The million gallons per day table takes all the flows over an average year, and divides by 365 days to get an "average" day value.

Table 4-5 Water Budget Components (in/yr)

	Period of Record	Inflow		Outflow		
		P	EDR	RO	BF	ET+Error
Cobbs Creek	1964 - 1990	42.1	0.05	10.6	8.1	23.4
Darby Creek	1964 - 1990	42.1	0.11	8.9	14.4	18.9

Table 4-6 Water Budget Components (MGD)

	Period of Record	Inflow		Outflow		
		P	EDR	RO	BF	ET+Error
Cobbs Creek	1964 - 1990	44.4	0.06	11.2	8.6	24.7
Darby Creek	1964 - 1990	79.6	0.2	16.8	27.3	35.7

4.3 Surface Water Characteristics

The above component tables contain values for runoff, ET, and baseflow. These values, however, are complicated by the fact that much of the water is collected in both separate and combined sewers. This section describes, in more detail, the surface water portion of the cycle.

Stormwater runoff ultimately reaches Darby and Cobbs Creeks and their tributaries through surface runoff, a combined or separate storm sewer, or a treated water discharge. An understanding of the range and frequency of flows, the stage-velocity-discharge relationship, and trends over time is important to a more complete watershed characterization. This information is useful in water quality management, habitat restoration and management, and potable water and flood control applications.

During the USGS/PWD cooperative program in the 1970's, the USGS established streamflow gauging stations at six locations in the Darby and Cobbs Creeks Watershed. These locations are presented in Figure 4-3. Table 4-7 contains summary information at each of the gauging stations for their respective periods of record. Historical rating curves are available for four of the stations and are shown in Figure 4-4.

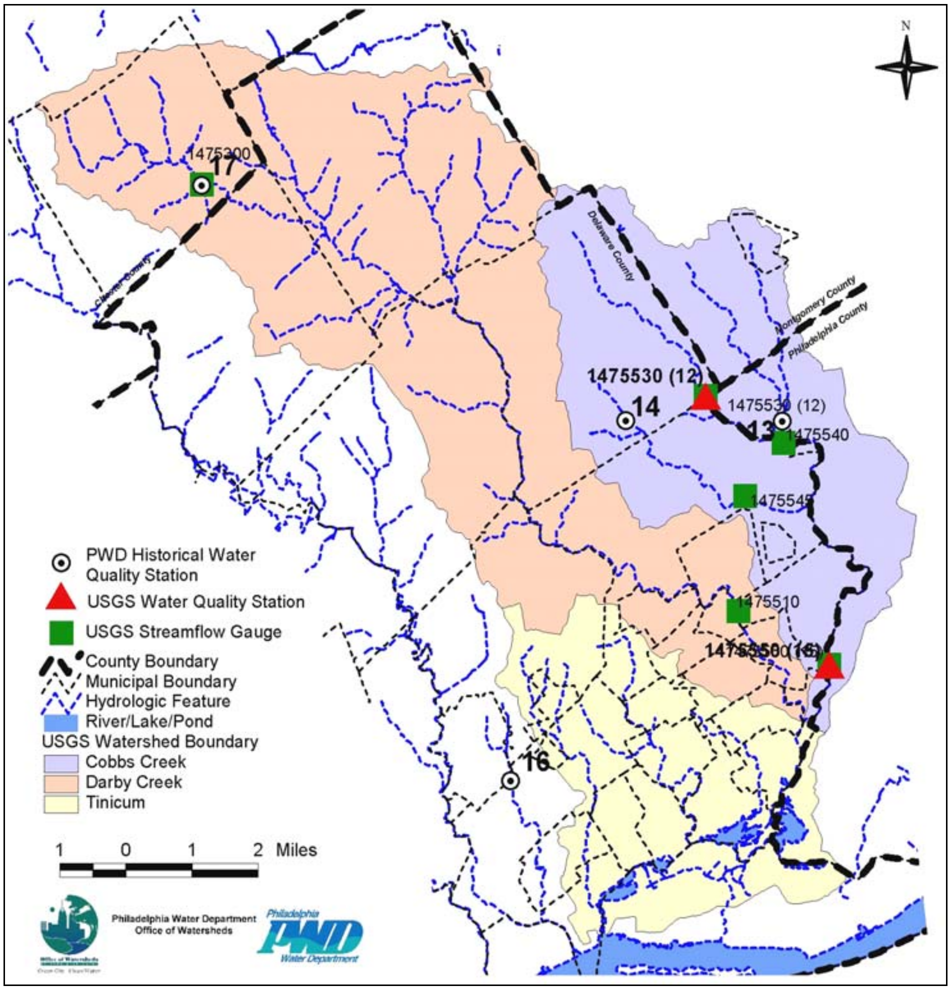

Figure 4-3 USGS Streamflow and Water Quality Gauges

Table 4-7 USGS Gauges and Periods of Record

Station ID	Location	Quality Data (Period)	Streamflow Data (Period)
01475300	Darby Creek At Waterloo Mills Near Devon, Pa.		4/28/1972-9/30/1994 6/28/1996-9/30/1997
01475530	Cobbs Creek At U.S. Highway No. 1 At Phila., Pa.	1/1/1965-3/3/1980	10/1/1964-9/30/1981
01475510	Darby Creek Near Darby, Pa.		2/1/1964-10/3/1990
01475550	Cobbs Creek At Darby, Pa.	11/9/70-3/3/80	1/1/1964-10/3/1990
01475545	Naylor Creek At West Chester Pike Near Phila., Pa.		6/1/1972-10/20/1978

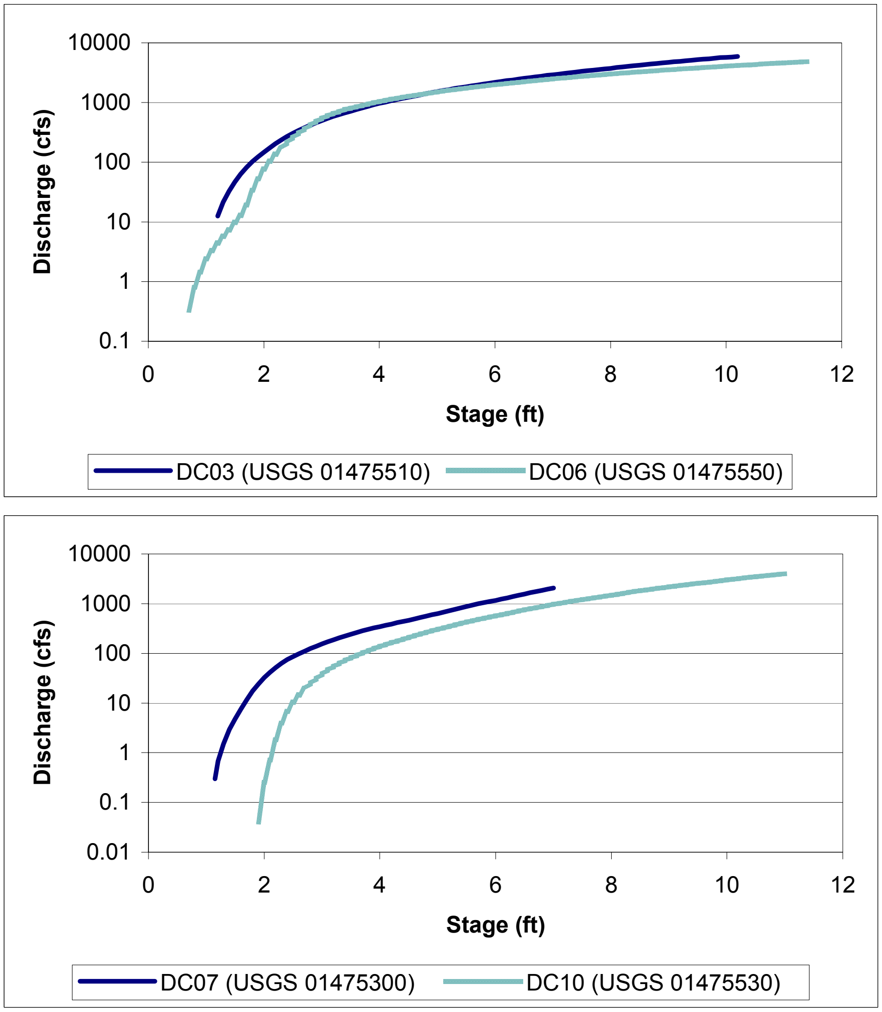

Figure 4-4 Historical Rating Curves for Four USGS Stations

4.3.1 Evaluation of Total Flow for Trends

Magnitude and Frequency of Flow

Cumulative distribution plots for each of the six gauges listed in Table 4-7 are presented in Figure 4-17. A cumulative distribution plot is a plot of discharge versus the percentage of time that a particular flow is not exceeded. These curves are not strictly probability curves because discharge is correlated to successive time intervals and is dependent upon season of the year. However, cumulative distribution plots provide a compact graphical summary of streamflow variability at the different gauging stations.

Trends in Total Flow

Modified Tukey box plots were used to identify seasonal discharge characteristics for both the upstream and downstream monitoring stations on Cobbs Creek. Tukey plots display statistical information including median, mean, minimum/maximum values, and selected percentile values as shown in Figure 4-5. Seasonal discharge characteristics are observed for an annual flow cycle using this approach. The discharge plots, discussed above, were used to delineate wet and dry flow regimes. A high flow season earlier in the year and a low flow season occurring later in the year are identified by the peak and trough locations on the plot. Discharges were plotted by weekly time segments, Figures 4-6 and 4-7, and monthly time segments, Figures 8-7 and 4-9.

Figures 4-10 and 4-11 present an analysis of the streamflow gauge data from USGS Gauge 01475300, Darby Creek at Waterloo Mills. This gauge is the only USGS gauge that remained operational through both the PWD/USGS Cooperative Program and the 1990s. Figure 4-10 shows an annual modified Tukey box plot of daily flow observations. This plot indicates that although average daily flow varies from year to year, generally, the flow regime has remained constant throughout the decades of the 1970s, 1980s, and 1990s. This observation holds even though some years the flows were statistically different from other years. Figure 4-11 shows the decade modified Tukey box plots. This plot indicated that although daily flows in the 1980s and 1990s are somewhat lower than flows in the 1970s, the differences are statistically insignificant.

4.3.2 Hydrograph Decomposition Analysis

Areas and Gauges Studied

As discussed in Section 2, the Cobbs Creek watershed and the lower portions of the Darby Creek watershed are highly urbanized and contain a large proportion of impervious cover. The hydrologic impact of urbanization can be observed through analysis of streamflow data taken from USGS gauges on Darby and Cobbs Creeks. In addition, data from French Creek in Chester County provide a picture of a nearby, less-developed watershed. Table 4-8 lists four gauges with available data, including their locations, periods of record, and drainage areas.

Table 4-8 Data Used for Baseflow Separation

Gauge	Name	Period of Record (yrs)	Drainage Area (sq.mi.)	N (days)	2N* (days)
01472157	French Creek near Phoenixville Pa.	33.0	59.1	2.26	5
01475550	Cobbs Creek at Darby Pa.	26.7	22.0	1.86	3
01475510	Darby Creek near Darby Pa.	26.7	37.4	2.06	5
01475300	Darby Creek at Waterloo Mills Pa.	25.4	5.15	1.39	3

The interval 2N* used for hydrograph separations is the odd integer between 3 and 11 nearest to 2N. N is calculated based on watershed area.

Baseflow Separation

Baseflow due to groundwater inflow is the main component of most streams in dry weather. Baseflow slowly increases and decreases with the elevation of the shallow aquifer water table. In wet weather, a stormwater runoff component is added to the baseflow. Estimation and comparison of these two components can provide insights into the relationship between land use and hydrology in urbanized and more natural systems.

Baseflow separation was carried out following procedures similar to those found in the USGS "HYSEP" program. The following text is taken from "HYSEP: A COMPUTER PROGRAM FOR STREAMFLOW HYDROGRAPH SEPARATION AND ANALYSIS U.S. GEOLOGICAL SURVEY Water-Resources Investigations Report 96-4040":

"Hydrograph analysis is a useful technique in a variety of water-resource investigations. Separation of streamflow hydrographs into base-flow and surface-runoff components is used to estimate the ground-water contribution to streamflow. Hydrograph-separation techniques also have been used to quantify the ground-water component of hydrologic budgets and to aid in the estimation of recharge rates. In addition, base-flow characteristics determined by hydrograph separation of hydrographs from streams draining different geologic terrains have been used to show the effect of geology on base flow (Sloto and others, 1991, p. 29-33).

“The HYSEP program uses three methods to separate the base-flow and surface-runoff components of a streamflow hydrograph—fixed interval, sliding interval, and local minimum. These methods can be described conceptually as three different algorithms to systematically draw connecting lines between the low points of the streamflow hydrograph. The sequence of these connecting lines defines the base-flow hydrograph. The techniques were developed by Pettyjohn and Henning (1979). Hydrograph separations were performed for the streamflow-measurement station French Creek near Phoenixville, Pa., using three methods. Each method is described below.

The duration of surface runoff is calculated from the empirical relation:

$N=A^{0.2}$

where N is the number of days after which surface runoff ceases, and A is the drainage area in square miles (Linsley and others, 1982, p. 210).

“The interval 2N* used for hydrograph separations is the odd integer between 3 and 11 nearest to 2N (Pettyjohn and Henning, 1979, p. 31). For example, the drainage area at the streamflow-measurement station French Creek near Phoenixville, Pa. (USGS station number 01472157), is 59.1 mi2. The interval 2N* is equal to 5, which is the nearest odd integer to 2N, where N is equal to 2.26. The N and 2N* values used for the four gauges in this analysis were listed in Table 4-8.

“The hydrograph separation begins one interval (2N* days) prior to the start of the date selected for the start of the separation and ends one interval (2N* days) after the end of the selected date to improve accuracy at the beginning and end of the separation. If the selected beginning and (or) ending date coincides with the start and (or) end of the period of record, then the start of the separation coincides with the start of the period of record, and (or) the end of the separation coincides with the end of the period of record.

“The sliding-interval method finds the lowest discharge in one half the interval minus 1 day [0.5(2N*-1) days] before and after the day being considered and assigns it to that day. The method can be visualized as moving a bar 2N* wide upward until it intersects the hydrograph. The discharge at that point is assigned to the median day in the interval. The bar then slides over to the next day, and the process is repeated.”

Summary Statistics

The results of the hydrograph decomposition exercise support the relationships between land use and hydrology discussed above. For convenience, the flows in Tables 4-9 and 4-10 are expressed as a mean depth (flow per unit area) over a one-year time period. Based on the French Creek gauge and the two Darby Creek gauges, the hydrologic behavior of these two systems is similar. Effective impervious cover allows sufficient groundwater recharge to give streamflow relatively natural characteristics; a mean of approximately 20% of annual rainfall contributes to the stormwater component of streamflow, and baseflow represents approximately 65% of total annual streamflow. This is fairly typical of streams in the Piedmont Province. Cobbs Creek exhibits behavior typical of a highly urbanized stream, with over 25% of rainfall contributing to stormwater runoff in a mean year and with mean baseflow comprising only 43% of mean annual streamflow.

Table 4-9 Summary of Hydrograph Separation Results Over the Period of Record

Gauge	Mean Total Flow (in/yr)	Mean Baseflow (in/yr)	Mean Runoff (in/yr)	Baseflow (% of Total Flow)	Runoff (% of Rainfall)
French Creek 01475127	20.3	12.9	7.4	64	18
Cobbs Creek 01475550	18.8	8.1	10.7	43	26
Darby Creek D/S 01475510	23.3	14.5	8.9	62	21
Darby Creek U/S 01475300	23.7	15.6	8.1	66	20

Table 4-10 Annual Summary Statistics for Baseflow and Stormwater Runoff

	Baseflow (in/yr)				Runoff (in/yr)			
	Mean	Max	Min	St.Dev.	Mean	Max	Min	St.Dev.
French Creek 01475127	12.9	20.8	5.8	3.8	7.4	15.4	2.9	3.1
Cobbs Creek 01475550	8.1	16.1	1.8	3.6	10.7	15.6	5.2	2.7
Darby Creek D/S 01475510	14.5	21.4	7.6	4.0	8.9	15.6	3.6	2.9
Darby Creek U/S 01475300	15.6	26.0	8.0	4.3	8.1	16.7	3.8	2.9

	Baseflow (% of Annual Rainfall)				Runoff (% of Annual Rainfall)			
	Mean	Max	Min	St.Dev.	Mean	Max	Min	St.Dev.
French Creek 01475127	31%	44%	15%	7%	17%	30%	7%	5%
Cobbs Creek 01475550	19%	31%	5%	7%	25%	33%	18%	3%
Darby Creek D/S 01475510	34%	44%	20%	8%	21%	31%	12%	4%
Darby Creek U/S 01475300	37%	51%	18%	9%	19%	32%	10%	5%

	Baseflow (% of Annual Total Flow)				Runoff (% of Annual Total Flow)			
	Mean	Max	Min	St.Dev.	Mean	Max	Min	St.Dev.
French Creek 01475127	64%	75%	53%	5%	36%	47%	25%	5%
Cobbs Creek 01475550	42%	54%	16%	10%	58%	84%	46%	10%
Darby Creek D/S 01475510	62%	75%	54%	6%	38%	46%	25%	6%
Darby Creek U/S 01475300	66%	78%	50%	6%	34%	50%	22%	6%

As expected, the quantity of stormwater runoff on a unit-area basis follows patterns of impervious cover in the drainage area. The French Creek watershed, the least developed, has the smallest amount of stormwater runoff both as an annual mean quantity (7.4 in) and as an annual mean percent of rainfall (17%). As expected, the highly-developed Cobbs Creek watershed has the most runoff both as an annual mean quantity (10.7 in) and as an annual mean percent of rainfall (25%). Further highlighting the effects of development, mean runoff from the Cobbs basin is almost 50% greater than mean runoff in the French Creek basin. The two Darby Creek gauges have an intermediate quantity of stormwater runoff; the downstream gauge, representing most of the Darby basin, has slightly more runoff (8.9 in) on a unit-area basis than the gauge representing the less-developed headwaters (8.1 in).

The summary statistics for stormwater runoff in Table 4-10 present some interesting results. The standard deviation of annual stormwater flows for Cobbs Creek, both in inches (2.7 in) and as a percentage of rainfall (3%), is the lowest of the four gauges studied, indicating that these flows are less variable from year to year. A possible explanation for this pattern is that the capture of some stormwater as part of combined sewage reduces the variability of runoff reaching streams.

Another interesting statistic is that the maximum annual amount of stormwater runoff as a percent of annual rainfall is between 30% and 33% for all four gauges. This result suggests that the maximum amount of runoff that can occur is dependent on the way the rainfall is distributed during the year. In a very wet year characterized by a significant number of larger (greater than 1 inch) storm events, saturated pervious cover responds more like impervious cover during the larger storms. If much of the total annual rainfall occurs in these larger storms (an unusual event), the annual runoff as a percent of total rainfall becomes similar for urbanized and less developed watersheds.

Expressing runoff as a percent of annual rainfall as in Table 4-10 provides an estimate of the upper bound of directly connected impervious area (DCIA), that portion of impervious surfaces that are hydraulically connected to the drainage system. In other words, percent DCIA may be less than this number but is no greater. Runoff from impervious surfaces that are not directly connected may ultimately infiltrate or evaporate rather than contributing to stormwater runoff. It is interesting to note that compared to the land use-derived estimates of total impervious cover presented in Section 4, estimated DCIA is no more than 55% of total impervious area in the Darby watershed and 51% in the Cobbs watershed. These estimates are calculated as the long-term mean runoff, as a percentage of rainfall, divided by the impervious cover estimate listed in Section 4. For example, runoff in the Cobbs watershed is 25% of rainfall on an annual mean basis, and impervious cover is estimated at 49% on an area-weighted basis. Therefore 25/49 = 51% is one estimate of DCIA.

The magnitude of groundwater-derived stream baseflow also depends on impervious cover because pervious areas are necessary for groundwater to recharge. As expected, the unit-area Cobbs Creek baseflows (8.1 inches) shown in Table 4-10 are smaller than those in either Darby Creek (15.6 inches upstream, 14.5 inches downstream) or French Creek (12.9 inches). Baseflow is between 62% and 66% of mean annual streamflow in Darby and French Creeks and only 43% of mean baseflow in Cobbs Creek. Although the Darby Creek watershed contains more impervious cover than the French Creek watershed, it has higher mean baseflows on a unit-area basis. The most likely explanation for this behavior is a difference in the groundwater yield of the geologic formations underlying each basin.

Example Time Series Graphs

Figures 4-12 through 4-14 provide some idea of trends in unit-area flow, baseflow, and runoff from year to year. Although there is considerable variability between years, flows at the four gauges generally follow the same patterns. For example, the Cobbs Creek gauge has the lowest unit-area baseflow and the highest stormwater runoff almost every year of the period of record. This agreement between gauges suggests that the conclusions drawn from long-term mean flows in the previous section are valid for most individual years.

The annual baseflow time series also demonstrates the effects of an extended drought period on stream baseflow in urbanized watersheds. During the drought years 1964-1965, rainfall was less than 30 inches compared to the annual mean of 41.5 inches. Baseflow was below average at the Darby and French Creek gauges, but it was extremely low at the Cobbs Creek gauge. When rainfall recovered to more typical levels in the ensuing years, baseflow at the Cobbs Creek gauge recovered more slowly than baseflow in the less urbanized basins. The data support the assertion that impervious cover increases a watershed's sensitivity to both extreme flood and extreme drought events.

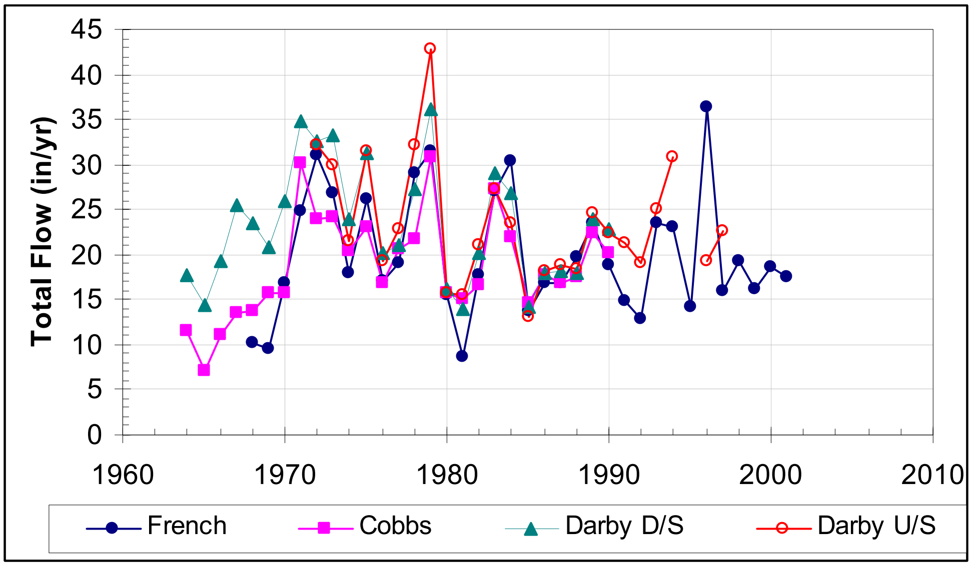

Figure 4-12

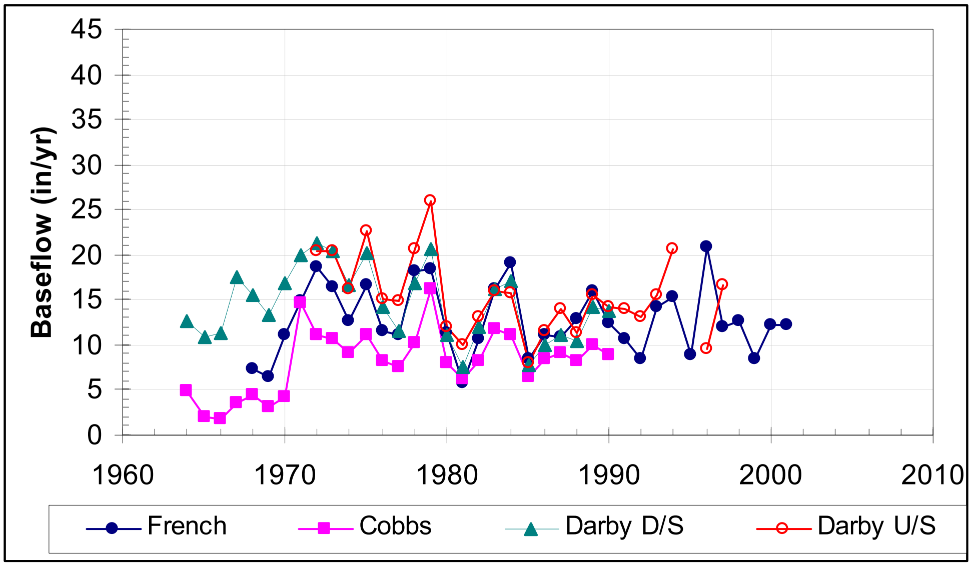

Figure 4-13

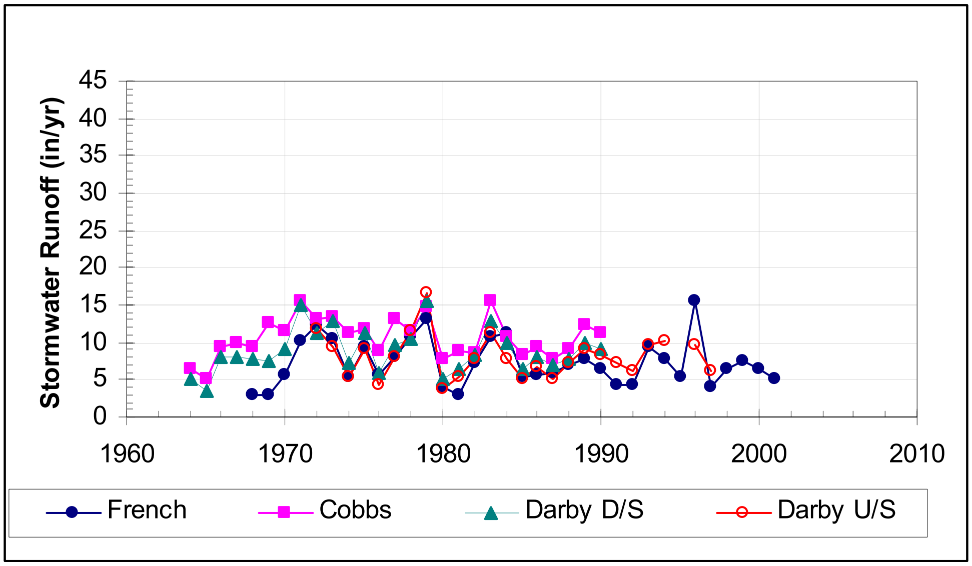

Figure 4-14

Cumulative Distribution

The cumulative distribution of average daily flow at the Cobbs and Darby gauges provides more evidence that the Cobbs gauge experiences greater extremes of flow. The graph shows the percent of daily flow observations (horizontal axis) that are equal to or less than a given value (on the vertical axis). For example, Figure 4-15 indicates that average daily flow at the Darby Creek gauge was less than 0.1 inches on about 90% of days observed. Cobbs Creek experiences greater extremes of flow than Darby Creek. On approximately 92% of days, flow in Cobbs Creek is less than flow in Darby Creek on a unit-area basis. On the driest 20% of days, flow in Cobbs Creek drops toward zero at a greater rate than flow in Darby Creek. On the wettest 8% of days, flow in Cobbs Creek is greater than flow in Darby Creek on a unit-area basis. These observations strengthen the evidence that Cobbs Creek is more prone to flash flooding than Darby Creek.

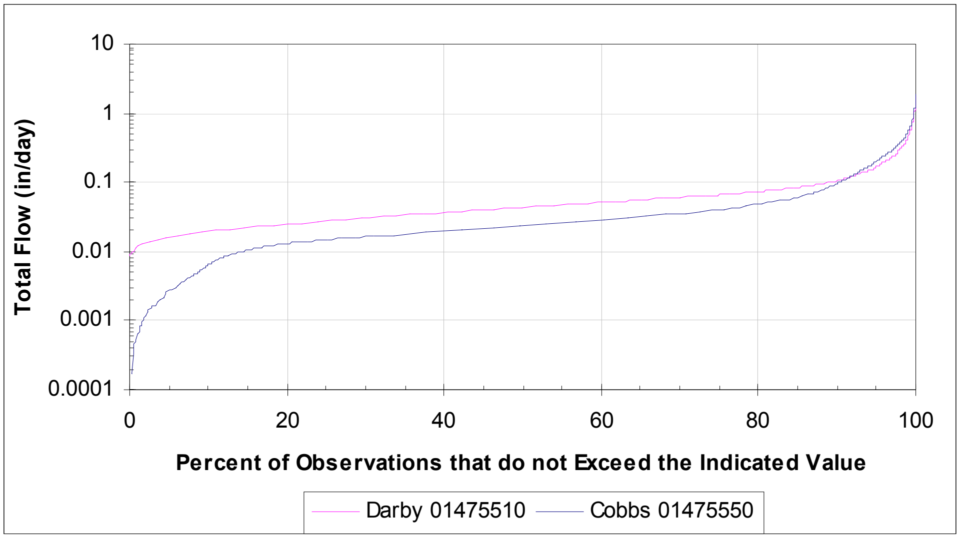

Figure 4-15 Cumulative Distribution of Total Flow

Another possible indicator of the degree of urbanization that was explored was a series of linear least-squares regressions of baseflow and runoff vs. seasonal rainfall. If the regression results were consistently strong ($r^2 >= 0.90$), then differences in slope and intersect between gauges might provide meaningful insights. However, regression results for baseflow vs. rainfall were poor, with r^2 values ranging from 0.11 to 0.40. Regression results for stormwater were better (Table 4-11) but still do not indicate a relationship strong enough to provide meaningful comparisons of different gauges over short periods of time. It is interesting to note that runoff and rainfall appear to be more closely correlated in more impervious basins.

Table 4-11 Correlation Coefficient of Stormwater Runoff and Rainfall

	Cobbs	Darby
Fall	0.73	0.66
Winter	0.76	0.67
Spring	0.90	0.82
Summer	0.63	0.54

A final indicator that was explored compared runoff as a percent of rainfall in one system to runoff as a percent of rainfall in a reference system. If this relationship were relatively constant from year to year, then it might provide a way to track changes in watershed conditions over a relatively short period of time. However, Figure 4-16 demonstrates that while runoff as a percent of rainfall is almost always greater in the Cobbs Creek watershed than in the French Creek watershed, the ratio between the two systems varies substantially from year to year. For this reason, this ratio is not likely to be a good indicator of hydrologic trends over time.

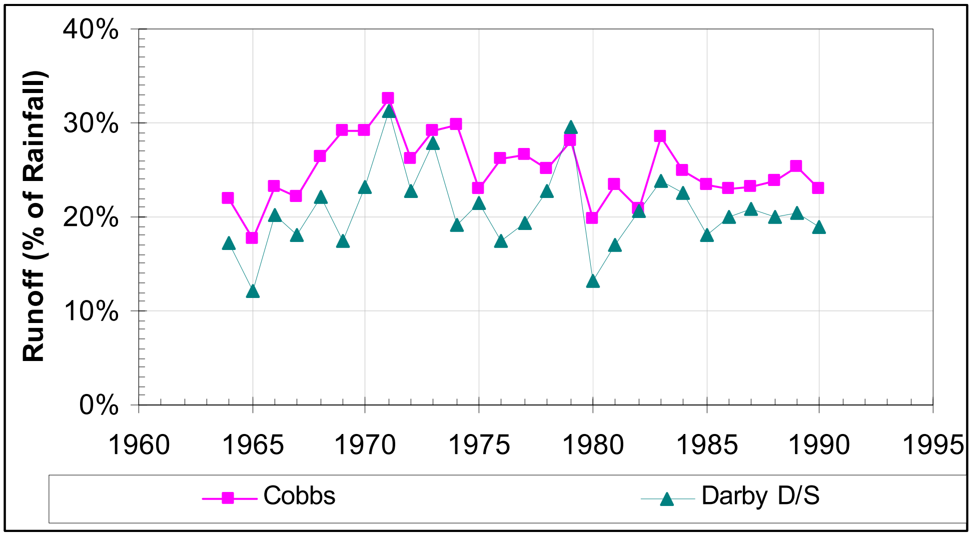

Figure 4-16 Runoff as a Percent of Rainfall in Two Systems

Characterization of Wet and Dry Weather Sampling Periods

The evaluation of water quality data begins with the segregation of water quality observations into wet and dry weather periods. This classification is based upon a combination of the following three factors: streamflow data when available, rainfall, and CSO occurrence data. To characterize the streamflow, cumulative distribution plots based on average daily USGS streamflow are plotted. Figure 4-17 shows the cumulative distribution for the six historical gauges on an annual basis. Because approximately 100 days per year are impacted by wet weather in the Philadelphia region, the 75th percentile flow for a particular stream is taken as a rough estimation of baseflow on a seasonal basis. This forms one basis for classification of wet and dry sampling periods. However, the lack of streamflow data and the fact that precipitation is spatially variable shifts focus towards the CSO occurrence data. Hence the evidence of CSO occurrence anywhere in the system becomes the main basis for characterizing the sampling periods as wet or dry.

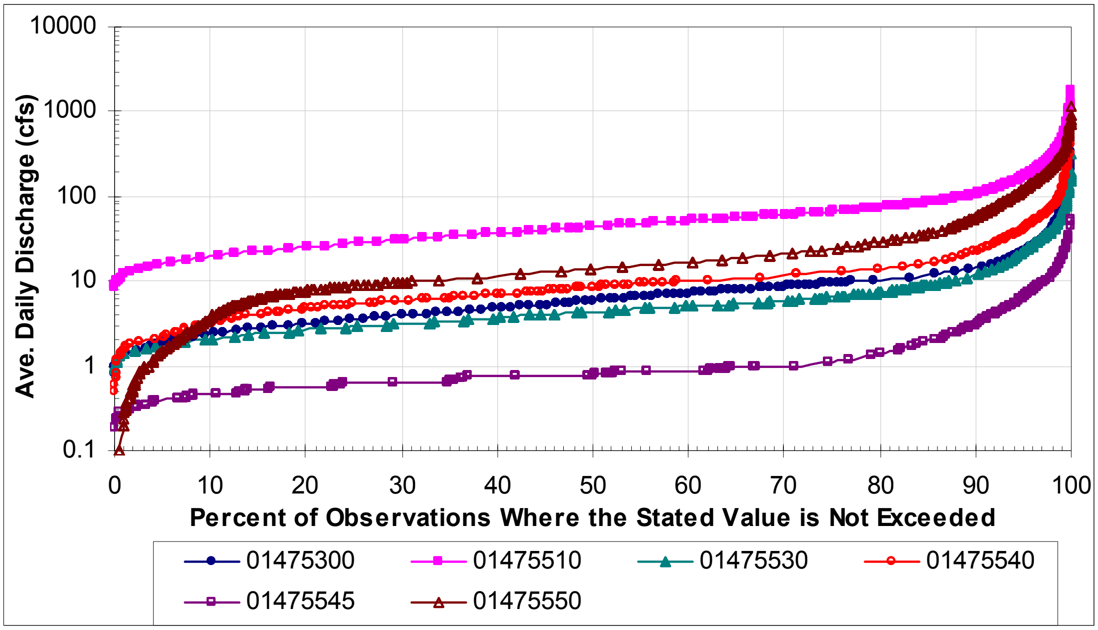

Figure 4-17 Cumulative Distribution of Historical USGS Gauge Data

Table 4-12 Wet Weather/Dry Weather Flow Estimates for Historical USGS Gauge Data

Gauge Name	Gauge Number	Season	Q3 (75%) (cfs)
Darby Creek at Waterloo Mills Near Devon	01475300	Annual	9.6

Cobbs Creek at Darby	01475550	Fall	20

An example of trends in rainfall and corresponding CSOs can be observed in Figures 4-18 and 4-19. Figure 4-17 shows rainfall and CSO data for three CSO outfalls for the period May 23 to 27, 1999. A total of 2.75 inches of rain occurs during the period and CSOs are active. Because CSOs are observed at multiple points in the system, it can be inferred that sampling sites throughout the system are impacted by CSO and stormwater. The discrete sampling done on May 25, 1999 was thus called a wet day. Figure 4-19 shows rainfall and CSO data for the period May 31 to June 4, 1999. This period is classified as dry because neither rainfall nor CSO occurs. Table 4-13 shows the wet or dry categorization of sampling periods when discrete samples were collected. Table 4-14 lists the wet dates in the continuous monitoring or Sonde deployment periods.

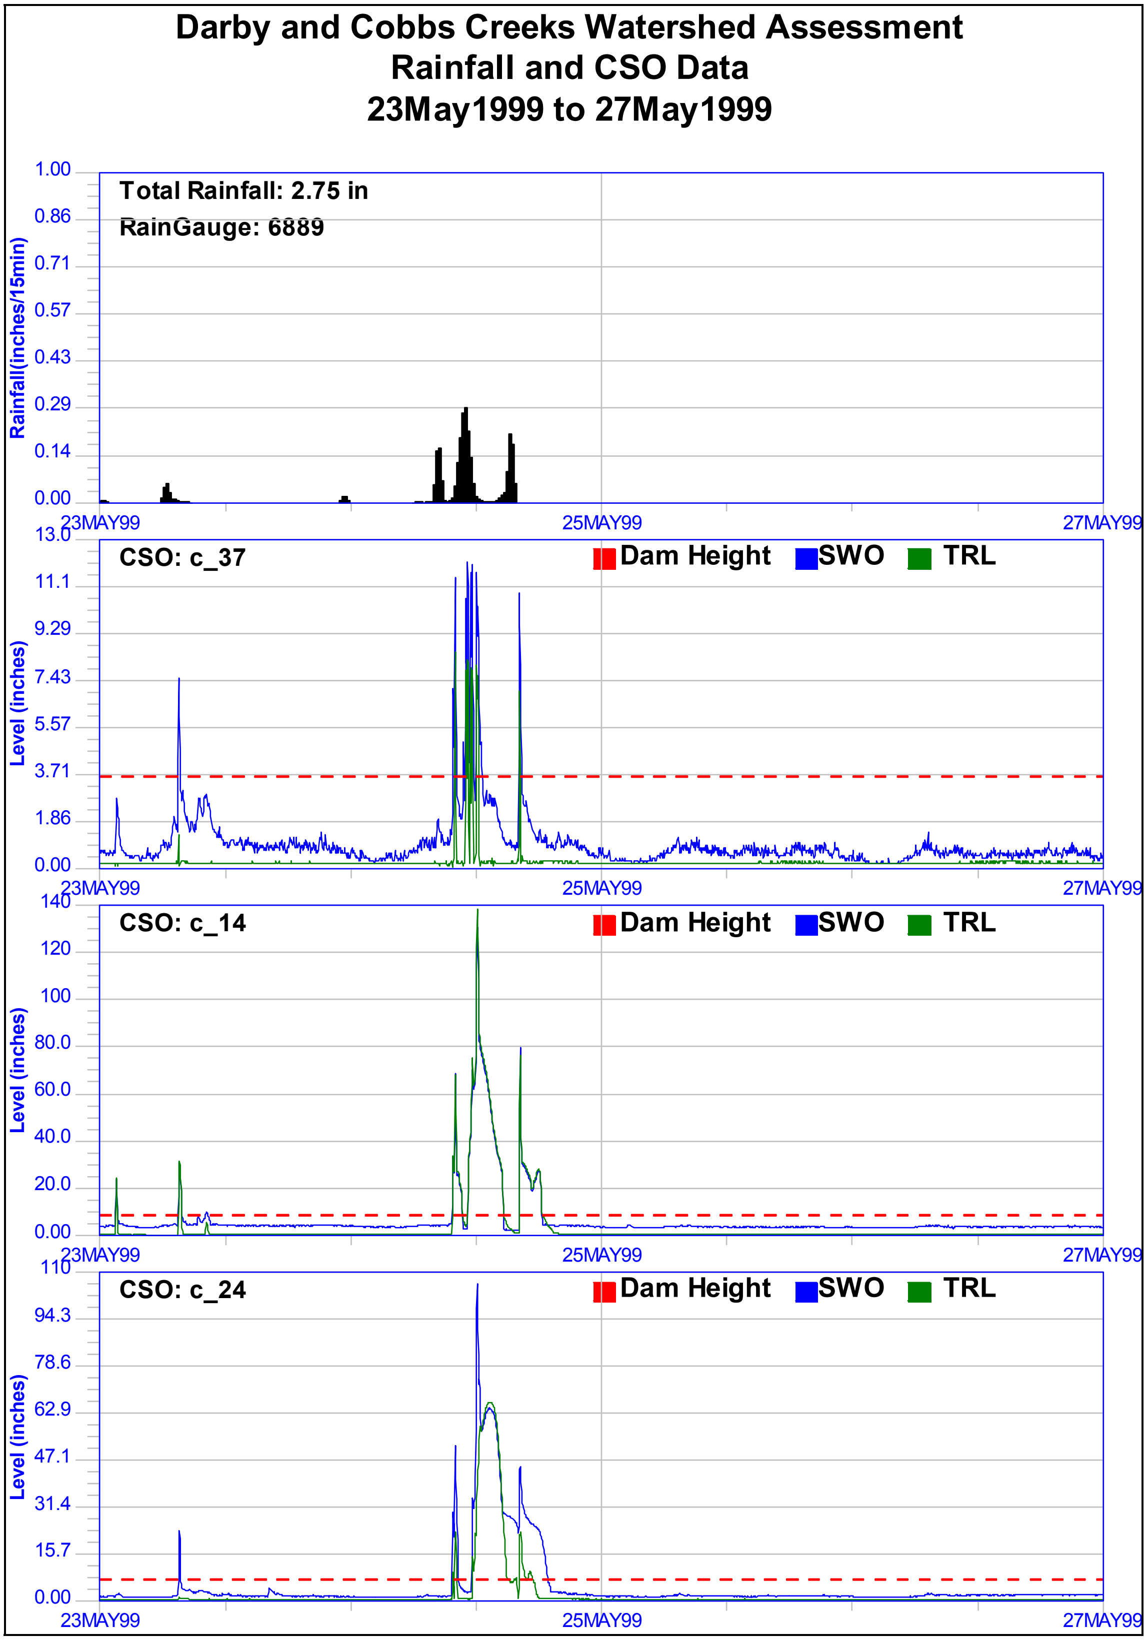

Figure 4-18 Rainfall and CSO plot for a wet period

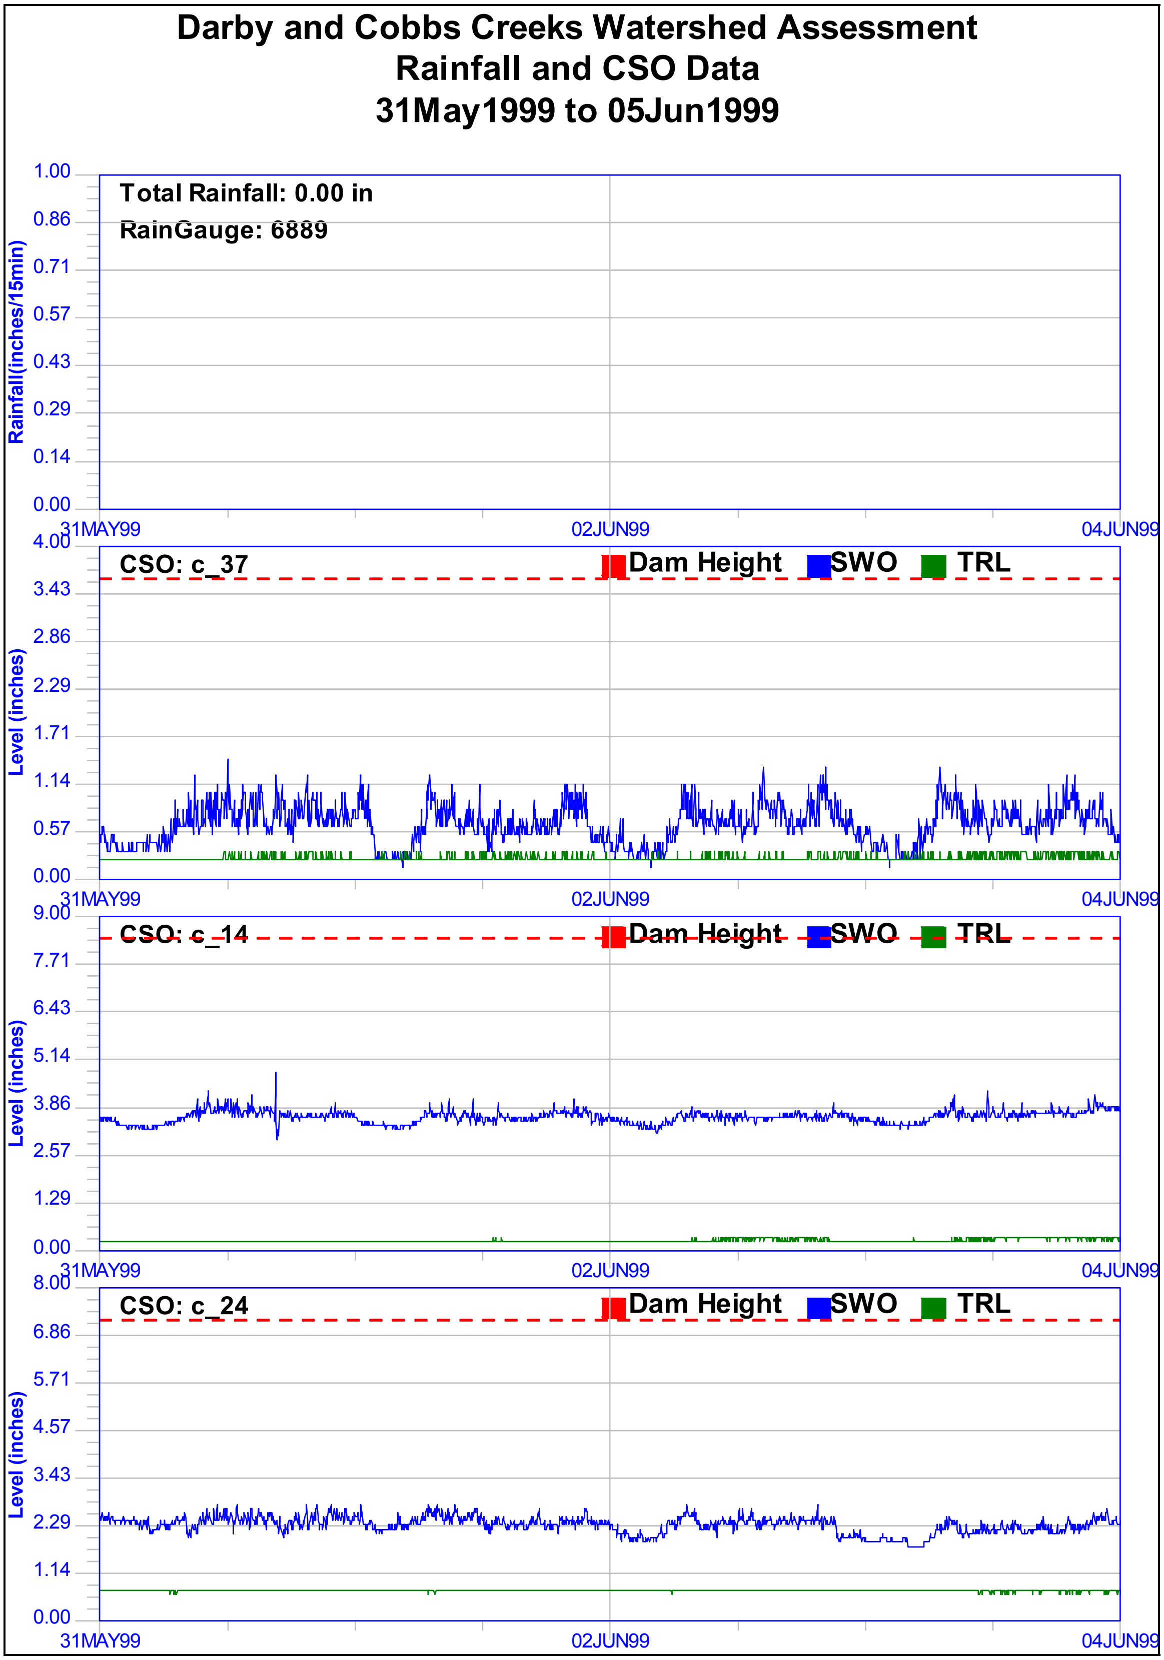

Figure 4-19 Rainfall and CSO plot for a Dry period

Table 4-13 Wet and Dry Period Characterization

Date/Period	Weather Status	Sampling Type
5/11/1999	DRY	Discrete
5/18/1999	DRY	Discrete
5/25/1999	WET	Discrete
6/2/1999	DRY	Discrete
6/8/1999	DRY	Discrete

4.4 Flooding

Introduction

A stormwater management plan has been prepared for the watershed by Delaware County under Pennsylvania's Act 167, the Storm Water Management Act of 1968. The Act 167 report contains a more detailed listing of flooding "trouble spots" and floodplain obstructions.

The Darby Creek Watershed River Conservation Plan discusses the role of floodplains and riparian areas in flood control: "Floodplains and the riparian areas buffering streams, rivers, lakes, and other water bodies are especially sensitive watershed zones. In their naturally vegetated and undisturbed state, floodplains and riparian areas provide critical stormwater management and flood control functions, both in terms of water quantity and water quality. For example, floodplains intercept and reduce unmanaged sheet flow runoff and absorb/contain out-of-bank flows as storms increase in intensity. Flood flows are stored, detained, and infiltrated into the vegetated floodplain zone."

Frequent damaging flooding does not appear to be a major concern within the study area. However, frequent smaller events of flooding occur in some locations, and damaging flooding has occurred during very large storms.

FEMA Floodplains and Flood Insurance Rate Maps

Information on floodplain extents, historical flooding events, and flood insurance rates is available from FEMA and provides an idea of flood hazards in the study area. The flood insurance rate map (Figure 4-20) provides a quick idea of the areas in the watershed that may experience flooding. As summarized in Table 4-15, Zones A and AE are areas where flooding is likely (1% or greater annual chance of occurrence) and zones X and X500 are areas where flooding is unlikely (less than an annual 1% chance due to elevation or flood protection structures). Conditions within the individual subwatersheds (i.e. Cobbs Creek, Darby Creek, and Tinicum) are discussed below.

Table 4-15 National Flood Insurance Program Zone Designations

Zone	Description
A	Zone A is the flood insurance rate zone that corresponds to the 100-year floodplains that are determined in the FIS by approximate methods. Because detailed hydraulic analyses are not performed for such areas, no base flood elevations or depths are shown within this zone. Flood insurance is generally mandatory in these zones.
AE	Zone AE is the flood insurance rate zone that corresponds to the 100-year floodplains that are determined in the FIS by detailed methods. In most instances, whole-foot base flood elevations derived from detailed hydraulic analyses are shown at selected intervals within this zone. Flood insurance is generally mandatory in these zones.
X and X500	Zone X is the flood insurance rate zone that corresponds to areas outside the 500-year floodplain, areas within the 500-year floodplain but not the 100-year floodplain (X500), and to areas of 100-year flooding where average depths are less than 1 foot, areas of 100-year flooding where the contributing drainage area is less than 1 square mile, and areas protected from the 100-year flood by levees. No base flood elevations or depths are shown within this zone. Flood insurance is generally not mandatory in these zones.

Floodplains and Flooding in the Cobbs Creek Subwatershed

Indian Creek and the upper and middle reaches of Cobbs Creek flow through Morris Park and Cobbs Creek Park, moderately sloped parkland where floodplain development is limited. This extensive undisturbed riparian area provides a hydrologic, aesthetic, and recreational benefit to the surrounding neighborhoods. The floodplain along the lower reaches of Cobbs Creek is relatively flat, and the original floodplain has been covered with fill material.

FEMA's Flood Insurance Study for Philadelphia (FEMA, 1996) indicates that low-lying portions of the greater Philadelphia area have experienced damaging flooding in the past during major tropical events, including Hurricanes Connie and Dianne in August 1955 and Hurricane Agnes in June 1972.

The FIS mentions that in 1974, Haverford Township experienced flooding problems along Cobbs Creek due to flow restrictions caused by a box culvert under Wynnfield Drive. This culvert may flood to a depth of four feet or more during intense rain events. Flooding is also known to occur along Naylors Run in Haverford Township.

The extreme southern reaches of Cobbs Creek, including portions of the Eastwick neighborhood, have experienced flooding during these events. On August 19, 1955, the Philadelphia Evening Bulletin noted "flooding of a portion of Eastwick near Buist Avenue to depth of ten feet over Cobbs Creek's banks and 400 evacuated by boat." Portions of the Eastwick neighborhood were also flooded in September 1999 as the remnants of Hurricane Floyd passed over the east coast. This area has existing flood protection measures, and future enhancement of these measures is under consideration by the Philadelphia Redevelopment Authority.

Flood profiles based on HEC-1/HEC-2 modeling from FEMA's Flood Insurance Study identify a few points where the crowns of roads may lie within the 50-year floodplain. Along Cobbs Creek, these include Cobbs Creek Parkway, Woodland Ave., and Church Lane. The crown of Beverly Boulevard is below the 50-year flood level where it crosses Naylors Run.

Floodplains and Flooding in the Darby Creek Subwatershed

The following text is taken from the Darby Creek Watershed River Conservation Plan:

"Over the years, development has encroached substantially into floodplains of the Darby Creek Watershed. In many places, this development has resulted in total stream enclosure/burial with virtual elimination of any semblance of the floodplain. Elsewhere, streams have been substantially channelized with structures that are built into and on the floodplain. Fill has been placed within floodplain areas to accommodate parking, roads, and other development elements, resulting in a broad array of impacts on natural floodplain functions. Even the relatively inoffensive clearing of floodplain areas with replacement as lawn and other landscaped areas takes its toll on the important water quality and water quantity functions of the natural floodplain.

"A major problem, as the data indicate, is that so much of the Darby Creek Watershed has been developed before the emergence of any floodplain regulations, the most notable of which are the Federal Emergency Management Agency (FEMA) set of minimum floodplain standards, which were modified and made more rigorous in the mid-1990's. At this time, virtually all of the 31 municipalities of the Darby Creek Watershed participate in the FEMA floodplain program; East Lansdowne is the one municipality in Delaware County which is not required to participate in the FEMA program. Most municipalities have incorporated minimum FEMA standards into their respective codes and ordinances, although some municipalities in Delaware County may not be in strict compliance with the FEMA program, especially given the FEMA program changes which occurred in the mid 1990's. (According to William Gothier at the Delaware County Conservation District, several municipalities may be in violation of FEMA program requirements; in cases of non-compliance with elements of the National Flood Insurance Program, municipalities could be suspended from the FEMA program and held responsible if flooding damages were to occur; in these cases, homeowners would be deprived of flood protection as part of the NFIP). In any case, a cursory review of the municipal ordinances requested from and made available by the municipalities for this RCP indicates that most municipalities have not gone beyond FEMA minimum requirements, although they are constitutionally enabled to enact more rigorous floodplain and riparian zone controls."

The FEMA Flood Insurance Study for Delaware County (1993) compiled flooding information from a number of anecdotal sources. It describes widespread flooding during Tropical Storms Diana in 1955, Hurricane Donna in 1960, a stationary front in September 1971, and Hurricane Agnes in 1972. In addition, it describes periodic flooding along Darby and Little Darby Creeks in Radnor Township due to undersized culverts; flooding occurs along Little Darby Creek behind Maplewood Avenue at the Mill Dam Club approximately once a year according to residents. Also in Radnor, flooding occurs along Ithan Creek due to undersized culverts in the vicinity of Iven Avenue and Creek Drive near the Township Building. The FEMA study mentions a flood control dam in Naylors Run Park and a detention basin on Naylors Run between Garrett Road and Sherbrook Boulevard, but states that the effectiveness of these measures has not been thoroughly tested. There are four dams in Upper Darby Township and one in Clifton Heights Borough, but these are not thought to perform significant flood control functions.

Low-lying points on roads identified from FEMA flood profiles are shown on Figure 4-20. These are defined as having a crown elevation below the 50-year flood elevation at the point of stream crossing, and include points on Church Lane, Cobbs Creek Parkway, and Baltimore Pike.

Floodplains and Flooding in the Tinicum Subwatershed

Darby Creek discharges to the Delaware River through the wetlands of the Tinicum Wildlife Refuge. In addition, developed areas within Tinicum Township drain directly to the wetlands. Virtually all of the watershed within the Tinicum area lies within the 100-year floodplain and is flood-prone, although flood protection and tidal control structures are in place along portions of Darby Creek, Long Hook Creek, and along many roads. Interstate 95 is built on fill material and forms a barrier to flood waters south of the highway. Development is prohibited within the Tinicum Wildlife Preserve itself (FEMA, 1996).

Section 5 Characterization of Water Quality

The purpose of this section is to characterize existing water quality in the surface waters of the Darby and Cobbs Creeks watershed. The watershed is divided into five sections: upper and lower Cobbs Creek, upper and lower Darby Creek, and the Tinicum area. Each section is represented by two to three sampling sites. Detailed information on the sampling sites is available in Section 3.

5.1 Historical Water Quality

5.1.1 PWD/USGS Cooperative Program (Water Quality and Flow Data)

In the early 1970's, the Philadelphia Water Department began a study in cooperation with the U.S. Geological Survey titled, "Urbanization of the Philadelphia Area Streams." The purpose of this study was to quantify the pollutant loads in some of Philadelphia's streams and possibly relate the degradation in water quality to urbanization. Two of the stations sampled for the study were in the Darby and Cobbs Creeks Watershed: Station 12, Cobbs Creek at U.S. Route 1, and Station 15, Cobbs Creek at Darby. Monthly "snapshot" water quality samples were collected at each site and analyzed for conductivity, BOD_5, total phosphate, ammonia, nitrite, nitrate, and fecal coliform. The program collected about 10 years of monthly samples. The water quality data collected for the Cobbs Creek stations showed a significant increase in BOD_5, ammonia, total phosphate, and fecal coliform between the upstream (12) and downstream (15) stations. These increases were attributed to malfunctioning regulators and higher pollutant loading rates during storm events. The loading rates were compared with estimates based on sampling data collected during the Phase I Reconnaissance Survey. The comparison is in Section 9 of the Comprehensive Characterization Report. Figure 5.1 shows the locations of the two monitoring stations from the PWD/USGS Cooperative Program. Also indicated on Figure 5.1 are the two locations where water quality samples were obtained during the 10 year study.

Partially through the cooperative program, the USGS also established streamflow gauging stations at six locations in the Darby and Cobbs Creeks Watershed. These locations are shown on Figure 5.1 and listed in Table 5.1. Table 5.2 contains summary information at each of the gauging stations for their respective periods of record. Historical rating curves are available for four of the stations and are shown in Figure 5.2.

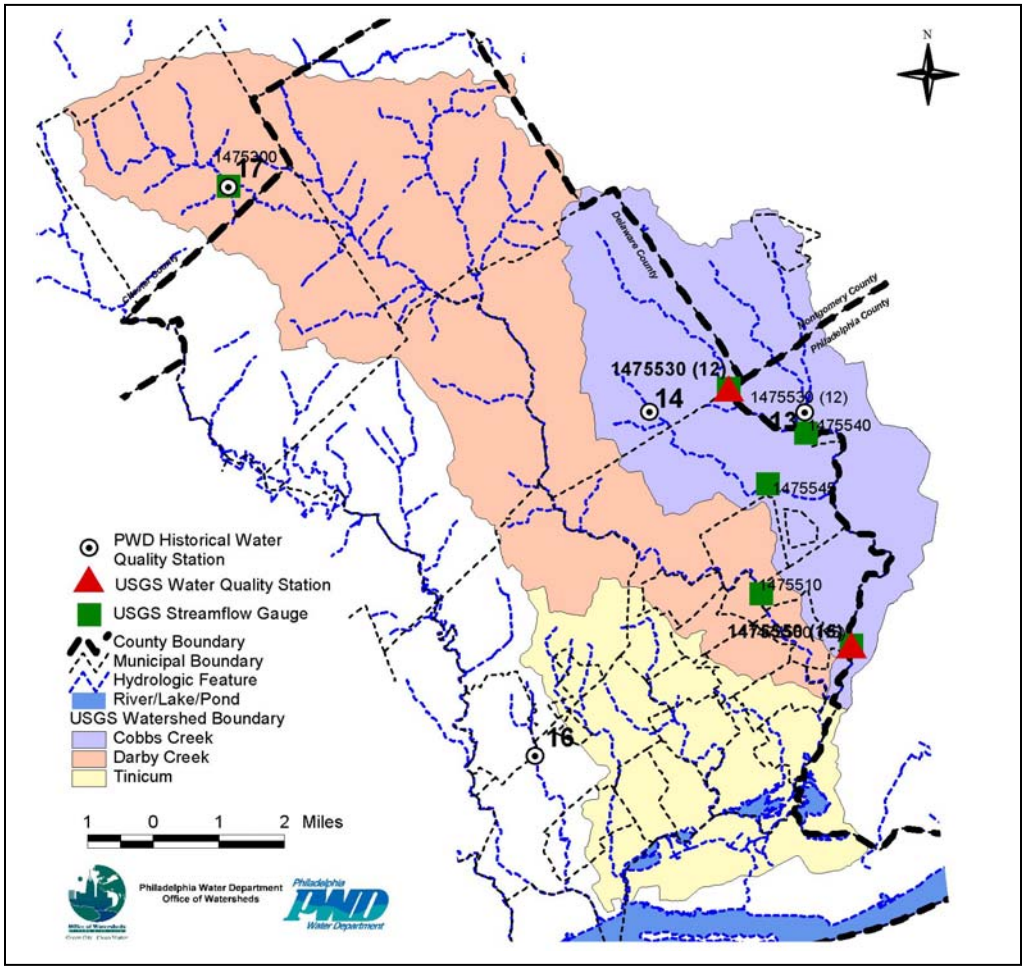

Figure 5.1 PWD/USGS Cooperative Program Water Quality Stations

Table 5.1 Periods of Record for Flow and Quality Data

Station ID	Location	Quality Data (Period)	Streamflow Data (Period)
01475300	Darby Creek At Waterloo Mills Near Devon, Pa.		4/28/1972-9/30/1994 6/28/1996-9/30/1997

01475510	8.6	64	1770
01475550	0	30	1150
01475545	0.18	1.7	54
01475540	0.50	14	480

5.1.2 STORET

The majority of the data available from STORET, USEPA's water quality database, for the Darby and Cobbs Creeks Watershed were from the PWD/USGS Cooperative Program, "Urbanization of the Philadelphia Area Streams." The STORET inventory of water quality data within the Darby and Cobbs Creeks Watershed is attached as Appendix B.

5.1.3 Evaluation of Water Quality Data

Analysis of the Philadelphia Water Department's water quality data from the "Urbanization of Philadelphia Stream Sites" report (1970-1980) was performed to assess the impact of the City (including its CSOs) on Cobbs Creek using two of the program's monitoring sites, as well as to provide a baseline for this watershed study. The upstream site is Cobbs at U.S. Highway No.1 (Station 12) and the downstream site is Cobbs at Darby (Station 15). The City's contribution to the pollution in Cobbs Creek is the difference in mass flux between the two stations. The water quality samples were collected monthly at each site by the U.S. Geological Survey and analyzed for conductivity, BOD_5, total phosphate, ammonia, nitrite, nitrate, and fecal coliform at the Water Department's laboratories. For the first three years, samples of metals also were collected and analyzed.

5.1.4 Baseline Water Quality

Tukey plots also were used to characterize water quality parameters by comparing total nitrogen, total phosphate, and fecal coliform load changes as Cobbs Creek passes through the city. Using the wet/dry flow splits determined during the lognormal probability analysis, paired box plots were compared over the 10-year period of water quality data collected. The total phosphate and fecal coliform plots, Figures 5.2 and 5.3, display an increased concentration from the upstream location at U.S. No. 1 to the downstream location at Darby. Malfunctioning regulators and higher loading rates during storm events are the most likely cause according to the study's report. However, other sources of fecal coliforms not previously considered include urban runoff, broken or leaking sewers, failing septic systems, and unanticipated pump station discharges from non-gravity separate sewer systems. In addition, total nitrogen concentrations, Figure 5.4, are higher within the upstream site and decrease after passing through the city. Some level of nitrification within the downstream portion of the stream may result in reduced levels of ammonia and nitrite.

Time series plots were developed for both monitoring sites from 1970-1980 for conventional water quality parameters and metals data and are available on the Partnership web site. These plots allow for visual identification and correlation to recorded storm events. Peak water quality measurements were identified with some recorded large storm events (i.e., hurricanes). Table 5.3 presents a quantitative summary of the water quality data from the PWD/USGS Cooperative Program. Table 5.4 qualitatively summarizes the data from the PWD/USGS Cooperative Program.

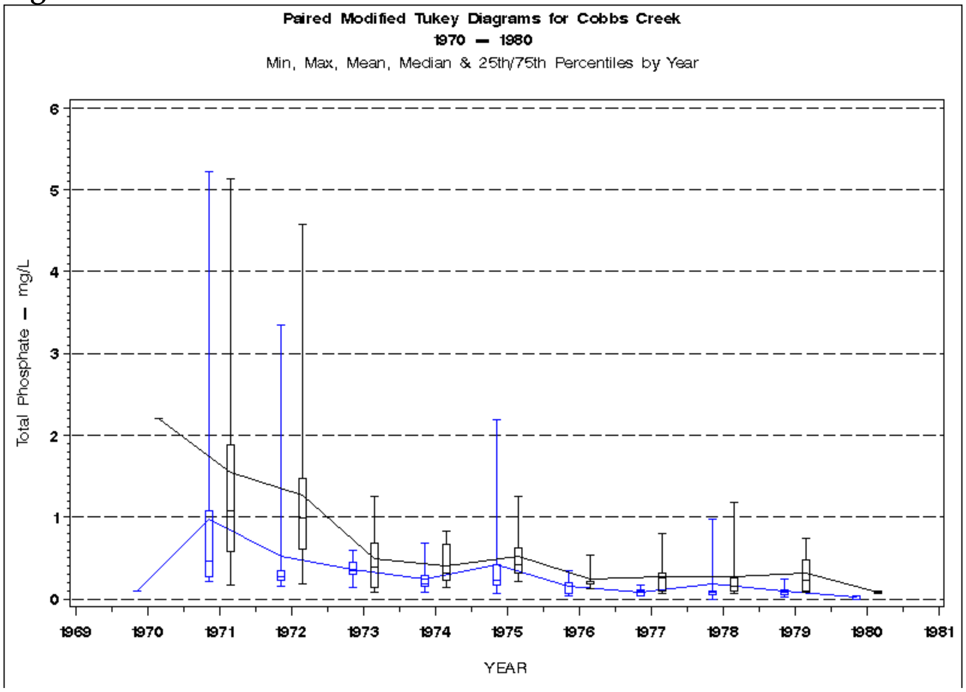
Figure 5.2



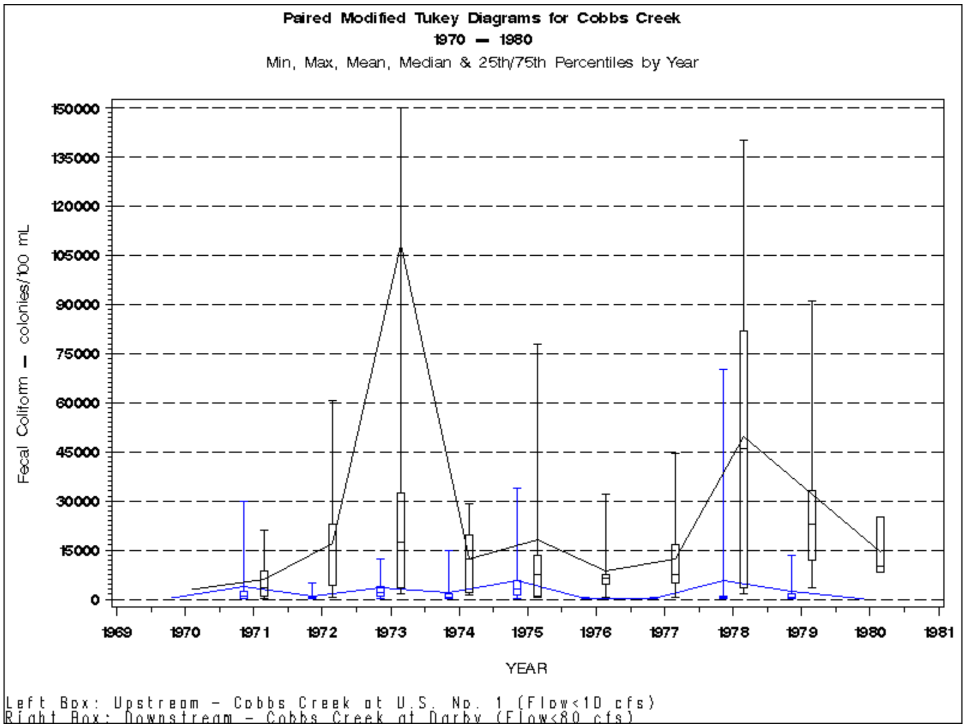


Figure 5.3

Figure 5.4

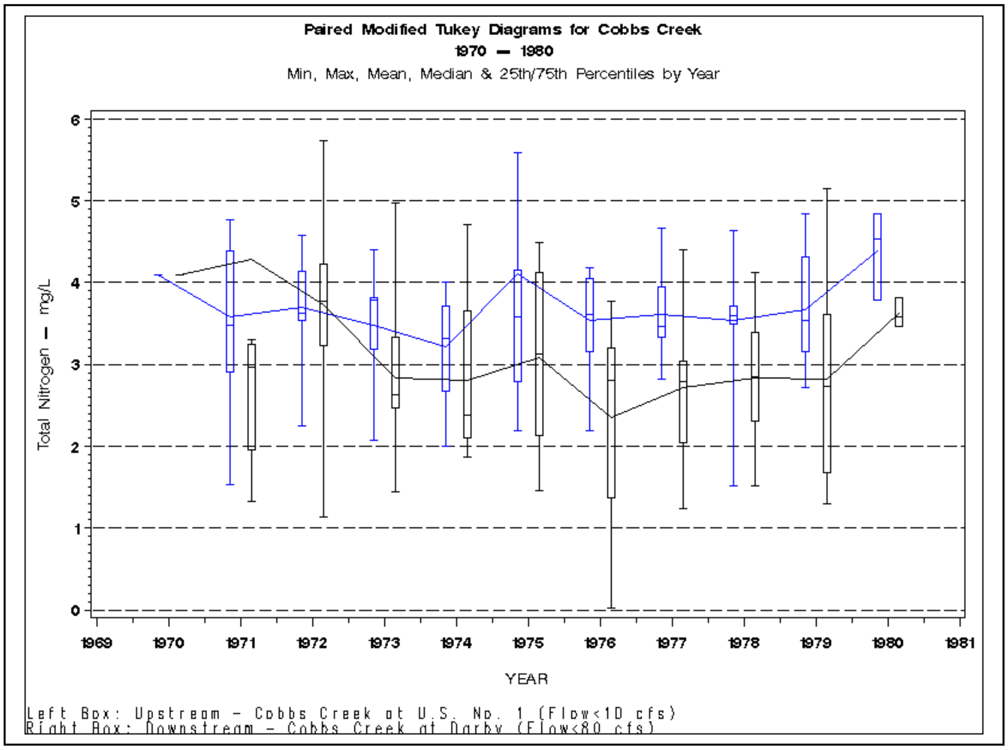

Table 5.4 Qualitative Summary of Water Quality Data Collected 1970-1980

Parameter	**Period of Observation**	**Comments**
Discharge	1970-1980	Discharge at the upstream and downstream sites follow the same pattern, with discharge increasing downstream.
Temperature	1970-1980	Water temperature goes through a seasonal cycle and differs very little between cross-sections.
pH	1970-1973	pH is lower at the downstream location for most of the samples. All the pH values fall between 6.5 and 8.5.
Specific Conductance	1970-1980	For most measurements, specific conductance was greatest at the downstream cross-section.
Dissolved Oxygen	1970-1980	DO concentrations at the upstream range seasonally from about 8 mg/L to 14 mg/L. DO concentrations at the downstream location are almost always lower and drop as low as 0 mg/L during some summers.
BOD	1970-1980	Upstream BOD loads are mostly less than 5 mg/L. Downstream BOD is higher but is usually still under 10 mg/L except for some peaks in mid-1971.
COD	1970-1973	COD concentrations range from about 0 to 30 mg/L at the downstream site and from about 5 to 45 mg/L at the upstream site. COD concentrations are greatest at the downstream site with the exception of three upstream peaks.
TOC	1970-1973	TOC concentrations range from about 0 to 10 mg/L at the upstream site and from about 0 to 25 mg/L at the downstream site. TOC concentrations are greatest at the downstream site with the exception of three upstream peaks.
Suspended Solids	1970-1973	Suspended solids are greatest in the downstream location, ranging as high as 60 mg/L, except for two peaks in the upstream concentration. Other than the peaks, upstream suspended solids are less than 10 mg/L.
Total Dissolved Solids	1970 – 1980	TDS was greatest at the downstream site for most samplings.

Table 5-4, continued

Organic Nitrogen	1972	The small number of data points for organic nitrogen concentrations show relatively constant values at the upstream site and values ranging between 0 and 2.25 mg/L at the downstream site.
Ammonia as Nitrogen	1970-1980	Other than downstream peaks as high as 20 mg/L in late 1971, most ammonia measurements are less than 2 mg/L. Downstream values are greater than upstream values for almost all measurements.
Nitrite an Nitrogen	1970-1980	Except for a few peaks, nitrite concentrations were less than 0.05 mg/L at the upstream location. Concentrations at the upstream location were higher and reached a maximum of 0.7 mg/L.
Nitrate as Nitrogen	1970-1980	Nitrate concentrations were greatest at the upstream location with very few exceptions.
Total Phosphate	1970-1980	The total phosphate concentration was greater at the downstream location for most measurements, reaching a maximum of 11 mg/L in late 1972.
Fecal Coliform	1970-1980	Fecal coliform counts appear to increase by a factor of approximately ten from the upstream to downstream locations.
Aluminum	1970-1973	The upstream and downstream concentrations follow the same shape. The downstream concentration is greater for two of the peaks, while the upstream concentration is greater for two other peaks.
Beryllium	1970-1973	All of the beryllium concentrations measured were less than 0.01 mg/L. These values were not graphed.
Cadmium	1970-1973	Most cadmium concentrations at the upstream and downstream locations are less than 0.001 mg/L. In 1971, the upstream peaks were earlier and greater than the downstream peaks. In 1972 and 1973, the downstream peaks are greater than the upstream peaks. The largest downstream peak is not reflected at the upstream location.
Calcium	1970-1973	The upstream and downstream concentrations follow the same shape. The downstream concentration is greater except for two times in late 1971 and mid-1972.
Chromium	1970-1973	Upstream concentrations are all less than 0.1 mg/L with the exception of one peak of about 1.7 mg/L in April 1972. Downstream concentrations range between 0 and 0.5 mg/L.
Cobalt	1970-1973	All upstream cobalt concentrations are less than 0.001 mg/L. All downstream concentrations are less than 0.001 mg/L except for one peak of 0.01 mg/L.
Copper	1970-1973	Many of the copper concentrations are less than 0.01 mg/L and plotted as zero. The downstream concentration reached five peaks of about 0.02 mg/L, and the upstream concentration reached three peaks of 0.03 to 0.06 mg/L.
Iron	1970-1973	The downstream iron concentration is greater than the upstream concentration except for one downstream peak in May 1973.
Lead	1970-1973	All the measured lead concentrations except for two are less than 0.05 mg/L. The downstream concentrations are greater than the upstream concentrations.
Magnesium	1970-1972	The upstream concentration varies between approximately 8 mg/L and 10 mg/L. The downstream concentration pattern follows a similar shape but has more extreme maximum and minimum values.
Manganese	1970-1973	The downstream concentration of manganese is greater than the upstream concentration except for three upstream peaks and the final reading.
Nickel	1970-1972	Measured nickel concentrations are less than 0.01 mg/L (plotted as zero) during the study period except for one peak that occurs both upstream and downstream. The downstream peak is larger in concentration and occurs about two months later than the upstream peak.
Silver	1970-1973	All of the silver concentrations measured were less than 0.001 mg/L. These values were not graphed.
Zinc	1970-1973	Other than four peaks in the upstream concentration, downstream concentrations of zinc are greater.

5.2 Summary of Water Quality Data Collected 1999-2002

PWD carried out a comprehensive sampling and monitoring program in the Darby-Cobbs watershed between 1999 and 2002 (see Section 3 of the Comprehensive Characterization Report). The first step in water quality analysis is to identify constituents of possible concern. Tables 5.5 and 5.6 list constituents monitored, applicable state water quality standards, number of samples, and number of samples that exceed the standards.

For dissolved oxygen, discrete sampling is not sufficient to characterize the condition of the stream. The magnitude of the diurnal pattern exhibited by DO is an indicator of the amount of algal activity in the steram, and the minimum DO occurs in darkness when sampling is impractical. For this reason, PWD has monitored dissolved oxygen on a continuous basis at several sites in the Cobbs Creek system (Figure 5.5). At sites DCC110 and DCC455, concentrations are occasionally (less than 5% of observations) below the average daily limit of 5 mg/L. The only site where concentrations are often below the average standard (20% of observations) and the instantaneous standard (5% of observations) is site DCC115. This site is just above the low dam at Woodland Ave.

Following the determination of parameters of possible concern, sites were identified where exceedance of these parameters has occurred. Table 5.7 lists the parameters of possible concern and sites where they have been identified. Locations of sampling sites are shown in Figure 5.6.

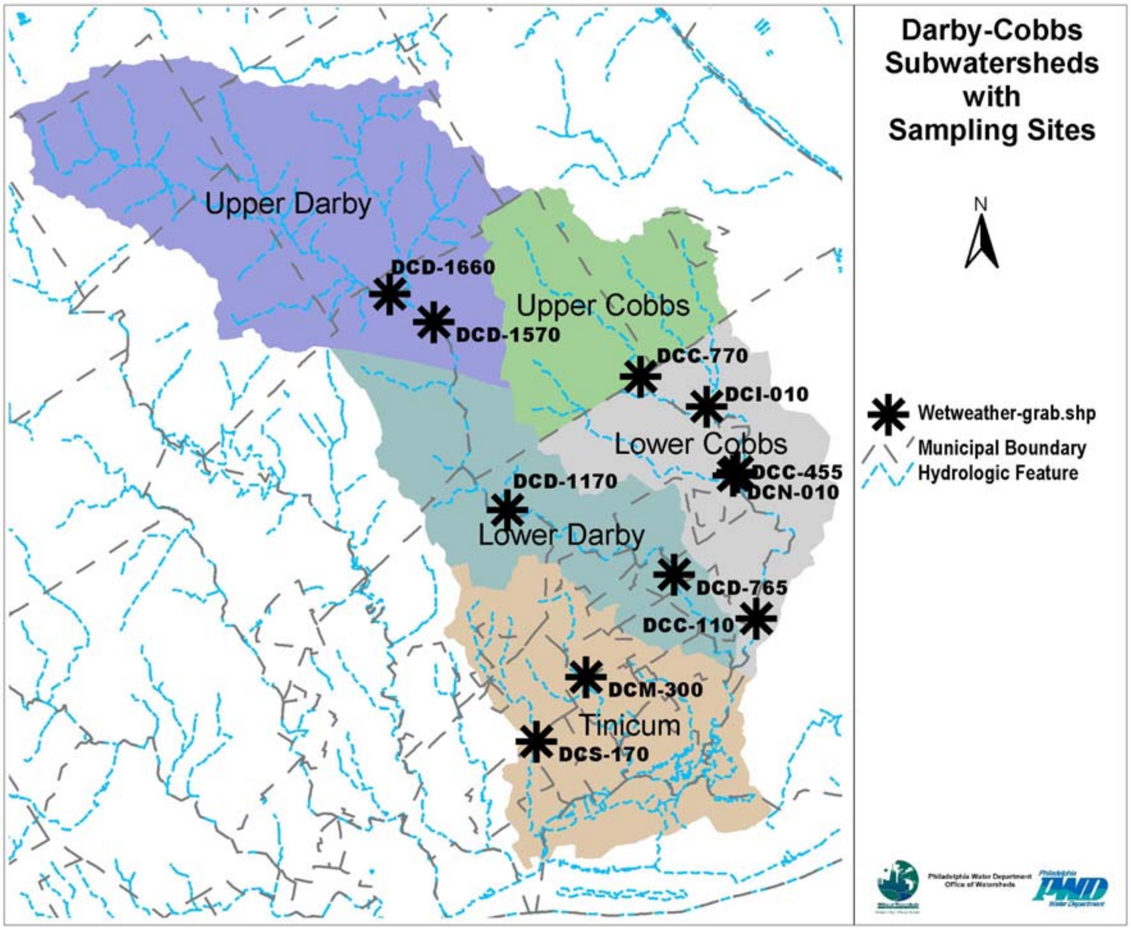

Figure 5.6 Subwatersheds and Sampling Sites

5.3 Detailed Discussion of Data Collected 1999-2000

5.3.1 Upper Cobbs Creek

Two sampling sites represent the headwaters and upper reaches of Cobbs Creek. Site DCC-770 is on the main stem of Cobbs Creek near the Philadelphia/ Montgomery County line, and DCI-010 is on Indian Creek just above the confluence with the main stem. These sites do not receive CSO inputs. Table 5.8 summarizes the mean concentrations of water quality constituents collected at the two sites.

Notes on tables in this section

- The individual data points used in calculation of these means are listed by site and date on the web site.
- For concentrations at or below the detection limit, half the detection limit is used in the calculation of the means listed above.
- For multiple observations during a wet weather event, a single value was chosen to represent the event as follows: for DO, the minimum; for pH, specific conductance, temperature, alkalinity, and turbidity, the mean; for all other parameters, the maximum. This single value was used in the calculation of means listed in the table above.

Upper Cobbs Physical Conditions: Temperature, pH, Solids, Conductivity, Turbidity

Figure 5.7 and 5.8 includes graphs of eutrophication related physical/chemical parameters and nutrients over the 1999 discrete sampling period at DCC-770. Other than the increase in temperature over the course of the summer, there are no obvious trends over time or between wet and dry dates.

Upper Cobbs Dissolved Oxygen

1335.5 hours of quality-assured continuous DO data are available for site DCC-770. Figure 5.9 includes graphs from four of these deployments. The data from July 9 to 12, 1999 (upper left) represent an uninterrupted dry weather period. Between July 26 and August 9, 2001 (upper right), several small wet weather events occurred. CSOs do not affect upper Cobbs sites, but they can be used to identified wet weather periods. Small quantities of CSO occur downstream on July 26 and 30. On Aug 10 and 12, larger CSOs occur throughout the system, including outfalls C_31, C_32 and C_33. Stormwater runoff and CSOs cause the noise or random variation in the measurements to increase slightly but have only a small effect on the overall magnitude or pattern of DO.

Similar effects are observed when a larger storm occurs on December 9-10, 2001 (lower left and lower right representing two instruments deployed concurrently). All data points are shown, but data that do not meet quality assurance criteria are shown with a thinner gray line. Quality assurance and control procedures developed to assess data from the urban environment are described in detail in the Appendix. Data points taken with a calibrated handheld instrument show that the lower right plot represents actual conditions more accurately except for a period during the runoff event. There does not appear to be a major difference in DO between dry and wet weather. In dry weather, the amplitude of the diurnal pattern is approximately 1.5-2.0 mg/L. The water column is often supersaturated in the afternoon.

The amplitude of the diurnal pattern at DCC-110 ranges from approximately 1.5 to 2.5 mg/L with an average of approximately 2.0 mg/L. The greatest amplitudes were observed during the autumn deployments and the least during summer deployments.

Figure 5.10 summarizes the range and cumulative distribution of DO in the Upper Cobbs and throughout the system. The plot shows the percentage of samples (on the horizontal axis) that are less than or equal to a range of DO concentrations (on the vertical axis). For example, DO at DCC-770 ranges from approximately 4 to 15 mg/L and is less than or equal to 6 mg/L for approximately 2% of quality-assured observations.

Upper Cobbs Nutrients

Mean inorganic nitrogen at DCC-770, including nitrate, nitrite, and ammonia, is 2.35 mg/L in dry weather and 2.00 mg/L in wet weather. Mean ammonia increases from approximately 2% of total nitrogen in dry weather to 4% in wet weather. Figure 5-8 shows the temporal trends at DCC-770 in nitrogen species, phosphorus species, and other parameters related to the trophic state of the site. DCC-770 generally has higher nitrate concentrations than those found further downstream.

Upper Cobbs Bacteria

Observed fecal coliform and *E. coli* concentrations at DCC-770 are on the order of 10^2/100 mL in dry weather and range higher than 10^4/100 mL in wet weather conditions. Similar trends are observed at DCI-010.

Upper Cobbs Metals

At both Upper Cobbs sites, mean concentrations of most metals are greater in wet weather. These metals include aluminum, chromium, copper, total iron, manganese, lead, and zinc. Cadmium samples are below the detection limit for all samples at both sites. For concentrations at or below the detection limit, half the detection limit is used in the calculation of mean and in temporal and spatial plots. Mean dissolved iron is lower in wet weather at both sites.

Upper Cobbs Fish Advisories

AMSA et al. (2002) recommend against using fish advisories alone as the basis for impairment listings, but they can provide a basis for further study and for establishment of water quality standards. Fish advisories are most often due to metals or organic chemicals. The April 2001 fish advisory for this watershed advises to limit consumption of White Perch, Striped Bass, and Carp to one meal a month, and to limit consumption of Channel Catfish to one meal every two months. American eel should not be eaten at all. This is all due to PCB pollution.

5.3.2 Lower Cobbs Creek

Three sampling sites represent lower Cobbs Creek. Site DCC-455 is on the main stem at Cobbs Creek Environmental Center, and DCN-010 is on Naylors Run just above the confluence with Cobbs Creek. Site DCC-110 is on the main stem about one mile above the confluence with Darby Creek. The two sites on the mainstem receive stormwater and CSO inputs, while the Naylors Run site receives only stormwater. Additional monitoring was conducted just upstream of the dam at DCC-110. Table 5.9 summarizes the mean concentrations of water quality constituents collected at the three sites.

Lower Cobbs Physical Conditions: Temperature, pH, Solids, Conductivity, Turbidity

The continuous data collected by the Sonde instruments provides a picture of how various water quality constituents interact in the urban environment during dry and wet weather. In a highly impervious environment, the streamflow hydrograph responds to wet weather with a sudden, high peak flow followed by a rapid recession back to baseflow. In the warmer months, stormwater runoff from hot pavement can increase water temperature by several degrees during a runoff event. Suspended solids and turbidity in the water column both increase during the course of a storm because of stormwater inputs. In addition, high velocity flows may re-suspend bed sediments and cause bank erosion, further increasing solids in the water column. Conductivity, an indirect measure of dissolved solids, typically decreases during a storm as stormwater runoff dilutes the ambient water.

Figure 5.11 displays the results of one Sonde deployment at DCC-110 during November 2000. The effects of urban runoff and high velocity on depth, turbidity, and conductivity are all apparent. Although warm pavement may cause sudden increases in stream temperature during wet weather, the temperature trend observed during this deployment is most likely the result of a front passing through and affecting air temperature. The average daily water temperature mirrors air temperature, but its changes are less pronounced due to the higher specific heat of water (Figure 5.11.1). When the storm front raises air temperatures to a high of 19 ^{o}C on November 10, instream water temperature increases approximately 2.5^{o}C to just under 15 ^{o}C over a period of six hours. Both air and water temperature drop after the passage of the storm front.

Lower Cobbs Dissolved Oxygen

A total of 2597 and 1337.75 hours of quality-assured continuous DO data were collected at the two mainstem lower Cobbs sites: DCC-110 and DCC-455 respectively. Figure 5.12 includes time series plots of DO measured during four deployments at DCC-110. July 9 to 12, 1999 (upper left) is an example of dry weather conditions at the site. A total of 0.96 inches of rain was produced by wet weather events during the period from June 2 to 15, 2000 (upper right). The event, on June 6, 2000, depresses observed DO for a brief period; however, it is difficult to tell whether this effect is due to instrument error or actual conditions. The second event causes what appears to be a random fluctuation in the data.

The deployment from May 11 to 24, 2001 (lower left) includes a larger wet weather event that triggers multiple CSOs. The signal becomes extremely erratic during the event and does not recover. The data from May 21 to the end of the period do not meet quality assurance criteria and are not included in analyses. During the late summer deployment from July 26 to August 6, 2001 (upper right), the trough of the observed diurnal pattern at DCC-110 is between 4 and 5 mg/L. The gradually decreasing saturation DO indicates that air temperature increased during this period.

Figure 5.13 includes four time series plots of continuous DO measured at site DCC-455. After the DO probe readings stabilize, the September 27 to October 5, 2000 deployment (upper left) is a good example of dry weather conditions at this site. During the period from July 27 to August 10, 2001 (upper right), there is some noise or random fluctuation in the data, but this deployment provides another good example of dry weather conditions with one small wet weather event of 0.49 inches.

The December 5 to 17, 2001 deployment at DCC-455 (lower left) begins with a dry weather period with an observed diurnal amplitude of approximately 4 mg/L. Concentrations measured by the Sonde are verified by two readings taken with hand-held meters. A wet weather event of 0.72 inches occurs on December 8 and causes the instrument to cease functioning until maintenance is performed on December 10. Data taken after the wet weather event, while they do not match the hand-held data points exactly, provide more evidence that the diurnal amplitude was large during this period. The deployment period from January 15 to 31, 2002 displays similar conditions including low water temperatures, high DO, and a large difference between daily maxima and minima.

The observed dry weather diurnal DO amplitude at site DCC-110 is between 1.5 and 2.5 mg/L for quality-assured data. At site DCC-455, the diurnal amplitude of the DO signal ranged from approximately 1.5 to over 4 mg/L for quality-assured data. The average amplitude was approximately 2.5 mg/L. Thus, there is some evidence that the amplitude is greater at DCC-455. Pronounced differences between the amplitude in different seasons were not observed.

Figure 5.10 includes the cumulative distribution of DO at four sites in the lower Cobbs. At DCC-110, DO ranges from between 4 and 15 mg/L, with 95% of measurements greater than 5 mg/L. At DCC-455, DO ranges from just below 4 to greater than 15 mg/L. DO at DCC-455 is generally greater than DO at DCC-110, but the range in measurements is greater at DCC-455. The two main stem Darby Creek sites have the greatest range of all monitored sites in the Darby and Cobbs Creeks watershed.

Figure 5.10 also includes 560 hours of data at site DCC-115, just above the dam at DCC-110. This site has the lowest DO of any monitored site in the system, with nearly 20% of observations below 5 mg/L. The monitor is located just upstream of the dam in a deep pool of very low velocity, poorly mixed water.

Lower Cobbs BOD

Observed mean BOD at the lower Cobbs sites is greater in wet weather than in dry weather. Figure 5-14 shows multiple BOD_{30} observations during a single event at DCC-110 between June 1 and 8, 2000. The concentration is lowest during the dry weather sample before the storm, reaches a peak during the storm, and recedes to its dry weather level after the storm.

BOD measured under idealized laboratory conditions does not always represent the amount of oxygen demand exerted in the field. Figure 5-15 includes four graphs of laboratory 30-day BOD data sheets for wet weather samples taken at DCC-110. Very little oxygen demand is exerted during the first 2 to 3 days of the test. Because travel time in Cobbs Creek is thought to be on the order of 1-2 days, it is unlikely that BOD will have a significant effect on instream DO except in poorly mixed pools.

Lower Cobbs Nutrients

Figures 5.16 through 5.23 compare concentrations of nitrogen and phosphorus species along the length of Cobbs Creek and throughout the Darby and Cobbs Creeks system. The plots show the mean and range of measurements, river miles, and wet weather status. Figures 5.24 through 5.27 display temporal trends for a variety of eutrophication-related parameters at sites DCC-110 and DCC-455.

Compared to upstream sites, observed mean inorganic nitrogen in the water column (nitrate, nitrite, and ammonia) under dry conditions decreases from 2.35 mg/L at DCC-770 and 1.96 mg/L at DCC-455 to 1.68 mg/L at DCC-110. Under dry weather conditions, ammonia makes up approximately 2% of total nitrogen at sites DCC-770 and 4% at site DCC-110. Under wet conditions, ammonia makes up approximately 4% of total nitrogen at DCC-770, 10% at DCC-455, and 17% at DCC-110. The mean and range of ammonia concentrations at DCC-455 and DCC-110 are roughly equal but are double those seen at DCC-770.

Inorganic phosphorus under dry weather conditions is below the detection limit of 0.04 mg/L at all three sites. Maximum wet weather phosphate concentrations are similar at the three Cobbs sites, although dry weather concentrations appear to increase from upper to lower Cobbs. It is difficult to estimate ratios of nitrogen to phosphorus due to the detection limit samples. If the phosphate concentration is taken as half the detection limit, the ratio of inorganic nitrogen to inorganic phosphorus in dry weather decreases from 117:1 at DCC-770 to 98:1 at DCC-455 to 83:1 at DCC-110. However, any unknown trend in the phosphorus concentration could significantly change these ratios.

Lower Cobbs Bacteria

Bacteria are present at Lower Cobbs sites at high concentrations under both dry and wet conditions. Mean dry weather fecal coliform at DCC-110 is 2.3×10^4 /100 mL. Under wet weather conditions when CSOs are active, fecal coliform may peak at 10^5/100 mL or higher as shown in wet weather sampling results (Figure 5-28). Similar trends are seen in *E. coli* (Figure 5.29).

At DCC-455, fecal coliform observations range from 460/100 mL in dry weather to 2×10^5/100 mL in wet weather. At DCN-010, observations range from 8×10^2/100 mL in dry weather to 3×10^5/100 mL in wet weather.

Figures 5.30 and 5.31 compare fecal coliform and *E. Coli* along the length of Cobbs Creek and throughout the Darby and Cobbs Creeks system. The plots show the mean and range of measurements, river miles, and dry or wet weather status. Mean and maximum bacteria counts increase from upper Cobbs to Lower Cobbs.

Lower Cobbs Metals

In most cases, metals concentrations are greater in wet weather than in dry. At DCC-110, mean concentrations of all sampled metals except cadmium are greater in wet weather. At DCC-455, the following mean metals concentrations are greater in wet weather: aluminum, chromium, copper, manganese, lead, and zinc. At DCN-010, the following mean metals concentrations are greater in wet weather: aluminum, chromium, copper, manganese, and zinc. All lead samples were below the detection limit at this site. Observed concentrations of Cd are at or below the detection limit in both dry and wet weather for the three sites representing the lower Cobbs.

When multiple wet weather samples are collected during a storm, there is a greater chance that the peak concentration will be measured. During wet weather sampling at DCC-110 , the concentrations of metals follow a pattern similar to the runoff hydrograph (Figures 5.32 through 5.35).

Dissolved iron clearly increases from upstream to downstream along the length of the Cobbs. Concentrations of iron and dissolved iron do not always follow the trend of increasing in wet weather. Compared to the dry weather mean, mean total iron increases in wet weather in both of the main stem sites but decreases slightly at the Naylors Run site. At DCC-110, dissolved iron has a mean of 0.217 mg/L under dry conditions and 0.226 mg/L under wet conditions. Wet weather sampling at DCC-110 indicates that both species increase during a June 2000 runoff event of 0.3 inches (Figures 5.32 and 5.33). At DCC-455, dissolved iron has a mean of 0.184 mg/L under dry conditions and 0.166 mg/L under wet conditions. At DCN-010, the mean dry weather concentration is 0.220 mg/L and the mean wet weather concentration is 0.168.

Lower Cobbs Fish Advisories

AMSA et al. (2002) recommend against using fish advisories alone as bases for impairment listings, but they can provide a basis for further study and for establishment of water quality standards. Fish advisories are most often due to metals or organic chemicals. The April 2001 fish advisory for this watershed advises to limit consumption of White Perch, Striped Bass, and Carp to one meal a month, and to limit consumption of Channel Catfish to one meal every two months. American eel should not be eaten at all. This is all due to PCB pollution.

5.3.3 Upper Darby Creek

The headwaters of Darby Creek are represented by data taken from site DCD-1570 and by a limited amount of data from DCD-1660. These sites are not impacted by known CSOs. Table 5.10 lists the mean dry and wet weather concentrations of water quality constituents at the two sites.

Table 5.10 Summary of Upper Darby Mean Water Quality

Upper Darby Physical Conditions: Temperature, pH, Solids, Conductivity, Turbidity

The continuous data collected by the Sonde instruments provides a picture of how various water quality constituents interact in the urban environment during dry and wet weather. Figure 5-36 includes graphs of multiple parameters for DCD-1660 between September 12 and September 24, 2000. Three wet weather events occurred during this period. The flood peaks are high, occur over short durations, and are followed by a rapid return to baseflow. Each flood peak is accompanied by a large increase in turbidity and a decrease in specific conductance. Temperature, DO, and pH all display characteristic diurnal patterns in dry weather.

Upper Darby Dissolved Oxygen

Continuous DO samples were collected during 8 periods at site DCD-1660. Data from the period October 13 to 27, 2000 (Figure 5.37 upper left) represent a dry weather pattern with the exception of one wet weather event of 0.41 inches on October 18. The period from June 2 to 15, 2000 (upper right) is similar to the previous period. Stormwater runoff appears to mute the diurnal pattern, but the pattern returns to its previous amplitude after less than 24 hours. Data reliability may have decreased after the second wet weather period, but the data still meet quality assurance criteria. Data from the periods June 2 to 15, 2000 (lower left) and July 14 to August 4, 2000 (lower right) display similar trends.

The amplitude of the diurnal variation at DCD-1660 is approximately 1 to 1.5 mg/L, the smallest of the sites studied. The amplitude is greatest during the summer deployments and smaller during the spring and fall.

Upper Darby BOD

At DCD-1570, mean BOD in the water column is greater in wet weather than in dry. At DCD-1660, there is not enough evidence to conclude that it is greater. Figure 5.38 shows the laboratory BOD measured over time for a sample taken at DCD-1660 on June 15, 2000, a wet weather day. The 30-day BOD is approximately 3 to 4 mg/L, but there is virtually no BOD exertion for the first 3 to 5 days.

Upper Darby Nutrients

Figures 5.16 through 5.23 display the means, ranges, and weather status of samples of nitrogen and phosphorus species taken along the length of Darby Creek and throughout the Darby and Cobbs Creeks system. Mean nitrate and ammonia concentrations increase slightly along the length of Darby Creek. Mean total phosphorus is greater at DCD-1660 than at DCD-1570.

Upper Darby Bacteria

Figures 5.30 and 5.31 display the means, ranges, and weather status of samples of fecal coliform and *E. coli* taken along the length of Darby Creek and throughout the Darby and Cobbs Creeks system. Mean and maximum counts both increase along the length of Darby Creek.

Upper Darby Metals

At the two Upper Darby sites, mean concentrations of aluminum, copper, iron, and manganese are greater in wet weather than in dry weather. Cadmium is at or below the detection limit for all samples. Dissolved iron is lower in wet weather than in dry at DCD-1570.

Upper Darby Fish Advisories

AMSA et al. (2002) recommend against using fish advisories alone as bases for impairment listings, but they can provide a basis for further study and for establishment of water quality standards. Fish advisories are most often due to metals or organic chemicals. The April 2001 fish advisory for this watershed advises to limit consumption of White Perch, Striped Bass, and Carp to one meal a month, and to limit consumption of Channel Catfish to one meal every two months. American eel should not be eaten at all. This is all due to PCB pollution.

5.3.4 Lower Darby Creek

Lower Darby Creek is represented by two sampling sites. DCD-1170 is in the northwest part of Upper Darby Township,and DCD-765 is upstream of the confluence with Cobbs Creek. These sites are impacted by stormwater but not by known CSOs. Table 5.11 lists the mean dry and wet weather concentrations of water quality constituents at the two sites.

Table 5.11 Summary of Lower Darby Mean Water Quality

		DCD-765		DCD-1170

Lower Darby Physical Conditions: Temperature, pH, Solids, Conductivity, Turbidity

The continuous data collected by the Sonde instruments provides a picture of how various water quality constituents interact in the urban environment during dry and wet weather. Figure 5.39 shows two dry weather periods separated by a wet weather event. During the initial dry weather period, temperature, pH, and DO all show a relatively constant diurnal pattern. The urban wet weather hydrograph is characterized by a high, short duration storm peak followed by a rapid return to baseflow in less than 24 hours. During the storm peak, a large increase in turbidity and a decrease in specific conductance are observed. The decrease in water temperature following the storm most likely corresponds to a decrease in air temperature. pH and DO data taken after the peak do not meet quality assurance criteria, as described in the Appendix.

Lower Darby Dissolved Oxygen

Continuous DO data were collected at DCD-765 during 8 periods between September 1999 and August 2001. The period from September 27 to October 5, 2000 (upper left, Figure 5-40), is an example of a dry weather DO pattern with an amplitude of approximately 1-2 mg/L. The period from October 13 to 26, 2000 (upper right) is an example of a mostly dry period with one small wet weather event. Runoff mutes the diurnal pattern, but it recovers within 24 hours of the storm passing. The muted effect can be explained by the diluting effect of stormwater runoff, although it is difficult to determine the role of instrument error in these readings. The amplitude of the signal in this case is approximately 2 to 2.5 mg/L. The period from July 26 to August 9, 2001 (lower left) is similar but includes several wet weather events. The deployment between September 1 and September 7, 2000 (lower right) begins with a dry weather period displaying an amplitude of 2 mg/L. Following the wet weather event, the data do not meet quality assurance criteria.

Overall, the amplitude of the diurnal DO variation at DCD-765 is approximately 2 mg/L. There are insufficient data to determine whether this amplitude varies between seasons.

Lower Darby BOD

Laboratory BOD tests conducted on wet weather samples at DCD-765 show that 5-day and 30-day BOD are greater in wet weather than in dry weather. When the samples are incubated in the laboratory for five days, the total oxygen demand generated is in the range of 2 mg/L. BOD exertion over 2-3 days, coupled with a high estimate of travel time in the stream, would mean that in-stream BOD is much less than 1 mg/L.

Lower Darby Nutrients

Inorganic nitrogen at DCD-765 has a mean concentration of 1.88 mg/L in dry weather and 1.73 mg/L in wet weather. Ammonia makes up approximately 3% of total nitrogen in dry weather and 7% in wet weather. Mean inorganic nitrogen at DCD-

1170 has a concentration of 2.20 mg/L in dry weather and 2.13 mg/L in wet weather. Ammonia makes up approximately 2% of total nitrogen in dry weather and 3% in wet weather.

At both DCD-765 and DCD-1170, phosphate is equal to or less than the detection limit for all samples except one wet weather sample on 7/20/99. At DCD-765, phosphate makes up approximately one-third of total phosphorus in both dry and wet weather. At DCD-1170, total phosphorus makes up approximately 62% of total phosphorus in dry weather and 35% in wet weather.

Figures 5.41 and 5.42 show the temporal relationships between discrete nitrogen and phosphorus species collected at DCD-765. Figures 5.16 through 5.23 display the means, ranges, and weather status of samples of nitrogen and phosphorus species taken along the length of Darby Creek and throughout the Darby and Cobbs Creeks system. Nitrate and ammonia concentrations increase along the length of Darby Creek. Total phosphorus is highest at the most upstream and most downstream sites.

Lower Darby Bacteria

Fecal coliform at the two Lower Darby sites ranges from a minimum of 190/100 mL in dry weather to greater than 10^5/100 mL in wet weather. *E. coli* ranges from a minimum of 100/100 mL in dry weather to a maximum of $2.6\text{x}10^4$ in wet weather. Figures 5.30 and 5.31 show how these concentrations compare to observations at other points in the system. Counts generally increase with distance downstream. At DCD-765, the mean and range of counts are similar to those in the combined-sewered areas of the Cobbs watershed.

Lower Darby Metals

Trends in metals between wet and dry weather are similar to those observed at other sites. Mean aluminum, chromium, copper, iron, manganese, lead, and zinc are all higher in wet weather for both sites. Cadmium is at or below the detection limit for all samples. Dissolved iron is greater in wet weather at DCD-765 but lower in wet weather upstream at DCD-1170. Figures 5.43 through 5.50 compare means, ranges, and weather status of metals concentrations observed along the length of Darby Creek and throughout the Darby and Cobbs Creeks system.

Lower Darby Fish Advisories

AMSA et al. (2002) recommend against using fish advisories alone as bases for impairment listings, but they can provide a basis for further study and for establishment of water quality standards. Fish advisories are most often due to metals or organic chemicals. The April 2001 fish advisory for this watershed advises to limit consumption of White Perch, Striped Bass, and Carp to one meal a month, and to limit consumption of Channel Catfish to one meal every two months. American eel should not be eaten at all. This is all due to PCB pollution.

5.3.5 Tinicum Area

Two sampling sites represent conditions in the Tinicum area. These include DCM-300 on Muckinipattis Creek and DCS-170 on Stony Creek.

Table 5.12 Summary of Tinicum Mean Water Quality

		DCM-300		DCS-170

Tinicum Dissolved Oxygen

Discrete samples of DO at DCS-170 range from 4.75 mg/L measured on 6/15/99 to 9.54 mg/L measured on 5/11/99. Observed DO at DCM-300 ranges from 4.36 mg/L measured on 6/29/99 to 9.90 mg/L measured on 5/11/99. Figures 5.51 and 5.53 display the temporal trend in dissolved oxygen and physical parameters for discrete samples collected in 1999.

Tinicum Nutrients

Mean total inorganic nitrogen (nitrate, nitrite, and ammonia) at site is 1.73 mg/L in dry weather and 1.41 mg/L in wet weather. Ammonia represents approximately 2% of total nitrogen in dry weather and 3% in wet weather. Figures 5.51 through 5.54 show the temporal trends in nitrogen and phosphorus species over the duration of the 1999 discrete sampling period. Nitrate concentrations are generally lower than those observed in other parts of the system, while ammonia concentrations are similar.

Tinicum Bacteria

Observed bacteria concentrations are similar at the two Tinicum sites, ranging from a minimum of 200/100 mL fecal coliform in dry weather to a maximum of 76,000/100 mL in wet weather. Figures 5.30 and 5.31 are visual representations of the range of concentrations found throughout the system in dry and wet weather. Mean and maximum counts are similar to those found at Upper Cobbs and Lower Darby sites.

Tinicum Metals

Mean concentrations of most metals increase from dry to wet weather at both sites, including aluminum, copper, lead, and zinc. Mean manganese concentrations are lower or unchanged in wet weather, and mean dissolved iron concentrations decrease at both sites in wet weather. Figures 5.43 through 5.50 compare means, ranges, and weather status of bacteria concentrations at the two Tinicum sites and throughout the Darby and Cobbs Creeks system.

Tinicum Fish Advisories

AMSA et al. (2002) recommend against using fish advisories alone as bases for impairment listings, but they can provide a basis for further study and for establishment of water quality standards. Fish advisories are most often due to metals or organic chemicals. The April 2001 fish advisory for this watershed advises to limit consumption of White Perch, Striped Bass, and Carp to one meal a month, and to limit consumption of Channel Catfish to one meal every two months. American eel should not be eaten at all. This is all due to PCB pollution.

Section 6 Characterization of Biology and Habitat

6.1 Historical and Existing Information

ANS Geomorphology Study

The Philadelphia Academy of Natural Sciences collected stream morphology data for four streams in the Darby and Cobbs Creeks watershed in August 1998. The data were collected in Fairmount Park for Indian Run, Indian Creek, Bocce Tributary, and Cobbs Tributary 3. The geographic data showing the location of the stream morphology study was not available at time of publication. The data provide information about streambed slope, cross-sectional properties, and sediment grain size distribution.

The thalweg (channel bottom elevation) plot for Indian Run shows that the stream has a slope of approximately 2.6% in the area studied. The channel is approximately 15 m wide and 1 m deep at the cross-sections measured. Based on the grain size distribution, the sediment is poorly sorted, with most particle diameters ranging from 10 mm (medium gravel) to 200 mm (small boulders).

The thalweg of the Indian Creek channel varies more than the elevation of the other three creeks studied, with several deeper pools along the length of the channel. The average slope of the creek in the area studied is 1.6%. The five cross-sections measured all have widths of approximately 15 m and depths of approximately 1 m. The sediment is poorly sorted, with most particles ranging between 1 mm (coarse sand) and 100 mm (cobbles) in diameter.

The Bocce Tributary has a relatively constant bottom slope of approximately 2.5%. The channel is narrower than the others studied, with a width between 4 m and 8 m. The sediment grain size distribution is similar to the distribution for Indian Creek, with most particle diameters ranging from 1 to 100 mm.

Cobbs Tributary 3 has an average slope of 2.5% along the section studied. The channel has a width of approximately 6 to 8 m and a depth of approximately 1.5 m. Most of the sediment particles range in diameter from 1 to 200 mm.

PADEP Aquatic Biological Investigation

The Pennsylvania Department of Environmental Protection, with assistance from the Philadelphia Academy of Natural Sciences, conducted an aquatic biological investigation in the Darby Creek Watershed in June of 1995 and May of 1996. They investigated the general biological health of the watershed and assessed the damage from improper pesticide use in May of 1996. Figure 6-1 presents the locations where investigations were conducted. Only one of the stations, Station 12, was located on Cobbs Creek.

Table 6-1 summarizes the general assessment information available from the study, including information on shading, erosion, stream bed material, vegetation, land use, and biological quality.

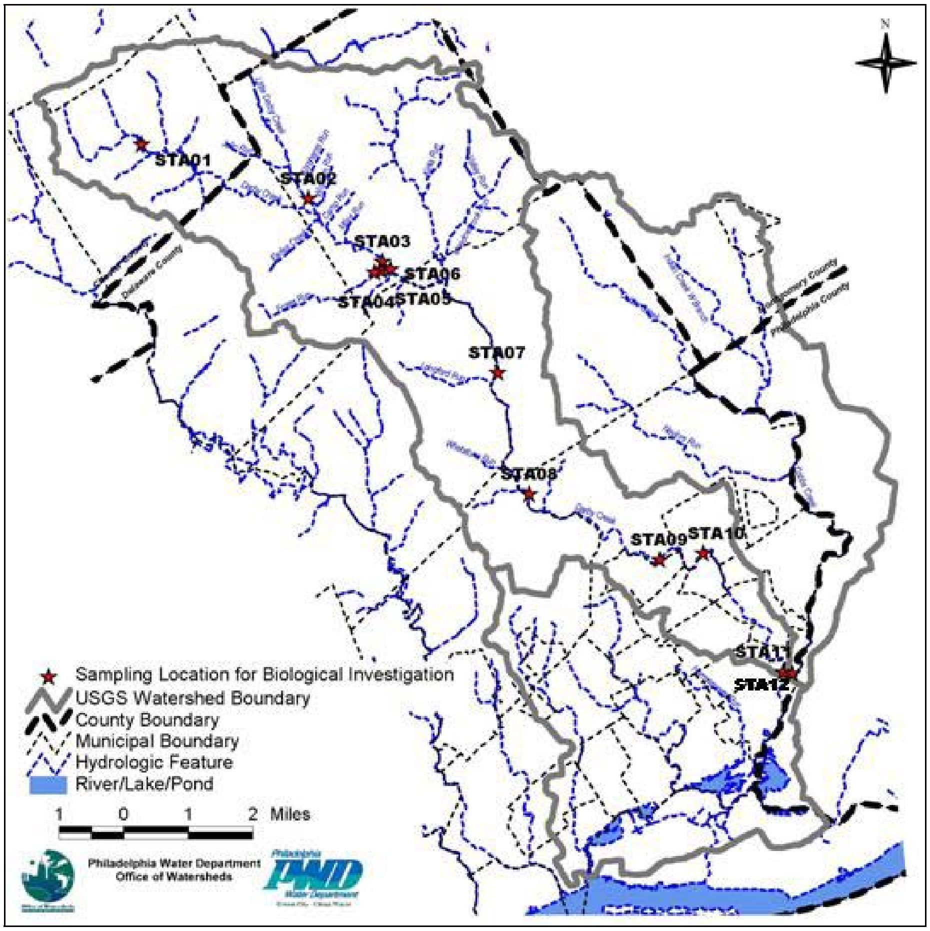

Figure 6-1 PaDEP/ANS Aquatic Biology Investigation 1995-1996

Water quality sampling indicated that the overall water quality in Darby Creek was good. The few parameters sampled above the detection limit but not threatening to fish were iron, aluminum, total suspended solids, and fecal coliform. Fecal coliform concentrations were only notable because they exceeded the Chapter 94 standards. In Cobbs Creek, low dissolved oxygen and elevated levels of ammonia, phosphorus, iron, lead and manganese were observed. The low dissolved oxygen and elevated nutrient levels led researchers to conclude that nutrient enrichment and associated plant growth were possibly affecting this part of Cobbs Creek adversely. Additional studies on Cobbs Creek were recommended to determine the level of impairment from nutrient enrichment and metals toxicity.

Benthic invertebrate data indicated fair conditions in the headwaters and Little Darby Creek and good conditions in some of the headwater tributaries. At other sampled stations, the benthic communities were considered poor. Fisheries data indicated fair conditions throughout the Darby Creek Watershed except for good conditions where the benthic community also was rated good. The fish habitat was thought to be better than indicated by the fisheries data.

Table 6-1 PaDEP/ANS Aquatic Biology Investigation

Station	Width (m)	Shading (%)	Erosion (%)	Silt (%)	Clay (%)	Sand (%)	Gravel (%)	Cobble (%)	Boulder (%)	Bedrock (%)	Veg-etation	Land Use	Biological Quality

Philadelphia Suburban Water Company

In May of 1997, Normandeau Associates conducted an ecological assessment of Cobbs Creek at the request of Philadelphia Suburban Water Company, eight months after observed fish mortality associated with a chlorinated drinking water main break. While the study concluded that the effects of the break were short term and that the recovery of the communities studied was complete, information from this biological assessment can be used for the Darby and Cobbs Creeks Watershed Study. The study area for the Normandeau Associates biological assessment runs from 500 feet above Manoa Road and extends 250 feet below City Line Avenue. All sampling occurred from within Cobbs Creek Park. Figure 6-2 shows the study area for the biological assessment.

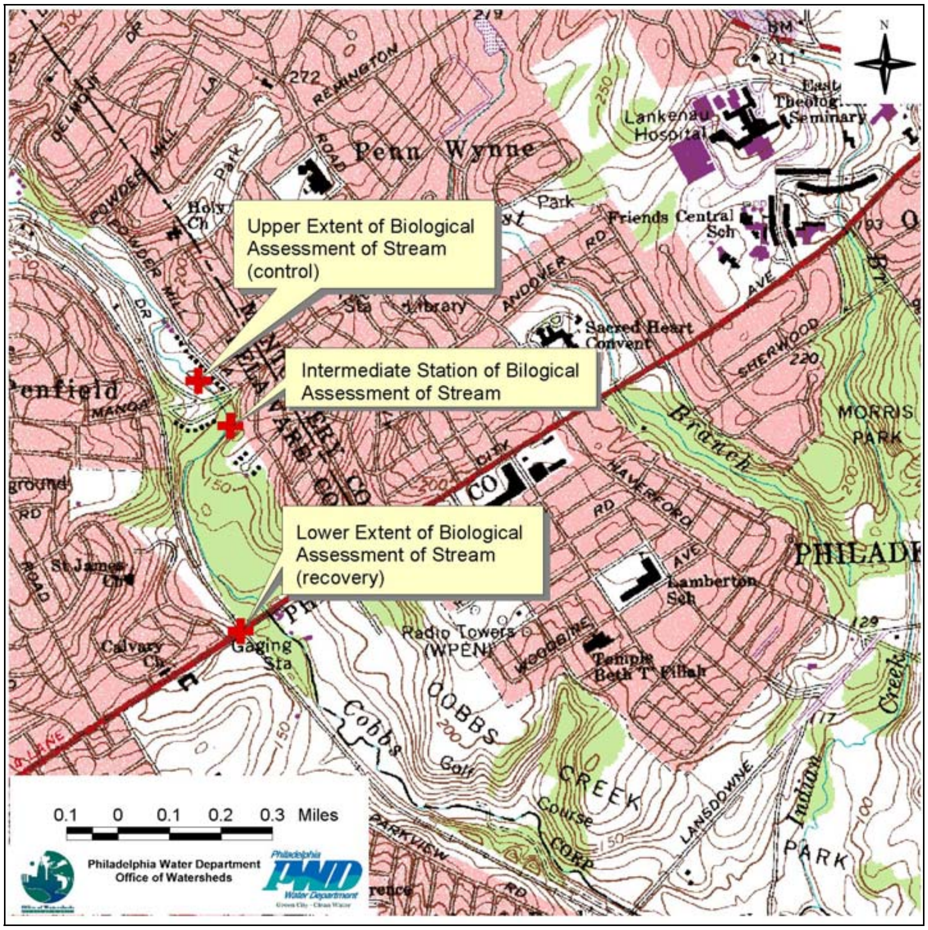

Figure 6-2 Biological Assessment for Philadelphia Suburban Water Company

During the biological assessment, the water temperature was unseasonably cool with temperatures in the range of 52 to 57 degrees F. Specific conductance ranged between 363 and 370 uS/cm.

Based upon USEPA's criteria for habitat assessment, the habitat in Cobbs Creek was rated as "good" to "excellent" in the study area. In the study area, habitat types of riffles, pools and backwater were present, but not throughout the study area. The invertebrate data, collected for the assessment, indicated poor taxonomy, domination by pollution tolerant species, and low diversity. The fisheries data indicated that although numerically dense, the fish community was species poor, containing a preponderance of blacknose dace and white suckers.

Pennsylvania Unassessed Waters Program

At the request of PWD, the Pennsylvania DEP (PaDEP) performed a biological assessment of the non-tidal portions of the Darby and Cobbs Creeks Watershed. For the assessment, 28 stations were chosen to represent the watershed based upon land use and stream order. Each station was evaluated using the Rapid Bio-assessment Protocol and EPA's habitat assessment methods. The assessments occurred between June and late October in 1998. The decisions to consider a station impaired or unimpaired were based upon the quality and quantity of habitat and macroinvertebrates.

The assessments indicated that 52 percent of the stations evaluated were impaired. Generally, impaired stations in the Darby and Cobbs Creeks Watershed were located below Route 3. Figure 6-3 presents the assessment locations and the State's delineation of impaired waters. The State listed the impaired stream segments below Route 3 in the Year 2000 303d list. Stormwater, CSOs, and habitat modification were surmised as the primary and secondary causes of impairment. As a result, TMDLs will need to be developed for pollutants causing stream impairment, once those pollutants are determined.

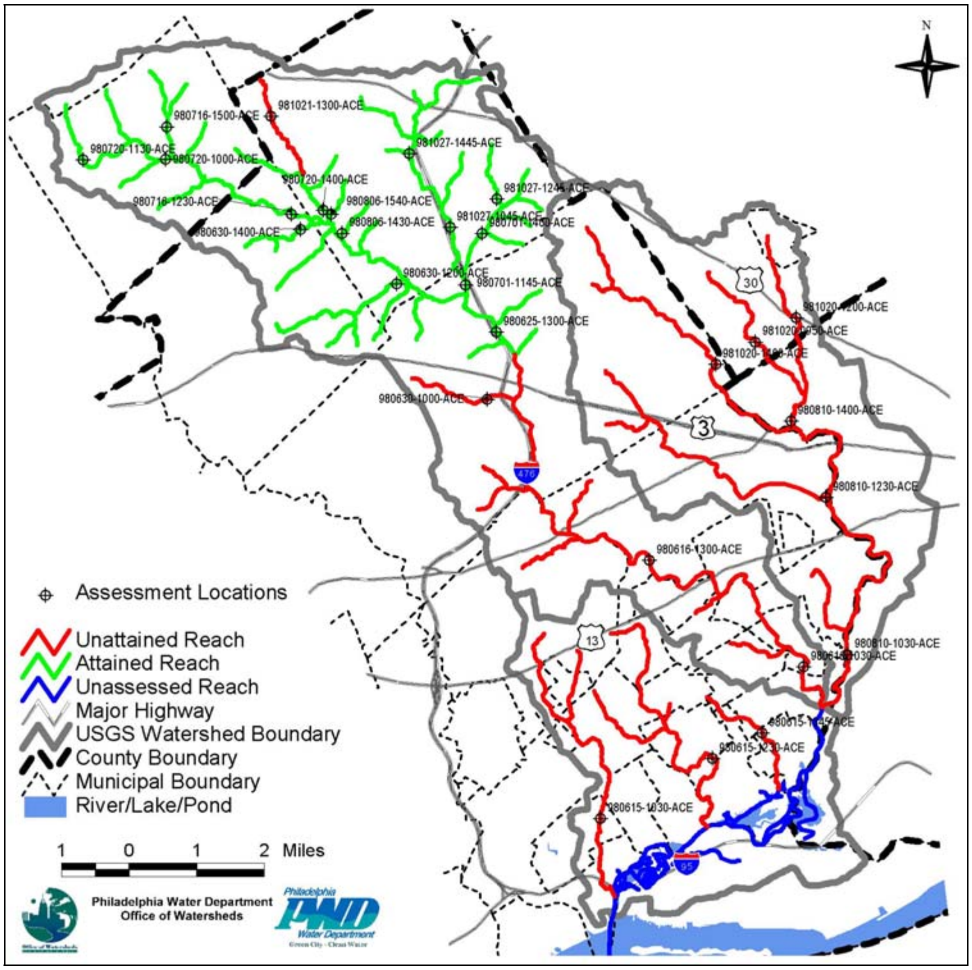

Figure 6-3 PaDEP Delineation of Impaired Reaches 1998

Darby Creek Valley Association

The Darby Creek Valley Association, a non-profit citizen's group, undertook a program to monitor aquatic ecosystem health at eleven sites in the Darby Creek watershed. These sites are shown on Figure 6-4. The program focused on monitoring of aquatic macroinvertebrate communities. The diversity of species and specific species present provide information about the degree of pollution in the stream. The data have not yet been published but will be made available on the internet at a future time.

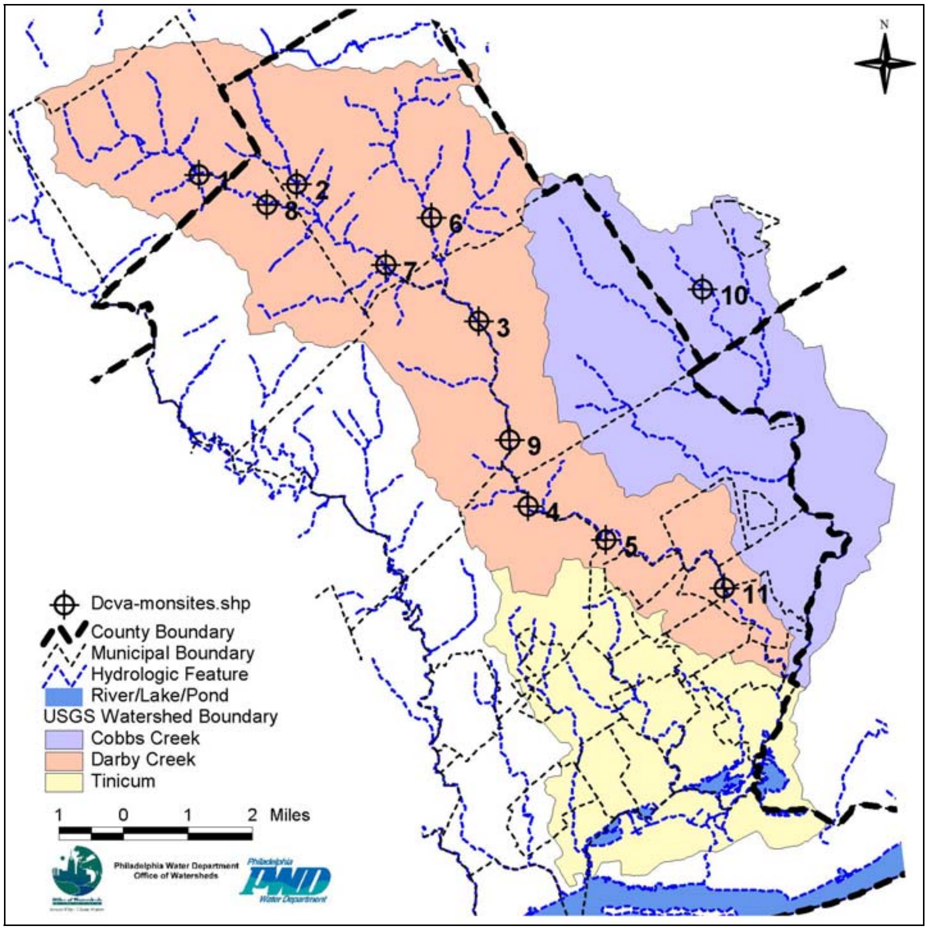

Figure 6-4 DCVA Stream Watch Macroinvertebrate Monitoring Sites

6.2 Preliminary Documentation on the Biological Assessment of the Cobbs Creek Watershed

6.2.1 Introduction

Biological monitoring is a useful means of detecting anthropogenic impacts to the aquatic community. Resident biota (e.g. benthic macroinvertebrates, fish, periphyton) in a water body are natural monitors of environmental quality and can reveal the effects of episodic and cumulative pollution and habitat alteration (Plafkin et. al. 1989, Barbour et al. 1995). Biological surveys and assessments are the primary approaches to biomonitoring.

The Philadelphia Water Department's Office of Watersheds and Bureau of Laboratory Services, along with the Academy of Natural Sciences and the Pennsylvania Department of Environmental Protection have been working together to develop a preliminary biological database to assess the aquatic integrity of the Darby-Cobbs watershed. Although each agency has different objectives for the data (e.g. rapid biological protocol assessments (RBPs), research and presentation, storm water permit compliance (NPDES), Phase II of Darby-Cobbs assessment), the main goal of this project was to avoid redundancy in data collection and to gather as much expertise in the field as possible. During this period, macroinvertebrate, ichthyfauna and habitat assessments were conducted at specified locations within Cobbs Creek watershed. Geographical Information Systems (GIS) databases and watershed maps were also constructed to provide accurate locations of the sampling sites. The Office of Watersheds and the Bureau of Laboratory Services then analyzed compiled data to provide both a quantitative and qualitative assessment of the biological integrity of Cobbs Creek and to provide insight on the current problems associated with this urban stream system. In addition, this report also addresses future assessments and potential solutions for the restoration of the Darby-Cobbs watershed.

6.2.2 Methodology

Fish Sampling

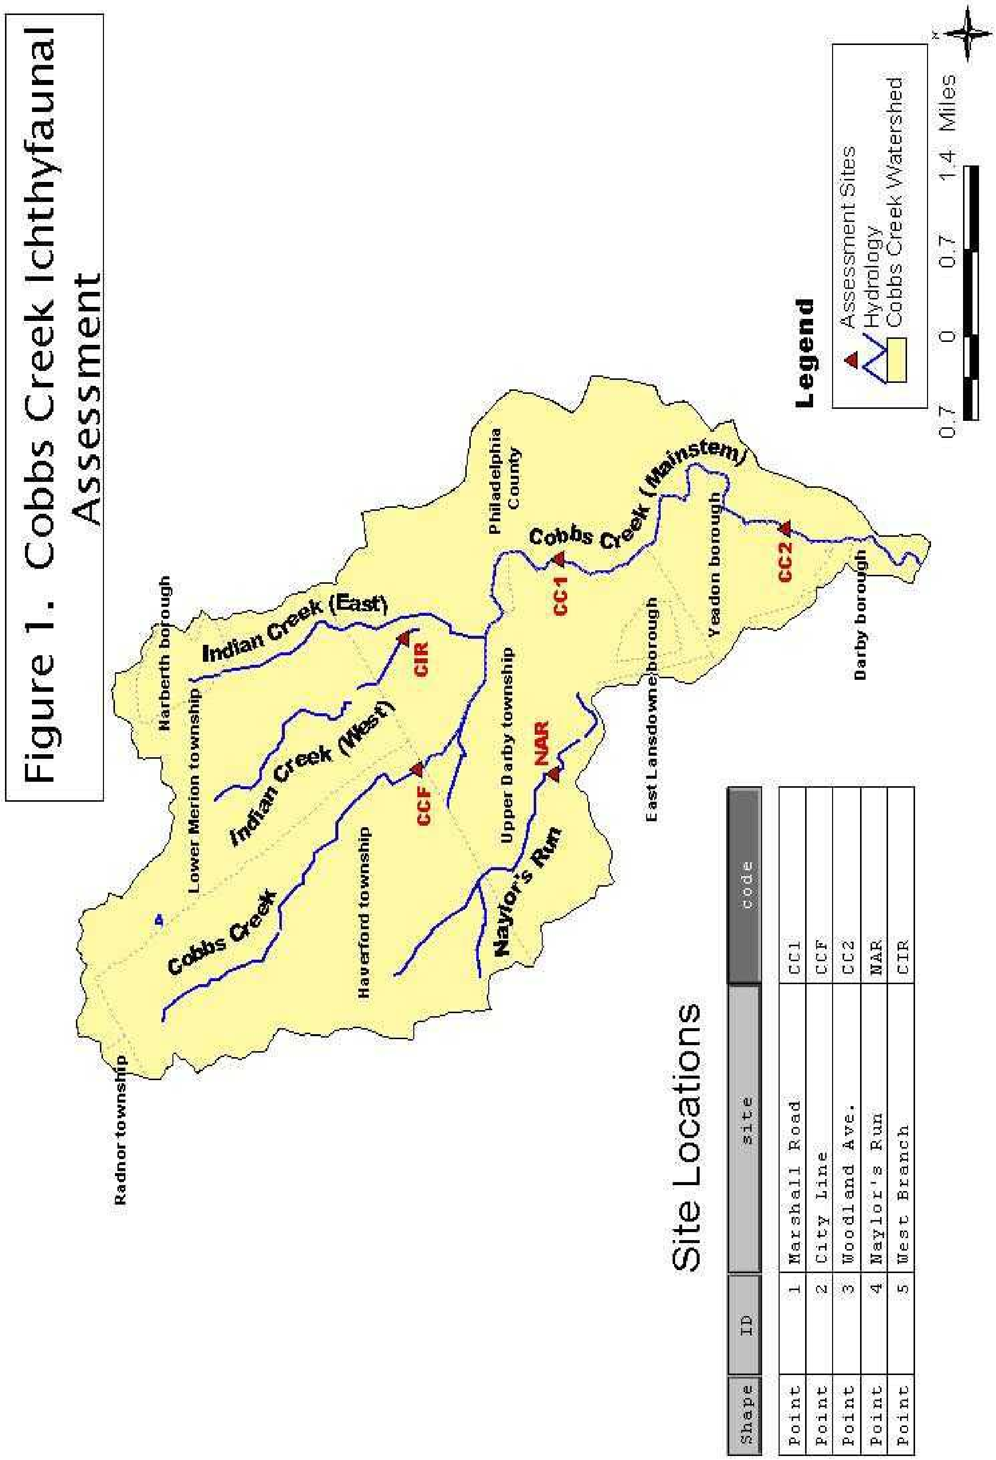
Five sampling stations were chosen on Cobbs Creek; three on the main stem and two sites on the smaller tributaries, West Branch Indian Creek and Naylor's Run. Prior to the main stem analysis, the Academy of Natural Sciences (ANS) completed their assessment on the three tributaries and were interested in completing a watershed analysis on Cobbs Creek. Data from these sites was provided to the Philadelphia Water Department and the Pennsylvania Department Of Environmental Protection (PADEP).

DCC-820: Main Stem (Cobbs Creek, Montgomery County): CCF

Sampling occurred on the main stem of the Cobbs Creek approximately 50 meters above City Line Avenue, Montgomery County (Latitude: 39°58′30.72″ Longitude: 75°16′51.60″, Figure 6-5). Using EPA protocols for rapid bioassessment, a 150 meter reach was measured using a graduated tape and both upstream and downstream portions were blocked off using standard seining nets. Two Coffelt backpack electro-shockers were operated at 50-75 watts direct current (DC). Fish were collected using D-frame dip nets, and identified to species and total length of each individual. Upon completion, an additional pass without replacement was completed.

The site name conventions in some graphics, including Figure 6-5 correspond to the current convention as follows:

Old Site Name Conventions	New Site Name Convention
CC1 / Site 1	DCC455
CCF / Site 2	DCC770
CC2 / Site 3	DCC110
NAR / Site 4	DCN215
CIR / Site 5	DCIW100



Shape	ID	site	code
Point	1	Marshall Road	CC1
Point	2	City Line	CCF
Point	3	Woodland Ave.	CC2
Point	4	Naylor's Run	NAR
Point	5	West Branch	CIR

Figure 6-5 Cobbs Creek Ichthyfaunal Assessment

DCC-175: Mainstem (Cobbs Creek, Philadelphia County): CC2

Sampling procedures occurred on the mainstem Cobbs Creek near Mt. Moriah Cemetery (Latitude: 39°56′4.92″ Longitude: 75°14′12.84″, Figure 6-5). Using EPA guidelines for ichthyfaunal assessment, a 200 meter reach was blocked off using standard seining nets. Fish collection, identification and health assessment at this location were similar to the DCC-820 collection. For more information on the methodology concerning fish assessment, refer to Barbour et. al. (1999).

DCN-215 and DCIW-100: (Tributaries To The Main Stem)

Prior to field sampling on Cobbs Creek main stem, the Academy of Natural Sciences conducted a field analysis on two tributaries, Naylor's Run (DCN-215) and West Branch Indian Creek (DCIW-100), and an additional site on the main stem of Cobbs Creek (DCC-505) (Figure 6-5).

3.3.2 Biological Assessment (Fish Biosurvey And Data Analysis)

Six metrics were used to assess the quality of the fish assemblages in Cobbs Creek (Table 6-2).

Table 6-2 Quantitative and Qualitative Analyses of Cobbs Creek Ichthyfaunal Community

1. **Species Richness**
2. **Species Diversity**
3. **Trophic Composition Relationships**
4. **Pollution Tolerance Levels**
5. **Disease and Parasite Abundance/Severity**
6. **Introduced (exotic) Species**
7. **Species descriptions***
   *Not used as a metric

Species Richness:

The first metric, species richness, addresses the total number of native fish species and generally signifies increased stream degradation as the number of species decreases. Number of native species, however, is strongly correlated to stream size at small stream sites and thus, it is important to develop species/waterbody size relationships for future assessments in the Darby-Cobbs watershed (Karr et al, 1986).

Species Diversity:

Species diversity, a characteristic unique to the community level of biological organization, is an expression of community structure (Brower et al., 1990). In general, high species diversity indicates a highly complex community. Thus, population interactions involving energy transfer (e.g. food webs), predation, competition and niche distribution are more complex and varied in a community of high species diversity. In addition, many ecologists support species diversity as a measure of community stability (i.e. the ability of community structure to be unaffected by perturbations). Using the Shannon-Weiner (H') index, the following formulas were used to calculate species diversity at each sampling location:

$$H' = -\sum (Pi)(\ln Pi), \qquad \text{(eq. 1)}$$

$$Pi = \frac{ni}{N}; \qquad \text{(eq. 2)}$$

where pi is the proportion of the total number of individuals n occurring in species I to the total number of species counted N.

Trophic Composition and Tolerance Designations:

Trophic composition metrics were used to assess the quality of the energy base and trophic dynamics of the fish assemblages (Plafkin et al., 1989). The trophic composition metrics offer a means to evaluate the shift toward more generalized foraging that typically occurs with increased degradation of the physiochemical habitat (Barbour et al., 1999). Pollution tolerance metrics were also used to distinguish low and moderate quality sites by assessing tolerance values of each species identified at the sampling locations. For a more detailed description of metrics used to evaluate the trophic and pollution designations of fish assemblages see Barbour et. al. (1999).

Disease and Parasite Abundance/Severity:

Two species, Rhinichthys atratulus and Catastomus commersoni, were used to assess the severity of parasite infestation on two fish populations. Using a sub-sample of individuals (n=15) located at Cobbs Creek at City Line (DCC-820) and Cobbs Creek near Woodland Avenue (DCC-175), the ranking of parasite infestation was based on the severity of trematode cysts, ranging from 0 (no infestation) to 3 (heavily infested). A one-way analysis of variance (ANOVA) was used to determine the significance of trematode cyst infestation on R. atratulus and C. commersoni between sites. While trematode cysts are generally not pathenogenic to fish species, the presence and severity of infestation represents a stressed and weakened community. Trematode cysts can cause damage to gill function (e.g. respiration) and skin defects (e.g. peeling and loss of proteins and fluids).

Proportion of Introduced/Exotic Species:

This metric was used as a qualitative approach to determine direct anthropogenic (e.g. human) effects on the stream ecosystem through introduction of non-native species. Generally, as environmental degradation increases, the percent of introduced species also increases. In addition, invasive species are also capable of shifting community dynamics by eliminating native species.

Species Descriptions:

Descriptions of habitat, functional feeding groups, reproduction and migratory processes of individual species were also created in this report to serve as an educational component for future work with community organizations, neighboring municipalities and educational systems within Philadelphia and surrounding school systems.

Benthic (Macroinvertebrate) Sampling

On December 6th-7th, 1999, the Pennsylvania Department of Environmental Protection (PADEP), Office of Watersheds and the Bureau of Laboratory Services conducted Rapid Bioassessment Protocols (RBP III) on seven sites (Figure6-6) in the Cobbs Creek watershed. Using EPA guidelines, macroinvertebrates were collected by placing a standard D-frame dipnet at the downstream portion of a riffle.

The substrate was then kicked and scraped manually one meter from the net aperture to remove all benthic species. This procedure was repeated at another riffle location with less flow. Specimens were then preserved in 95% ETOH (ethyl alcohol) and returned to the laboratory in polyethylene containers. In laboratory, samples were placed in a 11" x14" gridded (numbered) pan and random "plugs" were examined until 100 individuals were collected. Macroinvertebrates were identified to genus and population estimates were calculated. Using the following flowchart, the biological integrity and benthic community composition was determined (EPA guidelines for RBP III and PADEP Modified Rapid Biological Assessments) (Table 6-3):

Table 6-3: Biological Condition Scoring Criteria For RBP III

Metric	Biological Condition Scoring Criteria			
	6	4	2	0
Taxa Richness (a)	>80%	79-70%	69-60%	<60%
Hilsenhoff Biotic Index (Modified) (a)	<0.71	0.72-1.11	1.12-1.31	>1.31
Modified EPT Index (a)	>80%	79-60%	59-50%	<50%
%Contribution of Dominant Taxon (a)	<10	11-16	17-22	>22
%Modified Mayflies (a)	<12	13-20	21-40	>40
Ratio of Scrapers/Filter (b) Collectors	>50%	35-50%	20-35%	<20%
Community Loss Index (b)	<0.5%	0.5-1.5	1.5-4.0	>4.0
Ratio of Shredders/Total (b)	>50%	35-50%	20-35%	<20%

(a) Metrics used to quantify scoring criteria (PADEP)
Additional metrics used for qualitative descriptions of sampling locations (EPA)

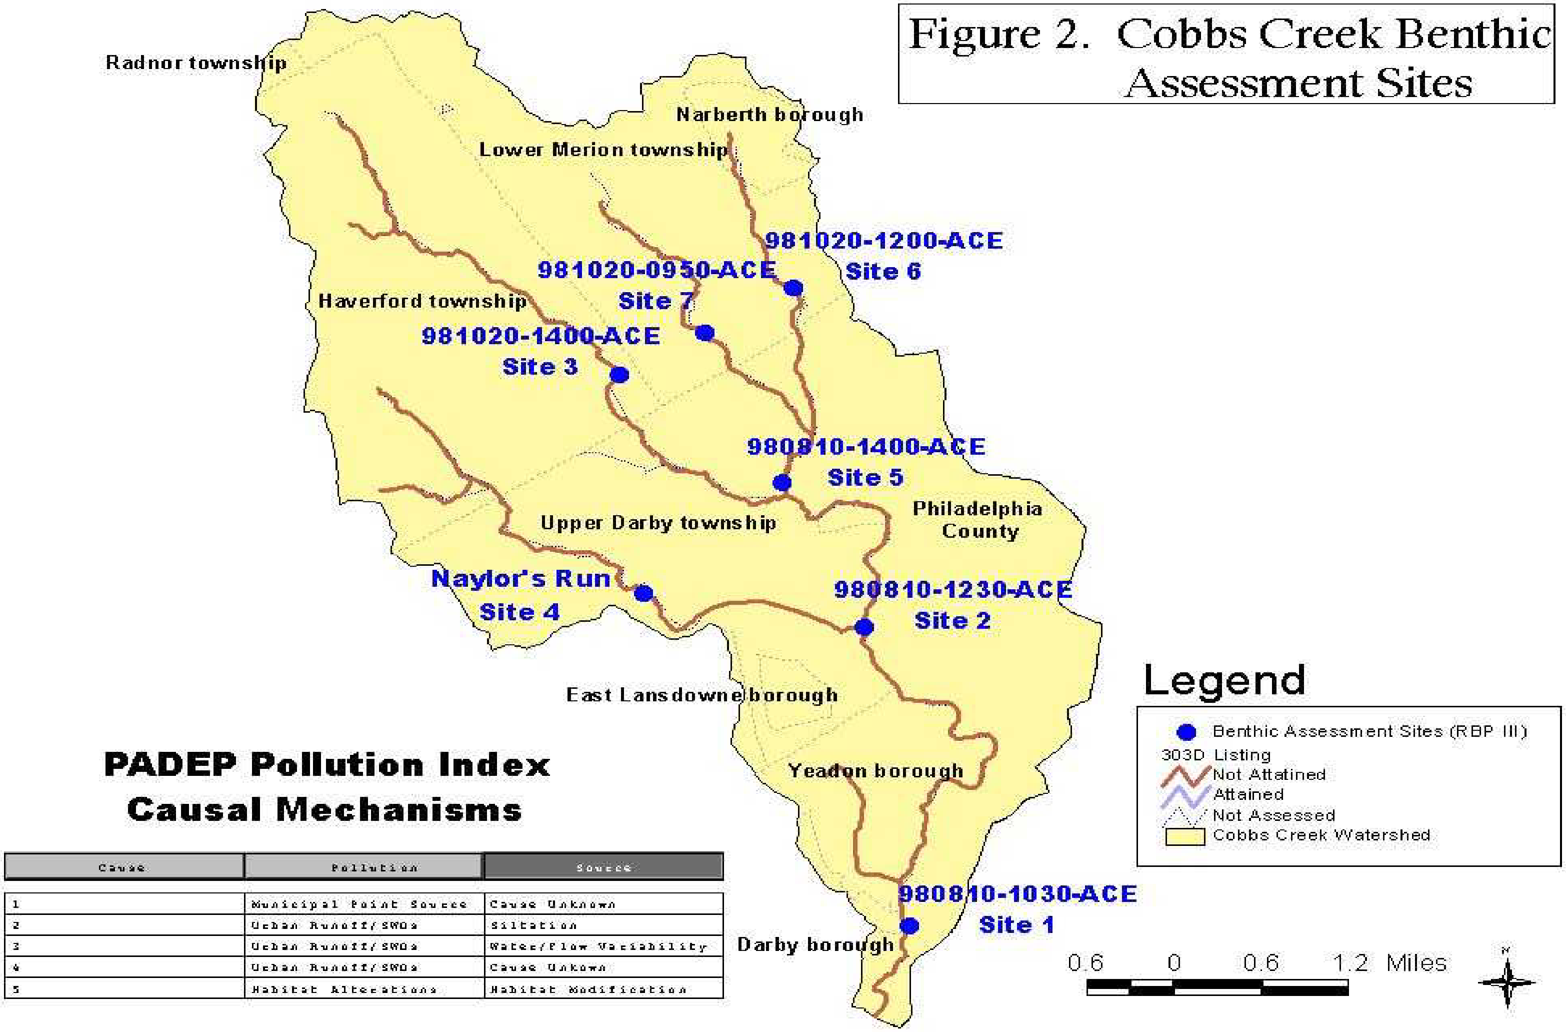


Figure 2. Cobbs Creek Benthic Assessment Sites

PADEP Pollution Index
Causal Mechanisms

Cause	Pollution	Source
1	Municipal Point Source	Cause Unknown
2	Urban Runoff/SWOs	Siltation
3	Urban Runoff/SWOs	Water/Flow Variability
4	Urban Runoff/SWOs	Cause Unkown
5	Habitat Alterations	Habitat Modification

Figure 6-6 Cobbs Creek Ichthyfaunal Assessment

Upon completion of the total biological scoring criteria, each site was compared to a reference site according to its drainage area and geomorphological attributes. The two reference sites chosen were Broad Run (located at the intersection of Chestnut Lane and Broad Run Road, West Bradford Township, Chester County) and French Creek (located at Coventry Road Bridge, South Coventry Township, Chester County). Using the following chart, a biological assessment of each site was established in attempt to create a baseline for monitoring trends in benthic community structure that might be attributable to improvement or worsening of conditions over time (Table 6-4):

Table 6-4 Bioassessment of Benthic Community Structure (RBPIII)

% Comparison to Reference Score [(a)]	Biological Condition Category	Attributes
>83%	Nonimpaired	Comparable to the best situation within an ecoregion. Balanced trophic structure. Optimum community structure for stream size and habitat quality.
54-79%	Slightly impaired	Community structure less than expected. Composition (species and dominance lower than expected due to loss of some intolerant forms. Percent contribution of tolerant forms increases.
21-50%	Moderately impaired	Fewer species due to loss of most intolerant forms. Reduction in EPT index.
<17%	Severely impaired	Few species present. If high densities of organisms, then dominated by one or two taxa.

(a)Percentage values obtained that are intermediate to the above ranges will require subjective judgment as to the correct placement. Use of the habitat assessment and physiochemical data may be necessary to aid in the decision process.

Habitat Assessment

Prior to the benthic procedures, habitat assessments at the seven sites were completed based on the Stream Classification Guidelines for Wisconsin (Ball, 1982) and Methods of Evaluating Stream, Riparian, and Biotic Conditions (Platts et al., 1983). Reference conditions were used to normalize the assessment to the "best attainable" situation. Habitat parameters are separated into three principal categories:

(1) primary, (2) secondary, and (3) tertiary parameters.

Primary parameters are those that characterize the stream "microscale" habitat and have the greatest direct influence on the structure of the indigenous communities.

Secondary parameters measure the "macroscale" habitat such as channel morphology characteristics. Tertiary parameters evaluate riparian and bank structure and comprise three categories: (1) bank vegetative protection, (2) grazing or other disruptive pressure, and (3) and riparian vegetative zone width. The following chart (Table 6-5) describes the analysis that was completed:

Table6-5: Habitat Assessment Criteria Used at Benthic Monitoring Stations*

Condition/Parameter	Condition			
	Optimal	**Suboptimal**	**Marginal**	**Poor**
Primary-Substrate And Instream Cover				
Instream Cover	**16-20**	**11-15**	**6-10**	**0-5**
Epifaunal Substrate	**16-20**	**11-15**	**6-10**	**0-5**
Velocity/Depth regimes	**16-20**	**11-15**	**6-10**	**0-5**
Secondary-Channel Morphology				
Channel alteration	**16-20**	**11-15**	**6-10**	**0-5**
Sediment Deposition	**16-20**	**11-15**	**6-10**	**0-5**
Frequency of Riffles	**16-20**	**11-15**	**6-10**	**0-5**
Channel Flow Status	**16-20**	**11-15**	**6-10**	**0-5**
Tertiary-Riparian and Bank Structure

*Habitat assessment parameters used were in agreement with Pennsylvania Department Of Environmental Protection's Unassessed Waters Program.

6.2.3 Results

Fish Analysis:

Rapid Bioassessment Protocol V (RBP V) (Plafkin et al. 1989) is perhaps the most common method for assessing fish communities by using an established Index of Biotic Integrity (IBI) similar to that described by Karr et al. (1986). Due to temporal differences in fish collection on Cobbs Creek by the Academy of Natural Sciences and the Office of Watersheds, the data provided by this sampling effort were used to assess the general condition of the resident fish population as a function of abundance and diversity. Trophic relationships, tolerance values and percent infestation were also used as a means to quantify the overall health of the fish assemblage. The taxonomic list and common names of fish collected in Cobbs Creek watershed are displayed as an attached appendix (Table 6-6). In addition, an identification list of fish species comprising habitat preference, reproductive strategies and feeding behaviors is also included in the appendix (Figure 6-7).

Species Richness And Diversity

Fish abundance, richness and diversity varied greatly among the five sampling locations (Table6-6).

Table 6-6 Species abundance, richness and diversity (H′) at the five sampling locations on Cobb Creek.

Species	DCIW-100	DCC-820	DCN-215	DCC-505	DCC-175
American Eel	0	15	19	6	8
Brown Bullhead	0	0	0	0	2
White Sucker	10	190	0	19	20
Banded Killifish	0	0	0	0	74
Mummichog	0	0	17	16	171
Redbreast Sunfish	0	0	3	0	31
Pumpkinseed	0	14	6	1	2
Common Shiner	0	415	21	52	1
Spottail Shiner	0	0	0	3	1
Swallowtail Shiner	0	5	549	145	49
Fathead Minnow	0	0	0	0	48
Green Sunfish	0	0	1	0	0
Blacknose Dace	86	651	333	59	48
Creek Chub	7	48	0	0	1
Total Number	**103**	**1338**	**949**	**301**	**456**
Total Taxa	**3**	**7**	**8**	**8**	**13**
Shannon-Weiner Diversity Index (H')	**0.56**	**1.23**	**0.97**	**1.44**	**1.85**

Cobbs Creek at Indian Run (DCIW-100) displayed the lowest fish density and species richness (n=3) (Figure 6-7). The dominant taxon at this location was Blacknose Dace, *Rhinichthys atratulus*, (83.0%), a generalist/insectivore feeder with the ability to withstand high levels of pollution. The Shannon Diversity Index (H') value at this location was 0.56, also indicating low species richness as well as low relative diversity (evenness).

Cobbs Creek at City Line Avenue (DCC-820) possessed the highest number of individuals, dominated by white sucker (*Catastomus commersoni*) (14.2%), and two cyprinid species, common shiner (*Luxilus cornutus*) (31.0%) and blacknose dace (*Rhinichthys atratulus*) (48.7%). In addition, the catadromous species, *Anguilla rostrata*, was also present at this location although means of migration from into the Cobbs Creek watershed appear to be impeded due to dam structures (e.g. Woodland Avenue).

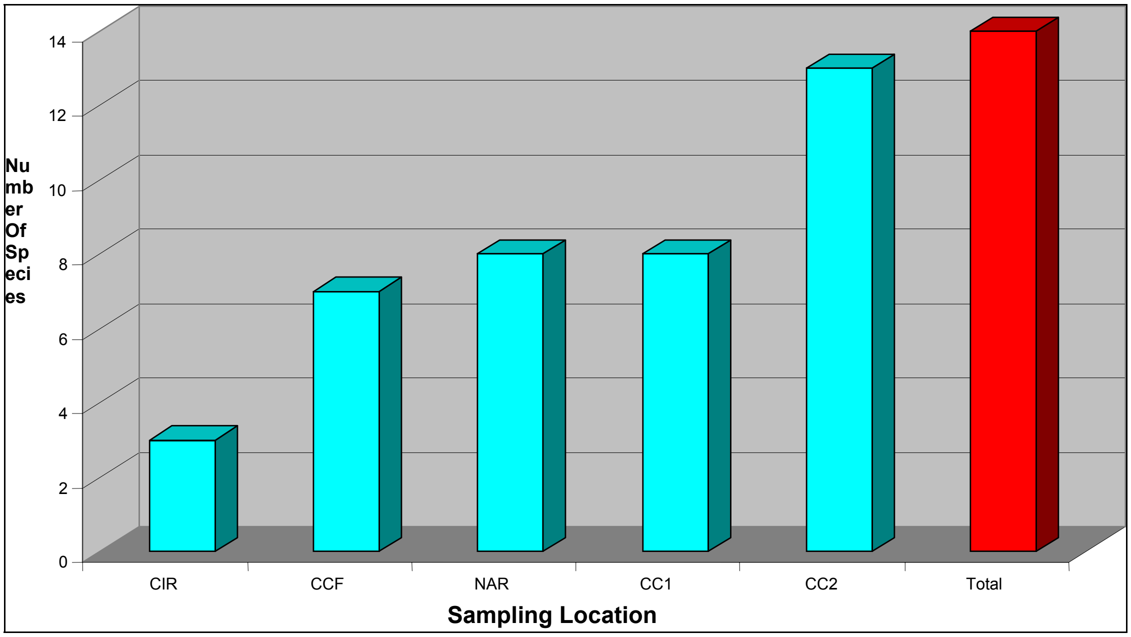

Figure 6-7 Number of species at each sampling location in Cobbs Creek.

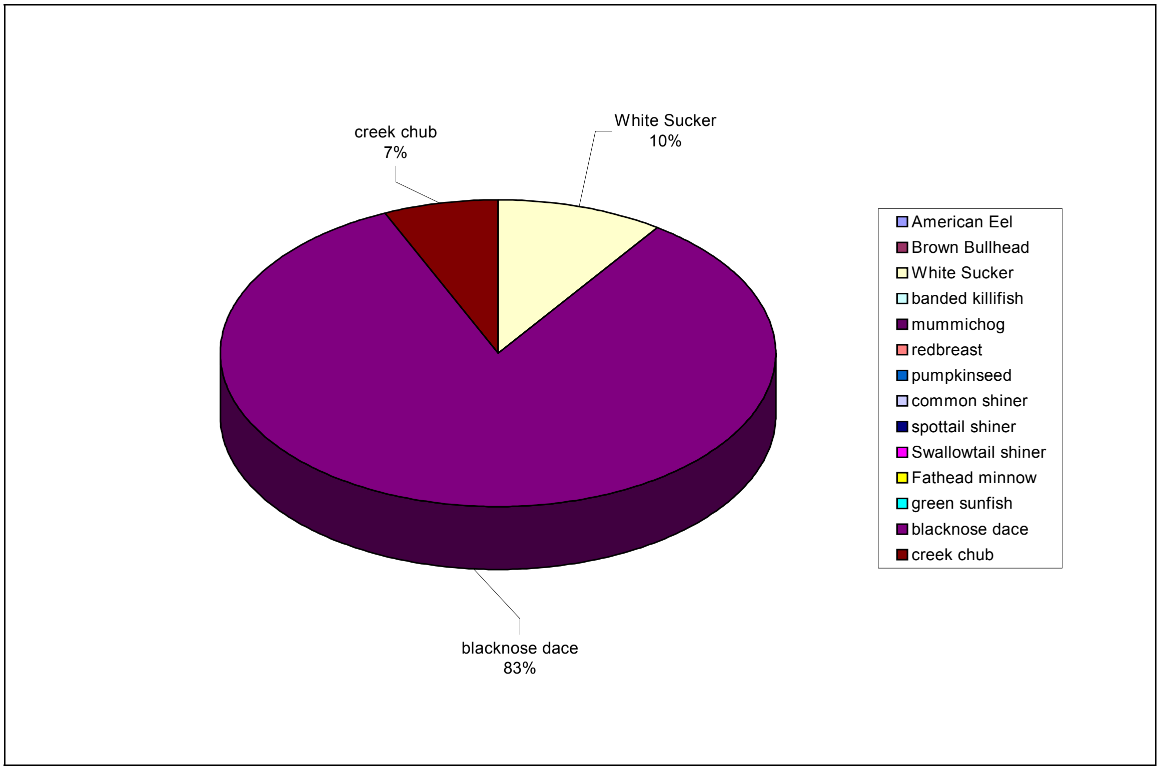

Figure 6-8 Species distribution (%) at West Branch Indian Run (DCIW-100)

Naylor's Run (DCN-215) and Cobbs Creek at Marshall Road (DCC-505) both contained a similar number of taxa (n=8) with dominant species being swallowtail shiner, *Notropis procne*, (57.9% and 48.2%, respectively) and blacknose dace, *R. atratulus* (35.1% and 19.6%, respectively). Common shiner, *Luxilus cornutus*, and mummichog, *Fundulus heteroclitus*, were also common species at these locations. Although Naylor's Run (DCN-215) station was higher in fish abundance (N=949) than Marshall Road (DCC-505) (N=301), the species diversity (H') value at DCC-505 was greater (1.44), indicating a more evenly distributed community.

Cobbs Creek at Woodland Avenue (DCC-175) displayed the highest species richness (n=13) and species diversity value (H'=1.855) of all the five monitoring locations. Dominant species at DCC-175 were *Fundulus diaphanus* (16.2%), *F. heteroclitus* (37.5%), *N. procne* (10.7%), *Pimephales promales* (10.5%) and *R. atratulus* (10.5%). While these metrics indicate a relatively diverse and evenly distributed community, four of the dominant species are classified as "pollution tolerant", capable of low oxygen concentrations and able to persist in physically and chemically degraded habitats.

Table 6-7 Species distribution (%) at all sites

SITES SPECIES	DCC-505	DCC-820	DCC-175	DCN-215	DCIW-100
American Eel	2.0	1.1	1.8	2.0	
Brown Bullhead			0.4		
White Sucker	6.3	14.2	4.4		
Banded Killish			16.2		10.0
Mummichog	5.3		37.5	1.8	
Redbreast			6.8	0.3	
Pumpkinseed	0.3	1.0	0.4	0.6	
Common shiner	17.3	31.0	0.2	2.2	
Swallowtail shinner	48.2	0.4	10.7	57.9	
Fathead minnow			10.5		
Green sunfish				0.1	
Blacknose dace	19.6	48.7	10.5	35.1	83.0
Creek chub		3.6	0.2		7.0
Spottail shinner	1.0				

Trophic Composition And Tolerance Designations

Functional feeding guilds for all five assessment sites are displayed in Table 6-8. Trophic designations (e.g. piscivore, invertivore, omnivore) of each taxon compiled in this report were obtained from literature by Barbour et al. (1999) and Halliwell et al. (1999). Results show that all sites are dominated by insectivores (80%-95%) with the exception of Cobbs Creek at Woodland Avenue (DCC-175) where the dominant functional feeding group is primarily generalist feeders (55.9%). In addition, the percent of piscivorous species at all locations is moderately low (1.1%-2.0%), with Indian Run (DCIW-100) containing no piscivorous species. This condition may be due to the lack of adequate habitat for large predatory species (e.g. deep pool systems).

Table 6-8 . Functional feeding guilds (%) at all sites

Functional Feeding Species	DCC-505	DCC-820	DCC-175	DCN-215	DCIW-100
Generalist Feeder	5.6	4.6	55.9	2.7	7
Insectivore	86.0	80.0	37.9	95.2	83.0
Omnivore	6.3	14.2	44.0	0.1	10.0
Piscivore	2.0	1.1	1.8	2.7	-

Tolerance values, expressed as the percentage of tolerant, intermediate and intolerant taxa, are shown in Figure 6-9. Fish assemblage at Indian Run (DCIW-100) showed the highest percentage (100%) of pollution tolerant species, consisting of three taxa (*Semotilus atromaculatus*, *Rhinichthys atratulus*, and *Catastomus commersoni*). Sites on Naylor's Run (DCN-215), Cobbs Creek at Marshall Avenue (DCC-505) and Cobbs Creek at Woodland Avenue (DCC-175) had similar percentages of moderately tolerant (58%-74%) and tolerant individuals (26%-42%). The percentage of pollution tolerant taxa at Cobbs Creek City Line (DCC-820) was substantially higher (66%) than the previously mentioned sites. More importantly, no sampling sites contained individuals classified as "pollution intolerant", indicating the probability of episodic periods of impaired water quality or habitat degradation.

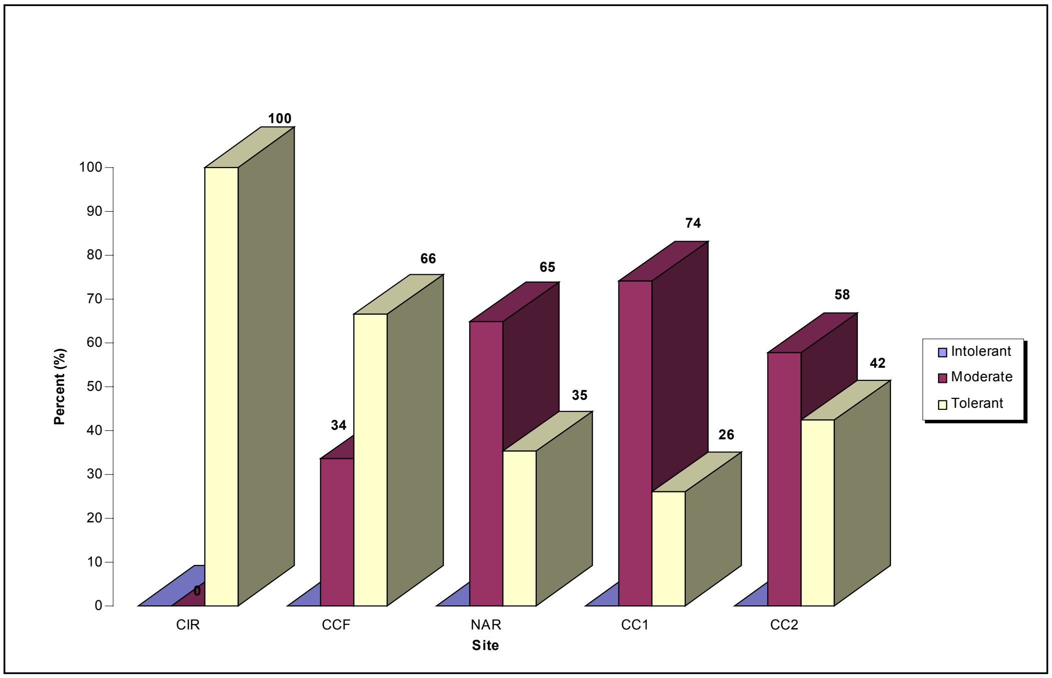

Figure 6-9 Fish tolerance levels at the five biomonitoring stations. Numbers indicate percentages in each tolerance category.

Disease and Parasite Abundance/Severity

Results from the study show significant differences in the amount of trematode infestation in both blacknose dace (R. atratulus) and white sucker (C. commersoni) between Cobbs Creek at City Line Avenue (DCC-820) and Cobbs Creek at Marshall Road (DCC-175) (p=0.0007 and p=0.0168, respectively) (Table6-9).

Table 6-9 ANOVA analysis of locational effects on trematode infestion in R. atratulus and C. commersoni shown as F statistics. Significance: *p<0.05, **p<0.01, and ***p<0.001.

Species	MS Effect	MS Error	F statistic
Blacknose Dace	8.533	0.581	14.688***
White Sucker	4.033	0.623	6.465*

Blacknose dace showed a higher abundance of trematode cysts at site DCC-175 (x=2.33 ± 0.72) when compared to site DCC-820 (x=1.27 ± 0.80) (Figure 3.15.). Similarly, severities of trematode cysts on white sucker at site DCC-175 were significantly higher than infestation rates at DCC-820 (x=1.87 ± 0.83 and x=1.13 ± 0.74, respectively).

Proportion of Introduced Species

Of the five sampling sites, Naylor's Run (DCN-215) and Cobbs Creek at Woodland Avenue (DCC-175) were the only sites that contained introduced/exotic species. These species were identified as green sunfish, *Lepomis cyanellus*, and fathead minnows, P*imephales promelas*. Although present, *L. cyanellus* and *P. promelas* at sites DCN-215 and DCC-175 were not dominant species within the community (0.001% and 0.105%, respectively).

Benthos

Scientific names and functional feeding groups of macroinvertebrates collected in Cobbs Creek watershed (11/10/99) are attached as an appendix. A master identification list of the macroinvertebrate community describing species specific attributes (e.g. life-history traits) and graphic representations of trophic designations are included in the appendix. Biological metrics calculated for the seven monitoring locations as well as the reference stations, French Creek and Broad Run, are also displayed in the Appendix .

DCC-110: (Cobbs Creek Mainstem, Philadelphia County):

The macroinvertebrate assemblage at DCC-110 received a total metric score of 6, representing 20.0% comparability to the reference conditions at French Creek and placing the benthos in the "moderately impaired" category (Tables 6-10 and 6-11). Samples collected in the 1999 survey were dominated by the filter-feeding caddisfly, Hydropsychidae. This dense filter-feeding assemblage appears to reflect the effects of moderate organic enrichment, and is indicative of an unbalanced community responding to an overabundance of a food resource---in this case Fine Particulate

Organic Matter (FPOM). The low abundance of scrapers relative to filtering collectors also corroborates that the FPOM has displaced periphyton as a food resource at DCC-110. Low taxa richness (56.3% comparability), an elevated Hilsenhoff metric (5.46) and the absence of modified EPT taxa (Hilsenhoff ≤ 3) indicate potentially episodic periods of poor water quality and/or habitat degradation.

DCC-110 received a total habitat assessment score of 109/240 and was the lowest habitat score received by a biomonitoring station during the 1999 survey. Total score reduction was mostly affected by low scores for epifaunal substrate, channel alteration, sediment deposition, frequency of riffles and riparian vegetative zone width. Stream reach characteristics included embedded riffle systems where 50%-75% of the gravel, cobble and boulder particles are surrounded by fine sediment. Well-defined pool systems were absent due to substantial sediment deposition throughout the stream reach.

Table 6-10 Metrics Used in Comparison of Cobbs Creek Stations to the Reference Sites.

Metric	DCC-110	DCC-455	DCC-865	DCN-185	DCIW-010	DCI-135	DCIW-185

Assessment Category	Partially Supporting	Partially Supporting	Comparable To Reference	Partially Supporting	Supporting	Partially Supporting	Partially Supporting

DCC-455: Cobbs Creek Mainstem and Naylor's Run Confluence (Philadelphia County):

DCC-455 received a biological scoring metric of 6 (20% comparability), placing the stream reach in the "moderately impaired" category, similar to that of DCC-110. Despite scoring high on the taxa richness metric (score: 6), all additional metrics received the lowest scores possible (score: 0). *Hydropsyche* sp. (n=20), *Cricotopus* sp. (n=14) and *Caecidotae* sp. (n=19) represented the three dominant taxa, all possessing Hilsenholff tolerance values ≥ 5. Similarly, the modified Hilsenholff score for DCC-455 was 6.31, indicating a tolerant macroinvertebrate assemblage. Functional feeding designations show a diverse trophic assemblage with filtering collectors and gathering collectors comprising a majority of the benthic community (34% and 31%, respectively). The absence of sensitive EPT taxa and modified mayflies also corresponds to the potential problems described at DCC-110.

The habitat assessment score at DCC-455 was 116/200, designating the site as "partially supporting" when compared to the reference station, French Creek (181/224). Reduction in habitat score at DCC-455 was due to low values for channel flow status, grazing or other disruptive pressure and riparian vegetative zone width. Riffle substrates were mostly exposed along with the decreased amount of water filling the stream channel. All additional scores, excluding sediment deposition (score: 16/20), ranged in the suboptimal to marginal categories.

DCC-865: Cobbs Creek Mainstem (Haverford Township, Delaware County):

The benthos assemblage at DCC-865 received a total metric score of 6, representing 20% comparability to "best attainable" conditions at French Creek. Dominant taxon at this sampling site was the net spinning caddisflies (*Hydropsyche* sp. and *Cheumatopsyche* sp.). The preponderance of hydropsychids (38% relative abundance) along with absence of a scraper population is similar to that of both DCC-110 and DCC-455, indicating the possibility of organic enrichment at this location. Also, the abundance of both filtering collectors (42%) and generalist feeders (16%) corroborates that FPOM is the dominant food resource in this area. DCC-865 received the highest Hilsenholff score (6.55) of all sites, indicating a moderately high pollution tolerant benthic community.

Despite being placed in the "moderately impaired" category for biological integrity, DCC-865 received the highest habitat assessment score (166/224) of all the seven sampling locations. High values were attributed to adequate instream cover, a well-defined channel with little evidence of accelerated sedimentation processes, ample vegetative cover along the banks and a substantial riparian buffer along the stream reach.

DCN-185: Naylor's Run (Upper Darby Township, Delaware County):

The macroinvertebrate assemblage at DCN-185 received a biological score of 10, representing 33.3% comparability to the reference station, Broad Run, and placing the benthic community in the "moderately impaired" category. Perhaps the most obvious problem associated with DCN-185 is the low abundance of macroinvertebrates collected and sorted at this location (n=54). The dominance of the hydropsychid caddisflies, categorized as filtering collectors (44%), high HBI score (6.28) and the lack of genera belonging to the Families Plecoptera, Trichoptera and Ephemeroptera are all indicators that Naylor's Run is biological impaired by physiochemical degradation along this reach.

In addition to benthic impairment, Naylor's Run received a total habitat score of 130/224, designating the site as "partially supporting" when compared to Broad Run. The reduction in habitat score is attributed to a heavily embedded substrate (score: 5/20) and the lack of riparian vegetation (score: 5/20). Despite having multiple riffle systems, all other metrics ranged in the suboptimal (11-15) and marginal (6-10) categories.

DCIW-010: Confluence of West Branch Indian Creek and East Branch Indian Creek (Philadelphia County):

DCIW-010 received a total biological score of 10 (33% comparability), placing the site in the "moderately impaired" category. The preponderance of Hydropsyche sp. and Cheumatopsyche sp. (48% relative abundance) at DCIW-010 is characteristic of a reach dominated by filtering collectors, indicating organic enrichment as a possible reason for the skewed community structure. Additional attributes of DCIW-010 are the absence of modified mayflies (Hilsenholff ≤ 3) and modified EPT taxa (Hilsenholff ≤ 3) and decreased ratio of shredder taxa to total taxa, all indicators of a biologically impaired stream reach.

The total habitat assessment score of DCIW-010 was 133/224, placing the stream reach in the "supporting" category. A decreased habitat score can be attributed to sediment deposition (score: 7) and riparian zone width (score: 5).

DCI-135: East Branch Indian Run (Lower Merion Township, Montgomery County):

DCI-135 benthos assemblage received a total metric score of 10, representing 33.3% comparability to "best attainable" conditions at Broad Run. In addition to the absence of modified mayflies and sensitive EPT taxa, the site is dominated by filtering collectors and gathering collectors (27% and 35%, respectively). A large proportion of shredder feeders (23%) represented by the genera *Cricotopus* sp. were present at the sampling site. Dominant taxa at the East Branch Indian Creek monitoring location were *Caecidotea* sp. (n=27), *Cricotopus* sp. (n=22) and Hydropsyche sp. (n=17).

East Branch of Indian Creek received a total habitat assessment score of 130/224, designating the site as "partially supporting" when compared to Broad Run. The decrease in overall habitat score can be attributed to channel flow status (score: 6) where a majority of flow composed approximately 50% of the channel, and the lack of a riparian zone (score: 2) where vegetation had been disturbed through anthropogenic influence (e.g. grass cutting, tree clearing).

DCIW-185: West Branch Indian Creek (Lower Merion Township, Montgomery County):

The total biological score at DCIW-185 was 4, representing 13.3% comparability to the reference site and designating the site as "severely impaired". All metrics scored poorly (score: 0) with the exception of percent dominant taxa (score: 4). Of the total amount of individuals collected (n=97), 66% belonged to the family *Hydropsychidae*, a pollution tolerant taxa indicative of possible organic enrichment. Similar to the other monitoring locations, West Branch of Indian Creek did not contain any modified mayflies, nor did the site include any modified EPT taxa. The ratio of scrapers to filtering collectors was also low, indicating an unbalanced community represented by pollution tolerant taxa (modified HBI=6.06).

When compared to the reference site, Broad Run, DCIW-185 received a total habitat score of 118/224 (67.82% comparability). Overall score reduction was attributed to the degraded condition of both banks and the lack of a riparian buffer. Habitat scores corroborated with the biological criteria, indicating an impaired stream reach due to anthropogenic stressors (e.g. bank erosion due to clear cutting).

6.2.3 Summary of Biology and Habitat by Reach

Upper Cobbs Creek

Seven sampling sites represent the headwaters and upper reaches of Cobbs Creek. Site DCI-135 is on Indian Creek main stem, 1.35 miles upstream of the confluence with Cobbs Creek. DCIW-185, DCIW-100, and DCIW-010 are located along Indian Creek West Branch. DCC-865, DCC-820, and DCC-770 are on the main stem of Cobbs Creek. These sites are all above the CSO-impacted area.

All of the Cobbs Creek subwatershed is considered unattained by PADEP, indicating that current conditions do not support designated uses. Additional RBP III benthic assessments at three sites score between 20% and 33% of the reference stream score and are classified as moderately impaired. The results of RBP V assessments indicate that fish species richness and diversity at DCIW-100 are the lowest of the sites studied in the Cobbs Creek subwatershed; however, it is important to consider the effect of stream size when evaluating these parameters. In addition, no piscivores were found at this site. Species richness and diversity at DCC-820 were similar to conditions found farther downstream on Cobbs Creek. All species found at DCIW-100 are considered pollution tolerant, while 66% of species found at DCC-820 are considered pollution tolerant and the remainder are considered moderately tolerant. Habitat scores ranged from 68% (DCIW-185, classified as partially supporting) to 92% (DCC-865, classified as comparable to the reference stream) of reference stream conditions.

Lower Cobbs Creek

Five sampling sites represent lower Cobbs Creek. DCN-215 is on Naylors Creek, 2.15 miles upstream of the confluence with Cobbs Creek. The remaining sites are on Cobbs Creek: DCC-505, DCC-455, DCC-175, and DCC-110. These sites receive both stormwater and CSO discharges.

All portions of the Cobbs Creek subwatershed are considered unattained by PADEP. Additional RBP III benthic assessments at two sites score only 20% of the reference stream score and are classified as moderately to severely impaired. The results of RBP V assessments indicate that fish species richness and diversity are greater in Lower Cobbs than higher in the watershed; however, the increase in stream size should be considered when comparing these numbers. A smaller percentage of highly pollution-tolerant species are found at lower Cobbs sites compared to sites located further upstream; however, no pollution-intolerant species are found. Habitat scores at the two lower Cobbs study sites are between 60% and 64% of the reference stream score and are classified as partially supporting.

Upper Darby Creek

The headwaters of Darby Creek are represented by data taken by PADEP and ANS at six sites upstream of PA Route 3 and numbered STA01 (farthest upstream) through STA06 (farthest downstream). These sites are not impacted by known CSOs.

Darby Creek and its tributaries north of Route 3 are classified as attained by PADEP. The health of the benthic ecosystem includes the full range from poor to very good depending on the site. Criteria based on fish range from fair to good. Some erosion was observed at all sites, and erosion generally increases with distance downstream.

Lower Darby Creek

PADEP/ANS sampling sites were STA07, just downstream of PA Route 3 in Delaware County, through STA10, near PWD sampling site DCD-765. These sites are classified as unattained by PADEP. The health of the benthic ecosystem is rated as poor at the three sites studied, and the health of the fishery is rated fair at the three sites studied. Observed erosion is generally greater at these sites than at the sites located in the upper portions of Darby Creek and its headwaters.

Tinicum Area

Data availability is limited in the Tinicum area. The non-tidal portions of this subwatershed are considered unattained by PADEP.

Section 7 Characterization of Wetlands

The locations and condition of existing wetlands have been extensively characterized in the Cobbs Creek watershed. Opportunities for enhancement of existing wetlands have been identified. Opportunities for creation of new wetlands, for both treatment and habitat, have been identified. The "Cobbs Creek Watershed Wetland Analysis", scheduled for release in 2004, documents the results of these studies.

Section 8 Characterization of Fluvial Geomorphology

The fluvial geomorphology (shape and condition of stream channels and banks) of Cobbs Creek has been extensively studied. The results of the study are documented in “Geomorphologic Survey – Level II: Guiding Principles for Fluvial Geomorphologic Restoration”, released in 2003.

Section 9 Active and Potential Sources of Water Quality Constituents

9.1 Model Description and Data Sources

Introduction

This subsection summarizes the results of a preliminary estimate of loading rates of various pollutants to Darby Creek, Cobbs Creek, and tributaries. The waters in the drainage area receive point source discharges including municipal wastewater, CSO and other urban and suburban stormwater, sanitary sewer overflows, and limited industrial storm, process, and cooling waters. Combined sewers service approximately 6% of the watershed. Nonpoint sources in the basin include atmospheric deposition, overland runoff from urban and suburban areas, and individual on-lot domestic sewage systems discharging through shallow groundwater. The results were obtained using the detailed Storm Water Management Model (SWMM) in the Cobbs Creek subwatershed and the simpler Watershed Management Model (WMM) in the Darby and Tinicum subwatersheds.

The Storm Water Management Model (SWMM)

The U.S. EPA's Storm Water Management Model (SWMM) was used to develop the watershed-scale model for Cobbs Creek. The major components of the SWMM model used in the development of the Cobbs Creek watershed model were the RUNOFF and EXTRAN modules.

The RUNOFF module was developed to simulate both the quantity and quality of runoff in a drainage basin and the routing of flows and contaminants to sewers or receiving body. The program can accept an arbitrary precipitation (rainfall or snowfall) hyetograph and performs a step by step accounting of snowmelt, infiltration losses in pervious areas, surface detention, overland flow, channel flow, and water quality constituents leading to the calculation of one or more hydrographs and/or pollutographs at a certain geographic point such as a sewer inlet. The driving force of the RUNOFF module is precipitation, which may be a continuous record, single measured event, or artificial design event.

The EXTRAN module was developed to simulate hydraulic flow routing for open channel and/or closed conduit systems. The EXTRAN module receives hydrograph inputs at specific nodal locations by interface file transfer from an upstream module (e.g. the RUNOFF module) and/or by direct user input. The module performs dynamic routing of stormwater flows through storm drainage systems and receiving streams.

The SWMM model development and calibration process is discussed in detail in the Cobbs Creek SWMM Model Report.

The Watershed Management Model (WMM)

The Watershed Management Model provides an overall framework for estimating pollutant loads within a watershed and can be used as a screening level model in the preliminary stages of total maximum daily load (TMDL) development. WMM was originally developed to assess watershed management plans but also works well as a screening level load estimator. WMM uses land use categories and associated event mean concentrations (EMCs) to determine the non-point source load contribution within individual watershed planning areas. The model also includes estimates for tabulated municipal and industrial process water discharges. WMM was used to develop screening-level loads for the Darby and Tinicum portions of the Darby-Cobbs watershed.

WMM uses land use type, imperviousness, and event mean concentrations to generate seasonal and annual runoff flows and pollutant loads. The model also includes annual loads for point sources, CSOs, baseflow, and septic systems. WMM was refined (version 4.3.1) through EPA's Rouge River Wet Weather Demonstration Project and by the City of Westminster, Colorado and includes a user-friendly graphical interface built on an EXCEL® data structure and macro program. Because EPA funded the development of WMM, the Rouge River version is available in the public domain. WMM 4.3.1 for EXCEL® was used for this application because of the greater flexibility in assigning geographically distributed baseflows and baseflow concentrations.

WMM's capabilities, appropriate to this phase of the Darby and Cobbs Creeks Watershed Study, include:

- Estimates stormwater runoff pollution loads for nutrients (total phosphorus; total kjeldahl nitrogen, including organic nitrogen and ammonia; and total nitrite and nitrate), metals (cadmium, copper, lead, and zinc), oxygen demand, and sediment based on EMCs, land use, percent imperviousness, and annual rainfall.
- Estimates pollutant loads from stream baseflow.
- Estimates pollution loads from failing septic system.
- Applies delivery ratio to account for reduction in runoff pollution load due to uptake or removal in stream courses.

Data Needs and Sources

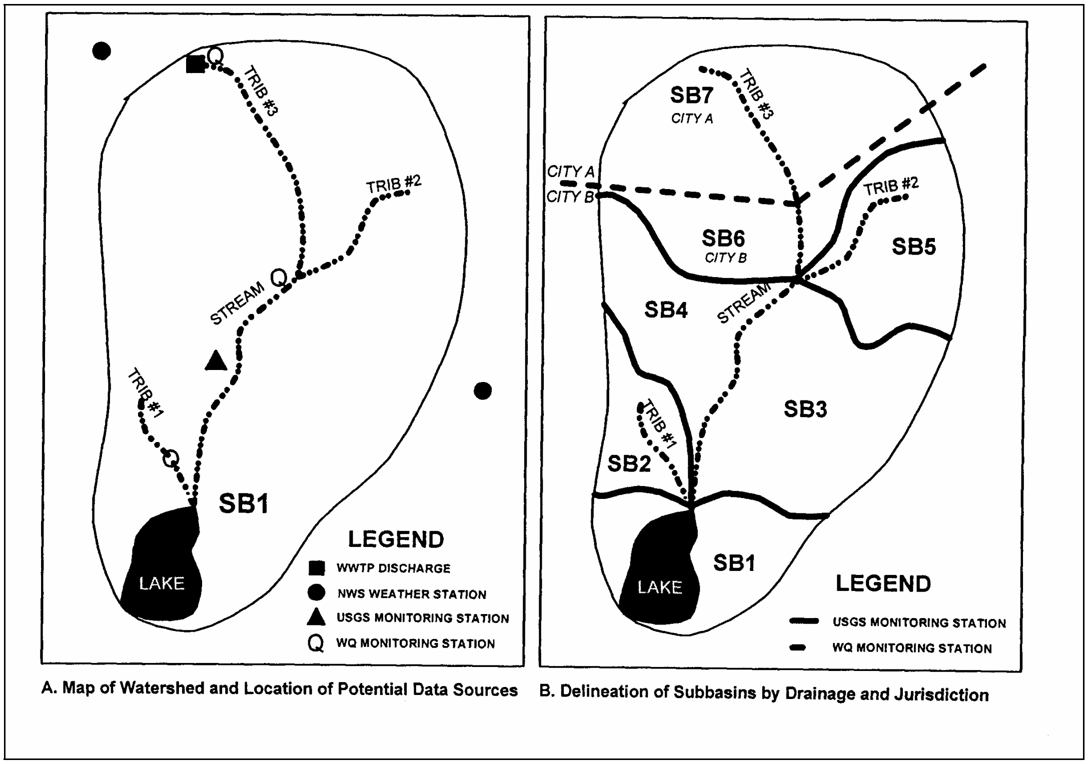
Table 9.1 presents the data requirements for screening-level applications of the Watershed Management Model and the sources of data used to develop the Darby and Cobbs Creeks Phase I load assessment model. A more detailed description of data used to build the SWMM model may be found in the associated report, "Watershed Scale Model Development".

Table 9.1 Data Requirements for WMM

Data Requirement	Use	Source for Darby-Cobbs
Subsheds	USGS topographic subwatersheds for Darby and Tinicum; topographic subwatersheds for separate-sewered areas in Cobbs; sewersheds for combined-sewered areas in Cobbs	Darby and Tinicum: USGS Cobbs separate-sewered areas: generated from elevation data Cobbs combined-sewered areas: PWD
Land Use	Used to define imperviousness and assign EMCs	Delaware Valley Regional Planning Commission
Imperviousness	Determines runoff volume in WMM; one factor affecting runoff volume in SWMM	Primarily Land Use. Population Density for Residential Land Uses (Manning, 1977 and Stankowski, 1974)
Event Mean Concentrations (EMCs)	Used to estimate pollutant loads from runoff	Literature values for stormwater concentrations; PWD treatment plant influent for sanitary concentrations
Baseflows	Used to estimate loads from background concentrations	USGS/PWD Cooperative Program
Other Loads	Point sources, CSOs, septic tanks	NPDES permits, CSO program, U.S. Census Bureau

Planning Areas/Units (Subsheds)

Delineation of subsheds in the SWMM model is discussed in detail in the associated report, "Watershed Scale Model Development". For WMM-based load estimates, the planning areas, or model units, for which WMM was compiled, are jurisdictional watersheds. Figure 9.1 presents WMM's conceptual framework for drainage area and sub-basin (model unit) delineation. USGS delineated sub-watersheds for streams tributary to Darby Creek were intersected with municipal jurisdictional boundaries to form the planning-level sub-areas. The USGS watersheds and the municipalities located wholly or partially within the watershed boundaries are shown in Figure 9.2.



A. Map of Watershed and Location of Potential Data Sources B. Delineation of Subbasins by Drainage and Jurisdiction

Figure 9.1 Conceptual Framework for Delineation of Model Units

The USGS delineated sub-basins and municipal boundaries were discussed in Section 2. The planning areas, also known as model units, are the intersection of the municipal boundaries and the watershed boundaries. These areas are identified by a sub-basin identifier, such as SB1, SB2, etc. The use of these planning units allows for loads to be summarized by sub-watershed and municipality and allows the city to determine its relative load contribution in comparison with other municipalities.

The planning areas or jurisdictional sub-watersheds range in size from less than 1 acre to greater than 3,000 acres. The mean size of the planning areas is about 430 acres with a median size of about 216 acres. The largest planning area is located in the Darby Creek Watershed on Darby Creek Branch D and Easttown Township, Chester County. The smallest basin is located in the southwestern most part of Sharon Hill Borough in Delaware County and drains a small portion of the Muckinipattis Creek A sub-basin. Eighty percent of the planning area is between 20 and 1000 acres.

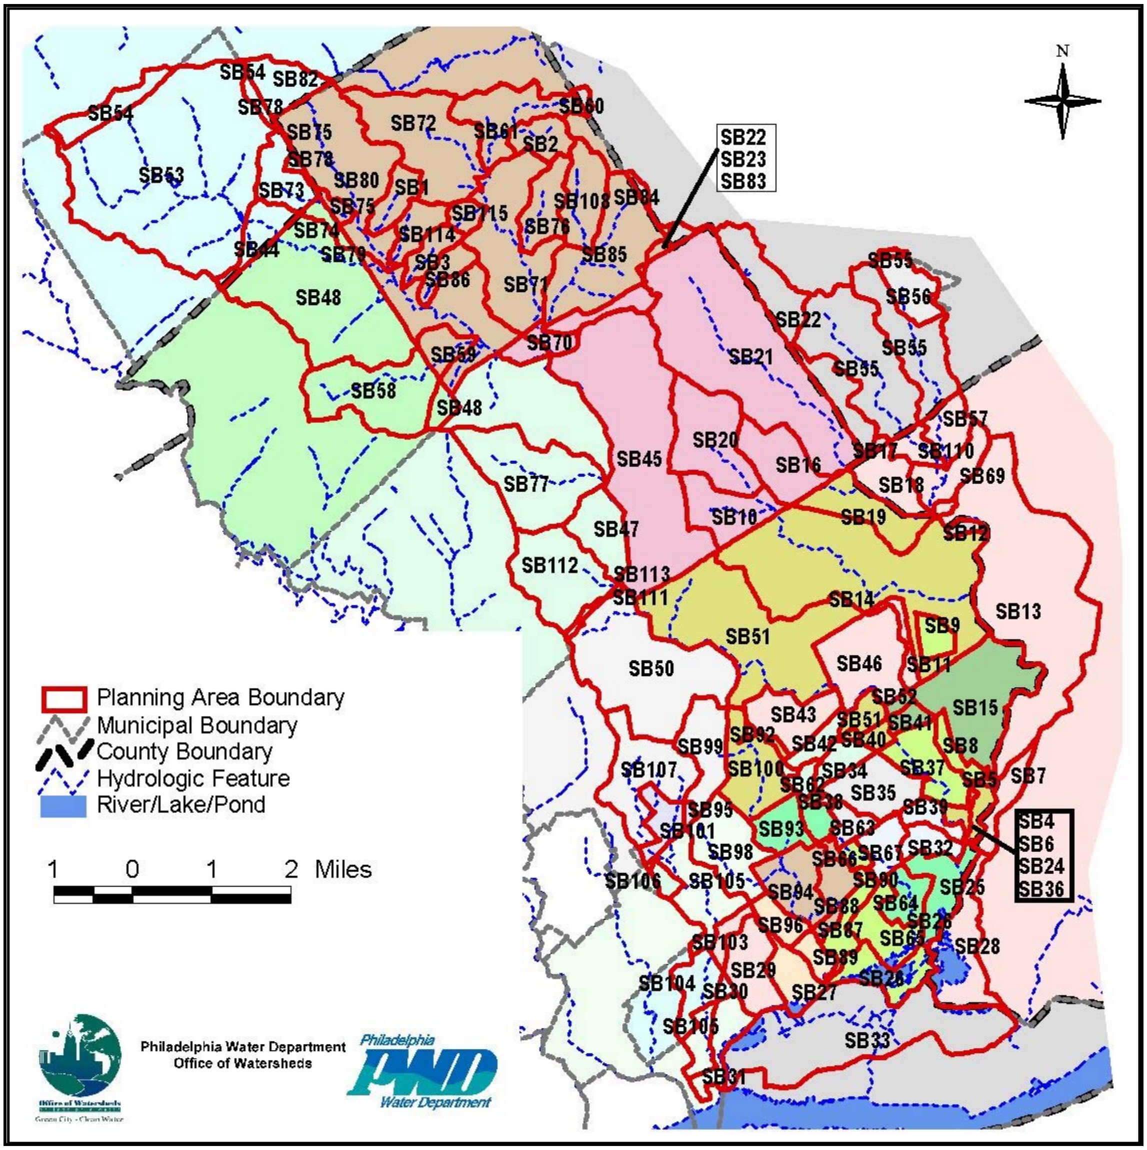


Figure 9.2 Planning Areas or Model Units

Land Use

Data used to define the land uses by planning area were compiled by the Delaware Valley Regional Planning Commission (DVRPC) and were discussed in detail in Section 2.

Land Surface Imperviousness and Runoff Volume

Estimated Imperviousness in the SWMM model is discussed in detail in the associated report, "Watershed Scale Model Development". For the WMM model, runoff coefficients used in the model were calculated from percent imperviousness values based on land use. Impervious area was determined for non-residential areas based on generally accepted percent imperviousness reported in the literature for various land use categories (Smullen, Hartigan, and Grizzard, 1978). For residential areas, percent imperviousness was based on population density. Generally, residential areas have much greater variability in percent imperviousness, which has been correlated with population density (Manning, 1987; Stankowski, 1974). Nine residential sub-categories were developed from the DVRPC land use data, based on a histogram of block group population density. The histogram of percent imperviousness based upon population density is shown in Figure 9.3. The categories were distributed so that each contained approximately the same number of census blocks. Table 9.2 presents the percent imperviousness associated with each land use category. Note that the 100 percent "impervious" assigned to water/wetlands simply means that all the water that falls on the waterbody, enters the water body, a slightly different definition than the imperviousness related to other land use.

Table 9.2 WMM Imperviousness by Land Use Category

Land Use	Imperviousness (%)
Agricultural/Pasture	5.0
Cemetery	5.0
Commercial	80.0
Golf Course	5.0
Transportation	30.0
Industrial	80.0
Regional Park	5.0
Residential 1	18.2
Residential 2	25.9
Residential 3	33.8
Residential 4	39.3
Residential 5	44.1
Residential 6	49.6
Residential 7	57.9
Residential 8	75.4
Residential 9	90.1
Urban Recreation	60.0
Vacant	5.0
Water/Wetlands	100.0
Wooded	5.0

WMM calculates annual runoff volumes for pervious and impervious areas in each land use category by multiplying the average annual rainfall volume by a runoff coefficient. Runoff coefficients can be adjusted to reflect local conditions and land uses. For impervious surfaces, a runoff coefficient of 0.95 is typically used (thus, 95 percent of the rainfall over an impervious surface is directly converted to runoff). The pervious area runoff coefficient typically used is 0.20. An important distinction about impervious areas is that not all runoff from impervious areas flows directly to a drainage system or river and is often routed to lawns or dry wells. Runoff that enters a drainage system or river is from "directly connected impervious areas (DCIA)". The DCIA percentage typically is 50% or more of the total impervious area percentage.

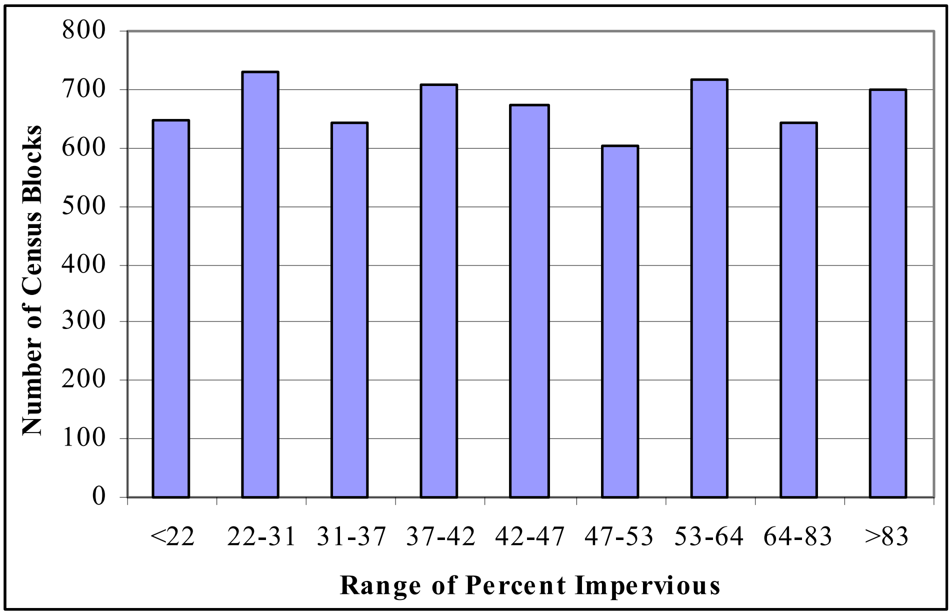

Figure 9.3 Distribution of Impervious Cover among Census Blocks

The total average annual surface runoff from land use, L, is calculated by weighting the impervious and pervious area runoff factors as follows:

$$R_L = [C_P + (C_I - C_P) * IMP_L] * I$$

where:

R_L = total average annual surface runoff from land use L (in/yr);
C_P = pervious area runoff coefficient;
C_I = impervious area runoff coefficient;
IMP_L = fractional imperviousness of land use L; and
I = long-term average annual precipitation (in/yr).

Total runoff from the watershed is the area-weighted sum of R_L for all land uses.

Event Mean Concentrations (EMCs)

Event Mean Concentrations (EMCs) are defined as the total mass load of a chemical parameter yielded from a site during a storm divided by the total runoff water volume discharged during the storm. The EMC is widely used as the primary statistic for evaluations of stormwater quality data and as the stormwater pollutant loading factor in analyses of pollutant loads to receiving waters.

Use of EMCs in Loading Analyses. Nonpoint source pollution loading analyses typically consist of applying land use- specific stormwater pollution loading factors to land use scenarios in the watershed under study. Loading rates of urban stormwater pollution (nutrients, metals, BOD, fecal coliform) are determined by the quantity of runoff from the land surface. Thus, they are closely related to the imperviousness of the land use type. Applying EMCs to calculated runoff volumes provides reasonable estimates of nonpoint source pollutant loadings, especially from urban areas.

Runoff volumes are computed for each land use category based on percent imperviousness of the land use and annual rainfall. These runoff volumes are multiplied by the land use specific EMC load factor (mg/L) to obtain nonpoint source pollutant loads by land use category. This analysis can be performed on a subarea or watershed-wide basis, and the results can be used to perform load allocation studies, to evaluate pollution control alternatives, or as input into a riverine water quality model.

The model calculates pollutant loads based upon nonpoint source pollution loading factors (expressed as lb/acre/year) that vary by land use and the percent imperviousness associated with each land use. The pollution loading factor M_L is computed for each land use L by the following equation:

$$M_L = EMC_L * R_L * K$$

where:

M_L = loading factor for land use L (lb/acre/year)

EMC_L = event mean concentration of runoff from land use L (mg/L); EMCs may vary by land use and pollutant

R_L = total average annual surface runoff from land use L (in/yr); and

K = 0.2266, a unit conversion constant.

By multiplying the pollutant loading factor by the acreage per land use and summing for all land uses, the total annual pollution load from a sub-basin can be computed. The EMC coverage is typically not changed for various land use scenarios within a given study watershed.

History and Sources of EMCs. Once point source discharges from treatment plants and industrial facilities were addressed in the 1970s and 1980s, more attention was focused on stormwater runoff from urban areas as a source of water quality degradation. As pollution from stormwater and urban drainage began to be investigated, studies focused on the types of pollution and methods to reduce the loads. However, these investigations did not consider the achievable level of improvement of receiving water bodies with the mitigation of stormwater pollution. In addition, many research studies concluded that additional and more comprehensive information was needed to make such assessments. This need led to the development of the Nationwide Urban Runoff Program, also known as NURP.

The goals of NURP were to develop and provide information to local decision makers, the States, EPA, and other parties for use in assessing the impacts of stormwater and urban runoff on water quality. The information collected also was intended to aid in the development of water quality management plans and provide a foundation for local, State and Federal policy decision making about water quality issues.

The NURP studies investigated 10 standard water quality constituents to characterize urban runoff. As a result of data collected through the NURP program, EMCs for these and other pollutants were developed from over 2,300 station-storms at more than 81 urban sites located in 28 different metropolitan areas. These studies greatly increased the knowledge of the characteristics of urban runoff, its effects upon the designated uses of receiving water bodies, and the performance efficiencies of various control measures. Pertinent conclusions from the NURP Program include:

- The variance of the EMCs, when data from sites are grouped by land use type or geographic region, is so great that differences in measures of central tendency among groups are not statistically significant.

- Statistically, the entire sample of EMCs and the medians of all EMCs among sites are log-normally distributed.

EMCs often are used in screening models such as WMM. The pollutant loads (L_i) are estimated as the product of the area of urban land (A_U), the rainfall-runoff depth as estimated by a modified rational formula approach (d_r), and a constant pollutant concentration (C_i), usually estimated from the EMCs reported by NURP (i.e., $L_i = C_i A_u d_r$).

Since the conclusion of the NURP Program in the 1980's, additional urban runoff quality monitoring data has been collected. One large effort conducted by the United States Geological Survey resulted in the collection of urban runoff data for over 1,100 station-storms at 97 urban sites in 21 metropolitan areas. Additionally, EPA required many major cities to collect urban runoff quality data as part of the application requirements for stormwater discharge permits under the National Pollutant Discharge Elimination System (NPDES). Data from 800 station-storms from 30 cities was gathered and incorporated into a database by CDM. CDM analyzed the data collected from NURP, USGS, and NPDES to assess if additional EMC observations (more degrees of freedom) would uncover statistically significant differences in EMCs among various land uses. While the resulting EMCs from the combined data sets did not indicate statistical differences in water quality among land uses, the pooled EMCs were significantly different than the NURP EMCs for several parameters (e.g., TSS, Cu, and Pb) and would produce different loading rates for urban areas. Table 9.3 indicates the EMCs used in the Darby and Cobbs Creeks Watershed Study and the source of each EMC value.

Table 9.3 Event Mean Concentrations

	Mean EMCs, mg/L											Source (Equivalent Category)

Note: All metals data are from Smullen (1999), except Highway. Atmospheric contributions are included in these values. The EMC for fecal coliform is based on NURP data as reported in NOAA (1987).

Baseflows

Most streams exhibit dry weather flow due to groundwater infiltration. As discussed in Section 4, baseflows for the individual planning areas were determined using USGS streamflow gauging data. To account for baseflow discharges as part of the average annual flow volume discharged from a watershed, an estimate of baseflow rate and quality is included in WMM. Concentrations of various constituents in baseflow are based on dry weather monitoring data.

Baseflow due to groundwater inflow is the main component of most streams in dry weather. Baseflow slowly increases and decreases with the elevation of the shallow aquifer water table. In wet weather, a stormwater runoff component is added to the baseflow. Estimation and comparison of these two components can provide insights into the relationship between land use and hydrology in urbanized and more natural systems. For a more detailed explanation of the baseflow separation techniques used see Section 4.3.

Constituent Source Types

For a watershed or TMDL study, an inventory of pollutant sources to the receiving water bodies must be compiled. The various types of sources usually considered are listed below. Note that urban stormwater runoff has some attributes of both point and nonpoint sources.

- Point (industrial and municipal dischargers, CSOs, SSOs);
- Nonpoint (stormwater, urban drainage, leaking septic systems);
- Background (instream, baseflow); and
- Atmospheric.

Municipal and Industrial Process Water Discharges. A file review of NPDES permits and Discharge Monitoring Reports (DMRs) for permitted dischargers within the Darby-Cobbs Creeks Watershed was performed at the Pennsylvania Department of Environment Protection in Conshohocken, PA. Information regarding site location, flow rates, and pollutant concentrations was gathered. Table 9.4 presents the list of dischargers and the information found for each point source.

Combined Sewer Overflows (CSOs). In many cities throughout the United States, stormwater runoff and sanitary wastewater are collected in the same sewer (a combined sewer). In dry-weather conditions, all flows are conveyed to and treated at a local or regional wastewater treatment plant. In wet-weather conditions, the capacity of the combined sewer system can be exceeded and discharges of mixed sanitary and stormwater then occur to receiving waters. The fraction of sanitary sewage in discharges varies from storm to storm, but is typically on the order of 10% over the long term, while the remaining 90% is untreated stormwater. For constituents where sanitary sewage and untreated stormwater concentrations are the same order of magnitude (e.g., TSS, nutrients), concentrations in CSO are similar or slightly higher compared to stormwater. For constituents where sanitary concentrations are typically lower (e.g., metals such as Pb, Cu, Zn), concentrations in CSO are slightly lower than in untreated stormwater. For bacteria and other pathogens, concentrations in CSO are an order of magnitude or higher than those found in stormwater.

Sanitary Sewer Overflows (SSOs). SSOs result in discharges of untreated wastewater that can affect stream quality and occasionally basements and city streets. The USEPA. has found that SSOs represent a significant health and environmental threat in areas where they occur frequently. Frequent SSOs may indicate that the capacity of the collection system is insufficient to convey the flows introduced or that the system is in need of maintenance or repair. Potential causes of excess flow include infiltration and inflow, illegal connections, population growth, and under-design. Problems requiring maintenance or repair may include broken or cracked pipes, tree roots, poor connections, and settling. Proper maintenance can help prevent problems or identify them before they become extremely costly to repair (USEPA, 2000).

Sanitary Sewer Overflows (SSOs) are a known source of bacterial and other pollution to the Darby and Cobbs Creeks watershed. Currently, no inventory of SSOs exists for the area within the four counties that contain the Darby and Cobbs Creeks Watershed. Since the data collection effort required to obtain SSO load information was beyond the scope of this screening-level study, SSO loads were not considered part of this study. An SSO assessment methodology will be implemented as part of the Phase II efforts.

Stormwater and Urban Drainage. Stormwater from areas with separate storm sewers contributes to water body impairment in highly urbanized, impervious catchments. Pollutants most frequently associated with stormwater include sediment, nutrients, bacteria, oxygen demanding substances, oil and grease, heavy metals, other toxic chemicals, and floatables. The primary sources of these pollutants include automobiles, roadways (pavement, bridges), housekeeping and landscaping practices, industrial activities, construction, non-storm connections to drainage systems, accidental spills and illegal dumping.

Septic Tanks. The number of septic tanks in Darby and Cobbs Creeks Watershed planning areas was estimated using 1990 Census data on population and housing. Comparison of water-only billed accounts with septic tank counts for the City of Philadelphia indicated a large discrepancy in the number of housing units with septic tanks. The 1990 census data estimated that 205 households were served by septic tanks in the Philadelphia portion of the watershed. However, a review of water-only accounts by the Water Department indicated that only 3 households within the City and the Cobbs watershed have septic tank or on-lot sewage disposal systems.

County agencies for Delaware, Montgomery, and Chester Counties were consulted about septic tank inventories/information in their areas. However, compilations of septic tank and on-lot sewer systems have not been completed to date. Detailed assessment of individual municipalities for septic tank and on-lot sewage disposal inventories and/or permits was beyond the scope of the current phase of this study.

Atmospheric Sources. Pollutants from atmospheric deposition on land surfaces are considered to be included in the calculations for the stormwater runoff. Direct deposition on water surfaces also is included in these calculations by the use of a water surface land use type. Specifically, precipitation falling on the water surface land use was assigned EMCs of nutrients and metals derived from rainfall data. For this study, the water surface EMCs were taken from the Chesapeake Bay Program literature (EPA, 1982).

Table 9.4 Active Point Sources Permitted Under NPDES

PA NPDES ID.	Site Name	Available Data
PA0056839	Sun Oil Company	Benzene, Total BTEX, Ethylbenzene, Toluene, Total Xylene, flow volume, and pH.
PA0011541	Sun Oil Company	Oil, Grease, Total Organic Carbon, flow volume, and pH.
PA0056685	SEPTA Victory Terminal	No water quality or flow data available.
PA0056642	Meenan Oil Company	Permitted discharge levels.
PA0052752	Mobil Oil Company	Benzene, Toluene, Xylene, and flow. Source removed in 1996.
PA0013323	Boeing Defense and Space Group	TDS, TSS, Oil and Grease, CN, Ag, Cd, Cr, Cu, Ni, Pb, Zn, and flow.
PA0028380	Tinicum Township Sewerage Authority	Settled solids, suspended solids, BOD, Chlorine residual, Fecal Coliform, pH and flow.
PA0057002	Township of Haverford Public Works	TSS, TDS, Mn, Mg, Color, Total Fe, Dissolved Fe, Barium, Specific Conductance, pH and flow.

9.2 Results: Estimated Annual Constituent Loads for the Cobbs Creek Subwatershed

Figures 9.4 through 9.12 show estimated loading rates for stormwater runoff and CSO. Table 9.5 breaks load estimates into two geographic regions, upper and lower Cobbs. The loads are estimates of the total input to the stream system. For example, the surface runoff listed for lower Cobbs (an area serviced partially by combined sewers) is relatively low because it does not include the volume that is captured, treated, and discharged outside the system. With some exceptions, higher pollutant loading rates are found in the lower Cobbs watershed, in and near the densely populated areas of Philadelphia. These results were obtained by using the SWMM model developed for Cobbs Creek. The specific components of the model that were utilized were the RUNOFF and EXTRAN modules.

Watershed	Area (ac)	Surface Runoff (in/yr)	Surface Runoff (MG)	BOD (ton/yr)	TSS (ton/yr)	Fecal (col/yr)	TN (ton/yr)	TP (ton/yr)	Cu (ton/yr)	Pb (ton/yr)	Zn (ton/yr)
Upper Cobbs	6,482	13.94	2046	145.5	813.2	2.76E+15	24.51	3.24	0.15	0.79	1.70
Lower Cobbs	4,202	17.93	2455	119.6	669.5	2.26E+15	20.30	2.67	0.12	0.68	1.41

9.2.2 Relative Contribution of Source Types

Figure 9.13 presents the approximate relative contribution each source (stormwater runoff from separate sanitary areas, baseflow, CSOs, industrial and municipal point sources, septic tanks, and atmospheric sources) contributes to the total potential load to the Delaware River from the Cobbs Creek watershed area. As expected in highly urbanized settings, runoff from separate sanitary areas is the dominant source of water pollution for most pollutant types except fecal coliform. Baseflow contributes a significant amount of total nitrogen. Separate sanitary overflows (SSOs) may be a significant source of pollutants, but information concerning these sources was insufficient to include in the current analysis. The results indicate that CSOs represent no more than 10% of the total load for any parameter except fecal coliform. The model indicates that over two-thirds of the fecal coliform introduced to the system is the result of CSOs; however, this portion may change when future work accounts for the contribution of SSOs. Industrial and municipal point sources are a relatively small source of pollutants. Septic tank loads are significant only for phosphorus and nitrogen. However, the reliability of the data available on septic tanks in the watershed is questionable. Atmospheric inputs, based on wetfall or concentrations within rainfall, are included in the EMCs for all land use types except for wetlands and open water. Atmospheric loads to wetlands and water were small (1% or less) but measurable.

Table 9.6 presents the average areal loads contributed by runoff from separate and combined sewer areas. Areal loads show the intensity of loading rather than total loads. The loads for all the parameters fall within the ranges shown on Figures 9.4 through 9.12. The areal loadings for most parameters are similar for the two sources, but the fecal coliform loads introduced by combined sewer areas are approximately 100 times greater per acre than those introduced by runoff from separate sewer areas. For comparison, the table includes loads for the other sources.

Sources of Uncertainty

Baseflow water quality information is based upon water quality sampling data obtained between 1999 and 2000. The data represents background conditions; if significant dry weather pollutant inputs are present, these will be reflected in the baseflow concentrations.

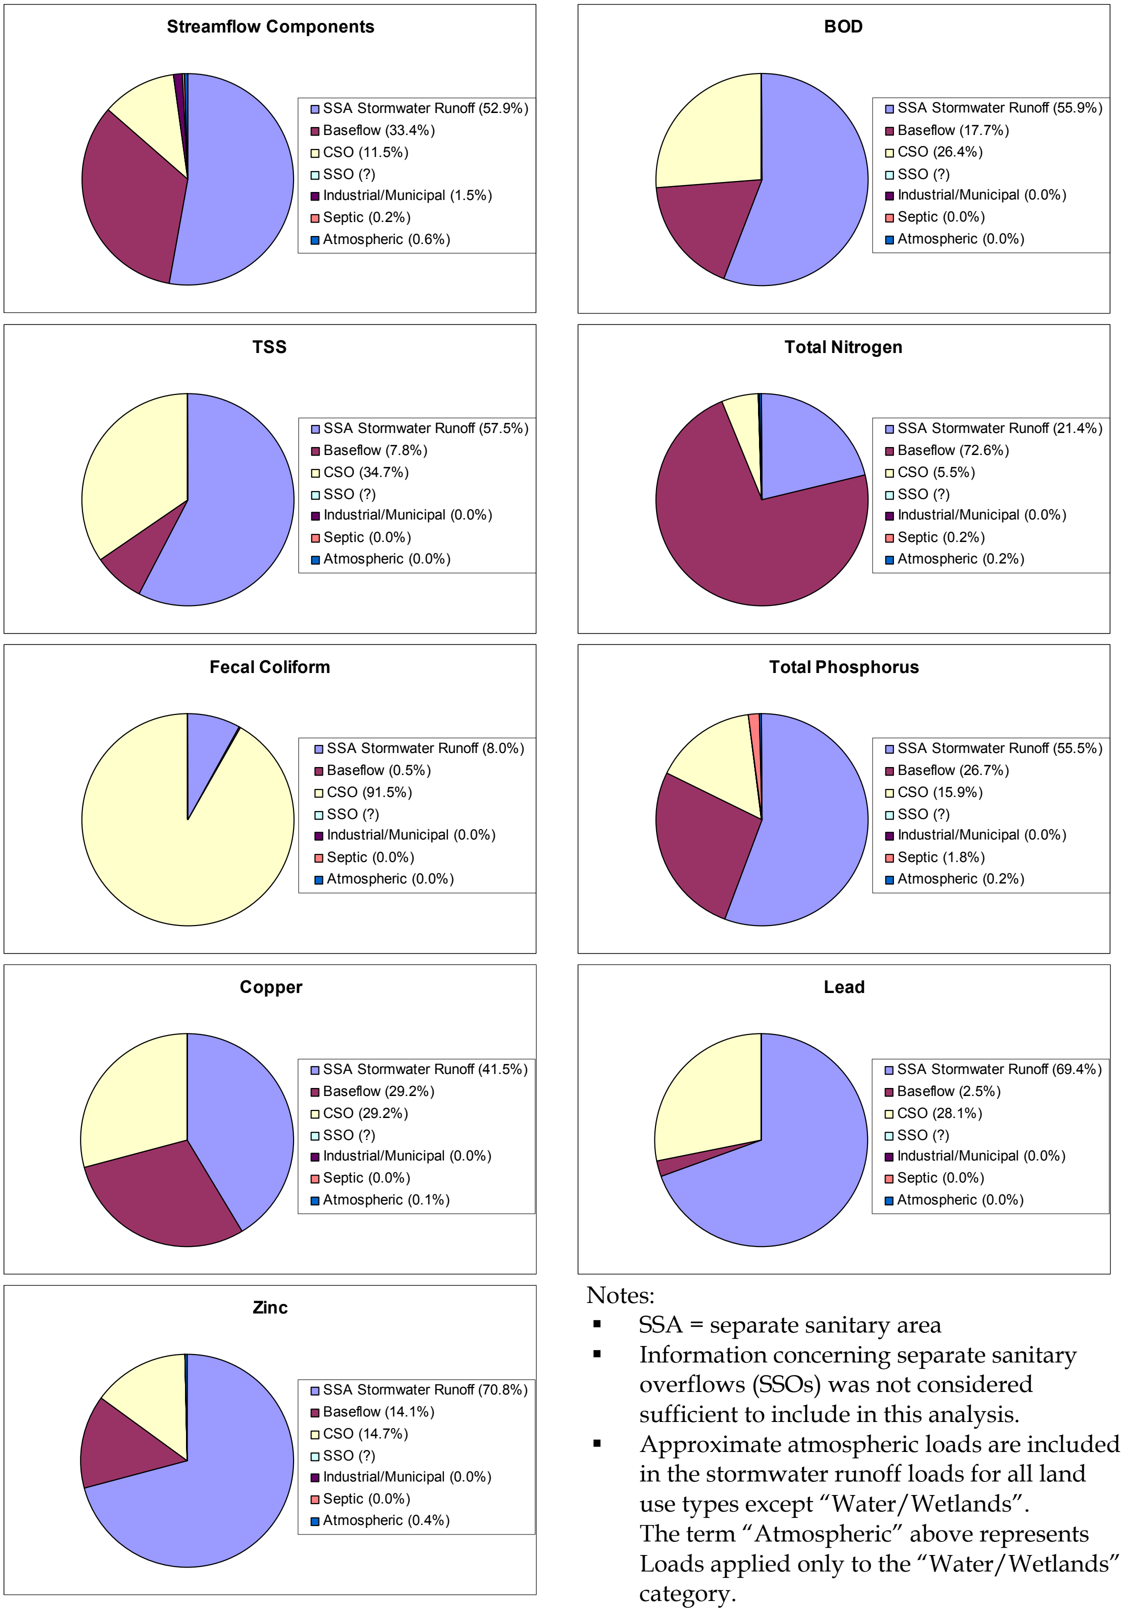
EMCs are based on literature values. The EMCs used for this study for urban land uses are from Smullen, Shallcross, and Cave (1999). These values represent a compilation of stormwater monitoring data from NURP, the USGS, and NPDES Phase I Municipal Stormwater Monitoring Requirements.

Sanitary sewer overflows (SSOs) are believed to be a significant potential source of bacterial and other pollution in the watershed. For the watershed study, estimates of SSO flows and pollutant loads were not calculated due to lack of readily available information on municipal sewer systems. Future studies may include a more thorough investigation of these sources.

Failures of septic tanks can contribute nutrient and bacterial loads to receiving waters. For this screening level study, the 1990 census data for on-lot septic systems was used to determine the number of septic systems in each drainage area. Although the census data indicated that over 200 septic systems were located within the Philadelphia portion of the Darby-Cobbs Creek watershed, water-only accounts indicated that three or fewer septic systems were located in this part of the watershed. Since extensive research into on-lot systems and Act 537 plans for Delaware and Chester Counties will be required, the 1990 census counts of septic systems were used for all portions of the Darby-Cobbs watershed study except Philadelphia.

Table 9.6 Cobbs Estimated Annual Areal Loads by Source (lb/ac except as noted)

Parameter	SSA Stormwater Runoff (lb/ac)	Baseflow	CSO	Industrial/ Municipal	Septic	Atmospheric
BOD	47.2	12.0	88	0	0	0
TSS	264	28.6	634	0	0	0
Fecal Coliform (col/ac)	4.47E+11	2.3E+10	2.04E+13	0	0	0
Total Nitrogen	8.00	21.7	8.22	0	0.072	0.062
Total Phosphorous	1.052	0.404	1.194	0	0.027	0.002
Copper	0.048	0.027	0.133	0	0	8.5E-05
Lead	0.262	0.007	0.421	0	0	1.0E-04
Zinc	0.555	0.088	0.456	0	0	2.5E-03



Notes:

- SSA = separate sanitary area
- Information concerning separate sanitary overflows (SSOs) was not considered sufficient to include in this analysis.
- Approximate atmospheric loads are included in the stormwater runoff loads for all land use types except “Water/Wetlands”. The term “Atmospheric” above represents Loads applied only to the “Water/Wetlands” category.

Figure 9.13 –Cobbs Estimated Annual Relative Contribution of Constituent Sources

9.2.3 Comparison of Load Estimates

Table 9.7 compares several loading rate estimates for Cobbs Creek. These estimates are based on historical water quality monitoring, 1999 water quality monitoring, and SWMM/WMM estimates. The loads from the monitoring data were calculated by applying wet weather and dry weather pollutant concentrations to USGS historical flow data. The resultant loads were averaged over the period of record to determine the average daily load.

Table 9.7 compares the loads of some conventional water quality parameters calculated from the results of the first 50 months of sampling of the PWD/USGS Cooperative Program “Effects of Non-Point Discharge on Urban Stream Quality,” reported by Radzuil, with loads calculated based on wet and dry flow regimes. Loads for metals and suspended solids were not reported. The calculated loads were developed by assigning wet and dry flow regimes and wet and dry concentrations, then accumulating the load over the discharge record. The estimated historical downstream load can be compared with Radzuil’s load for Cobbs Creek. The comparison suggests that the biochemical oxygen demand load increased for the duration of the cooperative program study. The phosphorus load may have been significantly reduced. Ammonia and nitrate loads were not calculated for the estimate. The loading rates estimated by SWMM/WMM are much larger than the instream mass load estimated from the current monitoring data. This difference is not a mistake but a result of the modeling philosophy:

- SWMM/WMM loads represent the total potential load to be delivered downstream and do not specifically account for the instream processes that reduce the total load.
- For the screening level study, the loads were used to estimate an overall delivery ratio for each pollutant, rather than estimate delivery ratios for various land uses by pollutant.
- The instream mass loads were based on limited, discrete, wet and dry weather monitoring data in addition to streamflow data from the 1970s.
- Loading is based on national EMCs which are measures of central tendency with significant variance. Local conditions may not be reflected by the national EMCs.

9.2.4 Delivery Ratios

The delivery ratio represents the fraction of the original pollutant load remaining after a particular pollutant travels downstream and is affected by instream processes. Data available in the literature indicate that the delivery ratio varies with drainage-area size. Some representative values calculated by the USDA for sediment are:

Drainage Area (sq. miles)	Delivery Ratio
0.5	0.33
10	0.18
100	0.10

However, the delivery ratios may vary substantially for any given size of drainage area. Other important factors affecting pollutant delivery include soil texture, relief (slope), types of erosion, sediment transport system, and deposition areas. For instance, a watershed with fine soil texture, high channel density, and high stream gradients would generally have a higher than average delivery ratio for watersheds of similar drainage area. Also, edge-of-field delivery ratios can approach 1.0 while delivery ratios for larger study areas can be less than 0.05. Instream processes also affect the delivery ratio. Such processes include deposition, sediment and water column diagenesis, remineralization, and volatilization. These processes are discussed in the next section.

Table 9.7 presents the calculated delivery ratios for two sites along Cobbs Creek (DC10 and DC06). Although delivery ratios might be expected to decrease with distance downstream, the Cobbs Creek data do not display such behavior. The delivery ratio for most pollutants increases from the upstream to the downstream cross-sections; the delivery ratios for total suspended solids, fecal coliform, and lead stay about the same. This trend may be largely explained by greater urbanization in the downstream reaches of Cobbs Creek; much of the loading occurs downstream where less time and distance are available for degradation processes to take place.

Table 9.7 Comparisons of Load Estimates for Cobbs Creek

	Historic Data		1999 Monitoring Data		1999 vs. Historical		Radzuil Loads	SWMM Estimate		Calculated Delivery Ratio

Note: "Upstream" corresponds to station 12 for the historical and Radzuil data, station DC10 for the 1999 monitoring data and USGS station 01475530 (Cobbs Creek near Philadelphia). "Downstream" corresponds to station 15 for the Historical and Radzuil data, station DC06 for the 1999 monitoring data, and USGS station 01475550 (Cobbs Creek at Darby).

9.3 Results: Estimated Annual Constituent Loads for the Darby Creek and Tinicum Subwatersheds

Figures 9.14 through 9.22 show estimated loading rates for stormwater runoff and CSO. Table 9.8 presents the estimates summarized by watershed. The loads are estimates of the total input to the stream system. Higher pollutant loading rates are found in the lower Darby and Tinicum subwatersheds, in and near the densely populated areas of Philadelphia. Lower loading rates occur in the upper Darby watershed, where there is more open space and less densely populated residential areas. Pollutant loadings, population density, and runoff all follow the same general trends. WMM was used to develop screening-level loads for the Darby and Tinicum portions of the Darby-Cobbs watershed.

9.3.2 Relative Contribution of Source Types

Figures 9.23 and 9.24 present the approximate relative contribution each source (stormwater runoff from separate sanitary areas, baseflow, CSOs, industrial and municipal point sources, septic tanks, and atmospheric sources) contributes to the total potential load to the Delaware River from the Darby and Tinicum subwatershed areas. As expected in highly urbanized settings, runoff from separate sanitary areas is the dominant source of water pollution for most pollutant types. Baseflow contributes a significant amount of total nitrogen. Separate sanitary overflows (SSOs) may be a significant source of pollutants, but information concerning these sources was insufficient to include in the current analysis. There are no combined sewer systems in the Darby and Tinicum subwatersheds. Industrial and municipal point sources are a relatively small source of pollutants. Septic tank loads are significant only for phosphorus and nitrogen. However, the reliability of the data available on septic tanks in the watershed is questionable. Atmospheric loads were not considered in the Darby and Tinicum subwatersheds.

Tables 9.9 and 9.10 present the average areal loads contributed by runoff from separate sewer areas (there are no CSOs). Areal loads show the intensity of loading rather than total loads. The loads for all the parameters fall within the ranges shown on Figures 9.14 through 9.22. For comparison, the table includes loads for the other sources.

Sources of Uncertainty

Baseflow water quality information is based upon water quality sampling data obtained between 1999 and 2000. The data represent background conditions; if significant dry weather pollutant inputs are present, these will be reflected in the baseflow concentrations.

EMCs are based on literature values. The EMCs used for this study for urban land uses are from Smullen, Shallcross, and Cave (1999). These values represent a compilation of stormwater monitoring data from NURP, the USGS, and NPDES Phase I Municipal Stormwater Monitoring Requirements.

Separate Sanitary Overflows (SSOs) are believed to be a significant potential source of bacterial and other pollution in the watershed. For the watershed study, estimates of SSO flows and pollutant loads were not calculated due to lack of readily available information on municipal sewer systems. Future studies may include a more thorough investigation of these sources.

Failures of septic tanks can contribute nutrient and bacterial loads to receiving waters. For this screening level study, the 1990 census data for on-lot septic systems was used to determine the number of septic systems in each drainage area. Although the census data indicated that over 200 septic systems were located within the Philadelphia portion of the Darby-Cobbs Creek Watershed, water-only accounts indicated that three or fewer septic systems were located in this part of the watershed. Since extensive research into on-lot systems and Act 537 plans for Delaware and

Chester Counties will be required, the 1990 census counts of septic systems were used for all portions of the Darby-Cobbs watershed study except Philadelphia.

Table 9.9 Darby Estimated Annual Areal Loads by Source (lb/ac except as noted)

Parameter	SSA Stormwater Runoff (lb/ac)	Baseflow	CSO	Industrial/ Municipal	Septic
BOD	54.6	8.32	0	0.073	0

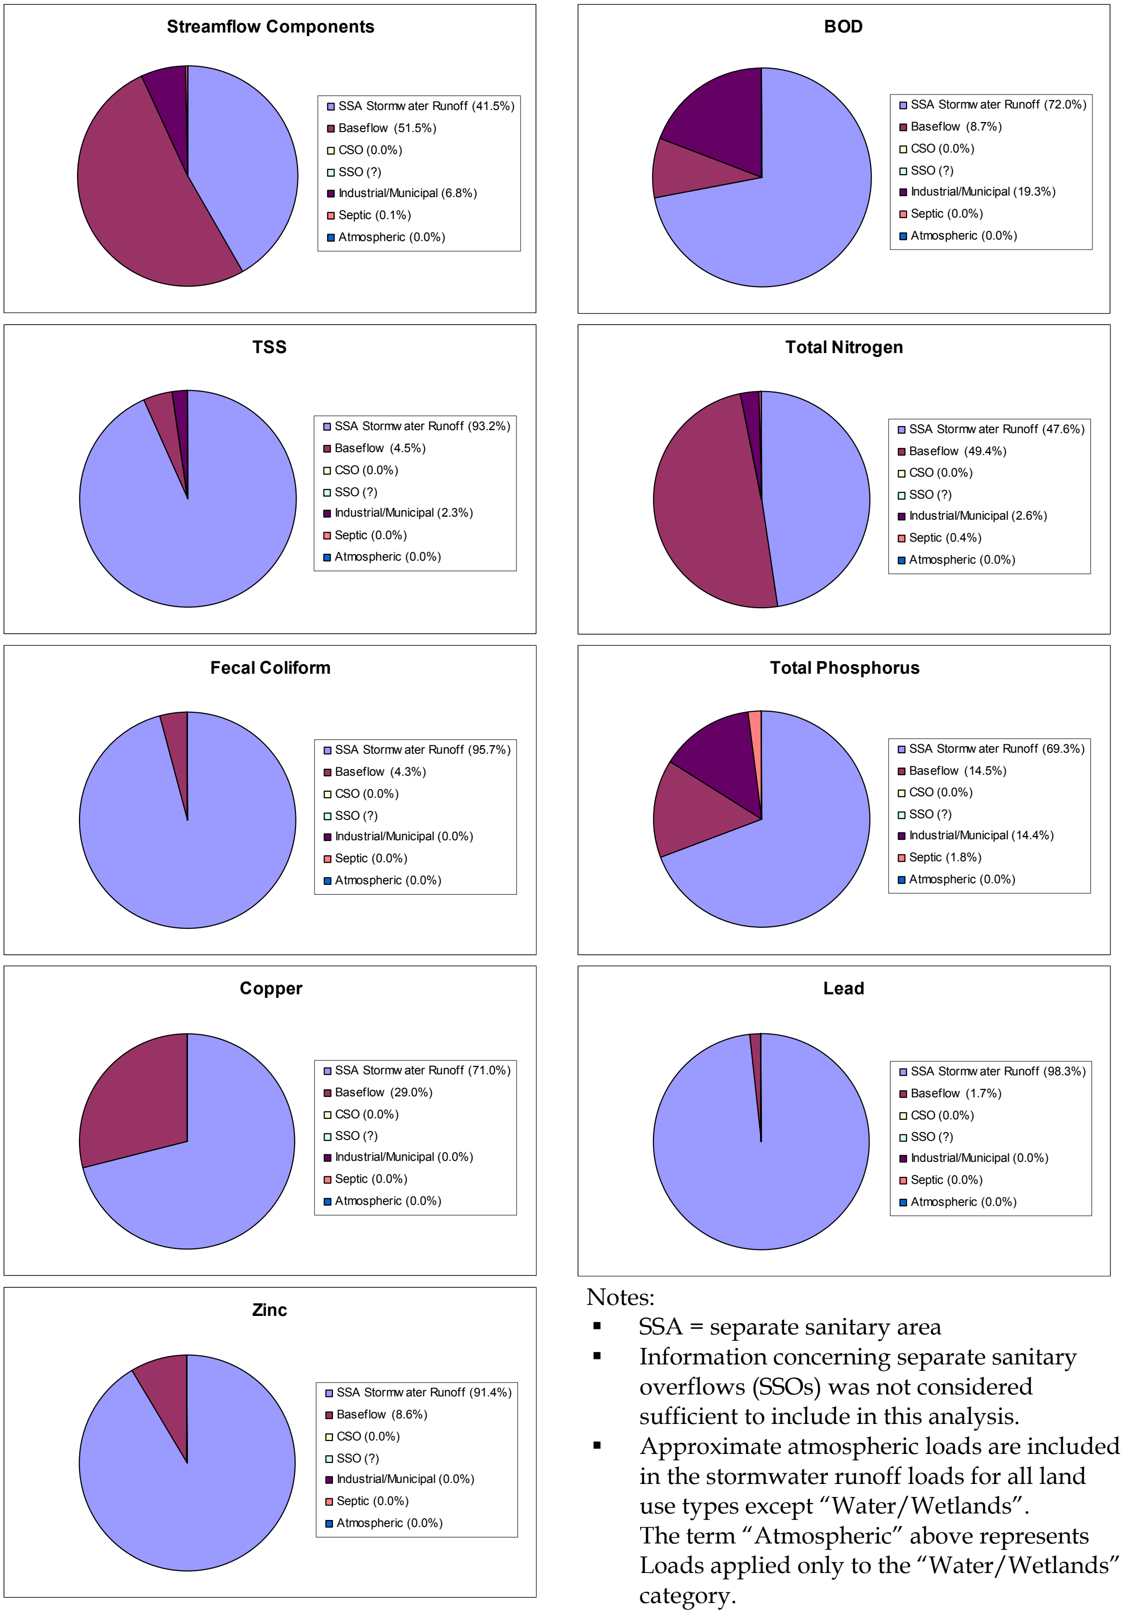
Zinc	0.189	0.014	0	0	0



Notes:

- SSA = separate sanitary area
- Information concerning separate sanitary overflows (SSOs) was not considered sufficient to include in this analysis.
- Approximate atmospheric loads are included in the stormwater runoff loads for all land use types except "Water/Wetlands". The term "Atmospheric" above represents Loads applied only to the "Water/Wetlands" category.

Figure 9.24 Tinicum Estimated Annual Relative Contribution of Constituent Sources

9.3.3 Comparison of Load Estimates

Separate loading rates were not estimated for upper Darby for two reasons. First, only one Cooperative Program site was located on Darby Creek, and its location (at Waterloo Mills, in the headwaters) does not represent a large enough portion of the watershed to compare to the 1999 monitoring and WMM-estimated loads. Second, the lack of USGS gauge data in the vicinity of DC05 causes difficulty producing a baseflow estimate.

Table 9.11 compares the loads of some conventional water quality parameters calculated from the results of the first 50 months of sampling of the PWD/USGS Cooperative Program "Effects of Non-Point Discharge on Urban Stream Quality," reported by Radzuil, with loads calculated based on wet and dry flow regimes. Loads for metals and suspended solids were not reported. The calculated loads were developed by assigning wet and dry flow regimes and wet and dry concentrations, then accumulating the load over the discharge record.

The loading rates estimated by WMM for some constituents are much larger than the instream mass load estimated from the current monitoring data. This difference is not a mistake but a result of the modeling philosophy:

- WMM loads represent the total potential load to be delivered downstream and do not specifically account for the instream processes that reduce the total load.
- For the screening level study, the loads were used to estimate an overall delivery ratio for each pollutant, rather than estimate delivery ratios for various land uses by pollutant.
- The instream mass loads were based on limited, discrete, wet and dry weather monitoring data in addition to streamflow data from the 1970s.
- Loading is based on national EMCs which are measures of central tendency with significant variance. Local conditions may not be reflected by the national EMCs.

9.3.4 Delivery Ratios

The delivery ratio represents the fraction of the original pollutant load remaining after a particular pollutant travels downstream and is affected by instream processes. Data available in the literature indicate that the delivery ratio varies with drainage-area size. Some representative values calculated by the USDA for sediment are:

Drainage Area (sq. miles)	Delivery Ratio
0.5	0.33
10	0.18
100	0.10

However, the delivery ratios may vary substantially for any given size of drainage area. Other important factors affecting pollutant delivery include soil texture, relief (slope), types of erosion, sediment transport system, and deposition areas. For instance, a watershed with fine soil texture, high channel density, and high stream gradients would generally have a higher than average delivery ratio for watersheds of similar drainage area. Also, edge-of-field delivery ratios can approach 1.0 while delivery ratios for larger study areas can be less than 0.05. Instream processes also affect the delivery ratio. Such processes include deposition, sediment and water column diagenesis, remineralization, and volatilization. These processes are discussed in the next section. Table 9.11 presents the calculated delivery ratios for one site near the outlet of Darby Creek (PWD sampling site DCD765).

Table 9.11 Comparisons of Load Estimates for Darby Creek

	1999 Monitoring Data	WMM Estimate	Delivery Ratio
Drainage Area (ac)	25,600	28,276	
Surface Runoff (in)	15.7	7.55	
BOD_5 (lb/day)	1,560	1,693	92%
TSS (lb/day)	1,940	10,332	19%
Total N (lb/day)	799	316	253%
Total P (lb/day)	22	38.83	57%
Fecal Coliform (col/day)	2.81E+12	1.17E+13	24%
Cu (lb/day)	1.13	1.81	63%
Pb (lb/day)	0.55	9.88	6%
Zn (lb/day)	2.66	21.22	13%

Note: Loading estimates based on monitoring data require a baseflow estimate. Unlike data for Cobbs Creek, USGS historical streamflow data for the Darby Creek watershed are insufficient to calculate separate loading rates for the upper portion of the watershed. Monitoring loads are based on data from DCD765 and USGS station 01475510, (Darby Creek near Darby).

Section 10 Discussion and Analysis

Sections 1 through 8 provide a wide range of information characterizing the geography, hydrology, water quality, biology, habitat, and fluvial geomorphology of the Darby and Cobbs Creeks watershed. The purpose of Section 10 is to examine the wide range of information presented in this report and to draw conclusions about the current state of the watershed. This analysis will provide a basis for future planning and management of the watershed.

10.1 Water Quality, Biology, and FGM Discussion

As part of the CCIWMP, the highest priority problems in the Cobbs Creek system were identified. With the exception of CSO-related issues, these same problems apply to some degree in the Darby and Tinicum subwatersheds. Given that the Cobbs Creek watershed is a highly urbanized watershed with both CSOs and significant stormwater flows, some of the highest priority problems include:

Dry Weather Water Quality and Aesthetics
- Water quality concerns including high fecal coliform during dry weather
- Dry weather sewage flows in separate sewered areas
- Trash-filled, unsightly streams that discourage residential use.
- Safety concerns along streams and stream corridors

Healthy Living Resources
- Degraded aquatic and riparian habitats
- Limited diversity of fish and benthic life
- Periodic, localized occurrences of low dissolved oxygen primarily associated with plunge pools and areas of stagnant water behind dams
- Utility infrastructure threatened by bank and streambed erosion
- Limited public awareness and sense of stewardship for Cobbs Creek

Wet Weather Water Quality and Quantity
- Water quality concerns including high fecal coliform during wet weather, and nutrients and metals during wet weather flows
- CSO impacts on water quality and stream channels
- Little volume control and treatment of stormwater flows in separate sewered areas

This section presents a brief summary of the analyses behind the watershed indicators presented in the CCIWMP. The data and analyses used to derive these results are documented in more detail in the Technical Memoranda and Comprehensive Characterization Report. The discussion covers each of five geographic areas as shown in Figure 10-1.

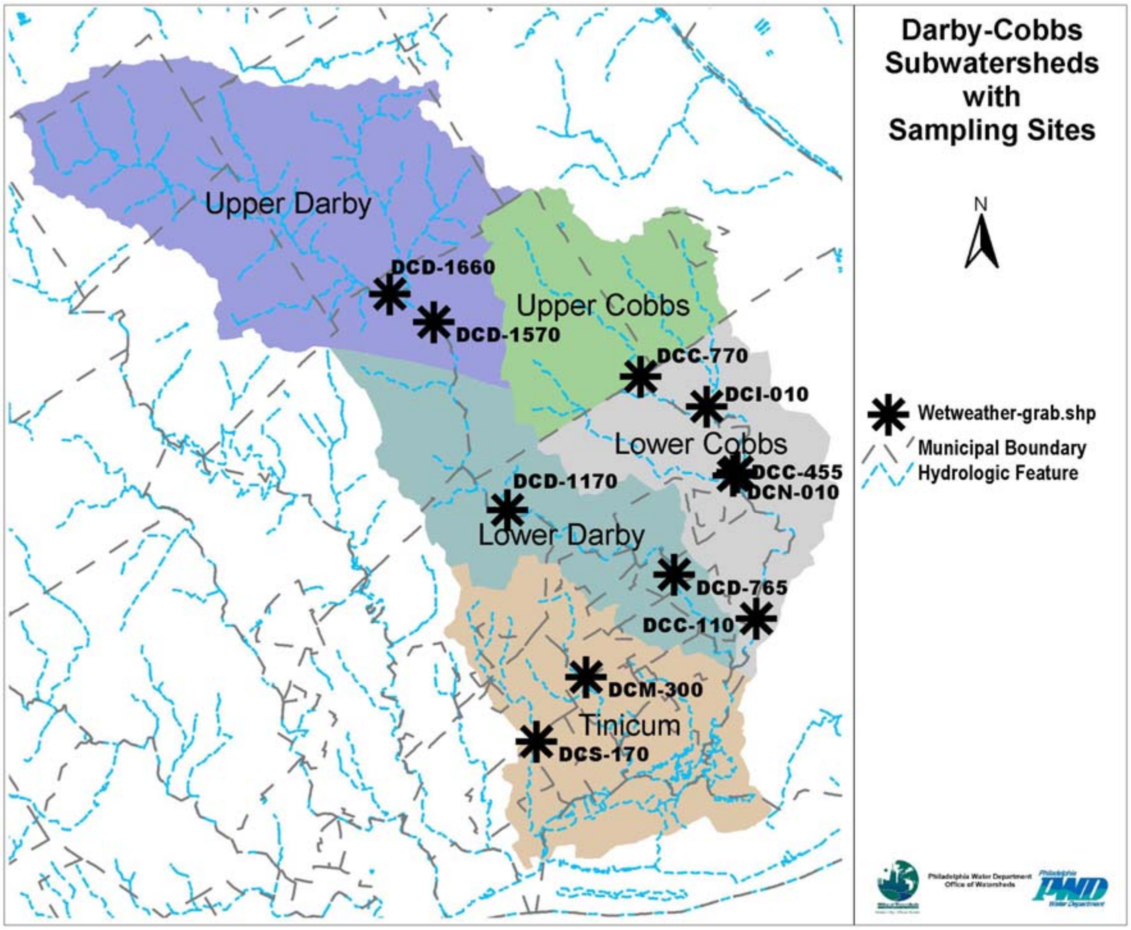


Figure 10-1 Subwatersheds and Sampling Sites

Upper Cobbs Creek

Two sampling sites represent the headwaters and upper reaches of Cobbs Creek. Site DCC-770 is on the main stem of Cobbs Creek near the Philadelphia/ Montgomery County line, and DCI-010 is on Indian Creek just above the confluence with the main stem. These sites do not receive CSO inputs.

Table 10-1 Status of parameters for Upper Cobbs

	Upper Cobbs Indicator Summary							
Site	1 Impervious Cover	2 Baseflow	3 Channel Type	5 Fish	6 Benthos	7 Bacteria	8 Metals	9 DO
DCC770	○	○	○	◐	○	○	●	●
DCI010	○	○	○		○	○	●	●
● Good ◐ Fair ○ Poor								

Land Use, Impervious Cover, and Stream Baseflow

The upper portion of Cobbs Creek consists of a mix of mainly residential land uses with disturbed urban soils, and significant natural park land along the stream corridor inside the City. Based on hydrograph separation analysis (documented in the Comprehensive Characterization Report), baseflow is approximately 43% of average annual rainfall for the Cobbs watershed as a whole. For French Creek, a reference stream with similar soils and geology, baseflow is 64% of average annual runoff. This difference is attributed to reduced groundwater recharge caused by urbanization.

Stream Channel Type and Trends

The headwaters of Cobbs Creek include East Indian Creek, West Indian Creek, and the upstream-most reaches of the main stem in Delaware County. Cross section surveys of East Indian Creek resulted in mostly B Rosgen channel types and a small number of F Rosgen channel types (Figure 10-2). A Rosgen channel type B is moderately entrenched, has a width/depth ratio greater than 12, and has moderate sinuosity. B channel types differ from F channel types since they generally have less steep, tall banks, and a deeper, more varied channel bed rather than being consistently flat. Sediment supply and bank erosion are usually high since they are actively changing through bed and bank erosion. Those East Indian Creek reaches classified as F channel types have completed downcutting and have undergone enough bank erosion to create a wide, flat bottom channel.

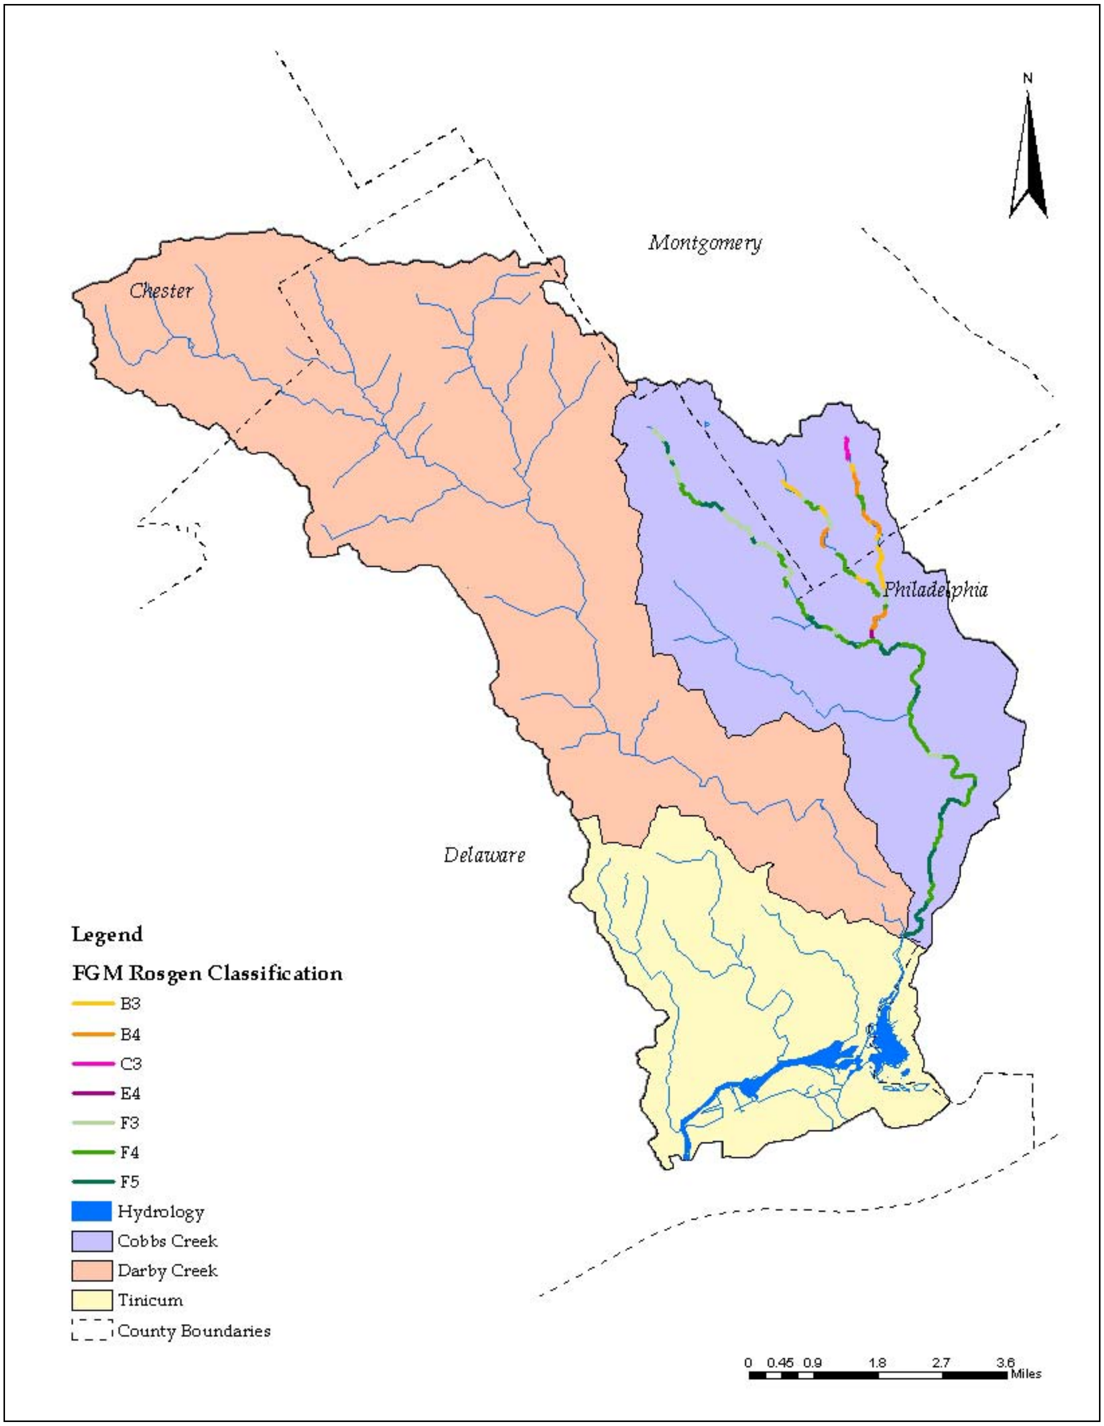

Figure 10-2 Fluvial Geomorphology Study - Rosgen Classification of Cobbs Reaches 2003

Bank conditions throughout East Indian Creek range from relatively stable in undisturbed areas to moderately eroded upstream of Lansdowne Avenue. Residential land use and regular mowing have limited the development of forested buffer, increased sediment supply, and facilitated bank erosion. Channel banks are the most degraded downstream of City Line Avenue where banks and adjacent slopes are the steepest within the subwatershed. These reaches are uncharacteristic of the remainder of the East Indian Creek subwatershed and are most similar to topography and valley types within the Cobbs Creek watershed.

Measured cross sections resulting in an F Rosgen channel type are located nearest the confluence with Cobbs Creek. These reaches have completed downcutting and possibly over-widening more quickly than the upstream reaches classified as B channel types. Existing channel geometry for the East Indian Creek suggests that the downstream end of East Indian Creek is further ahead in the channel migration process than the upstream portion. Over time, all reaches within East Indian Creek are expected to become F channel types and follow the same channel migration pattern over geologic time to transition to a stable C channel type.

West Indian Creek reaches are classified as B and F channel types. Overall, the upstream most portion of the channel is a B channel type and the downstream portion is an F channel type. The mid-section of West Indian Creek contains a transitional area where short overwidened F sections alternate with sections of entrenched, actively degrading B portions. West Indian Creek contains a greater percentage of F channel type than East Indian Creek, although both are still actively adjusting.

Most of West Indian Creek is surrounded by residential development where private homeowners have cleared forested buffers, reducing the buffer width to create additional lawn space or landscape their yards. Reaches downstream of City Line Avenue are the only ones within the subwatershed where a minimum of a 100-foot forested buffer remains. Additionally, 10 of the 15 reaches assessed are disturbed by in-stream structures, utilities, or road crossings.

Overall, bank erosion and sediment supply within the West Indian subwatershed were low and only a few isolated occurrences of more degraded banks were observed. None of the reaches assessed were determined to have high bank erosion or sediment supply ratings. Banks throughout this subwatershed are an average of 5 feet tall, although there are a few instances of banks that are higher than 6 feet tall. Additionally, existing conditions of West Indian Creek provide few indications of whether the channel is aggrading or degrading. Therefore, the reach bed stability was indeterminate throughout West Indian Creek.

The stream condition and stability of West Indian Creek are also influenced by a dam and pond located just downstream of Remington Road. West Indian Creek appears to have been redirected to the dam and away from the original channel located to the west of the pond. The original channel is approximately 5-8 feet wide, which is considerably smaller than the creek both upstream and downstream of the pond, and appears stable. Although the dam and associated structures appear to be in good condition, water in the pond was stagnant at the time of the field assessment. Because the dam and pond outfall downstream of Remington Road interrupt flow through the West Indian Creek, they are influencing the stability of the channel downstream.

West Indian Creek is also expected to follow the same channel migration pattern as Cobbs and East Indian Creek. West Indian Creek most likely was a stable B or C channel that began downcutting when development increased and has continued to adjust since that time. Since a greater percentage of West Indian Creek has migrated to an F channel type than in East Indian Creek, existing conditions suggest that West Indian Creek is further ahead in the channel migration process. Stream reaches within the West Indian Creek that are currently classified as B channel types are expected to over-widen and become F channel types over geologic time. Should no additional land use changes occur within the watershed, West Indian Creek will most likely begin forming depositional features and creating a more narrow, meandering channel within the old channel banks.

Channel cross section measurements and calculations show that the entire Cobbs Creek classifies as a Rosgen type F channel. A Rosgen type F channel is entrenched, has a width/depth ratio greater than 12, and has a low sinuosity. A low entrenchment ratio (less than 1.4 = a highly entrenched channel), allows for very high bank erosion, sediment supply and lateral over-widening in an effort to create a new floodplain within the channel. Lateral bars and moderated riffle/pool sequences are often present. F channel types generally have low slopes, ranging from less than 1 to 1%.

Bank conditions in Cobbs Creek vary throughout the watershed, and generally worsen as the Creek progresses downstream. Channel banks within the headwaters are no taller than 5 feet and are at least 60% vegetated. Bankfull width of the Creek in the headwaters is an average of 25 feet wide.

Currently, the majority of Cobbs has ceased downcutting and is continuing to over-widen. Evidence of over-widening is exhibited as undercutting and vertical banks. The majority of Cobbs Creek is expected to continue widening through bank erosion. The upstream-most portion is expected to begin downcutting and become more entrenched prior to beginning the over-widening stage that the remainder of the Creek is currently undergoing. The rate of channel over-widening will slow, or cease, when deposition is initiated in the channel.

Stream Biology

Indicators based on species abundance and diversity are poor in this portion of the system. Designated uses are considered unattained by PADEP, and both benthic and fish-based indicators indicate a moderately- to severely-impaired system. The sampling site on Indian Creek West Branch receives the lowest scores of any sampling site. However, habitat assessments are generally more positive. Site DCC-865, on Cobbs Creek main stem, scores the highest with respect to the reference stream of any sampling site in the system.

Pollutant Loads and Water Quality

Estimated loadings of water quality constituents, including nutrients, metals, and bacteria, are moderate compared to other portions of the watershed. However, mean nitrate concentrations measured at DCC-770 were some of the highest in the system. Observed DO concentrations meet state standards and are adequate to support aquatic life. The magnitude of the daily DO fluctuation is moderate at upper Cobbs sites, suggesting that excessive algal biomass is not present. Dry and wet weather bacteria counts are not as high as those found in the combined-sewered portion of the watershed, but they still rarely meet standards. With the exception of a small number of lead samples, concentrations of metals are low in dry and wet weather.

Lower Cobbs Creek

Three sampling sites represent lower Cobbs Creek. Site DCC-455 is on the main stem at Cobbs Creek Environmental Center, and DCN-010 is on Naylors Run just above the confluence with Cobbs Creek. Site DCC-110 is on the main stem about one mile above the confluence with Darby Creek. The two sites on the mainstem receive stormwater and CSO inputs, while the Naylors site receives only stormwater. Additional monitoring was conducted at DCC-115, just upstream of the dam at DCC-110.

Table 10-2 Status of parameters for Lower Cobbs

	Lower Cobbs Indicator Summary							
Site	1 Impervious Cover	2 Baseflow	3 Channel Type	5 Fish	6 Benthos	7 Bacteria	8 Metals	9 DO

DCC110	⭕	⭕	⭕	⭕	⭕	⭕	◗	◗
DCN010/DCN208	⭕	⭕		⭕	⭕	⭕	🟢	🟢
🟢 Good ◗ Fair ⭕ Poor								

Land Use, Impervious Cover, and Stream Baseflow

The lower portion of the Cobbs Creek watershed is highly urbanized and highly impervious, with high-density residential areas in the City, a mix of high- and lower-density residential areas in Montgomery County, commercial land uses along highway corridors, and park land along riparian corridors. Combined sewers serve the Philadelphia portion of the watershed. Based on hydrograph separation analysis (documented in the Comprehensive Characterization Report), baseflow is approximately 43% of average annual rainfall for the Cobbs watershed as a whole. For French Creek, a reference stream, baseflow is 64% of average annual runoff.

Stream Channel Type and Trends

Bank conditions throughout Cobbs Creek vary throughout the watershed and generally worsen as the Creek progresses downstream. As the Creek progresses downstream, banks transition to greater than 6 feet tall and less than 50% vegetated. Bankfull width varies from 25 feet to approximately 60 feet wide.

Existing sediment supply and reach bed stability also worsen as the Creek continues downstream. Reaches in the headwaters are an average of 25 feet wide at bankfull and increase to an average width of 60 feet near the confluence with Darby Creek.

Generally, it is the goal of an F channel type to cease downcutting and begin depositing bed materials as alternating lateral bars. Deposition forming lateral bars in turn continues the over-widening process. Alternating lateral bars will slowly build over time through exchange of sediment during bankfull events to effectively decrease the width of the channel accessible by base flow. Limiting the width of the channel through the creation of alternating lateral bars will yield a greater sinuosity and a new, lower floodplain. Although an F channel type is not considered stable, it will generally migrate to a stable C channel type over geological time.

Currently, the majority of Cobbs has ceased downcutting and is continuing to over-widen. Evidence of over-widening is exhibited as undercutting and vertical banks. The majority of Cobbs Creek is expected to continue widening through bank erosion. The rate of channel over-widening will slow, or cease, when deposition is initiated in the channel.

Stream Biology

As has historically been the case in many urban stream ecosystems, the moderately impaired benthic community and pollution tolerant fish assemblages in Cobbs Creek are an apparent result of habitat deterioration and episodic water quality degradation throughout the watershed. All of the Cobbs watershed is classified as unattained by PADEP. Sampling sites are moderately to severely impaired based on benthic criteria. Habitat is classified as partially supporting aquatic life uses at approximately 60% of the reference stream condition.

Cobbs Creek watershed is a highly urbanized region where traditional methods of stream bank "reconstruction" and storm water management have significantly channelized the stream, creating a system which is not in dynamic equilibrium (i.e. the amount of erosion and sedimentation is not equal to the amount of sediment transport out of the system). Furthermore, this aquatic ecosystem has lost much of its link magnitude (e.g. small first order streams) and wetland systems due to development and increased impervious surfaces. By changing the "natural" state of the stream, development has altered the hydrologic profile, decreasing the time to peak flow and increasing the peak flow itself. In doing so, events reaching or exceeding bankfull stage are no longer managed by the stream channel and flood plain. Typical events scour stream banks, fill pool systems and cover riffle structures with sediment at an accelerated rate. As a result, a highly ephemeral (short-lived) system with increased sediment deposition, decreased habitat heterogeneity (e.g. pool-riffle-run systems) and unstable stream banks has been created. Biologically, these processes have had a deleterious effect on the benthic and ichthyfaunal communities inhabiting Cobbs Creek. Three of the most important attributes of streams for macroinvertebrate and fish persistence are oxygen, food, and habitat. Although the first two attributes are equally important, habitat modifications and loss of habitat appear to be the primary reasons for decreases in species diversity and fecundity, skewed population dynamics and increases in "pollution tolerant" species in Cobbs Creek.

Benthic invertebrates rely heavily on riffle systems as primary habitat to carry out most or all of their life cycles. Morphologically, many species have evolved and adapted to handle increased flow over riffle systems (e.g. dorsally flattened bodies, claws for clinging). However, increases in flow, sediment deposition and scouring in Cobbs Creek have impeded reproductive and feeding strategies of many species of macroinvertebrates. Those individuals not adapted to extreme hydrologic fluctuations have been extirpated from this area. Also, sediment deposition has created embedded riffle systems where eggs are either scoured downstream or covered by layers of fine and course sediment. By decreasing the species richness and evenness of the benthic community, functional feeding groups have also been modified. Many species responsible for conditioning course particulate organic matter (CPOM), are no longer present in this watershed (e.g. Order: *Plecoptera*). Organisms well adapted to hydrologic extremes and pollution, such as blackflies (Family: *Simuliidae*), *Hydropsychid* caddisflies (Family: *Hydropsychidae*) and midges (Family: *Chironomidae*) currently dominate the assessed areas. In addition to the community dynamics, the fluvial geomorphological profile in Cobbs Creek has created temporary riffles where spates may virtually change the "aqua-scape" in a period of days.

Like the benthic invertebrate community, fish communities rely heavily on various habitats within a stream reach. Many species (e.g., *Etheostoma olmstedi*) have adapted to shallow riffles systems for food acquisition. Other species (e.g. *Micropterus* sp.) rely on large pools for foraging and reproduction. Stream runs with vegetated areas are also important habitat components for many species of fish. Extremes in the hydrologic profile of Cobbs Creek have also contributed to decreased species diversity and offspring of fish within this area. Many species rely on vegetation or rocks to deposit their eggs, while other species build nests that are closely guarded by the parent or parents. Extreme flow conditions contribute to the deposition of sediment in pool systems and scouring regions where offspring have been deposited, thus increasing mortality rates in eggs and fry populations. In addition, pool systems in this area are highly dynamic (e.g., a moderately sized pool can be covered within a few days).

Pollutant Loads and Water Quality

Pollutant loading estimates generally correspond to degree of development, as represented by population density, in the separate-sewered areas, and are some of the highest in the system. BOD, TSS, and bacteria loading estimates are relatively high in the combined-sewered areas, while nutrient loading estimates are relatively low due to the proportion of captured flows. Estimates of metals loadings are mixed compared to other portions of the system.

Storm hydrographs at DCC-455 and DCC-110 in this portion of the system display the high intensity, low-duration behavior typical of highly urbanized, highly impervious systems; these high-velocity flows are erosive and can present a problem for aquatic life. Turbidity also increases sharply in wet weather and may indicate a combination of fine sediment in stormwater runoff, and streambed and bank erosion.

There is evidence to indicate that lower Cobbs sites, and DCC-455 in particular, may be eutrophic. Observed nitrate generally decreases along Cobbs Creek main stem; mean nitrate at DCC-455 is greater than mean nitrate at DCC-110, and observed nitrate concentrations at DCN-010 are among the highest in the system. The large daily range in DO and qualitative observations at DCC-455 suggest that this site is the most biologically active among the sites sampled. Continuous data suggest that DO at DCC-110 is below the level needed to support aquatic ecosystems approximately 5% of the time. DCC-115, located just above a low dam, experiences the lowest DO of any site due to poor mixing.

Bacteria counts in the lower Cobbs exceed standards in both dry and wet weather and in both combined- and separate-sewered areas. Copper, lead, and zinc exceed standards in wet weather at DCC-110. Stormwater outfalls and combined sewer overflows (CSOs) have also exacerbated the problems of sedimentation and erosion as well as contributed to episodic periods of reduced water quality.

Upper Darby Creek

The headwaters of Darby Creek are represented by data taken from site DCD-1570 and by a limited amount of data from DCD-1660. These sites are not impacted by known CSOs.

Table 10-3 Status of parameters for Upper Darby

	Upper Darby Indicator Summary							
Site	1 Impervious Cover	2 Baseflow	3 Channel Type	5 Fish	6 Benthos	7 Bacteria	8 Metals	9 DO
DCD1660	⭕	🟢			🟢	◗	🟢	◗
DCD1570	⭕	🟢			🟢	🟢	🟢	🟢
	🟢 Good	◗ Fair	⭕ Poor					

Land Use, Impervious Cover, and Stream Baseflow

The upper portion of the Darby Creek watershed is the least urbanized portion of the system and consists of mixed residential, commercial, park land, and golf course land uses. Estimates of pollutant loads are relatively low with the exception of commercial areas in the northern-most portion of the watershed. Hydrograph separation analysis of a USGS gauge in the headwaters (01475300) indicates that baseflow comprises approximately 66% of mean annual flow, similar to an undeveloped system.

Stream Biology

The upper portion of the Darby Creek watershed is listed by PADEP as attaining its designated uses. Benthic indicators range from poor to very good at different sites, and fish indicators range from fair to good. Habitat assessment data are limited. Although the area is less urbanized than other portions of the Darby and Cobbs Creeks watershed, continuous monitoring data of depth and turbidity still display the high flood peaks and short durations typical of urban flows. Qualitative assessments by ANS and PADEP indicate that some erosion has occurred, and the amount of erosion generally increases from upstream to downstream along the length of the Darby.

Pollutant Loads and Water Quality

Although many estimated pollutant loads are low in the area, estimated nitrogen and phosphorus loads are moderate, as expected from landscaped areas. DO is generally adequate to support aquatic life, although water temperatures occasionally exceed standards for designated cold water fisheries. DO fluctuations are smaller than those observed in other parts of the system, suggesting less algal activity and a less-enriched system. Bacteria counts are lower than those found downstream, but most samples still do not meet standards. Concentrations of metals increase in wet weather but do not exceed standards for protection of aquatic life.

Lower Darby Creek

Lower Darby Creek is represented by two sampling sites. DCD-1170 is on the main stem downstream of PA Route 3, and DCD-765 is upstream of the confluence with Cobbs Creek. These sites are impacted by stormwater but not by known CSOs.

Table 10-4 Status of parameters for Lower Darby

	Lower Darby Indicator Summary							
	1	2	3	5	6	7	8	9
Site	Impervious Cover	Baseflow	Channel Type	Fish	Benthos	Bacteria	Metals	DO
DCD1170	○	○			○	○	●	●
DCD765	○	○			○	○	●	●

● Good ◐ Fair ○ Poor

Land Use, Impervious Cover, and Stream Baseflow

The lower portion of the Darby Creek watershed consists primarily of a mix of single and multiple-family residential land uses. The estimated average annual runoff is 17.8 inches or 43% of average annual rainfall; this level of imperviousness is similar to upper Cobbs, less than lower Cobbs, and greater than upper Darby. As in other separate-sewered areas, estimated constituent loadings generally follow trends in imperviousness and population density. Continuous monitoring data indicate high-intensity, short-duration runoff events occur that are likely to cause erosion of streambeds and banks.

Stream Biology

PADEP lists lower Darby Creek, defined as the area below PA Route 3, as unattained for designated uses. ANS and PADEP list benthic quality as poor and fish quality as fair. Habitat data are limited, but observed erosion is generally greater than that observed further upstream. These conditions suggest that in addition to some instances of degraded water quality in wet weather, urban flow modifications are degrading habitat.

Pollutant Loads and Water Quality

There is some evidence that DCD-765 may be nutrient-enriched. Nitrate and ammonia concentrations increase slightly over the length of Darby Creek, although they are generally lower than those found in the Cobbs Creek system. DO is less than the state standard during some wet weather events.

Bacteria counts are lower in dry weather than those found in Cobbs Creek; however, wet weather bacteria counts are similar to those found in the combined-sewered areas of Cobbs Creek. Metals concentrations increase in wet weather as they do throughout the system and sometimes exceed state standards at DCD-765.

Tinicum

Two sampling sites represent conditions in the Tinicum area. These include DCM-300 on Muckinipattis Creek and DCS-170 on Stony Creek.

Table 10-5 Status of parameters for Tinicum

	Tinicum Indicator Summary							
	1	2	3	5	6	7	8	9
Site	Impervious Cover	Baseflow	Channel Type	Fish	Benthos	Bacteria	Metals	DO
DCM300	○				○	○	●	●
DCS170	○				○	○	●	●

● Good ◐ Fair ○ Poor

Land Use, Impervious Cover, and Stream Baseflow

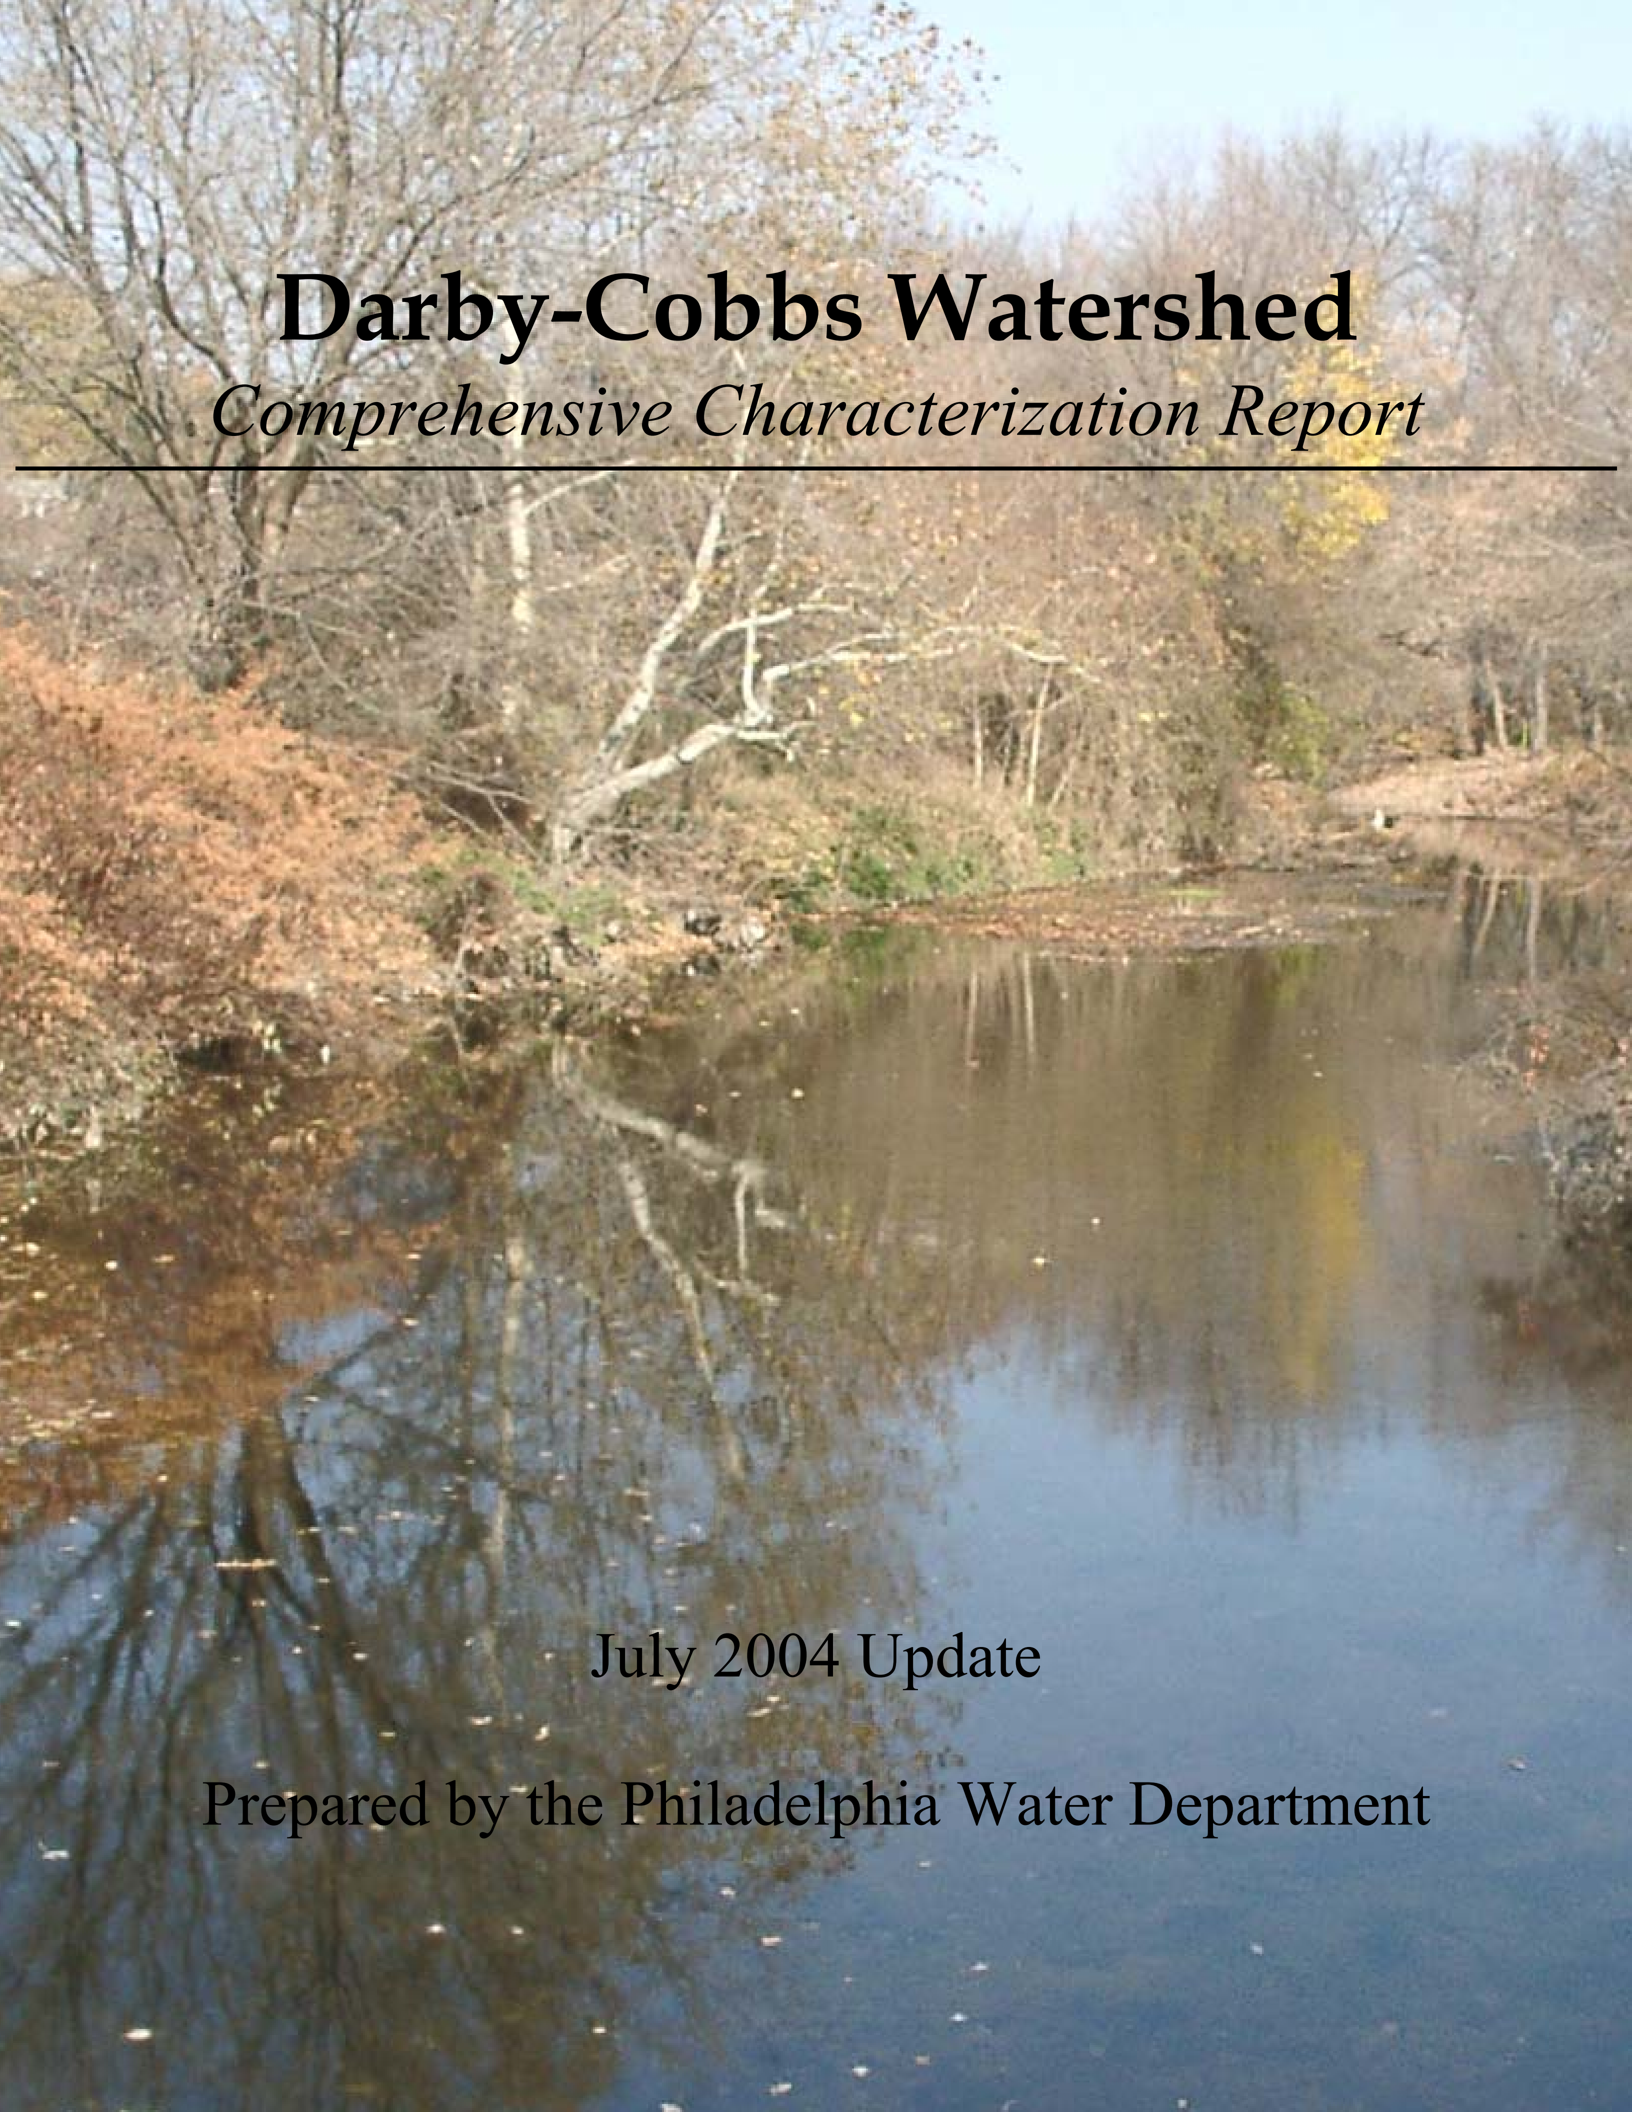
The Tinicum watershed consists of residential and commercial development to the northwest and undeveloped wetlands and marshes to the southeast. The more developed portion of the watershed results in moderate pollutant load estimates relative to other portions of the watershed.

Stream Biology

PADEP lists the area as unattained based on benthic macroinvertebrate species diversity.

Pollutant Loads and Water Quality

Discrete DO samples sometimes were less than state standards in dry and wet weather. Nitrate is generally lower in Tinicum than in other parts of the system, but ammonia is generally greater. Metals concentrations are elevated and sometimes exceed state standards in wet weather.



Darby-Cobbs Watershed

Comprehensive Characterization Report

July 2004 Update

ACKNOWLEDGEMENTS

Philadelphia Water Department (PWD) would like to thank those individuals who devoted their time and energy to assist water department personnel in completing the comprehensive assessment of Darby-Cobbs Watershed. In particular, Mike Boyer and Alan Everett of the Pennsylvania Department of Environmental Protection (Southeast Regional Office) were instrumental in field assistance and quality control/quality assurance oversight. Paula Conolly (D.S. Winokur), Virginia Ranly (D.S. Winokur) and Gary Martens (Camp, Dresser & McKee) provided support with field work, database management and Geographic Information Systems (GIS).

PWD would also like to thank Drexel University's Cooperative Program for providing highly qualified students to assist in various monitoring programs. More specifically, Kelly Anderson, Rick Howley and Jim Pagana contributed to the fieldwork effort and assisted in data organization.

In addition to the aforementioned individuals and agencies, scientists from the Office of Watersheds (OOW) and Bureau of Laboratory Services (BLS) would like to extend their gratitude to individuals within the Water Department for their involvement in the assessment. Maureen Jaroszewski, Marla Johnson, Steve Ostrowski, Joe Roman, Cindy Rettig and staff, and the staff of the Central Receiving Unit were actively involved with fieldwork activities and/or laboratory analyses.

SECTION 1: INTRODUCTION

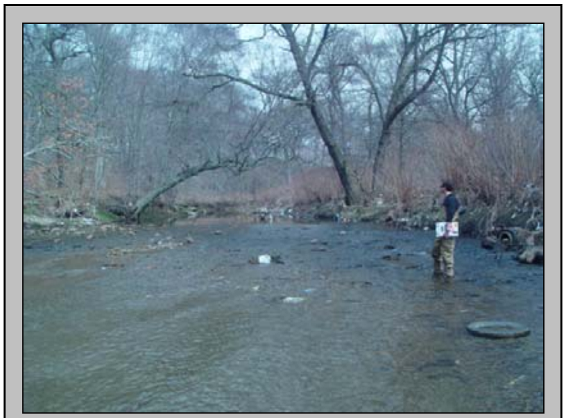
This report summarizes the Philadelphia Water Department's (PWD) Watershed Sciences Group 2003 comprehensive assessment of Darby-Cobbs Watershed. Since the last comprehensive assessment, conducted in 1999, the understanding of the watershed has been advanced by numerous studies and modeling exercises, funded largely by the Commonwealth of Pennsylvania (e.g., Acts 167, 104b3 and 537). These investigations, combined with considerable urban planning and community stewardship efforts, have culminated in the Cobbs Creek Integrated Watershed Management Plan (CCIWMP). Comprehensive watershed assessments conducted in 1999 and 2003 informed the decision-making and prioritization processes of the plan, and future assessments will complement state water quality criteria in providing a scientific means to measure improvements once restoration activities are implemented.

While improvements to the watershed are interrelated and will happen concurrently, the CCIWMP presents the overall goal of watershed restoration as a series of targets: A) dry weather water quality, B) healthy living resources, and C) wet weather water quality. Management plan targets are addressed by various components of this comprehensive watershed assessment, including physical habitat assessments, water quality monitoring, and algae, benthic macroinvertebrate, and fish surveys. Since components of an aquatic ecosystem are interrelated, this integrative approach allows for a greater understanding of factors affecting the aquatic ecosystem that would not be possible if individual elements were studied alone. Of primary importance is understanding how the physical and chemical attributes of streams affect algae, invertebrate, and fish communities, because healthy aquatic communities cannot survive in the absence of healthy habitats.

As impairments are identified and corrected, the Watershed Sciences Group is responsible for measuring improvements quantitatively. If improvements are unsatisfactory or absent, PWD and its CCIWMP partners must identify remaining causes of impairment. Many tools available to aquatic biologists were developed to identify impairments due to organic pollution from point sources and runoff. Traditional bioassessment tools may not be useful for monitoring BMPs. Reference site conditions may not be replicable due simply to differences in climate and geography. Interpretation of bioassessment data must integrate results of other data collection efforts so as not to misattribute impairment to less important, or even unrelated, causes. Lastly, our investigations suggest that biogeography and dispersal ability of sensitive indicator organisms may play an important role in how quickly improvements, as measured by bioassessment techniques, manifest themselves following stream restoration or improvements in water quality.

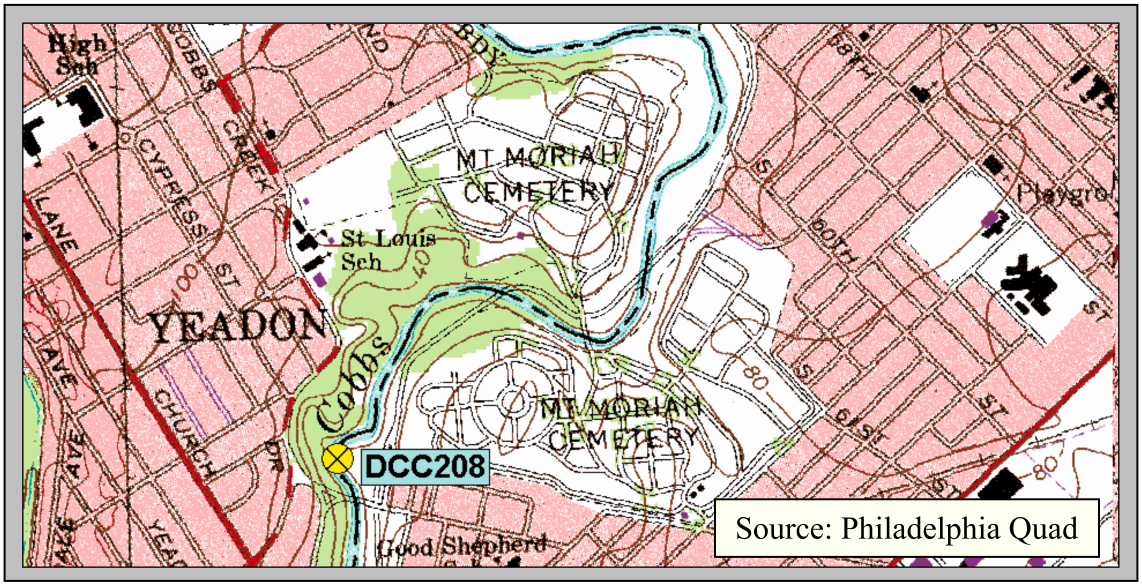
SECTION 2: SITE LOCATIONS AND DESCRIPTIONS

2.1. *DCC 208: Darby-Cobbs Study Area* **Philadelphia County**



Upstream view of DCC208

Downstream view of DCC208



Source: Philadelphia Quad

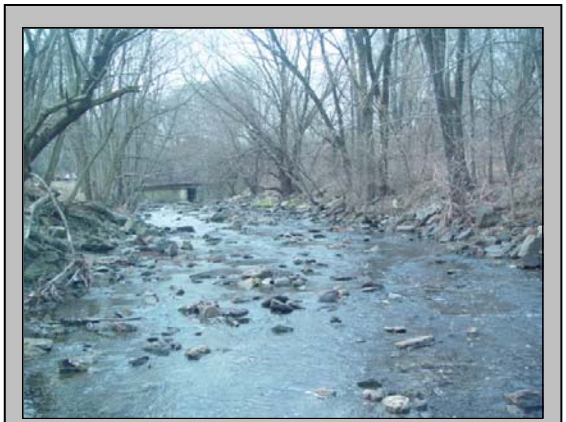
Location:

Access gained from 65th Street and the Cobbs Creek Parkway. (Latitude: -75.24459, Longitude: 39.93046)

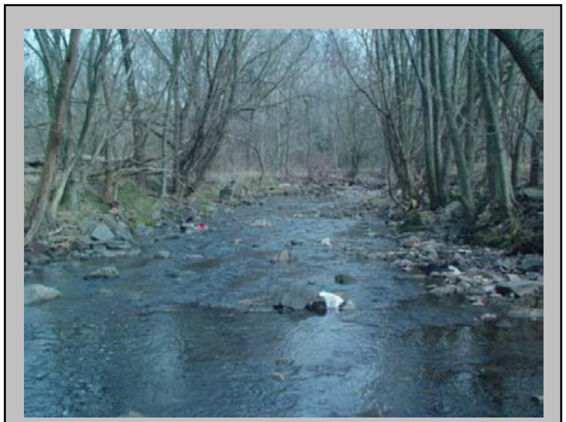
Description:

DCC208 is located upstream of a bridge near 65th Street and Cobbs Creek Parkway. The surrounding land use consists of a residential area and a cemetery. Cobbs Creek Parkway runs along the left bank of the creek at this location.

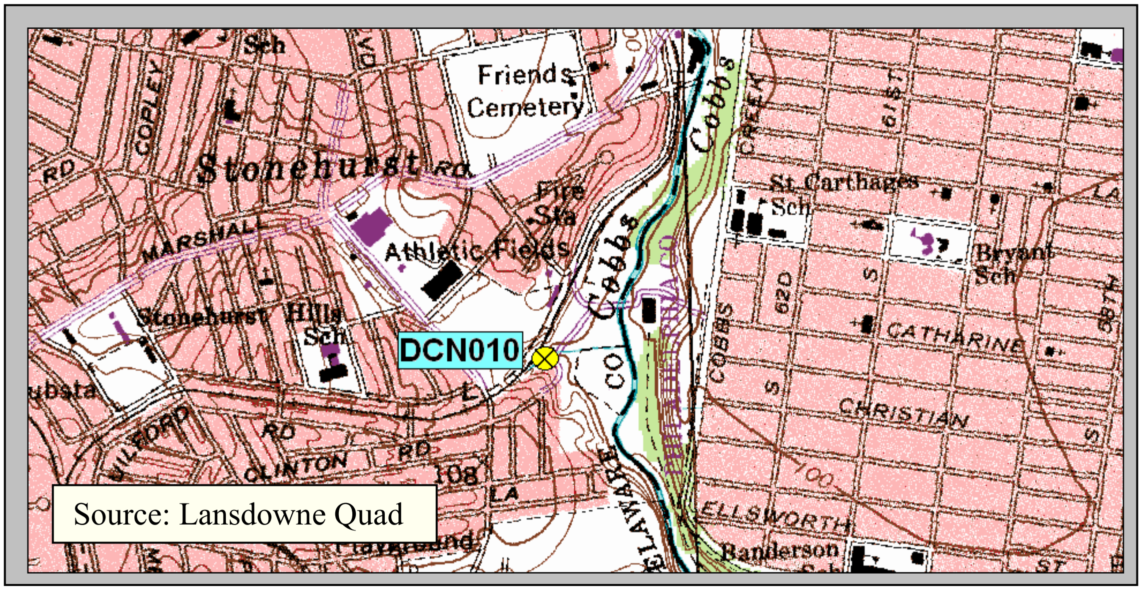
2.2. DCN 010: Darby-Cobbs Study Area Delaware County



Upstream view of DCN010



Downstream view of DCN010



Source: Lansdowne Quad

Location:

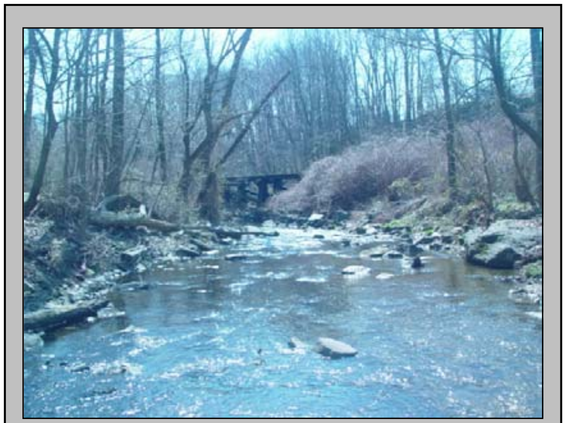
Access gained from Walnut Park Road off of 69th Street. (Latitude: -75.25336, Longitude: 39.95100)

Description:

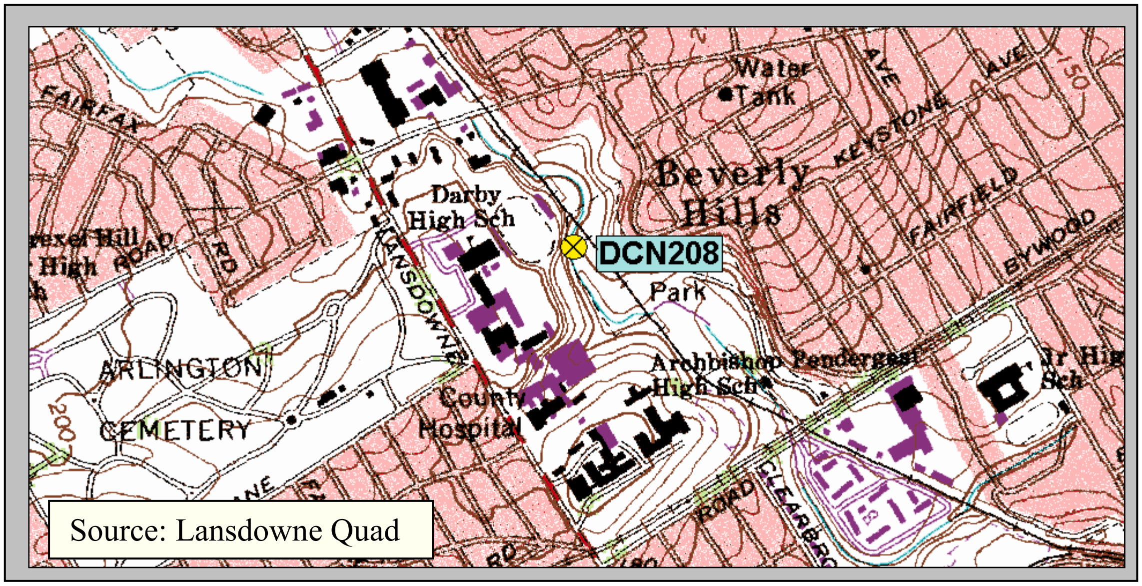
Site DCN010 is located on Naylors Run, just upstream of the confluence with Cobbs Creek. The site contains a lot of artificial substrate (concrete, bricks, etc.). The surrounding land use is field/pasture and residential.

2.3. *DCN 208: Darby-Cobbs Study Area* Delaware County

Upstream view of DCN208



Downstream view of DCN208



Source: Lansdowne Quad

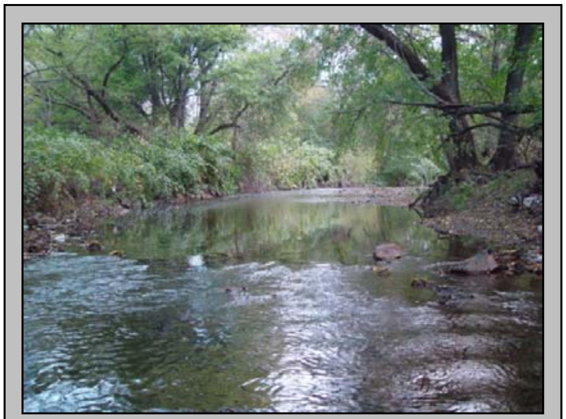
Location:

Access gained off of Garrett Road across from Barclay Square. (Latitude: -75.28287, Longitude: 39.95743)

Description:

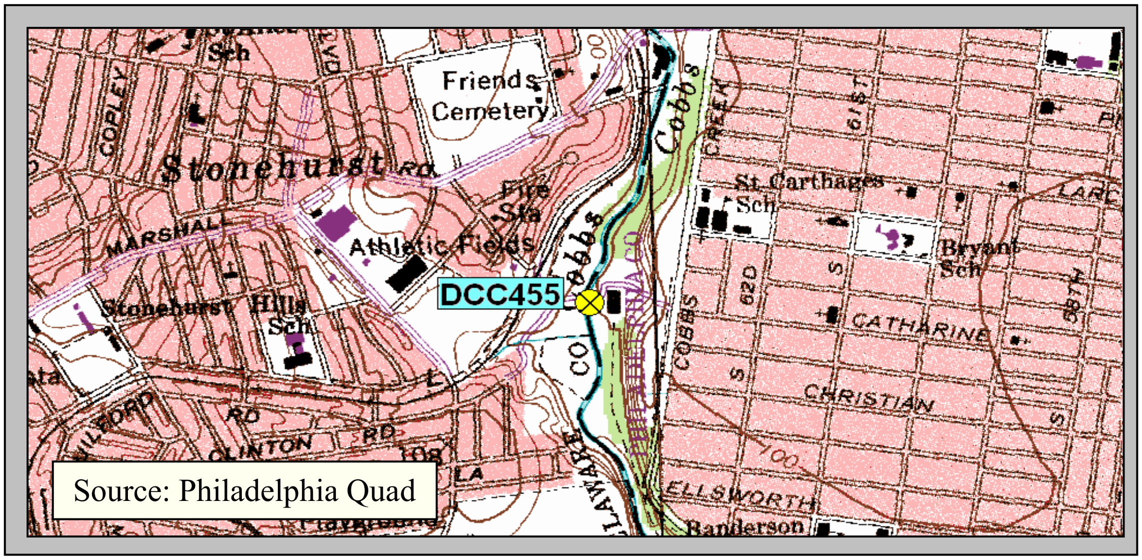
DCN208 is located on Naylors Run near Upper Darby High School. The surrounding land use is residential, and obvious sources of nonpoint source pollution exist near the site. A dam is present 250 meters downstream from the site, at which point the stream is also channelized.

2.4. DCC 455: Darby-Cobbs Study Area Philadelphia County



Upstream view of DCC455

Downstream view of DCC455



Source: Philadelphia Quad

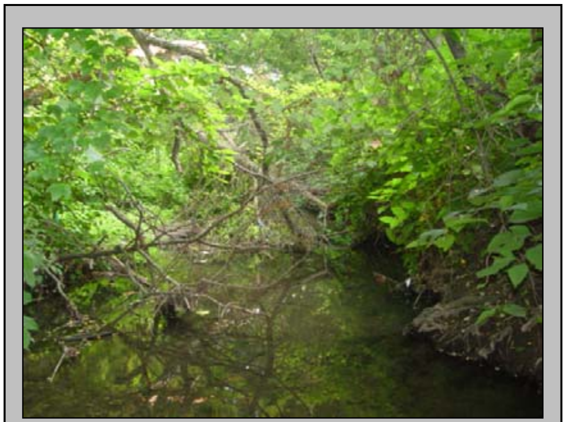
Location:

Access gained from the Cobbs Creek Community Environmental Education Center. (Latitude: -75.25203, Longitude: 39.95178)

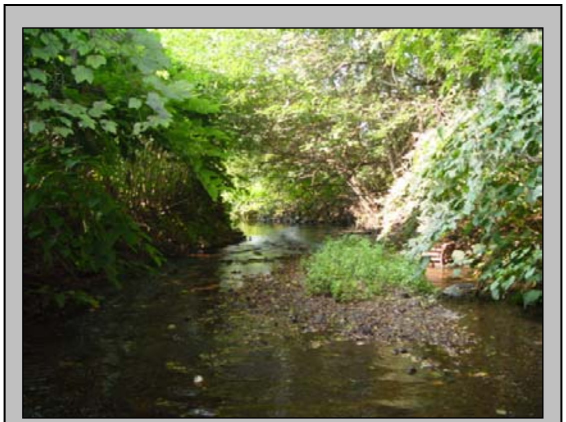
Description:

Site DCC455 is located 200 meters upstream of the footbridge behind the Cobbs Creek Community Environmental Education Center. The site is within the Cobbs Creek portion of Philadelphia's Fairmount Park. The surrounding land use is parkland and residential.

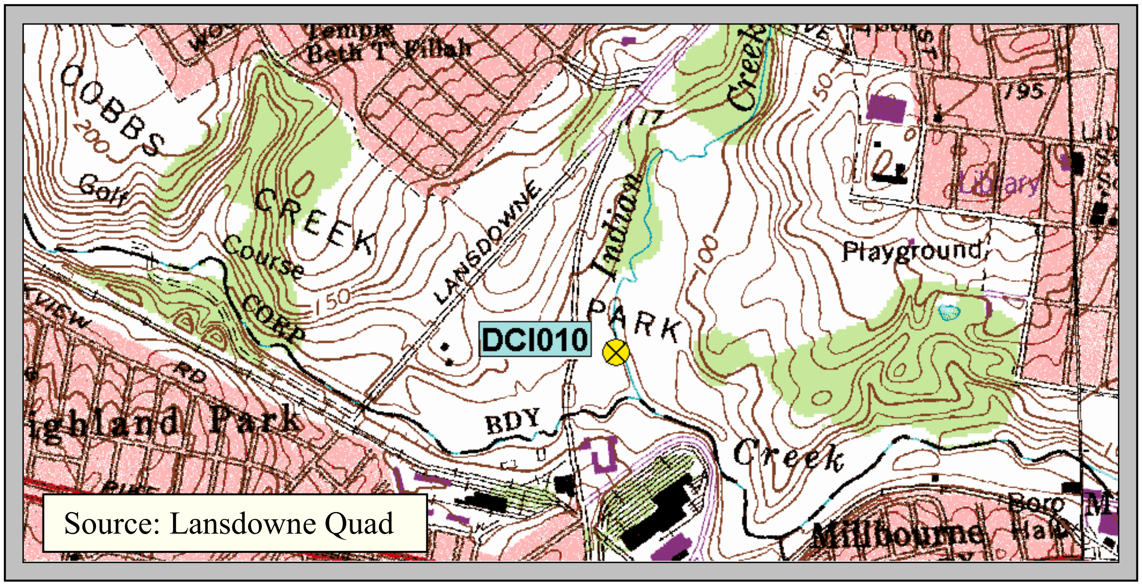
2.5. *DCI 010: Darby-Cobbs Study Area* Montgomery County



Upstream view of DCI010



Downstream view of DCI010



Source: Lansdowne Quad

Location:

Access gained from Cobbs Creek Golf Course near Haverford Avenue. (Latitude: -75.26084, Longitude: 39.96726)

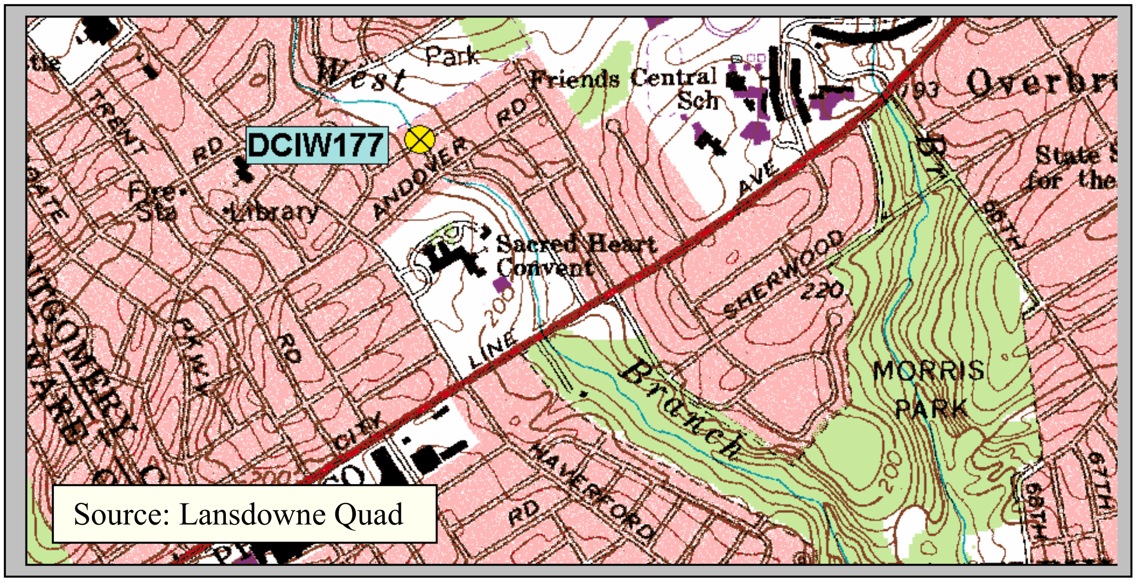
Description:

Site DCI010 is located within the Cobbs Creek Golf Course on Indian Creek. The site is positioned 100 meters upstream up a golf cart crossing. The surrounding land use is Cobbs Creek Golf Course.

2.6. *DCIW 177: Darby-Cobbs Study Area* Montgomery County

Upstream view of DCIW177

Downstream view of DCIW177



Source: Lansdowne Quad

Location:

Access gained at Manoa and Wiltshire Roads. The site is adjacent to Penn Wynne Playground. (Latitude: -75.27062, Longitude: 39.98483)

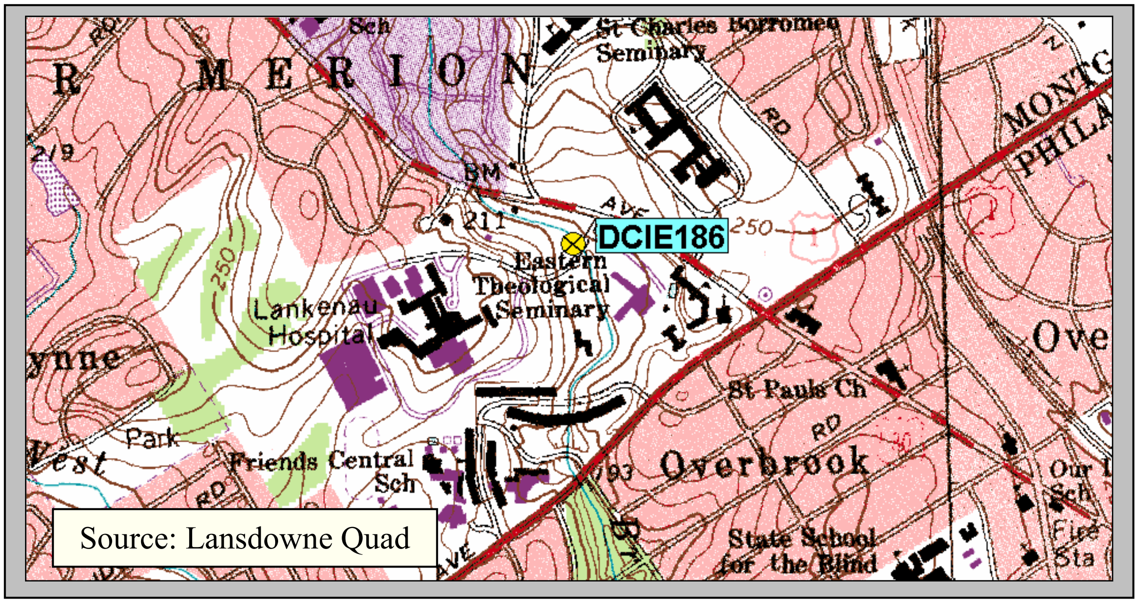
Description:

Site DCIW177 is located on the west branch of Indian Creek near City Line Avenue. The stream is channelized at this portion with vegetation established on the banks. The surrounding land use is a mowed grass ballfield.

2.7. DCIE 186: Darby-Cobbs Study Area Montgomery County

Upstream view of DCIE186

Downstream view of DCIE186



Source: Lansdowne Quad

Location:

Access gained from Lankenau Hospital parking area. (Latitude: -75.25912, Longitude: 39.98964)

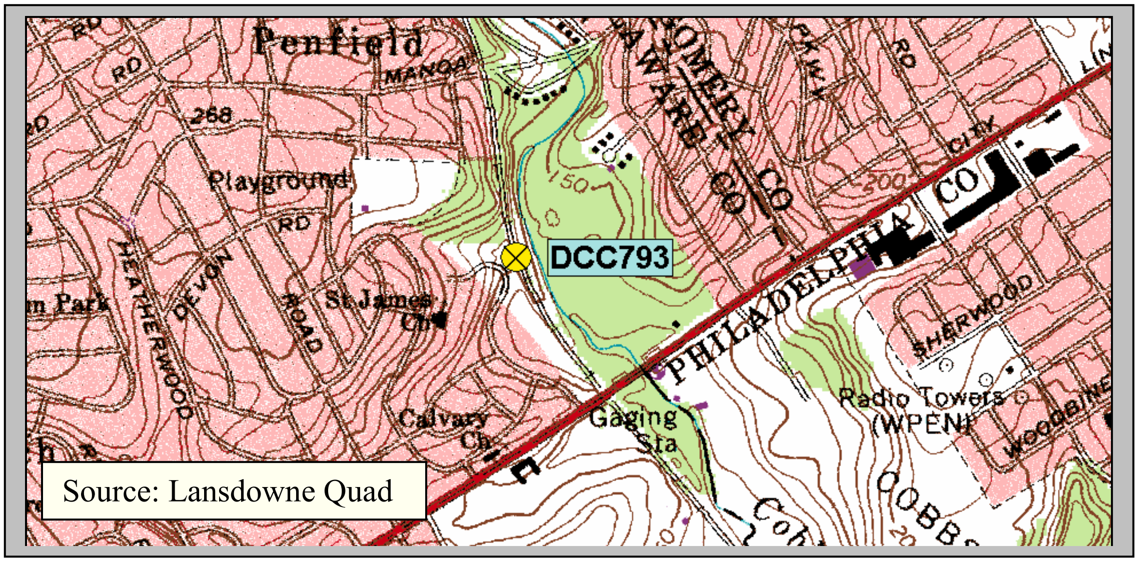
Description:

DCIE186 is located on the East Branch of Indian Creek near the Lankenau Hospital. The surrounding land use consists of the hospital as well as other commercial facilities and residential areas.

2.8. DCC 793: Darby-Cobbs Study Area Delaware County

Upstream view of DCC793

Downstream view of DCC793



Source: Lansdowne Quad

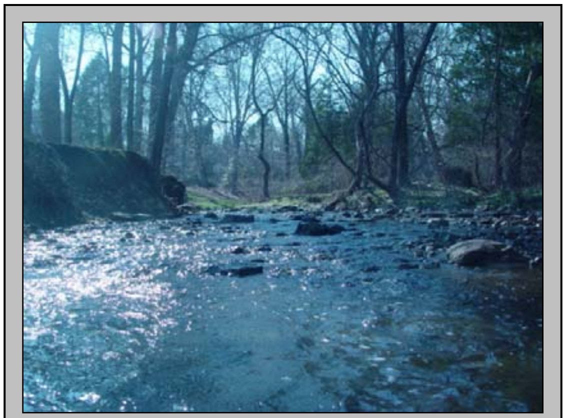
Location:

Access gained by a private road on the Grange Estate Property near City Line Avenue (official entrance off of Myrtle Street). (Latitude: -75.28322, Longitude: 39.97710)

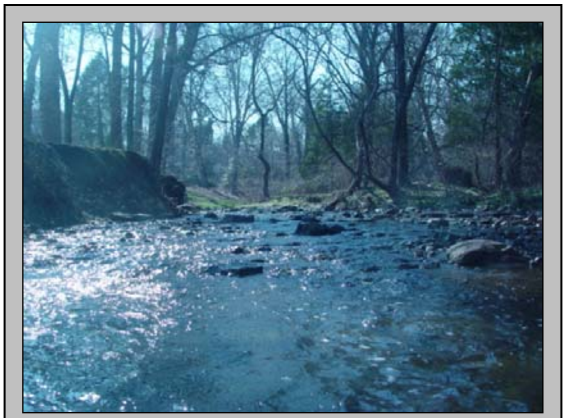
Description:

DCC793 is located on the edge of a private estate. The surrounding land use is residential and field/pasture land. The Creek passes underneath a railroad track close to the site.

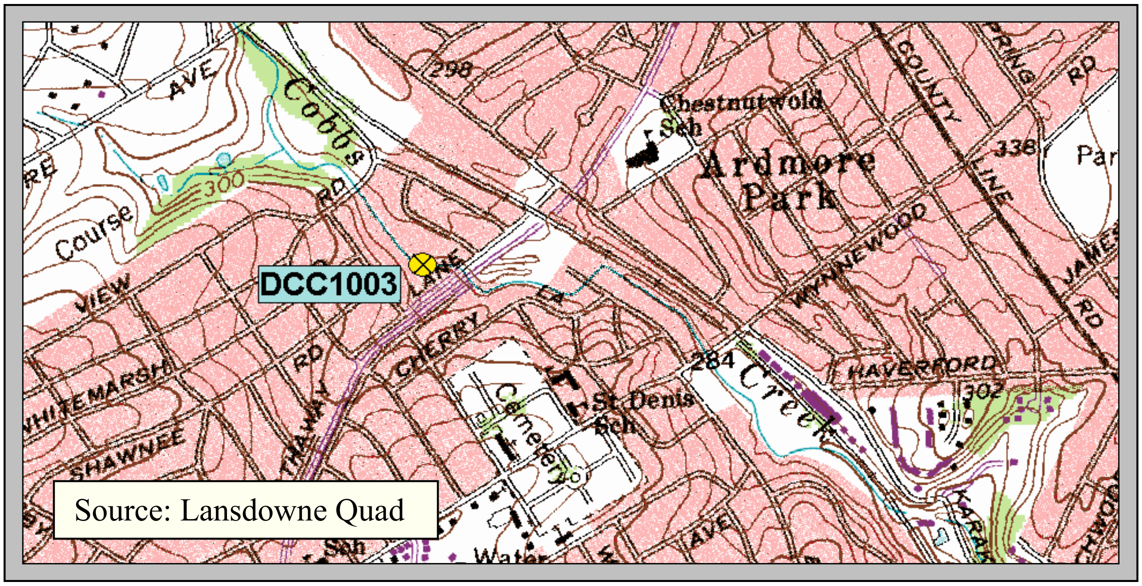
2.9. *DCC 1003: Darby-Cobbs Study Area* Delaware County



Upstream view of DCC1003



Downstream view of DCC1003



Source: Lansdowne Quad

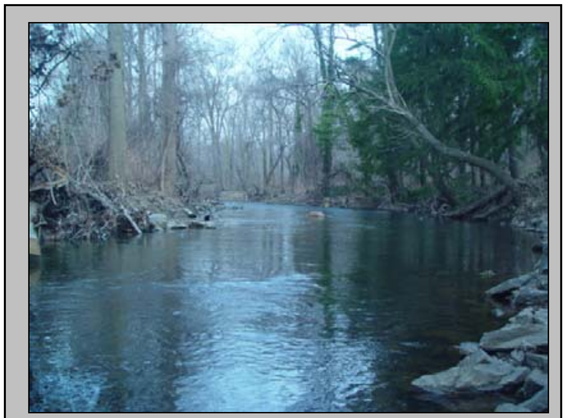
Location:

Access gained from Hathaway Bridge on Hathaway Lane off of Haverford Road. (Latitude: -75.30657, Longitude: 39.99499)

Description:

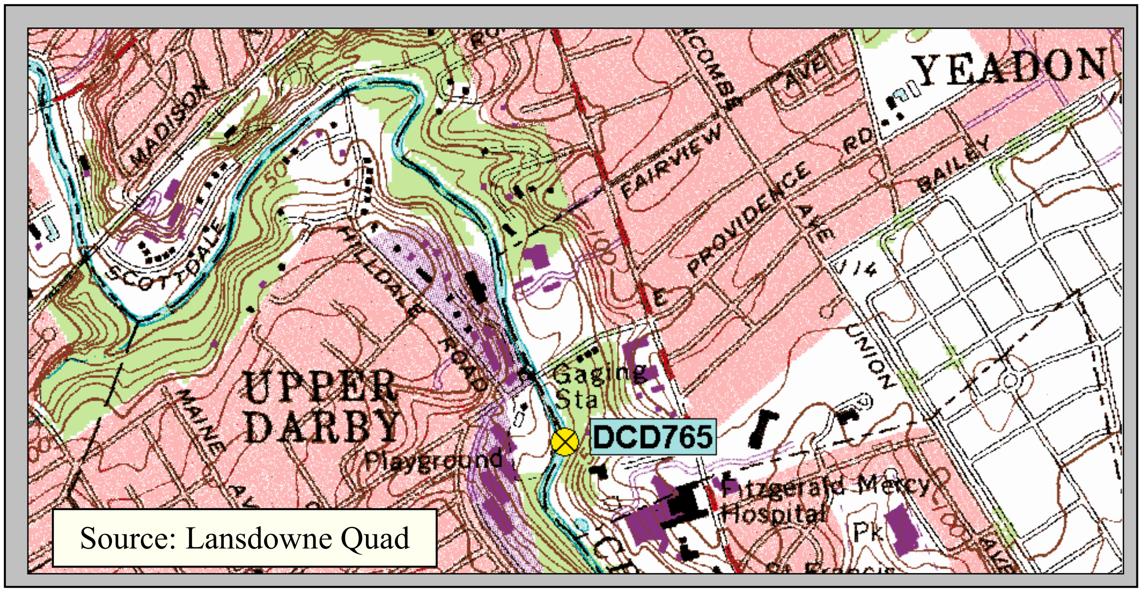
DCC1003 is the most upstream site on Cobbs Creek. It is located just upstream of the bridge on Hathaway Lane. The surrounding land use is single-family residential housing.

2.10. DCD 765: Darby-Cobbs Study Area Delaware County



Upstream view of DCD765

Downstream view of DCD765



Source: Lansdowne Quad

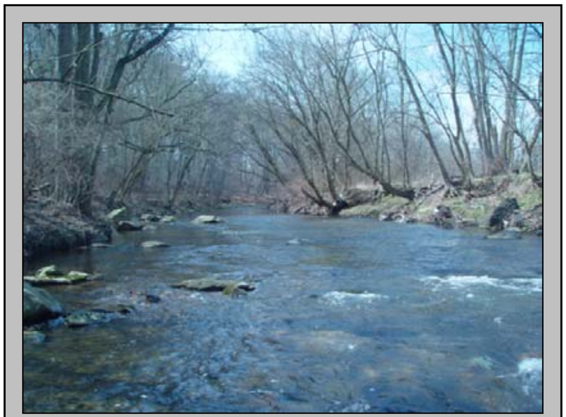
Location:

Access gained from the ballpark and playground located on Providence Road. The site is 100 meters downstream of Providence Road. (Latitude: -75.27214, Longitude: 39.92807)

Description:

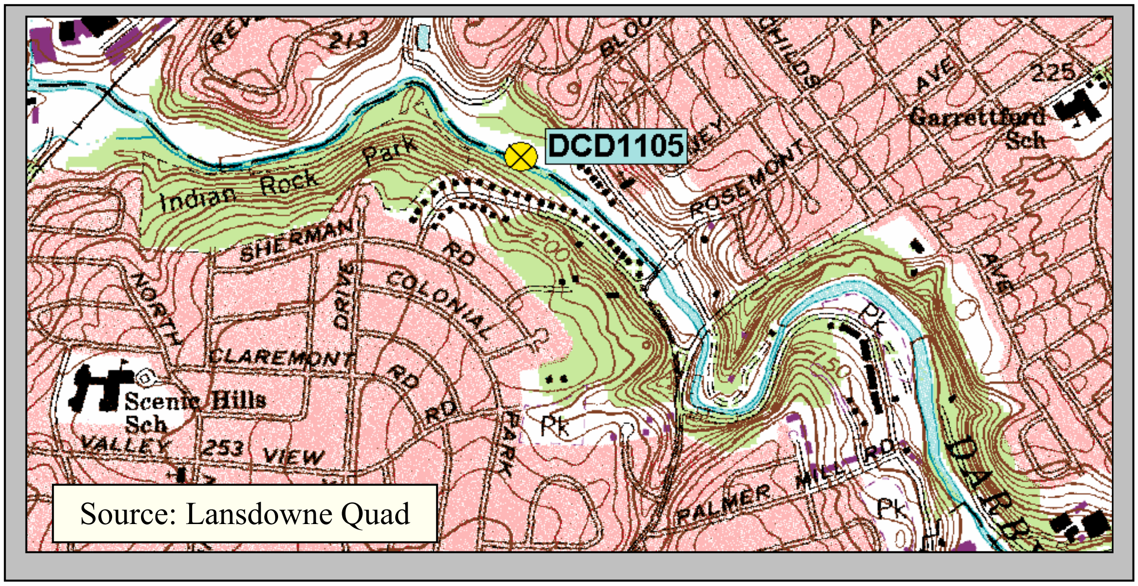
The general land use surrounding DCD765 is residential and commercial. The area immediately surrounding the site includes a baseball field and playground. The left bank of the stream reach has been modified with riprap.

2.11. DCD 1105: Darby-Cobbs Study Area Delaware County



Upstream view of DCD1105

Downstream view of DCD1105



Source: Lansdowne Quad

Location:

Access gained through the delivery entrance at Drexelbrook Apartments on Bloomfield Ave. The stream segment is reached by driving through the parking lot past a large white banquet facility and is 250 meters past a yellow gate. (Latitude: -75.31195, Longitude: 39.94261)

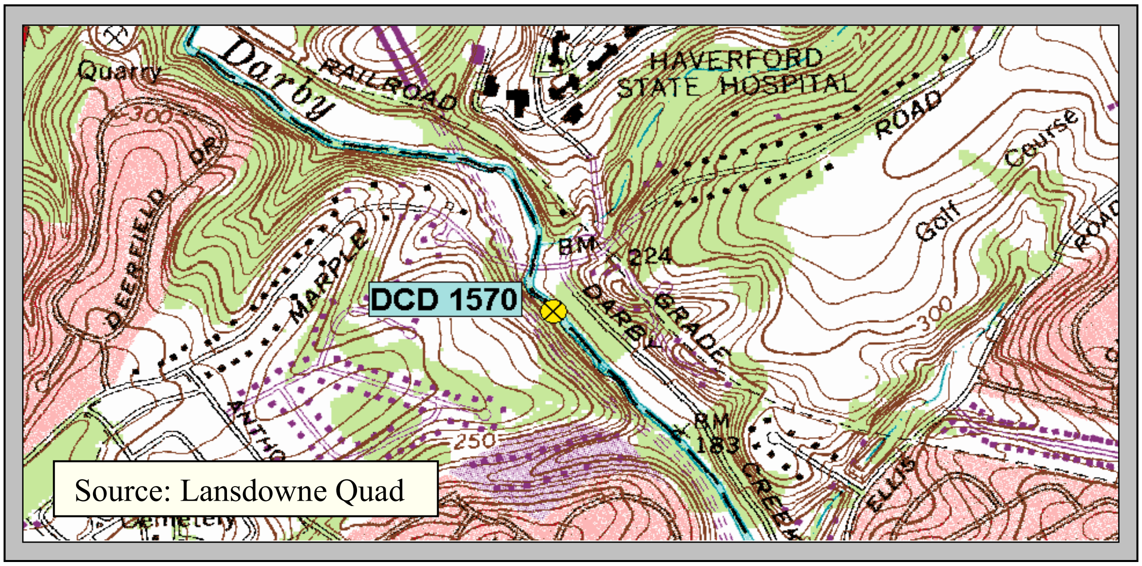
Description:

DCD1105 is located off of Bloomfield Avenue near Indian Rock Park. Forest and residential land use surround the site. Riprap has been placed on the left bank of the reach.

2.12. DCD 1570: Darby-Cobbs Study Area Delaware County

Upstream view of DCD1570

Downstream view of DCD1570



Source: Lansdowne Quad

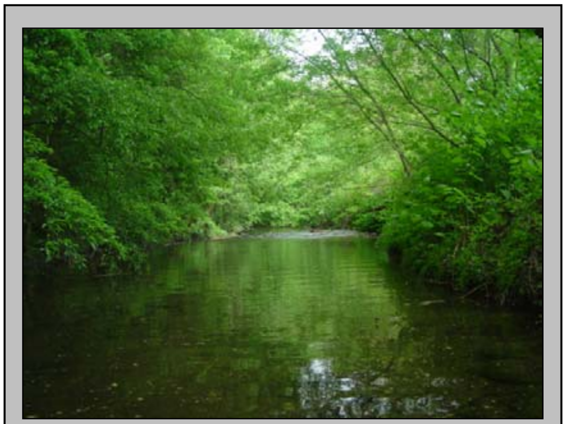
Location:

Access gained from Darby Creek Road. The creek was reached by use of an access road typically chained off by RHM Sewer Authority. (Latitude: -75.34313, Longitude: 39.98887)

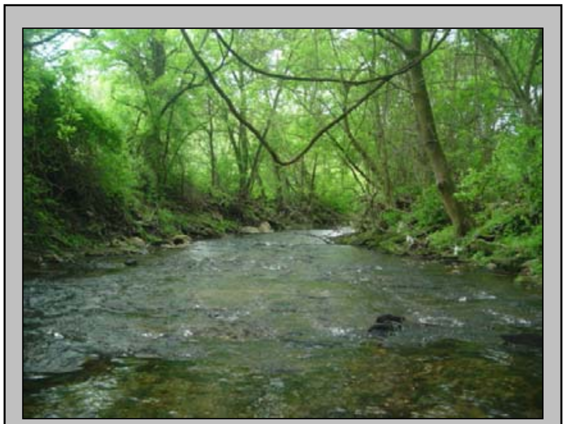
Description:

Site DCD1570 is located off of Darby Creek Road near the Marple Road overpass of Interstate 476. The site is situated alongside Interstate 476. The predominant land use surrounding the site is forest and the interstate highway.

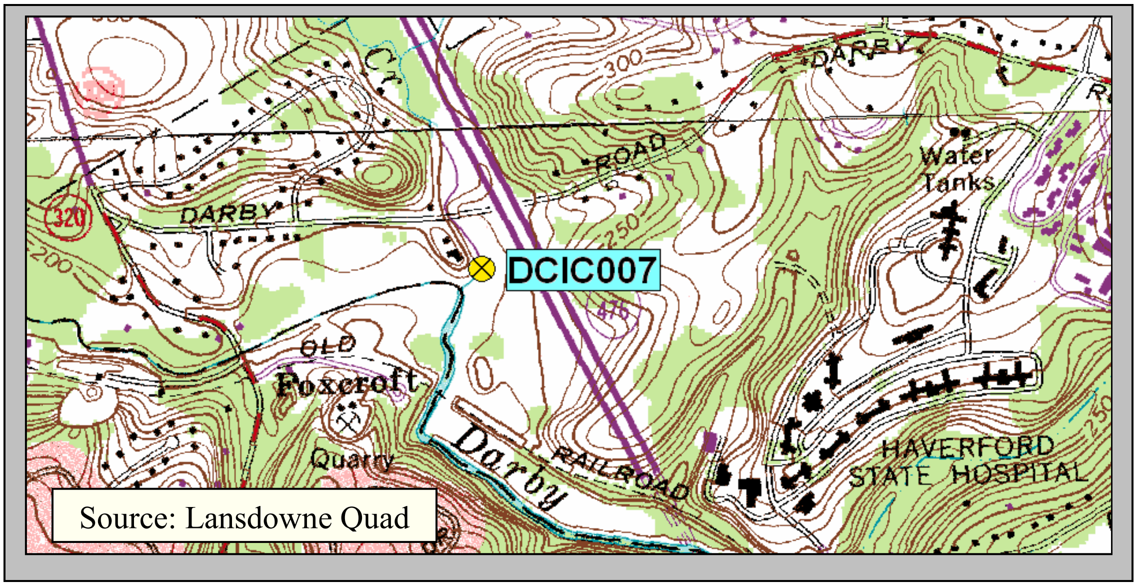
2.13. DCIC 007: Darby-Cobbs Study Area Delaware County



Upstream view of DCIC007



Downstream view of DCIC007



Source: Lansdowne Quad

Location:

Access gained from Darby Road in Radnor Township. Site is located 75 meters downstream of Darby Road. (Latitude: -75.35076, Longitude: 39.99756)

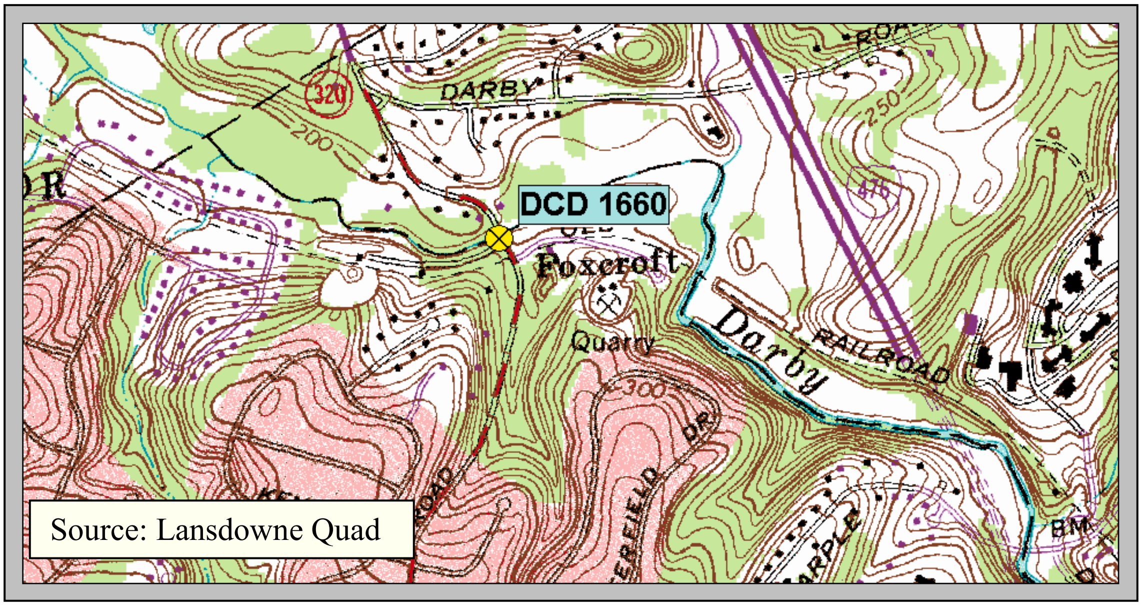
Description:

Site DCIC007 is located on Ithan Creek just downstream of Darby Road near the confluence of Ithan and Darby Creeks. The site is close to Interstate 476 and the Darby Creek Valley Park. The land use surrounding the site is field/pasture and residential.

2.14. DCD 1660: Darby-Cobbs Study Area Delaware County

Upstream view of DCD1660

Downstream view of DCD1660



Source: Lansdowne Quad

Location:

Access gained from Sproul Road (Route 320) near the intersection with Darby Road. (Latitude: -75.35633, Longitude: 39.99574)

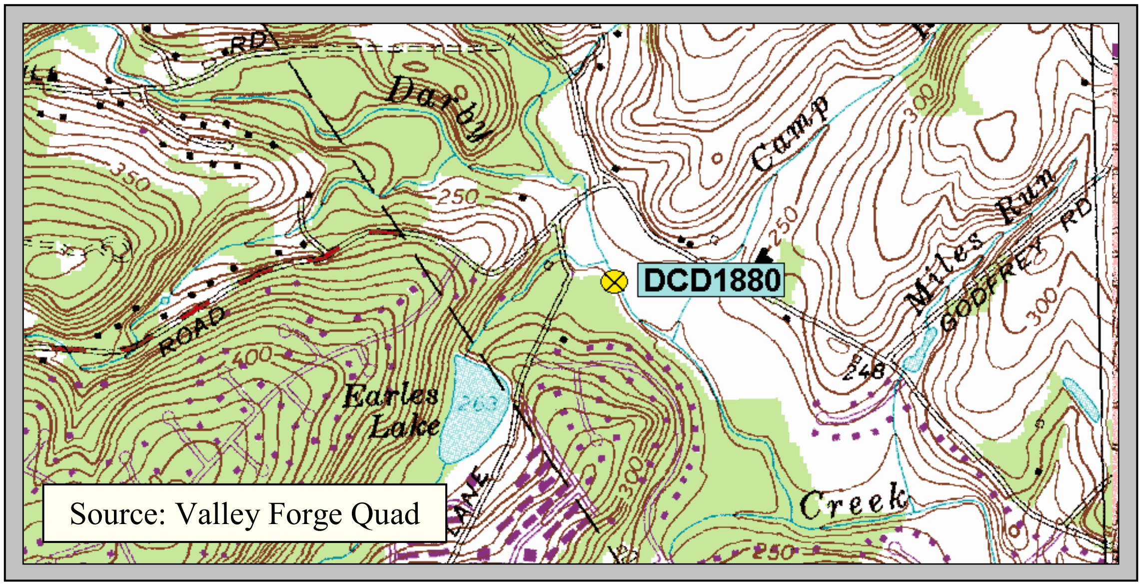
Description:

Site DCD1660 is located just downstream of Sproul Road near its intersection with Darby Road. The surrounding land use is residential.

2.15. DCD 1880: Darby-Cobbs Study Area Delaware County

Upstream view of DCD1880

Downstream view of DCD1880



Source: Valley Forge Quad

Location:

Access gained from Saw Mill Road near the intersection with Earles Lane.
(Latitude: -75.38683, Longitude: 40.01051)

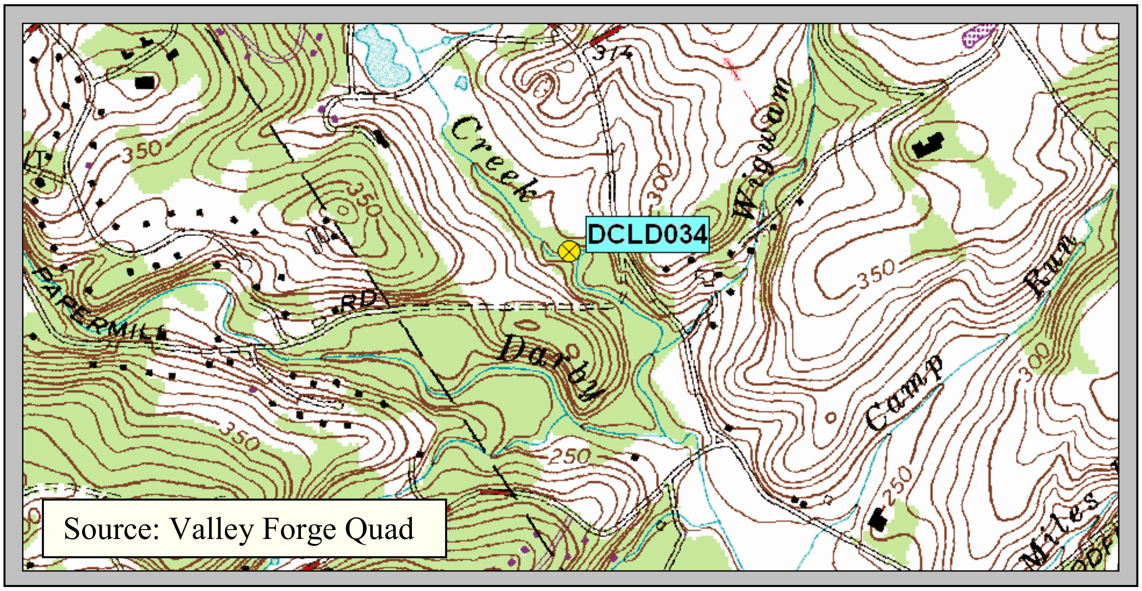
Description:

DCD1880 is located in Sawmill Park in Radnor Township, near the intersection of Saw Mill Road and Earles Lane. The site is just downstream of the confluence with Little Darby Creek. The surrounding land use is predominantly agricultural.

2.16. DCLD 034: Darby-Cobbs Study Area Delaware County

Upstream view of DCLD034

Downstream view of DCLD034



Source: Valley Forge Quad

Location:

Access gained from Darby-Paoli Road. The site is within The Willows Park in Radnor Township. (Latitude: -75.39029, Longitude: 40.01636)

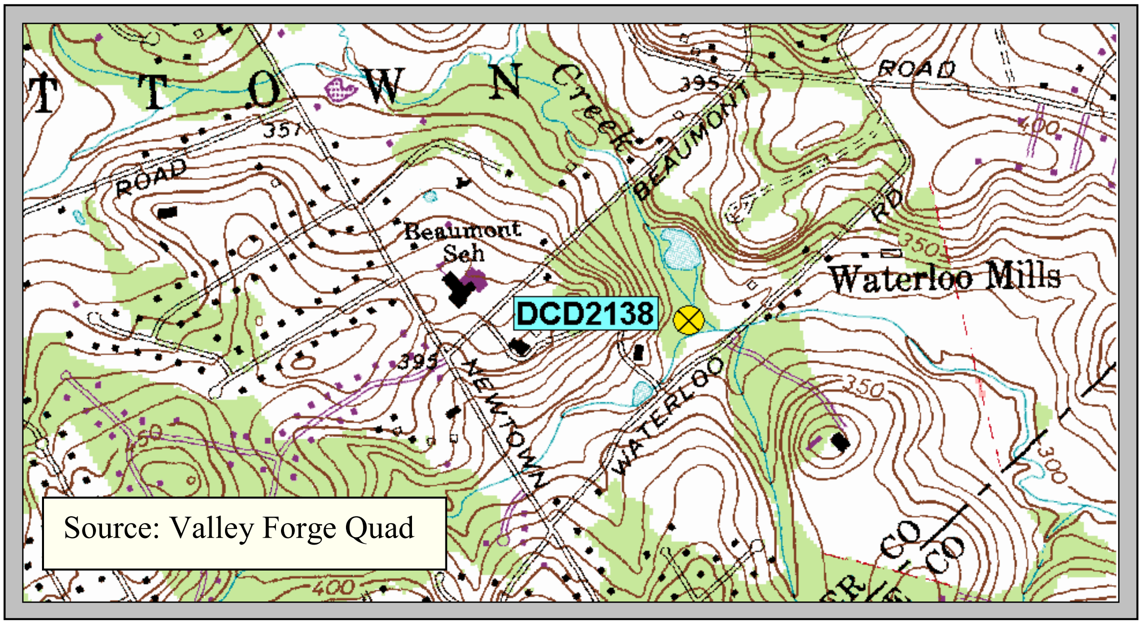
Description:

DCLD034 is located on Little Darby Creek in Radnor Township, Delaware County. The site is off of Darby-Paoli Road in The Willows Park. The surrounding area is field and pasture. A dam is located upstream of the sampled stream reach.

2.17. DCD 2138: Darby-Cobbs Study Area Chester County

Upstream view of DCD2138

Downstream view of DCD2138



Source: Valley Forge Quad

Location:

Access gained from Waterloo Road, east of Darby-Paoli Road. (Latitude: -75.42304, Longitude: 40.02276)

Description:

DCD2138 is the most upstream sampling site on Darby Creek. The site is located within an area managed by the Brandywine Conservancy on Waterloo Road in Chester County. The site is forested, and there is no evidence of nonpoint source pollution.

SECTION 3: WATERSHED DELINEATIONS AND MONITORING LOCATIONS

3.1. Watershed Location

The Darby-Cobbs Watershed is defined as the land area that drains to the mouth of Darby Creek at the Delaware Estuary, encompassing approximately 80 square miles of southeast Pennsylvania (Figure 1). This area includes portions of Chester, Delaware, Montgomery, and Philadelphia Counties. Cobbs Creek drains approximately 14,500 acres or 27% of the total watershed area, and discharges into Darby Creek. The Darby Creek Watershed drains approximately 29,000 acres or 55% of the total study area, and discharges to the Delaware River. Designated uses of Darby-Cobbs Watershed include warmwater fishery, trout stocked fishery, and migratory fishes (25 PA§ 93.9e).

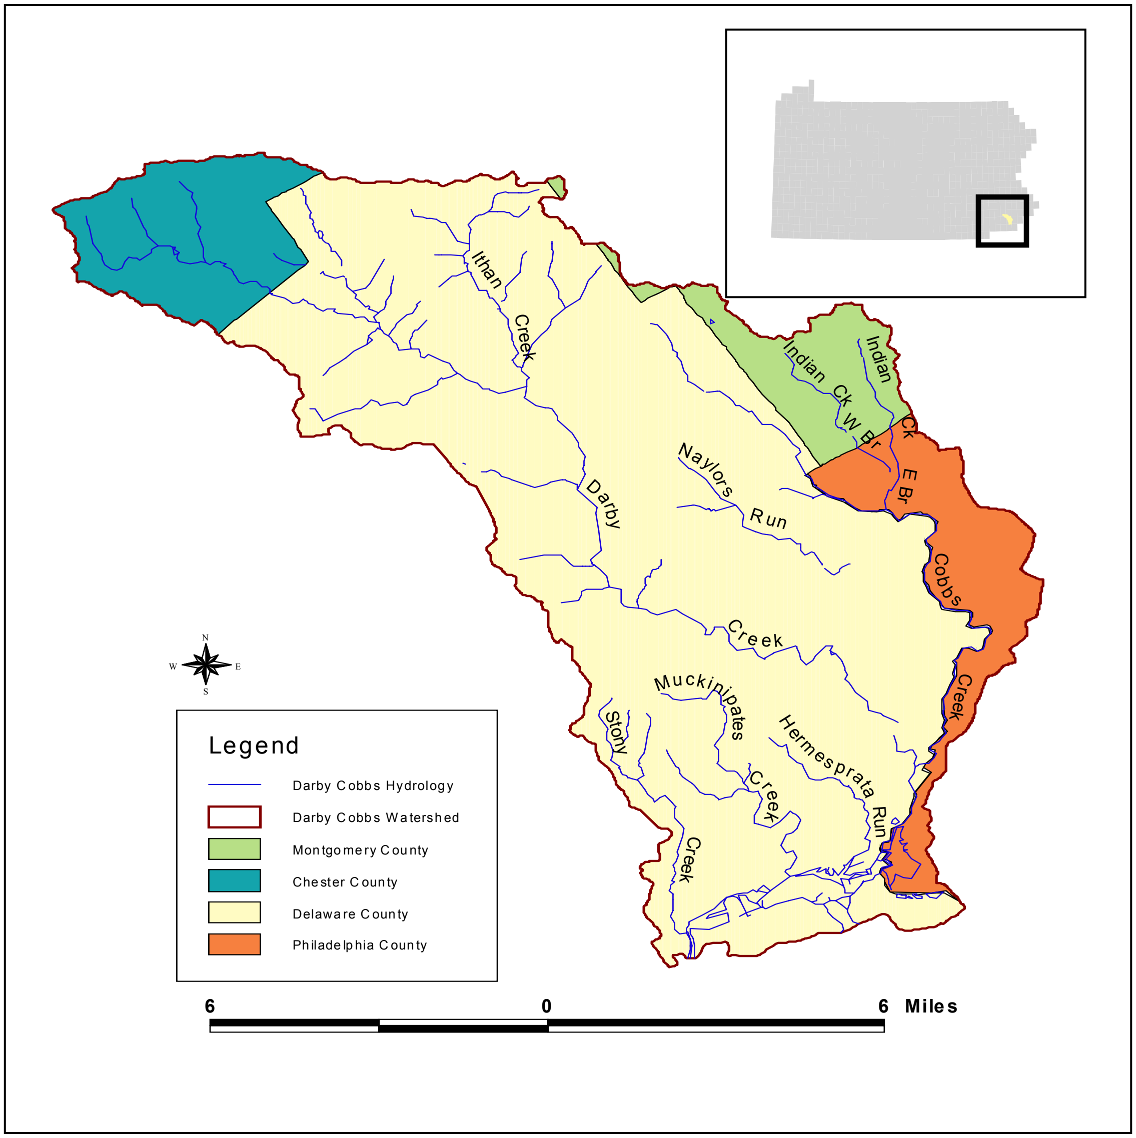


Figure 1. Darby-Cobbs Watershed and associated tributaries.

3.2. *Watershed Land Use*

Figure 2 shows land use patterns in the Darby-Cobbs Watershed consist primarily of single family residential areas (78.3%). Parklands (wooded and recreational areas), represent approximately three percent of land usage in the watershed, but make up a significant portion of land adjacent to Darby-Cobbs Watershed, providing buffer zones around the creek and its tributaries.

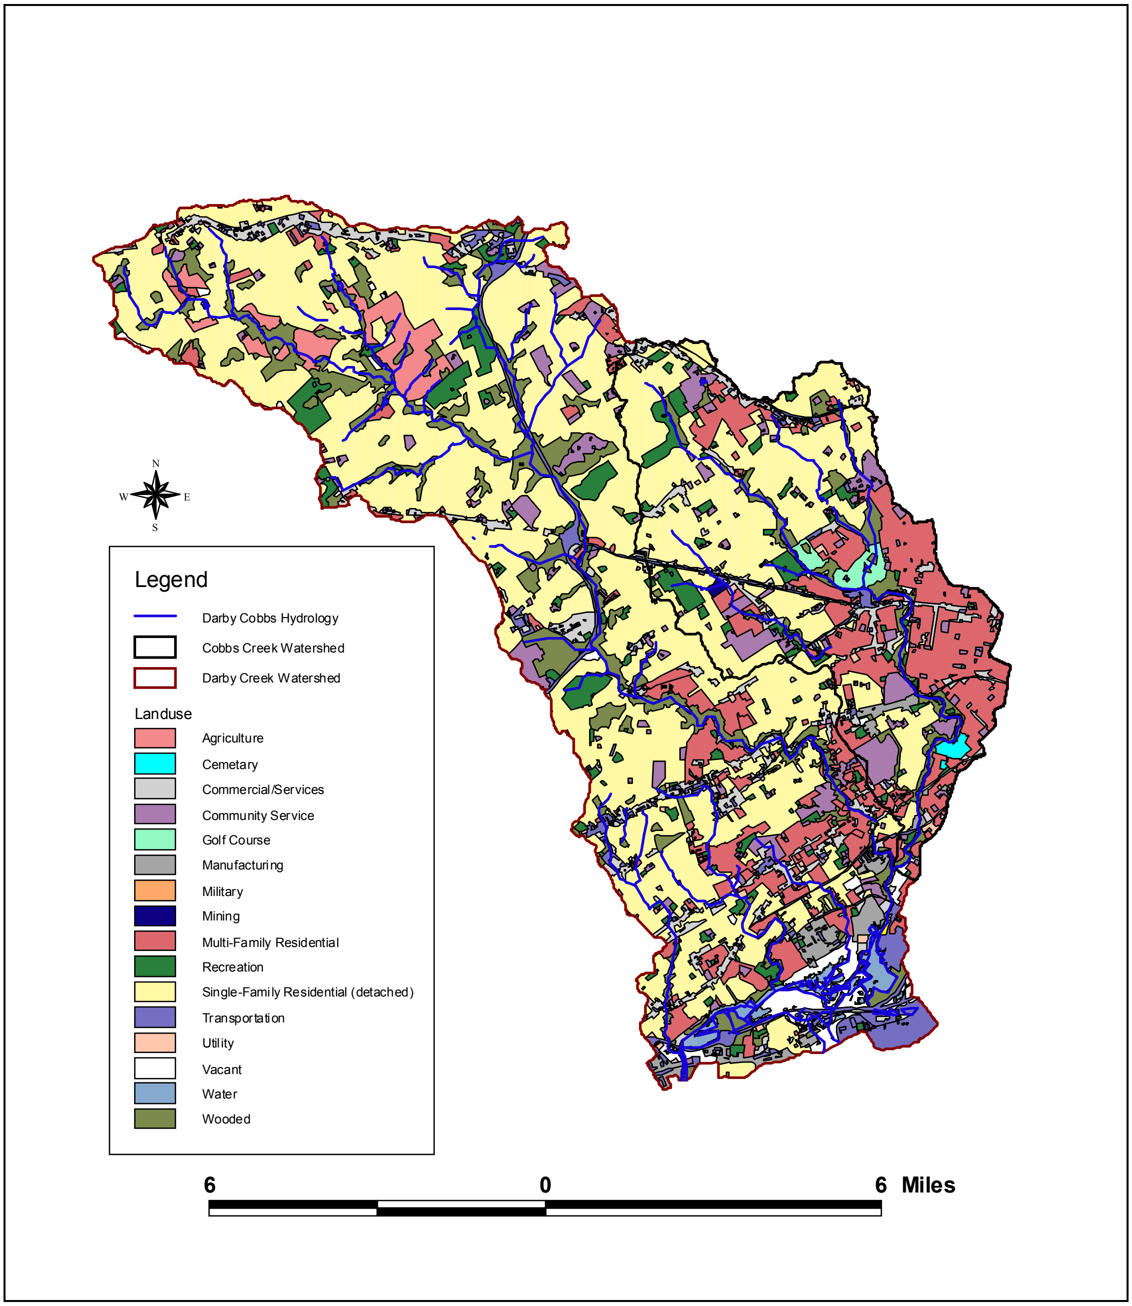

Figure 2. Darby-Cobbs Watershed land use patterns.

3.3. PWD Monitoring Locations (2003)

PWD has 27 monitoring locations in Darby-Cobbs Watershed, six of which are located on the main stem of Cobbs Creek, and 14 of which are located on the main stem of Darby Creek. The remaining seven are located on tributaries, namely the east and west branches of Indian Creek, Ithan Creek, Little Darby, and Naylor's Run. Figure 3 displays locations of these monitoring sites, as well as the type of assessments performed (i.e., discrete chemical, RBP III, habitat, RBP V, or tidal assessments).

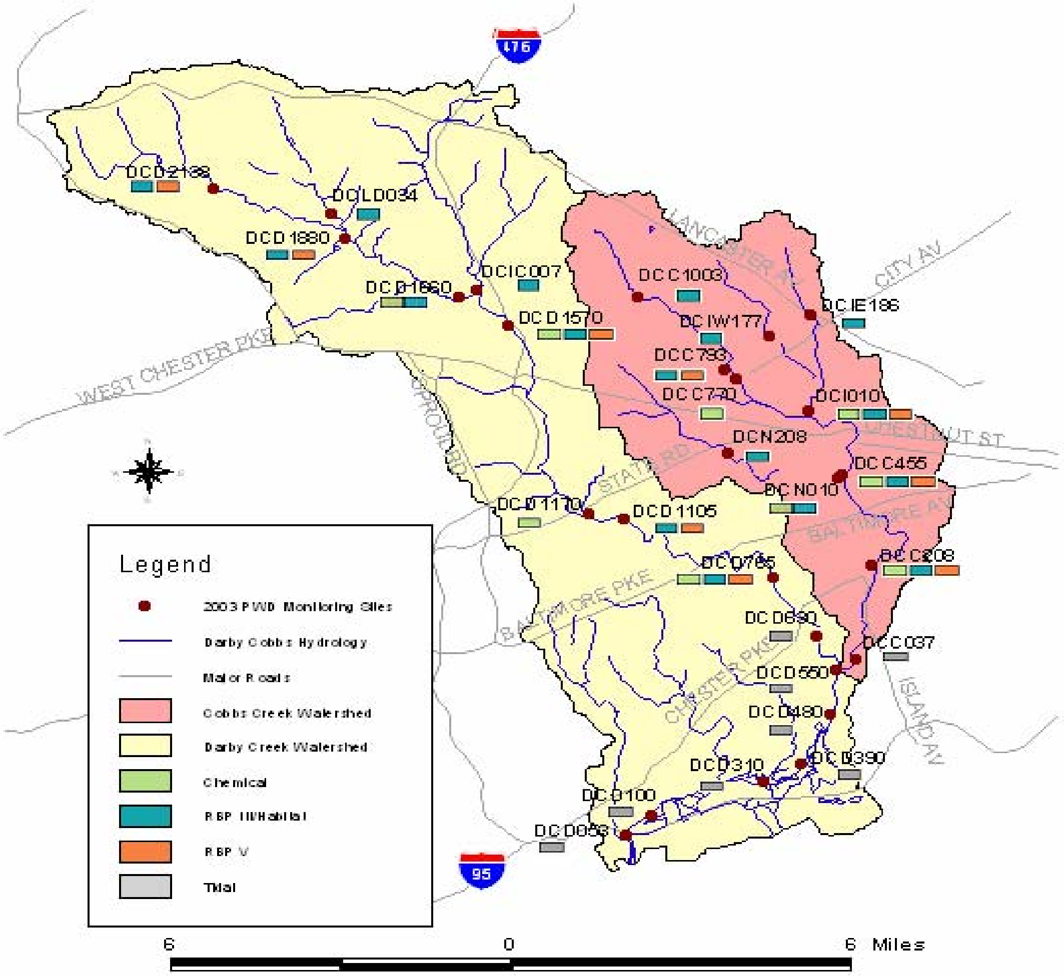

Figure 3. PWD monitoring locations in the Darby-Cobbs Watershed.

3.4. PWD Continuous and Wet Weather Monitoring Locations

Of 27 PWD monitoring locations in Darby-Cobbs Watershed, five sites were designated as continuous and wet weather monitoring locations in 2003 (Figure 4). More specifically, each location was a deployment site for an automated sampler (i.e., Sonde), which continuously measures dissolved oxygen, specific conductance, pH, depth, turbidity, and temperature, or an Isco automated sampler, which collects samples later analyzed in the laboratory for ammonia, fecal coliform, BOD_5, metals, and other relevant parameters at scheduled times during wet weather events.

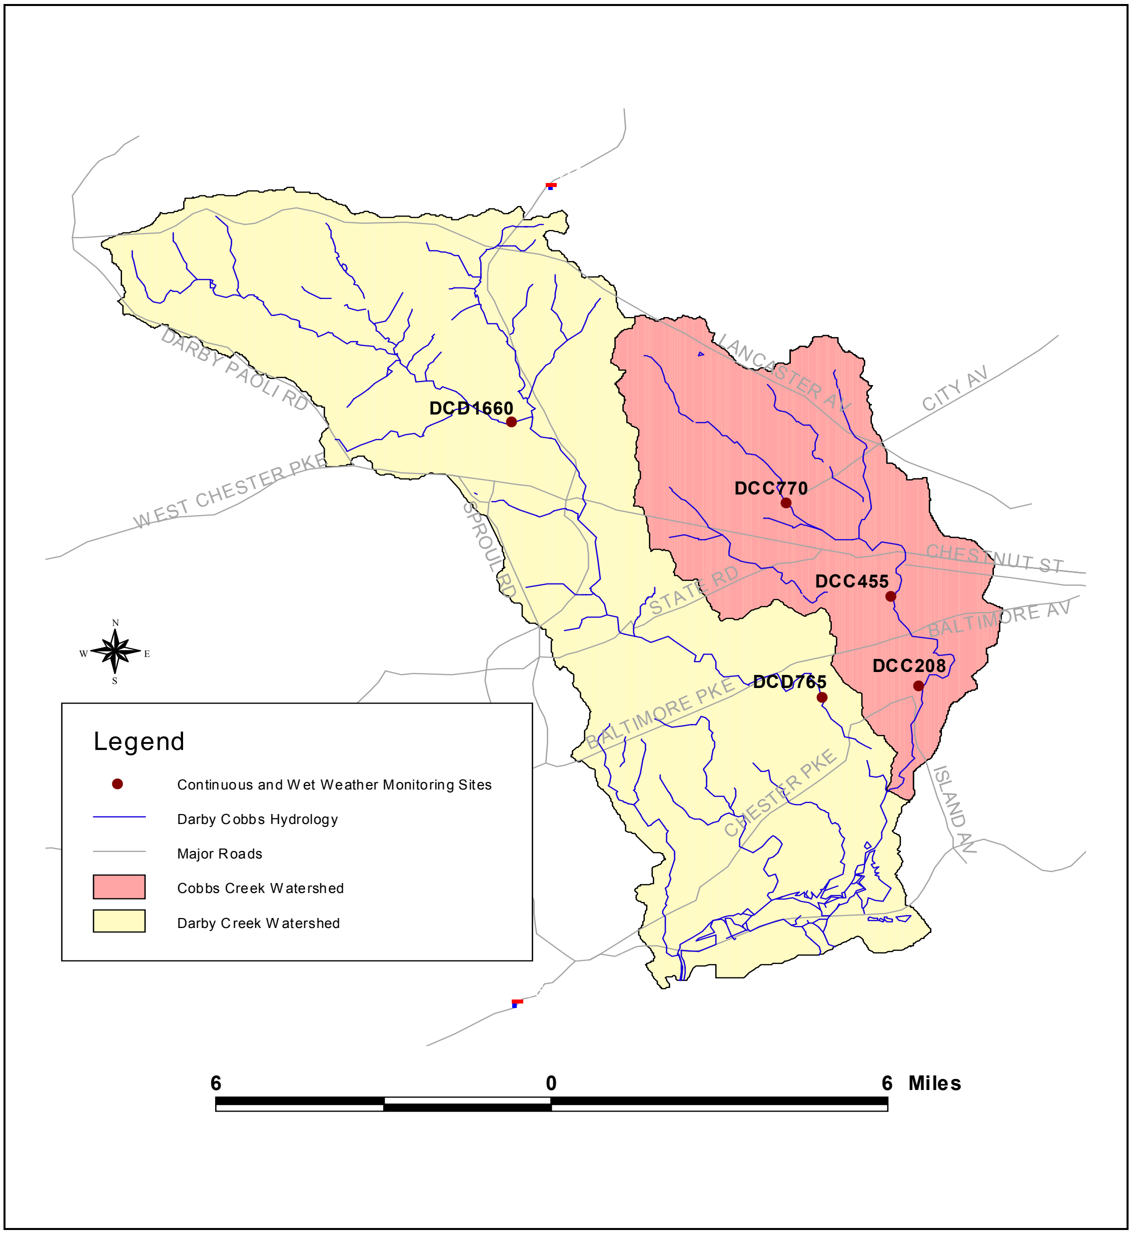

Figure 4. PWD continuous and wet-weather monitoring locations in Darby-Cobbs Watershed

3.5. PWD Tidal Assessment Monitoring Locations

Six of 27 PWD monitoring locations in Darby-Cobbs Watershed are tidal assessment sites (Figure 5). The tidal assessment area extends approximately 6.6 miles upstream from Darby Creek's confluence with the Delaware River. Tidal assessments also extended approximately 0.8 miles into the Darby main stem and approximately 0.4 miles into the Cobbs Creek main stem from the confluence of the two creeks.

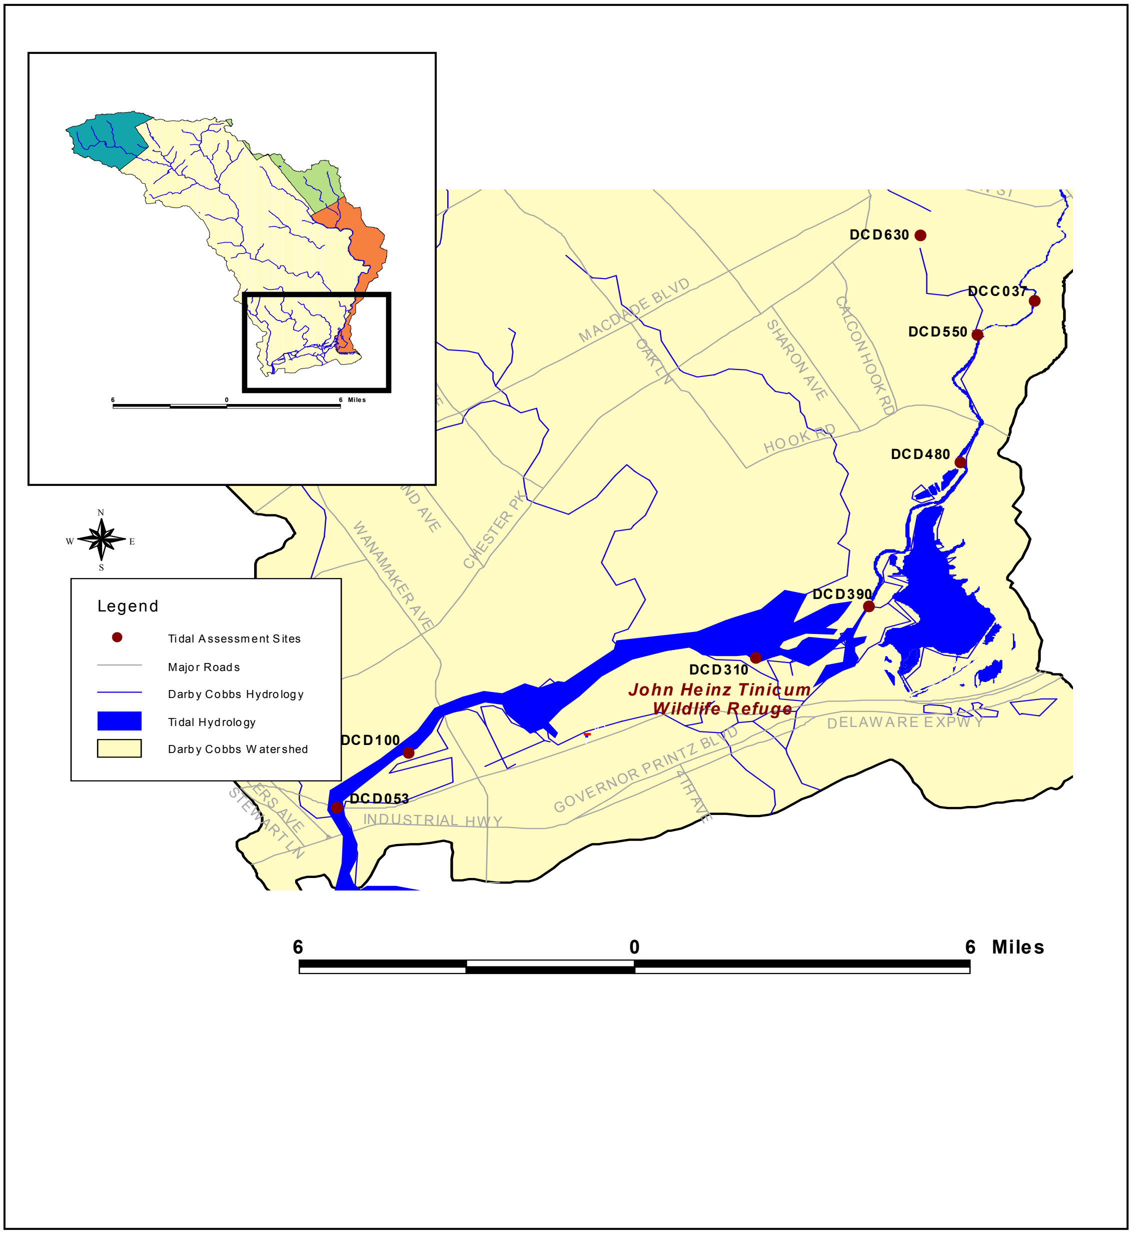

Figure 5. Tidal assessment locations in lower Darby Creek.

3.6. PADEP Monitoring Locations and Attainment Status

As part of its Statewide Surface Water Assessment Program, formerly the Unassessed Waters Program, PADEP conducted modified rapid bioassessment protocols at 28 locations in Darby-Cobbs Watershed. PADEP used benthic macroinvertebrate and habitat data collected during the assessments to determine the health of Darby-Cobbs Watershed and to identify potential stressors on stream segments determined to be impaired, or "not attaining" their designated uses. Figure 6 depicts PADEP's 28 monitoring locations as well as designations made by PADEP for stream segments in Darby-Cobbs Watershed.

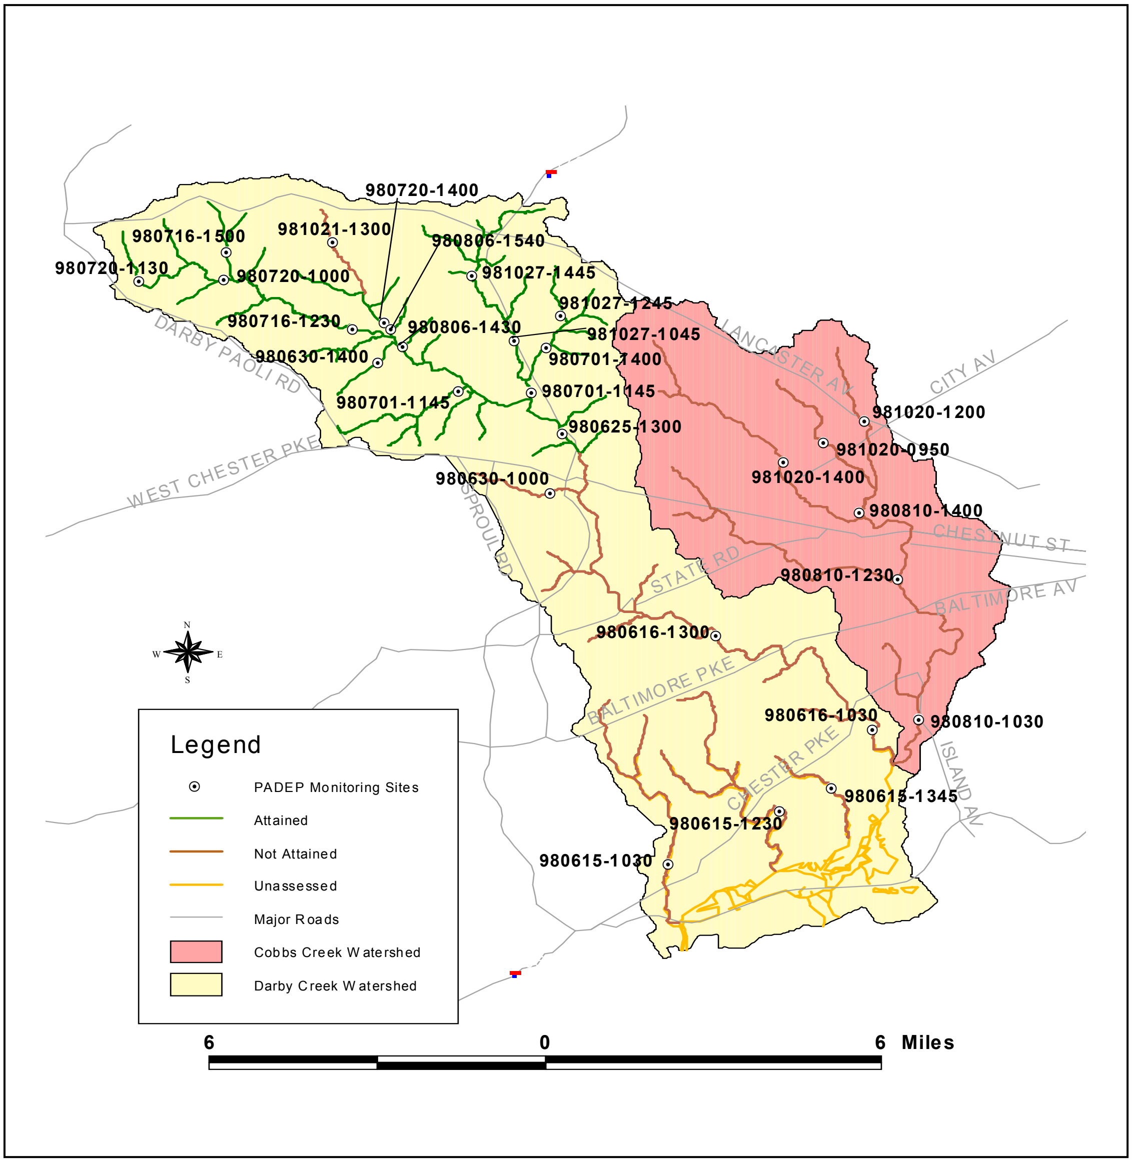

Figure 6. PADEP surface water assessment locations (1998-1999)

3.7. Historical United States Geological Survey (USGS) Monitoring Locations (1964-1990)

The United States Geological Survey (USGS) has historically monitored water quantity and quality at four locations in Darby-Cobbs Watershed (Figure 7). Water quality monitoring at the four stations in Cobbs Creek began in 1967, but was eventually terminated by 1983. Similarly, measurements of stream flow (Q) commenced in 1964 and were discontinued at all locations by 1990.

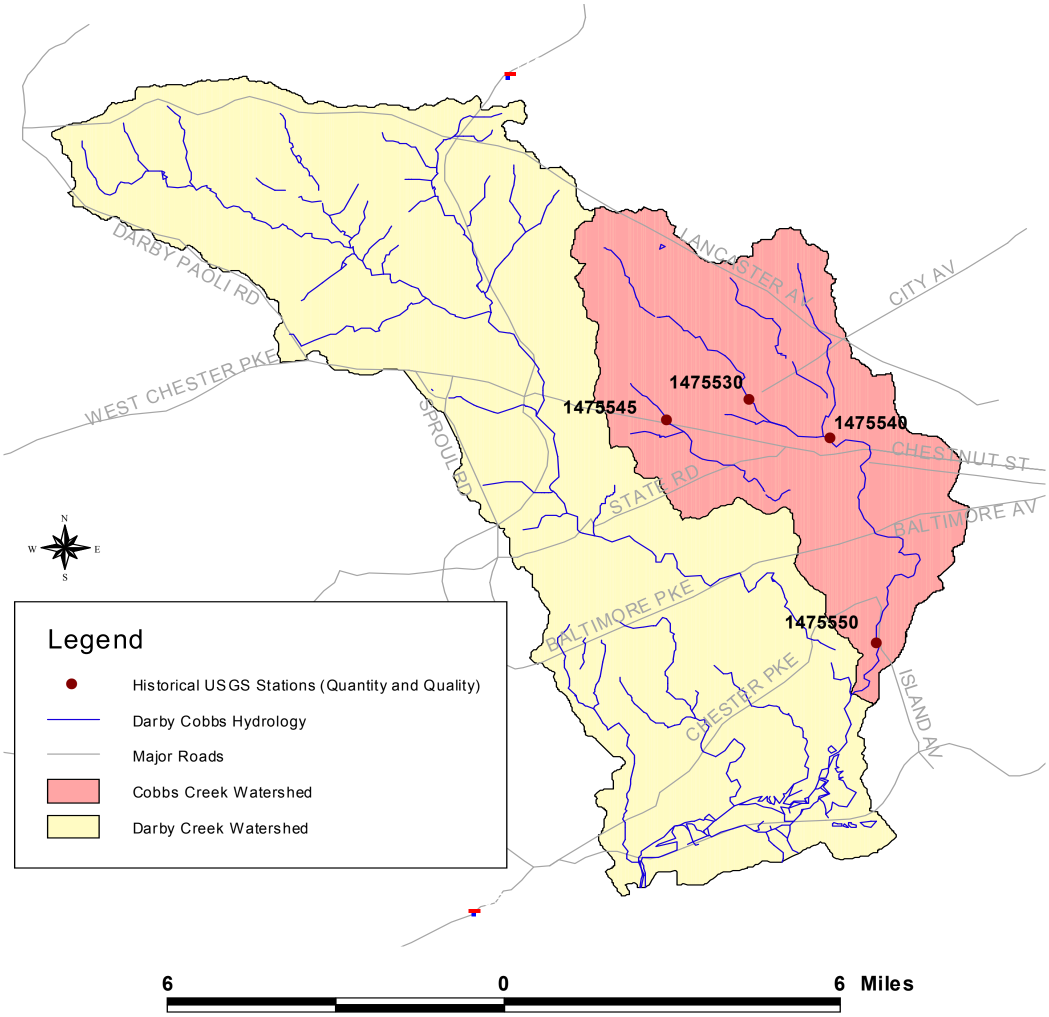

Figure 7. Historical USGS monitoring locations in Darby-Cobbs Watershed.

SECTION 4: METHODS

Standard Operating Procedures for Philadelphia Water Department's Watershed Assessment Program are available on the world-wide web at the following URL: http\\: phillywater.org

4.1. Benthic Macroinvertebrate Sampling

During 3/1/03 to 3/27/03, the Philadelphia Water Department conducted Rapid Bioassessment Protocols (RBP III) at seventeen (n=17) locations within Darby-Cobbs Watershed. Using EPA guidelines, macroinvertebrates were collected by placing a standard ($1m^2$) kicknet at the downstream portion of a riffle. The substrate was then kicked and scraped manually one meter from the net aperture to remove benthic invertebrates. Four rocks of varying size were randomly chosen within the sampling sites and manually scraped to remove benthic invertebrates. This procedure was repeated at another riffle location with less flow. Specimens were then preserved in 70% ETOH (ethyl alcohol) and returned to the laboratory in polyethylene containers. In the laboratory, samples were placed in an 11" x 14" gridded (numbered) pan and random "plugs" were examined until 100 individuals were collected. Macroinvertebrates were identified to genus, and population estimates were calculated.

4.1.1. Metrics:

Using the following chart, the biological integrity and benthic community composition was determined (EPA guidelines for RBP III and PADEP Modified Rapid Biological Assessments) (Table 1).

Table 1. Biological condition scoring criteria for RBP III.

Metric	Biological Condition Scoring Criteria			
	6	4	2	0
Taxa Richness (a)	>80%	79-70%	69-60%	<60%
Hilsenhoff Biotic Index (Modified) (a)	<0.71	0.72-1.11	1.12-1.31	>1.31
Modified EPT Index (a)	>80%	79-60%	59-50%	<50%
%Contribution of Dominant Taxon (a)	<10	11-16	17-22	>22
%Modified Mayflies (a)	<12	13-20	21-40	>40
Ratio of Scrapers/Filter (b) Collectors	>50%	35-50%	20-35%	<20%
Community Loss Index (b)	<0.5%	0.5-1.5	1.5-4.0	>4.0
Ratio of Shredders/Total (b)	>50%	35-50%	20-35%	<20%

[a] Metrics used to quantify scoring criteria (PADEP)

[b] Additional metrics used for qualitative descriptions of sampling locations (EPA)

Upon completion of the total biological scoring criteria, each site was compared to a reference site according to its drainage area and geomorphologic attributes. The reference sites chosen were French Creek, located at Coventry Road Bridge, South Coventry Township, Chester County and Rock Run, a tributary of French Creek (Appendix A). Using the following chart, benthic quality of each site was established to identify spatial trends of impairment along the river continuum (Table 2).

Table 2. Biological condition categories for RBP III.

% Comparison to Reference Score [(a)]	Biological Condition Category	Attributes
>83%	Nonimpaired	Comparable to the best situation within an ecoregion. Balanced trophic structure. Optimum community structure for stream size and habitat quality.
54-79%	Slightly impaired	Community structure less than expected. Species composition and dominance lower than expected due to loss of some intolerant forms. Percent contribution of tolerant forms increases.
21-50%	Moderately impaired	Fewer species due to loss of most intolerant forms. Reduction in EPT index.
<17%	Severely impaired	Few species present. If high densities of organisms, then dominated by one or two taxa.

(a) Percentage values obtained that are intermediate to the above ranges will require subjective judgment as to the correct placement. Use of the habitat assessment and chemical data may be necessary to aid in the decision process.

4.2. Ichthyofaunal (Fish) Sampling

4.2.1. Fish Collection in Non-Tidal Portions

Between 6/16/03-7/8/03, PWD biologists conducted fish assessments at nine (n = 9) locations within Darby-Cobbs Watershed (Figure 3). Fish were collected by electrofishing as described in EPA's Rapid Bioassessment Protocol V (RBP V) (Barbour et al., 1999). Depending on stream conditions, Smith-Root backpack or tote barge electrofishers were used to stun fish. A 100m reach of the stream was blocked at the upstream and downstream limits with nets to prevent immigration or emigration from the study site. Each reach was uniformly sampled, and all fish captured were placed in buckets for identification and counting. An additional pass without replacement was completed along the reach to insure maximum likelihood population and biomass estimates.

4.2.2. Fish Collection in Tidal Portions

Between 7/10/03-8/25/03, staff biologists completed fish assessments at eight (n=8) tidal locations in the Darby-Cobbs Watershed (Figure 5). Tote-barge electrofishers were used at the two most upstream tidal reaches of Darby and Cobbs Creeks (DCD 630 and DCC 037, respectively). Fish inhabiting nonwadeable tidal portions of the Darby-Cobbs Watershed were collected with Smith-Root electrofishing apparatus mounted aboard a small aluminum-hulled jonboat. Electrofishing was conducted for ten-minute intervals in a downstream direction, targeting areas with suitable fish habitat. It was not feasible to install block nets or otherwise prevent net movement of fish into or out of the sampling area.

4.2.3. Sample Processing

Fish were identified to species, weighed (± 0.01 g) with a digital scale (Model Ohaus Scout II) and measured to the nearest 0.1 cm using a Wildco fish measuring board. Large fish that exceeded the digital scale's capacity were weighed using spring scales (Pesola). Any external deformations, lesions, tumors, cysts, or disease were noted during processing. Species that could not be identified in the field (e.g., small or juvenile cyprinids) were preserved with 10% formalin solution and stored in polyethylene bottles for laboratory identification.

To facilitate the process of acquiring total fish biomass and to reduce field time, a simple linear regression was developed between weight (g) and length (cm). Approximately 20 individuals of each species were weighed, and total lengths were measured. Once 20 individuals of each species were measured (both weight and length), biomass (g) for each fish was calculated using the regression analysis. Results of the regression analysis on individual fish species can be found in Appendix B. Similar procedures were conducted at the reference locations (i.e., French Creek and Rock Run) to obtain a discrete measure of the condition of the fish assemblages at each assessment location.

4.2.4. Fish IBI Metrics:

The health of fish communities in Darby-Cobbs Watershed were based on the technical framework of the Index of Biological Integrity (IBI) developed by Karr (1981). The analysis entailed the definition of "ecoregional-specific" metrics pertinent to the fish assemblages located in the lower Schuylkill River Drainage. Standardized metrics (i.e., indices) were then integrated to provide an overall indication of the condition of fish assemblages at each assessment location. Individual metrics within the fish IBI framework were also used to provide quantitative information regarding a specific attribute of the respective assessment location (e.g., pollution tolerance values). In addition to IBI metrics, other metrics were incorporated into the design to evaluate the overall ecological health of fish assemblages and as a means of comparison of each assessment site. Tables 3 and 4 describe the various indices and scoring criteria used for the IBI metrics in the Darby-Cobbs Watershed. Additional metrics used in the analysis are displayed in Table 5.

Table 3. Metrics used to evaluate the Index of Biological Integrity (IBI) at representative sites. *

Metric	**Scoring Criteria**		
	5	3	1
1. Number Of Native Species	>67%	33-67%	<33%
2. Number Of Benthic Insectivore Species	>67%	33-67%	<33%
3. Number Of Water Column Species	>67%	33-67%	<33%
4. Percent White Sucker	<10%	10-25%	>25%
5. Number Of Sensitive Species	>67%	33-67%	<33%
6. Percent Generalists	<20%	20-45%	>45%
7. Percent Insectivores	>45%	20-45%	<20%
8. Percent Top Carnivores	>5%	1-5%	<1%
9. Proportion of diseased/anomalies	<1%	1-5%	>5%
10. Percent Dominant Species [a]	<40%	40-55%	>55%

*Metrics used are based on modifications as described in Barbour, *et al.*, 1999.

[a] Metric based on USGS NAWQA study (2002).

Table 4. Index Of Biological Integrity (IBI) score interpretation.*

IBI	Integrity Class	Characteristics
45-50	**Excellent**	Comparable to pristine conditions, exceptional assemblage of species
37-44	**Good**	Decreased species richness, intolerant species in particular
29-36	**Fair**	Intolerant and sensitive species absent; skewed trophic structure
10-28	**Poor**	Top carnivores absent or rare; omnivores and tolerant species dominant
<10	**Very Poor**	Few species and individuals present; tolerant species dominant; diseased fish frequent

* IBI score interpretation based on Halliwell, *et al*., 1999.

Table 5. Additional metrics used to evaluate fish assemblage condition.

Metric	Assessment Type
Species Diversity	Shannon (H') Diversity Index
Trophic Composition	Percentage of Functional Feeding Groups
Tolerance Designations	Percentage of Pollution Tolerant, Moderate And Intolerant Species
Modified Index Of Well-Being	MIwb Index

4.2.5. Species Diversity:

Species diversity, a characteristic unique to the community level of biological organization, is an expression of community structure (Brower, *et al*., 1990). In general, high species diversity indicates a highly complex community. Thus, population interactions involving energy transfer (e.g. food webs), predation, competition and niche distribution are more complex and varied in a community of high species diversity. In addition, many ecologists support species diversity as a measure of community stability (i.e., the ability of community structure to be unaffected by, or recover quickly from perturbations). Using the Shannon (H') Diversity Index formula, species diversity was calculated at each sampling location:

$$H' = -\Sigma\, n_i/N * \ln(n_i/N): \qquad \text{(eq. 1)}$$

where n_i is the relative number of the *i*th taxon.

4.2.6 Trophic Composition and Tolerance Designations:

Trophic composition metrics were used to assess the quality of the energy base and trophic dynamics of the fish assemblages (Plafkin *et al*., 1989). The trophic composition metrics offer a means to evaluate the shift toward more generalized foraging that typically occurs with increased degradation of the physiochemical habitat (Barbour et al., 1999). Pollution tolerance metrics were also used to distinguish low and moderate quality sites by assessing tolerance values of each species identified at the sampling locations. This metric identifies the abundance of tolerant, moderately tolerant and pollution intolerant individuals at the study site. Generally, intolerant species are first to disappear following a disturbance. Species designated as intolerant or sensitive should only represent 5-10% of the community; otherwise the metric becomes less discriminating. Conversely, study sites with fewer pollution intolerant individuals may represent areas of degraded water quality or physical disturbance. For a more detailed description of metrics used to evaluate the trophic and pollution designations of fish assemblages, see Barbour, *et al*., (1999).

4.2.7. Modified Index of Well-Being (MIwb):

Modified Index of Well-Being (MIwb) is a metric that incorporates two abundance and two diversity measurements. Modifications from the Ohio EPA (1987), which eliminate pollution tolerant species, hybrids and exotic species, were incorporated into the study in order to increase the sensitivity of the index to a wider array of environmental disturbances. MIwb is calculated using the following formula (equation 2):

$$\mathrm{MIwb} = 0.5*\ln N + 0.5*\ln B + H_N + H_B \qquad \text{(eq. 2)}$$

where;

N = relative numbers of all species
B = relative weight of all species
H_N = Shannon index based on relative numbers
H_B = Shannon index based on relative weight

4.2.8. Biomass Per Unit Area:

This metric evaluates the relative biomass of fish within a given site relative to the area sampled. In general, as streams increase in width, the biomass of fish tends to increase in areas of suitable habitat, physical stability and appropriate water quality. Decreases in biomass per unit area may be attributed to episodic or chronic periods of degraded water quality and/or poor habitat heterogeneity.

4.3. Habitat Assessment

4.3.1. EPA Habitat Assessment

Prior to benthic macroinvertebrate sampling procedures, habitat assessments at 17 sites were completed based on the *Stream Classification Guidelines for Wisconsin* (Ball, 1982) and *Methods of Evaluating Stream, Riparian, and Biotic Conditions* (Platts et al., 1983). Reference conditions were used to normalize the assessment to the "best attainable" situation. Habitat parameters are separated into three principal categories: (1) primary, (2) secondary, and (3) tertiary parameters. Primary parameters are those that characterize the stream "microscale" habitat and have greatest direct influence on the structure of indigenous communities. Secondary parameters measure "macroscale" habitat such as channel morphology characteristics. Tertiary parameters evaluate riparian and bank structure and comprise three categories: (1) bank vegetative protection, (2) grazing or other disruptive pressure, and (3) riparian vegetative zone width. The following chart lists the various parameters addressed during habitat assessments (Table 6):

Table 6. Habitat assessment criteria used at benthic monitoring stations.

Condition/Parameter	Condition			
	Optimal	Suboptimal	Marginal	Poor
Epifaunal Substrate/Available Cover	16-20	11-15	6-10	0-5
Pool Substrate Characterization	16-20	11-15	6-10	0-5
Pool Variability	16-20	11-15	6-10	0-5
Sediment Deposition	16-20	11-15	6-10	0-5
Embeddedness	16-20	11-15	6-10	0-5
Velocity/Depth Regime	16-20	11-15	6-10	0-5
Frequency of Riffles (or bends)	16-20	11-15	6-10	0-5
Channel Flow Status	16-20	11-15	6-10	0-5
Channel Alteration	16-20	11-15	6-10	0-5
Channel Sinuosity	16-20	11-15	6-10	0-5
Bank Stability**	10-9	8-6	5-3	2-0
Vegetative Protection**	10-9	8-6	5-3	2-0
Riparian Vegetative Zone Width**	10-9	8-6	5-3	2-0

**Both right and left banks are assessed separately.

4.3.2. Habitat Suitability Index (HSI) Model Methods

4.3.2.1. Model History and Assumptions

Prior to the development of Instream Flow Incremental Methodology (IFIM), a number of Habitat Suitability Index (HSI) models were developed by the U.S. Fish and Wildlife Service (USFWS). Based on empirical data and supported by years of research and comprehensive review of scientific literature, these models present numerical relationships between various habitat parameters and biological resources, particularly gamefish species and species of special environmental concern. Through evaluation of various input parameters, models arrive at a final index value between 0 and 1, a score of 1 corresponding to the ideal habitat condition, and zero indicating that some aspect of the habitat is unsuitable for supporting a naturally reproducing population of the species of interest.

Numerous assumptions are inherent with use and interpretation of the models. First and foremost is the assumption that habitat features alone are responsible for determining abundance or biomass of the species of interest at the study site. Clearly, no species exists in a vacuum; aside from habitat variables, other ecological and environmental interactions can strongly influence biological communities. HSI indices assume that users will use good professional judgment, consult with regional experts when necessary, and consider the possible effects of other factors (e.g., competition, predation, toxic substances and other anthropogenic factors) when interpreting model output.

4.3.2.2. Model Data Requirements

Most types of data required by HSI models were available for all sites within Darby-Cobbs Watershed. However, a number of habitat parameters were not directly measured in a fashion best suited for use with HSI models and required additional interpretation or normalization. Few water quality parameters were measured with equal sampling effort across all sites; some parameters were measured with continuous monitoring instruments at some sites and grab samples or hand-held meters at other sites. Some variables were not directly measured at some sites; to facilitate HSI analysis at these sites, (conservative) values were substituted based on sampling conducted at nearby sites and reference sites in neighboring watersheds. Turbidity data were excluded from the analyses entirely because all HSI were developed using Jackson Turbidity Units (JTU), which cannot be converted to/from modern Nephelometric Turbdity Unit (NTU) data. Any other significant modifications to the variables or the modeling approach are explained in Section 5.3.5. (Habitat Suitability Indices). A list of all HSI input variables for the seven HSI models applied to Darby-Cobbs watershed appears in Table 7.

Table 7. Habitat Suitability Index (HSI) variable matrix.

HSI Model Variable Matrix	Variable Type	Blacknose Dace	Common shiner	Creek Chub	Fallfish	Longnose Dace	Redbreast Sunfish	Smallmouth Bass

4.3.2.3. Suitability Index Expressions

HSI models use three major types of Suitability Index (SI) expressions or mathematical relationships to compute the suitability of a given habitat variable; they are (in increasing order of complexity): 1.) categorized relationships, 2.) linear equations (or more commonly, series of linear equations bounded by inflection points), and 3.) suitability curves. Categorized relationships are used for a limited number of HSI variables in which the relationship between the habitat feature and suitability for the species of interest is fairly simple. Substrate size categorization is one example; many HSI models use dominant substrate type categories (e.g., silt, sand, gravel, cobble, boulder, bedrock). Other SI variables that may be defined by simple categorization are temperature, dissolved oxygen, pH or, or in some cases, the variability of these measurements (Figure 8). Categorized data were processed directly within Microsoft Excel spreadsheet HSI models.

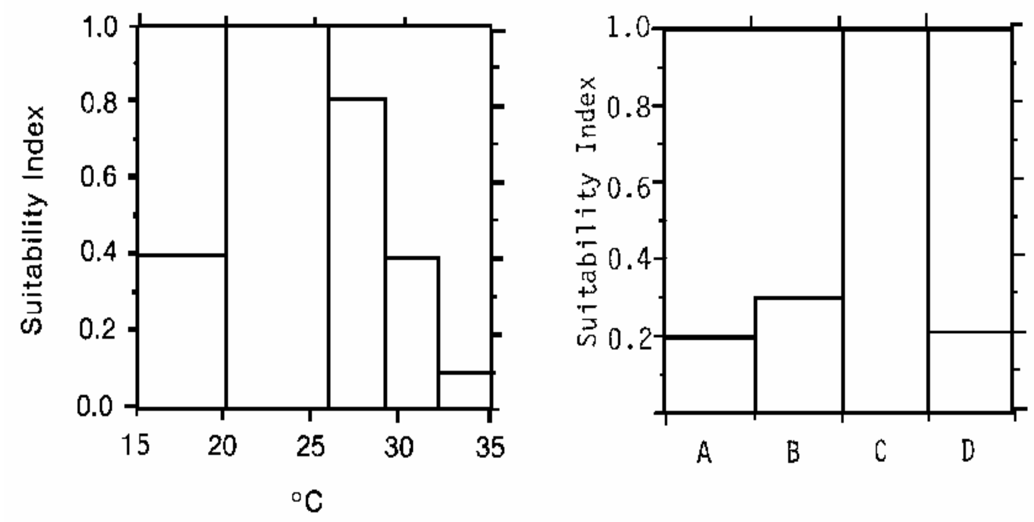

Figure 8. Categorized expressions in HSI models.

Many SI variables are defined by a series of linear relationships bounded by inflection points (i.e., a collection of linear relationships that roughly approximate a curve). Many of these relationships include a range of unsuitable (SI=0) values, a range of ideal (SI =1.0) values, or both. Although all types of SI variables were, in some cases, defined by series of linear relationships (Figure 9), these expressions were less likely to be employed as models increased in complexity. As models become more complex, there is a corresponding increased focus on development of SI curves. SI variables defined by linear relationships were processed using linear equations and boolean commands directly in Excel spreadsheet models.

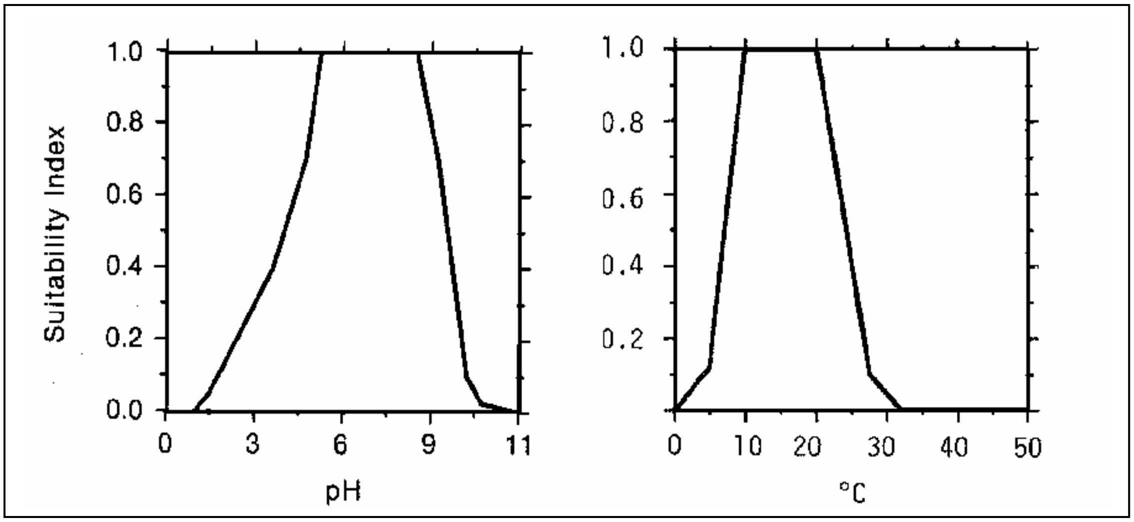

Figure 9. Linear expressions in HSI models.

SI curve relationships are considered the most precise and continuous of SI relationships, and therefore, appear more frequently in more complex HSI models. For example, curves allow models to accurately represent the non-linear, sub-asymptotic change in SI expected as a habitat variable approaches complete unsuitability or ideal suitability (SI score 0 or 1 respectively). Two general SI curve shapes were common, modified parabolae and "s-curves", though there was considerable variation in actual curve shape between different SI variables (Figure 10). As curve equations were not provided with HSI model documentation, lookup tables were generated by scanning curves with data extraction software (Data Thief). Subsequent data processing was handled in Excel.

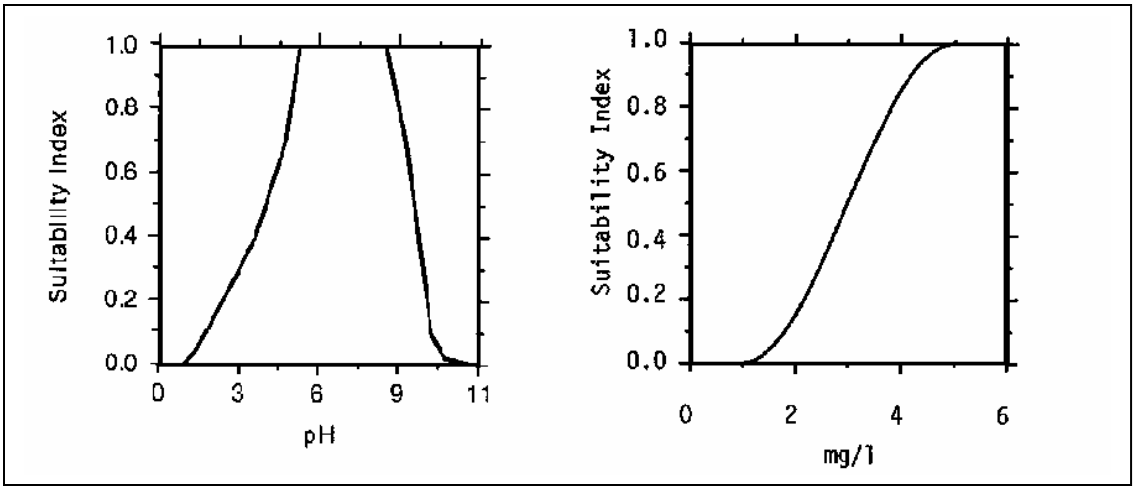

Figure 10. Curve relationships in HSI models.

4.3.2.4. Model Evaluation

HSI model output for each site was compared to EPA habitat data results. With the exception of Longnose dace HSI data, HSI model output was compared to observed fish abundance and biomass with correlation analyses. Several habitat models likely require modification in order to be useful in guiding or evaluating stream habitat improvement activities. While time constraints precluded the modification of models to better suit Darby-Cobbs Watershed, it is hoped that such modifications will increase the usefulness of these models in the future.

4.4. Chemical Assessment

4.4.1. Fixed Interval Chemical Sampling

Bureau of Laboratory Services staff collected surface water grab samples at nine locations within Darby-Cobbs Watershed for chemical and microbial analysis. Sampling events were planned to occur at each site at weekly intervals for one month during three separate seasons. Actual sampling dates were as follows: "winter" samples collected 2/13/03, 2/20/03, 2/27/03, and 3/20/03; “spring” samples collected 3/27/03, 5/22/03, 5/29/03, 6/05/03, and 6/12/03; “summer” samples collected 8/14/03, 8/21/03, 8/28/03, and 09/04/03. A total of 117 discrete, or “grab” samples were taken. To add statistical power, additional discrete water quality samples from PWD's wet-weather chemical sampling program were included in analyses when appropriate.

Locations of 2003 water quality sampling sites are depicted in Figure 3 of Section 3. Sites DCC770, DCC455, DCC208, DCD1570, DCD1170, DCD765, DCI010 and DCN010 were included in PWD's baseline chemical assessment of Darby-Cobbs Watershed in 1999. Sites in the Tinicum sub-basin (DCM300 and DCS170) were sampled in 1999 but not in 2003. A single new site (DCD1660), located on Darby Creek upstream of its confluence with Ithan Creek, was added for 2003.

Discrete sampling was conducted on a weekly basis and was not specifically designed to target wet or dry weather flow conditions. Depending on which definition of "dry weather" was used, six or seven sampling events occurred during dry weather. This data is most pertinent to Target A of the Watershed management Plan (Dry Weather water quality and aesthetics). Specifically addressed are indicators seven and eight- chemical and microbial constituents that are influential in shaping communities of aquatic systems or that are indicative of anthropogenic degradation of water quality in the watershed.

4.4.2. Wet-Weather Targeted Sampling

Target C of the Darby-Cobbs Integrated Watershed Management Plan addresses water quality in wet weather. Yet characterization of water quality at several widely spatially distributed sites simultaneously over the course of a storm event presents a unique challenge. Automated samplers (Isco, Inc. models 6712, 6700) were used to collect samples during two runoff-producing rain events in July and September 2003. The automated sampler system obviated the need for BLS team members to manually collect samples, thereby greatly increasing sampling efficiency. Automated samplers were equipped with vented instream pressure transducers that allowed sampling to commence beginning with a small (0.1ft.) increase in stage. Once sampling was initiated, a computer-controlled peristaltic pump and distribution system collected grab samples at 1 hr. intervals.

Use of automated samplers allows for a greater range of flexibility in sampling programs, including flow-weighted composite sampling based on a user defined rating curve, but stage discharge rating curves at these sites were poorly defined for larger flows. Furthermore, one automated sampler was an older model (model 6700) incapable of taking samples based on observed rate of change in stream stage. Though some difficulties were encountered due to a combination of mechanical failure, individual site characteristics, and/or vandalism, the one hour fixed interval was found to be generally satisfactory in collecting representative samples over a storm event (Appendix C). PWD continues to refine methods of sampling stormwater and experiment with alternative automated sampling programs.

4.4.3. Continuous Water Quality Monitoring

Physicochemical properties of surface waters are known to change over a variety of temporal scales, with broad implications for aquatic life. Several important, state-regulated parameters (e.g., dissolved oxygen, temperature, and pH) may change considerably over a short time interval, and therefore cannot be measured reliably or efficiently with grab samples. Self-contained data logging continuous water quality monitoring Sondes (YSI Inc. Models 6600, 600XLM) were deployed between 8/14/03-9/14/03 at five sites within Darby-Cobbs watershed in order to collect DO, pH, temperature, conductivity and depth data (Figure 4 in Section 3). Sondes continuously monitored conditions and discretized the data in 15 min increments.

Extended deployments of continuous water quality monitoring instruments in urban streams have presented many challenges: drastic increases in stream flow and velocity, probe fouling due to accumulation of debris and algae, manpower required for field deployment and maintenance, and the need to guard against theft or vandalism. With refinements to Sonde enclosures and increased attention to cleaning and maintenance, PWD's Bureau of Laboratory Services has made wide-reaching improvements in the quality and recoverability of continuous water quality data, particularly dissolved oxygen (DO) data.

4.4.4. RADAR Rainfall Data and Analysis

Because storm events are inherently variable and do not evenly distribute rainfall spatially or temporally, PWD contracted with Vieux and Associates to obtain discretized measurements of rainfall intensity during storm events targeted by wet weather sampling. For each 15 minute interval, RADAR tower-mounted equipment measured high frequency radio wave reflection in the atmosphere above Darby-Cobbs watershed. This information was provided to PWD as a series of relative reflectivity measurements for individual 1km^2 blocks. The resulting grid allowed for the summing of relative rainfall intensity within the sub-shed served by each sampling site over the course of each individual storm event (Figures 11 and 12). Individual intensity measurements were also graphed and arranged sequentially to produce animated time-series rainfall accumulation graphics. This analysis, combined with data from the PWD rain gauge network and stream stage measurements logged by the automated sampler, allowed for more thorough analysis of water quality data, particularly in determining whether some areas or subsheds may have contributed more runoff than others.

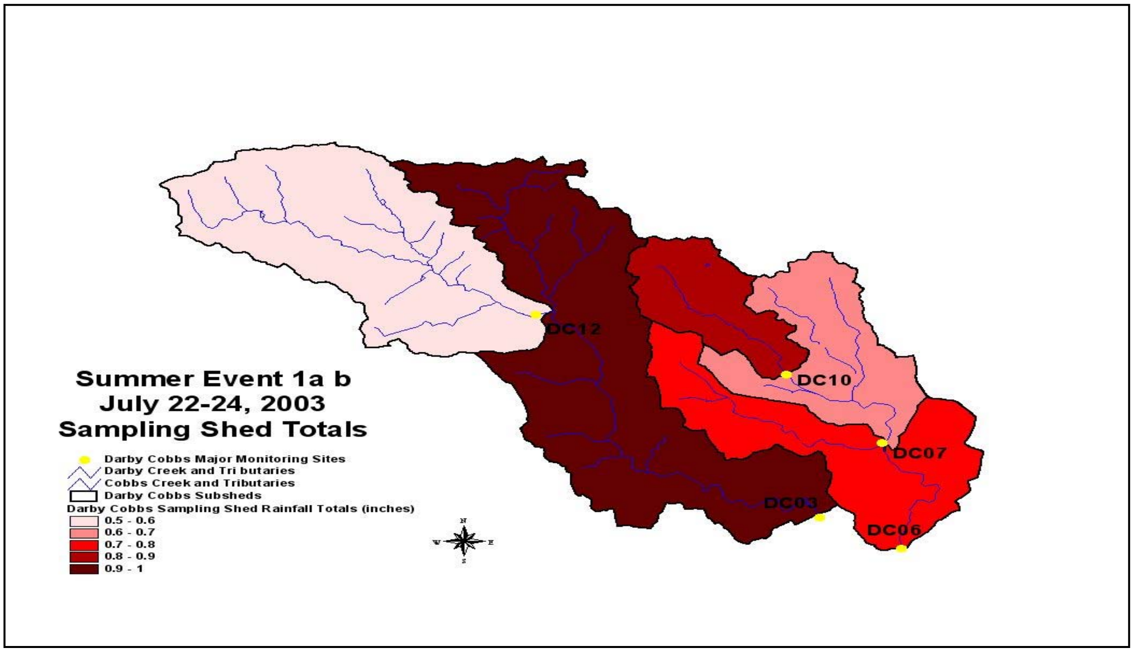

Figure 11. RADAR Rainfall totals by subshed (7/22/03-7/24/03).

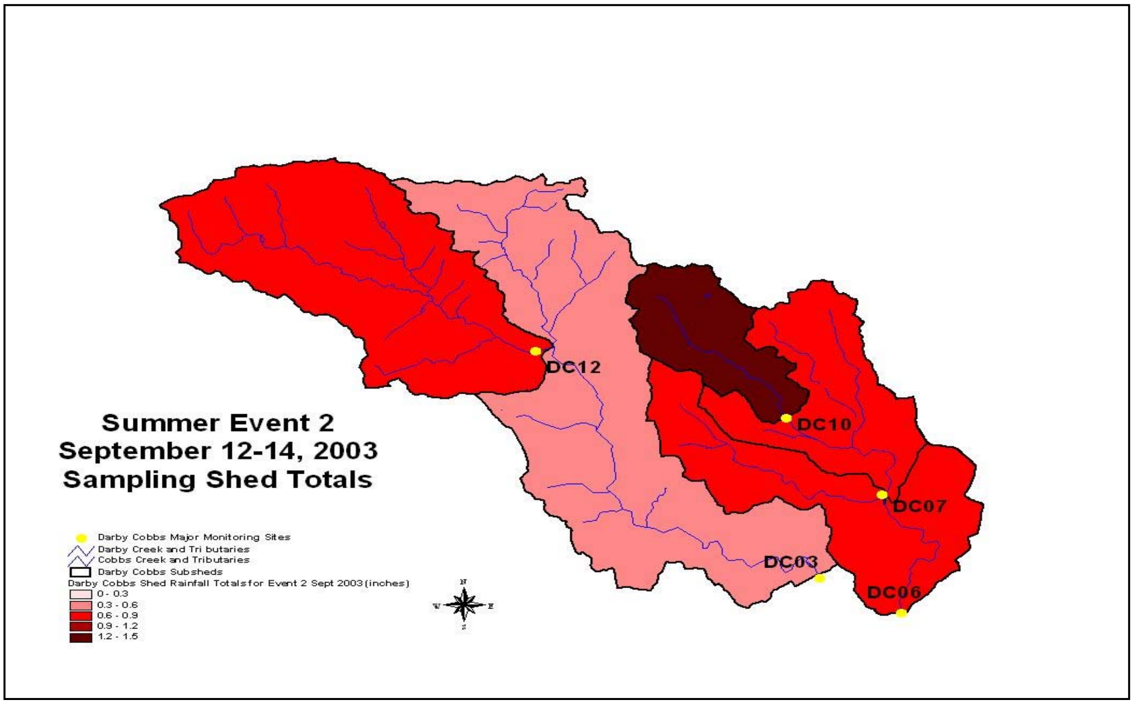

Figure 12. RADAR Rainfall totals by subshed (9/12/03-9/14/03).

SECTION 5: RESULTS AND DISCUSSION

5.1. Benthic Macroinvertebrate Assessment

Study of benthic macroinvertebrate communities has historically been one of the most important tools used in stream water quality assessment. While several key aspects of benthic macroinvertebrate ecology make them ideally suited as bioindicators, their widespread use as such is predicated upon practical concerns. Benthic macroinvertebrates are nearly cosmopolitan in distribution and can be collected by almost anyone in almost any wadeable stream without specialized skill or equipment. Furthermore, identification, to at least the family level, can usually be accomplished in the field without specialized equipment. Because of the ease of their collection and potential discriminatory power of sampling results, thousands of macroinvertebrate surveys are performed each year by governmental and tribal agencies, academic researchers, environmental organizations, volunteer groups, and students of all ages.

While some measures of macroinvertebrate community structure (e.g., diversity indices) may provide meaningful information alone, conclusions of most analyses and metrics are enhanced by, or require, comparison to an unimpaired reference site. However, unimpaired reference sites are often difficult to identify in southeastern Pennsylvania due to extensive development and agricultural land uses. The most logical application of the reference site approach is a pair of sites upstream and downstream of a suspected source of impairment. The downstream site in this scenario has a rather constant source of colonists, or "drift". In regions where impairments occur watershed-wide and first order streams have been eliminated, one cannot assume that study sites have a constant upstream source of immigrants. The most likely means of colonization of these sites is by winged adults. Life history attributes of many invertebrate taxa (e.g., short lifespan of adults, flight capability, and predilection to disperse over upland habitats) reduce the likelihood that impaired sites within a widely impaired region will be recolonized frequently.

Sites in Darby-Cobbs Watershed were compared to reference sites on French Creek and Rock Run, in Chester County, PA. Reference sites were chosen to reflect the range of stream drainage areas in Darby-Cobbs Watershed, yet extensive impervious cover in portions of Darby-Cobbs Watershed complicates this comparison. Due to exaggerated storm flows and concomitant erosion, many sites in Darby-Cobbs Watershed may be categorized as first or second order streams, yet exhibit geomorphological attributes (e.g., bankfull discharge area) similar to sites with much larger drainage areas. These details are addressed in greater detail in Section 5.3 Habitat Assessment

5.1.1. Watershed Overview

A total of 2,114 individuals of 40 taxa were collected and identified during the 2003 benthic macroinvertebrate survey of Darby-Cobbs Watershed. Mean taxa richness of all sites within the watershed was 14.3 (Table 8). Overall, moderately tolerant (89.74%) and generalist feeding taxa (75.72%) dominated the watershed. Mean Hilsenhoff Biotic Index (HBI) of all assessment sites was 5.63 (Figure 13). Overall, the watershed lacked

Table 8. Biological condition results for RBP III.

	DCIC007	16	2	5.65	51.32%	0.00	6.67	Severely Impaired

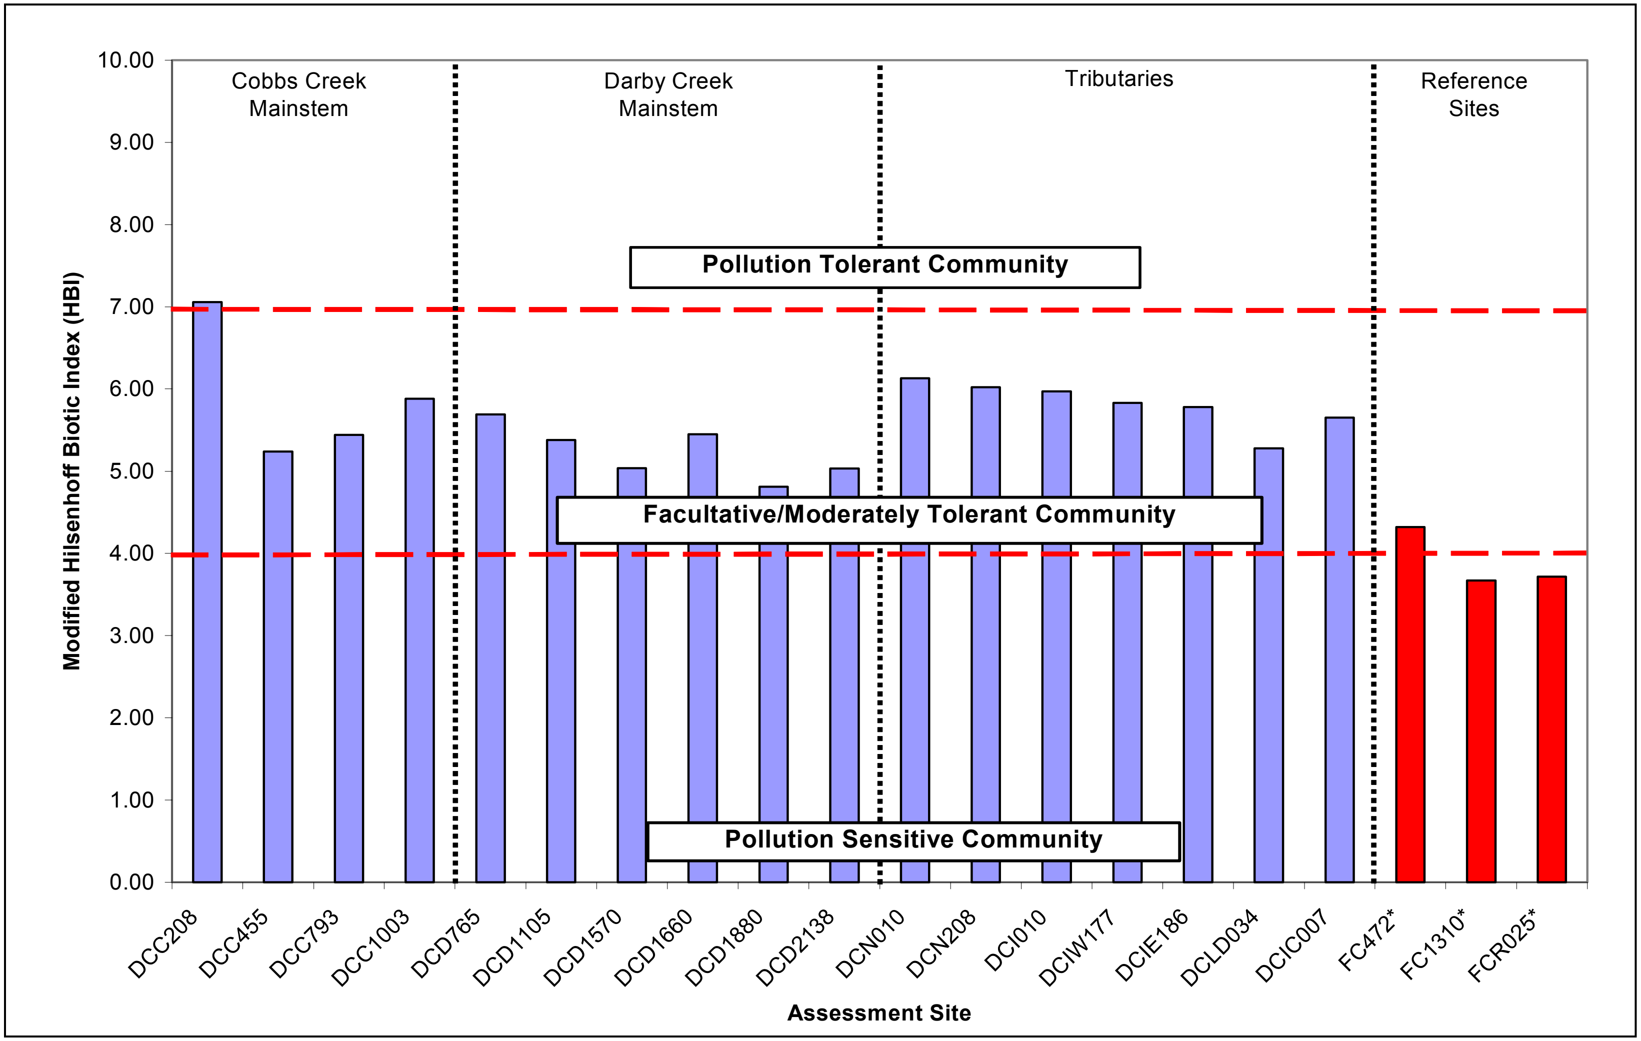

Figure 13. Modified Hilsenhoff Biotic Index (HBI) scores of assessment sites in Darby-Cobbs Watershed.

pollution sensitive Ephemeroptera, Plecoptera, and Trichoptera (EPT) taxa. While present at four upstream Darby Creek sites, abundance of EPT taxa was very low (Figure 14). Midges (family Chironomidae) and net-spinning hydropsychid caddisflies (*Hydropsyche* and *Cheumatopsyche*) dominated the benthic assemblage of most sites within the watershed (percent contribution ranged from 23.14% to 74.07%). Annelids, riffle beetles, isopods, amphipods, tipulids, gastropods, and oligochaetes were also present throughout the watershed.

Basic analysis of raw benthic macroinvertebrate abundance data yields a number of ecological community attributes, such as taxa richness, diversity and evenness, as well as metrics specific to the study of benthic macroinvertebrate communities: modified Ephemeroptera/Plecoptera/Trichoptera (EPT) and Mayfly indices; feeding categorizations; and tolerance measures, including the Hilsenhoff Biotic Index (HBI). While the sampling protocol (a modification of USEPA's RPBIII) was not designed as a quantitative method, the number of subsamples, or plugs, required to count the minimum number of organisms also provided some qualitative data.

The Hilsenhoff Biotic Index (HBI) is used to rate the overall pollution tolerance of a site’s benthic macroinvertebrate community. The HBI is reference site based and oriented toward the detection of organic pollution. HBI scores are unitless and can theoretically range from zero (very sensitive) to ten (very tolerant). Mean HBI score of sites within Darby-Cobbs Watershed was 5.63. The dominance of moderately tolerant individuals and general lack of pollution sensitive taxa contributed to the elevated HBI. Mean HBI score of reference sites was 3.90. Differences in HBI score between assessment and reference sites greater than 0.71 are considered an indicator of impairment. Mean HBI score of sites within Darby-Cobbs exceeded mean reference site score by 1.73, which suggests widespread impairment.

General Tolerance measures are intended to be representative of relative sensitivity to perturbation and may be expressed as numbers of pollution tolerant and intolerant taxa or percent composition (Barbour et al. 1999). Moderately tolerant individuals (89.72%) were collected with greatest frequency in Darby-Cobbs Watershed. Sensitive taxa were poorly represented (3.80%). Abundance of pollution-tolerant taxa may be a response to watershed-wide disturbances.

Feeding measures consider categorized functional feeding groups (e.g., scraper, shredder, collector-gatherer) and provide information regarding the balance of feeding strategies in the benthic community (Barbour et al. 1999). The trophic composition of benthic macroinvertebrate communities at most sites within Darby-Cobbs Watershed was skewed toward generalist-feeding filterers and collectors (75.72%) Generalist-dominated communities in the Cobbs and Indian Creek subsheds may be indicative of an unbalanced community responding to an overabundance of a food resource (i.e., fine particulate organic matter-FPOM) (Fiorentino, 2000). Limitation in food sources limits the competitive ability of specialized feeders.

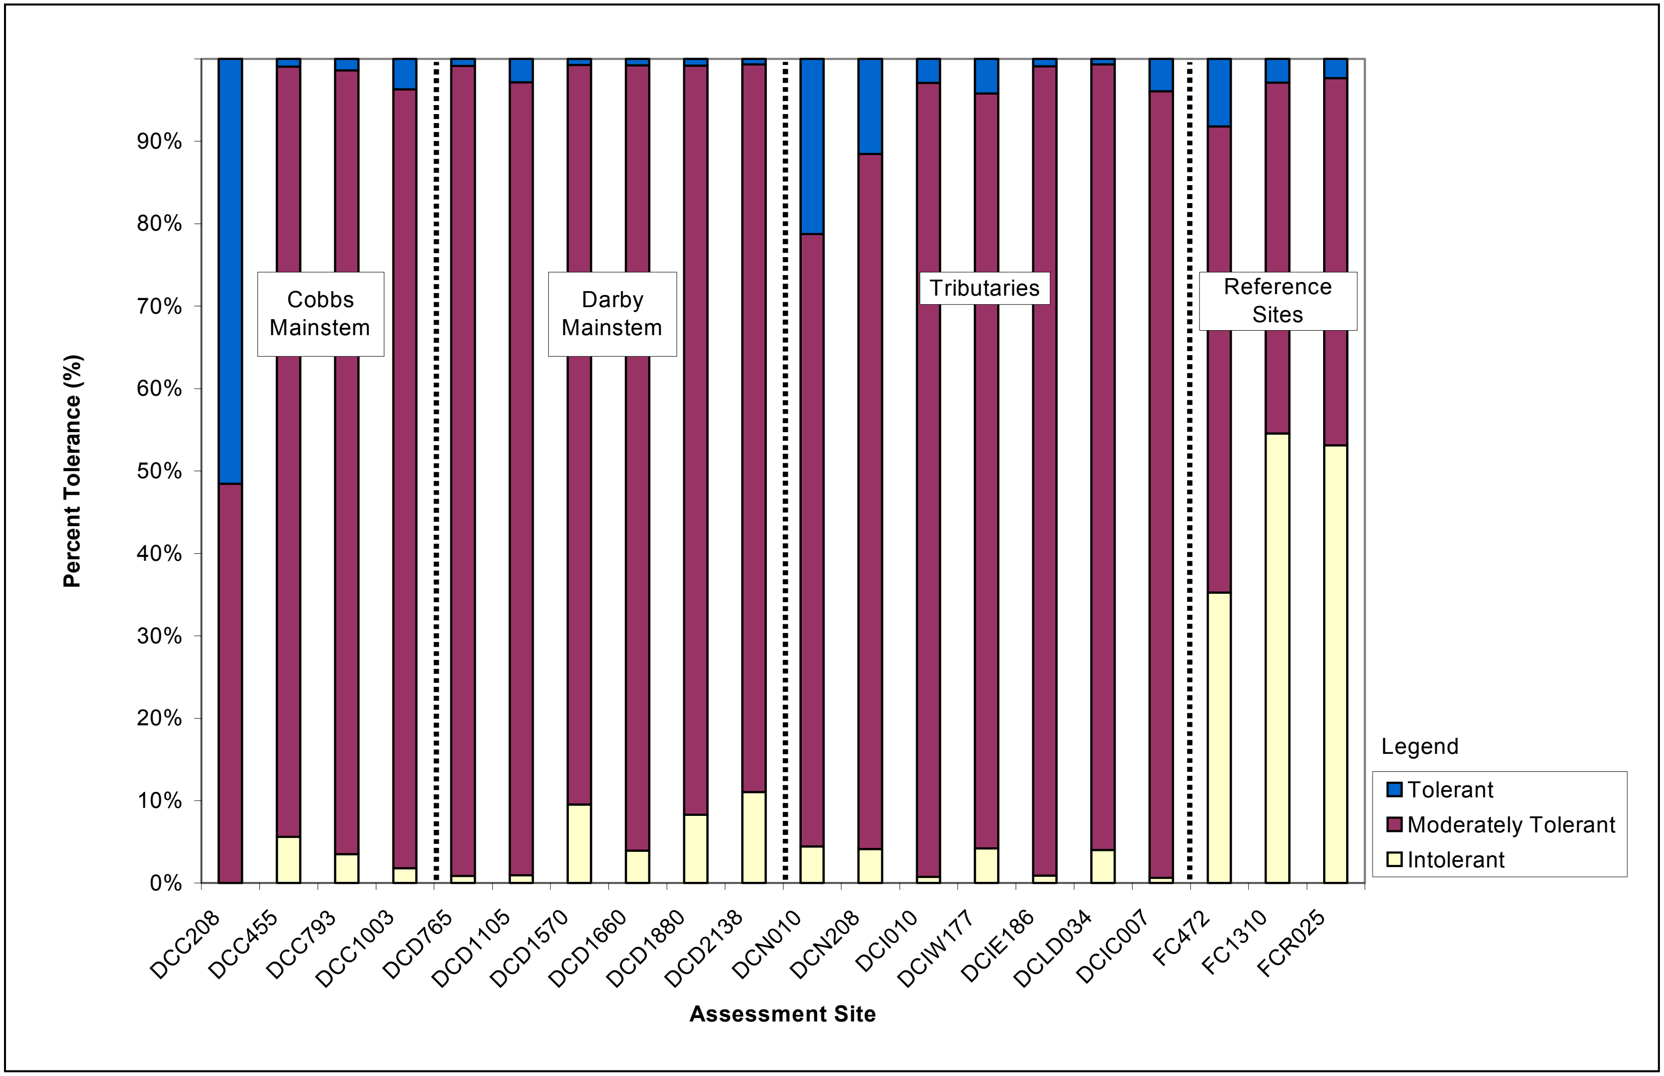

Figure 14. Pollution tolerance values (%) of macroinvertebrate assemblages at each assessment site in Darby-Cobbs Watershed.

However, specialized feeding groups are generally more sensitive to disturbance than generalist feeders. Generalist-dominated assemblages throughout the watershed, especially in Darby Creek watershed, may reflect effects of other environmental disturbances (e.g., flow modification) completely unrelated to organic enrichment. As most benthic macroinvertebrate metrics are aimed at detecting impairment due to organic enrichment, care must be taken not to misinterpret the findings of these tests, especially in light of potentially contradictory habitat and water chemistry data.

5.1.2. Cobbs Creek Mainstem Sites

5.1.2.1. DCC208

With a total biological score of four (4), DCC208 was designated "severely impaired" (13.3% comparison). Four plugs were sorted in order to obtain 100 individuals. DCC208 had low taxa richness (n=12) and no EPT taxa present. Physid snails dominated the benthic assemblage at the site (42.42%) which contributed to the highest HBI score (7.06) of all assessment sites. Due to the large snail population, scrapers (57.58%) and tolerant individuals (51.52%) dominated the assemblage.

5.1.2.2. DCC455

The total biological score at DCC455 was eight (8) out of 30. With a 26.67% comparison, the site was designated "moderately impaired". The site had a slightly elevated HBI score (5.24) and was dominated by net-spinning caddisflies (66.35% total; 44.86% *Hydropsyche* and 21.50% *Cheumatopsyche*). The abundance of Hydropsychidae skewed the trophic feeding structure of the site toward filterers (66.36%). No EPT taxa were collected, and the site had low taxa richness (n=12). A broken sanitary sewer upstream of the assessment discovered shortly after benthic sampling may have contributed to the impaired macroinvertebrate community.

5.1.2.3. DCC793

DCC793 earned a biological score of 12. This score was a 40.0% comparison to the reference condition at FCR025, and the site was deemed "moderately impaired". DCC793 had low taxa richness (n=15), although it was the highest of all assessment sites on Cobbs Creek. Only one EPT taxon was present (*Chimarra*), and the site had an elevated HBI score of 5.44. Similar to other downstream Cobbs Creek sites, DCC793 was dominated by filter feeding Hydropsychidae (*Hydropsyche* 39.44% and *Cheumatopsyche* 21.13%). Hydropsychids and chironomids comprised 83.10% of all individuals in the analyzed sample.

5.1.2.4. DCC1003

The assessment site at DCC1003 received a total biological score of four (4), which was a 13.3% comparison to FCR025. The relative density of macroinvertebrates was low at DCC1003. Three plugs were needed to acquire 100 individuals. There was low taxa richness (n=12) and an absence of EPT taxa at the site. The majority of individuals in the sample were midges (57.80% Chironomidae), and the trophic composition of the site was dominated by gatherers (61.47%). With most metrics scoring zero (0), DCC1003 was designated "severely impaired".

5.1.3. Darby Creek Mainstem Sites

5.1.3.1. DCD765

DCD765 received a total metric score of zero (0) out of a possible 30. The site was designated "severely impaired". To obtain 100 individuals, five sub-samples were sorted. DCD765 had the highest HBI score (5.69) and lowest taxa richness (n=11) of all mainstem Darby Creek assessment sites. The amphipod *Gammarus* dominated the benthic assemblage (68.70%), and the feeding structure at DCD765 consisted of mainly generalist collector-gatherers (75.65%). The low density of macroinvertebrates, dominance of moderately pollution tolerant taxa (98.26%) and high proportion of generalists contributed to the site's impairment designation.

5.1.3.2. DCD1105

The assessment at site DCD1105 received a biological score of eight (8). The site had a 20.0% comparison to FC472 and was designated "moderately impaired". DCD1105's metric comparison score fell between the moderate and severely impaired biological condition categories. A taxa richness of n=17 and relatively low percent dominant taxon (32.08% Chironomidae), lead to a "moderately impaired" status designation. Only one EPT taxon (*Chimarra*) was present, and the HBI score at DCD1105 was an elevated 5.38. All trophic levels were represented but generalist feeders dominated the sample (62.26% gatherers and 23.58% filterers). The site had a low relative density. Four sub-samples were sorted to obtain the necessary 100 individuals.

5.1.3.3. DCD1570

The total biological score at DCD1570 was 14—a 46.67% comparison to the reference condition at FC472. The site at DCD1570 was designated "moderately impaired". DCD1570 had one of the lowest HBI scores (5.04) and had the greatest number of EPT taxa (n=4) of all Darby-Cobbs assessment sites. The assemblage had relatively low percent dominant taxon (33.09% Chironomidae), but the trophic structure lacked shredders. The assemblage was dominated by gatherers (44.85) and scrapers (36.03%).

5.1.3.4. DCD1660

The macroinvertebrate assemblage at DCD1660 scored four (4) when compared to the reference conditions at FC1310. The site was designated "severely impaired". Impairment was due to the dominance of midge larvae (61.42%) and an elevated HBI score (5.45). DCD1660 had low taxa richness (n=14) and only one EPT taxon (*Chimarra*) was identified in the sub-sample. All feeding groups were present, but specialized feeders (scrapers, shredders, and predators) were not well represented. Generalist feeding gatherers (67.7%) dominated the assemblage.

5.1.3.5. DCD1880

DCD1880 had a total biological score of 10 out of 30, which represents a 33.33% comparison to FC1310. DCD1880 had the lowest HBI score (4.81) of all 2003 assessment sites, and also had low percent dominant taxon (23.14% Chironomidae). Three EPT taxa were present in the analyzed sub-sample, and the taxa richness (n=17) was fair. DCD1880 was designated "moderately impaired".

5.1.3.6. DCD2138

The assessment site at DCD2138 received a total biological score of 16, which was a 53.3% comparison to FC1310. The site was designated "slightly impaired". DCD2138 was the only site in the 2003 survey to be deemed only slightly impaired. DCD2138 had the highest taxa richness (n=23) of all assessment sites, and received an HBI score of 5.03. Three EPT taxa were identified in the sub-sample from DCD2138, and it had low percent dominant taxon (34.42% Chironomidae). The trophic structure at DCD2138 was balanced, and the site had the highest proportion of intolerant macroinvertebrates of all sites.

5.1.4. Darby-Cobbs Tributary Sites

5.1.4.1. DCN010

DCN010 had a total biological score of 12, and the site was designated "moderately impaired". The assemblage at the site had good percent dominant taxa, as the two major taxa (Lumbriculidae and *Hemerodromia*) each comprised 15.04% of all individuals, but Lumbriculidae and *Hemerodromia* are moderately tolerant and tolerant taxa, respectively. In addition, DCN010 had a balanced trophic structure. Despite the relatively favorable balance of the assemblage at DCN010, the sites had an overall lack of macroinvertebrates. Nine sub-samples were sorted in order to obtain the required 100 individuals for metrics. The site had an elevated HBI score (6.13) and a very high percentage of tolerant individuals (21.24%). The "moderately impaired" designation for DCN010 may not accurately reflect the biological condition at the site due to the low taxa richness of the reference site FCR025. This factor may have skewed the metric scores of DCN010.

5.1.4.2. DCN208

The total biological score at DCN208 was ten (10). The site was deemed “moderately impaired” based on a 33.33% comparison to the reference condition. Similar to other sites, DCN208 had an elevated HBI score (6.02) and an absence of EPT taxa. The community had low taxa richness, but good percent dominant taxa. Chironomid larvae and *Cheumatopsyche* each comprised 23.97% of the benthic assemblage. The total numbers of net-spinning caddisfly taxa (Hydropsyche and Cheumatopsyche) comprise 44.63% of all individuals. Generalist feeding gatherers and filterers composed 82.65% of the trophic structure of the site. The impaired biological conditions at DCN208 may be due in part to much of Naylors Run being encapsulated.

5.1.4.3. DCI010

The assessment site at DCI010 scored four (4) out of 30 when compared to FCR025. There was a 13.33% percent comparison to FCR025, and the site was designated “severely impaired”. DCI010 had very high percent dominant taxon (Chironomidae 60.29%), and no EPT taxa were present. The site also had low taxa richness and an elevated HBI score (5.97). The abundance of chironomids caused gatherers (66.91%) to dominate the trophic structure of the site. Generalist feeding macroinvertebrates composed 95.59% of the total number of individuals. Upon visiting DCI010, field personnel were informed by golf course staff that water at the site was frequently an opaque gray color, possibly due to sewage in the creek.

5.1.4.4. DCIW177

The benthic assemblage at DCIW177 received a total biological score of ten (10), which represents a 33.33% comparison to FCR025. The site was designated “moderately impaired”. One EPT taxon (*Glossosoma*) was identified in the sub-sample, but only one individual was found. The site had low taxa richness (n=12) and a high HBI score (5.83). All trophic levels were represented, but specialized feeders were almost absent. Generalist feeders comprised 94.96% of the macroinvertebrate community. The percent dominant taxon (37.82% Chironomidae) was fair.

5.1.4.5. DCIE186

DCIE186 scored only two (2) out of 30. With 13.33% comparison, the site was designated “severely impaired”. DCIE186 had an elevated HBI score (5.75), and no EPT taxa. The site had the lowest taxa richness (n=11) and the highest percent dominant taxon (74.07% Chironomidae) of all the assessment sites. All trophic groups were present at the site, but gatherers (82.41%) dominated the community. 98.15% of all individuals at the site were moderately tolerant.

5.1.4.6. DCLD034

The macroinvertebrate assemblage at DCLD034 scored four (4) out of 30. DCLD034 had an elevated HBI score (5.28) and high percent dominant taxon (51.68% Chironomidae). The site had only one EPT taxa (*Chimarra*) and low taxa richness (n=13). Moderately tolerant taxa dominated the benthic assemblage. The metrics at DCLD034 had a 13.33% comparison to FCR025 deeming it "severely impaired".

5.1.4.7. DCIC007

The total biological score at DCIC007 was two (2). The score of two corresponded to a "severely impaired" designation (6.67% comparison). The site had an elevated HBI score (5.65) and a taxa richness of n=16. There were two EPT taxa (*Agraylea* and *Chimarra*) present in the sub-sample analyzed. The trophic composition was skewed toward generalist feeding gatherers (59.21%) due to the abundance of chironomids (51.32% of individuals). The benthic macroinvertebrates at DCIC007 were sampled approximately two months (5/12/03) after all other assessment sites were sampled. The observed biological integrity could be due to seasonal changes and not degraded water quality conditions.

5.2. Fish Assessment

5.2.1. Overview

A total of 12,882 individuals of 44 species representing 13 families were collected throughout Darby-Cobbs Watershed in the 2003 bioassessment (Table 9). Blacknose dace (*Rhinichthys atratulus*) and Banded killifish (*Fundulus diaphanus*), two taxa highly tolerant of poor stream conditions, were most abundant and comprised approximately 33% of all fish collected. Other common species were White sucker (*Catostomus commersoni*), Mummichog (*Fundulus heteroclitus*), Common shiner (*Luxilus cornutus*), and Swallowtail shiner (*Notropis procne*). Of 44 species collected, seven species comprised 78% of the entire fish assemblage. Similarly, four species made up nearly 70% of total biomass, with white sucker and American eel (*Anguilla rostrata*) contributing greater than 55%. In general, Darby Creek had greater species richness, but Cobbs Creek had higher abundance, density (individuals per unit area), and catch rates (catch per unit effort).

Trophic composition evaluates quality of the energy base and foraging dynamics of a fish assemblage. This is a means to evaluate the shift towards more generalized foraging that typically occurs with increased degradation of the physicochemical habitat (Barbour et al., 1999). Generalist feeders (54.7%) and insectivores (38.2%) dominated Darby-Cobbs Watershed, with 6.1% top carnivores and approximately 1% herbivores and filter feeders. Trophic composition was fair compared to reference sites. In Cobbs Creek, top carnivore and insectivore taxa abundance decreased while abundance of generalist feeders increased in an upstream direction (Figure 15). Also, percentage of White suckers (*C. commersoni*) increased in an upstream direction, as White suckers typically increase in abundance in degraded streams. In Darby Creek, abundance of generalist feeders increased, whereas the percentage of insectivore taxa decreased in an upstream direction.

Table 9. Species list and relative abundance of fish taxa collected in the Darby-Cobbs Watershed.

Scientific Name	Common Name	Number Of Individuals Identified
Alosa aestivalis	Blueback Herring	42
Alosa sapidissima	American Shad	1
Ameiurus catus	White Catfish	1
Ameiurus natalis	Yellow Bullhead Catfish	1
Ameiurus nebulosus	Brown Bullhead Catfish	60
Ambloplites rupestris	Rock Bass	76
Anguilla rostrata	American Eel	555
Carassius auratus	Goldfish	11
Catostomus commersoni	White Sucker	831
Cyprinella analostana	Satinfin Shiner	219
Cyprinus carpio	Common Carp	32
Cyprinella spiloptera	Spotfin Shiner	9
Dorosoma cepedianum	Gizzard Shad	3
Esox lucius x Esox masquinongy	Tiger Muskellunge	1
Etheostoma olmstedi	Tessellated Darter	237
Exoglossum maxillingua	Cutlips Minnow	442
Fundulus diaphanus	Banded Killifish	1917
Fundulus heteroclitus	Mummichog	1088
Gambusia affinis	Mosquitofish	3
Hybognathus regius	Eastern Silvery Minnow	117
Ictalurus punctatus	Channel Catfish	2
Lepomis auritus	Redbreast Sunfish	651
Lepomis cyanellus	Green Sunfish	8
Lepomis gibbosus	Pumpkinseed Sunfish	129
Lepomis auritus x Lepomis gibbosus	Sunfish Hybrid	1
Lepomis macrochirus	Bluegill Sunfish	52
Luxilus cornutus	Common Shiner	1018
Micropterus dolomieui	Smallmouth Bass	23
Micropterus salmoides	Largemouth Bass	6
Morone americana	White Perch	1
Morone saxatilis	Striped Bass	1
Notemigonus crysoleucas	Golden Shiner	11
Notropis hudsonius	Spottail Shiner	200
Notropis procne	Swallowtail Shiner	1465
Oncorhynchus mykiss	Rainbow Trout	26
Pimephales notatus	Bluntnose Minnow	65
Pimephales promelas	Fathead Minnow	148
Pomoxis nigromaculatus	Black Crappie	1
Rhinichthys atratulus	Blacknose Dace	2157
Salvelinus fontinalis	Brook Trout	1
Salmo trutta	Brown Trout	31
Semotilus atromaculatus	Creek Chub	143
Semotilus corporalis	Fallfish	24
Umbra pygmaea	Eastern Mudminnow	1

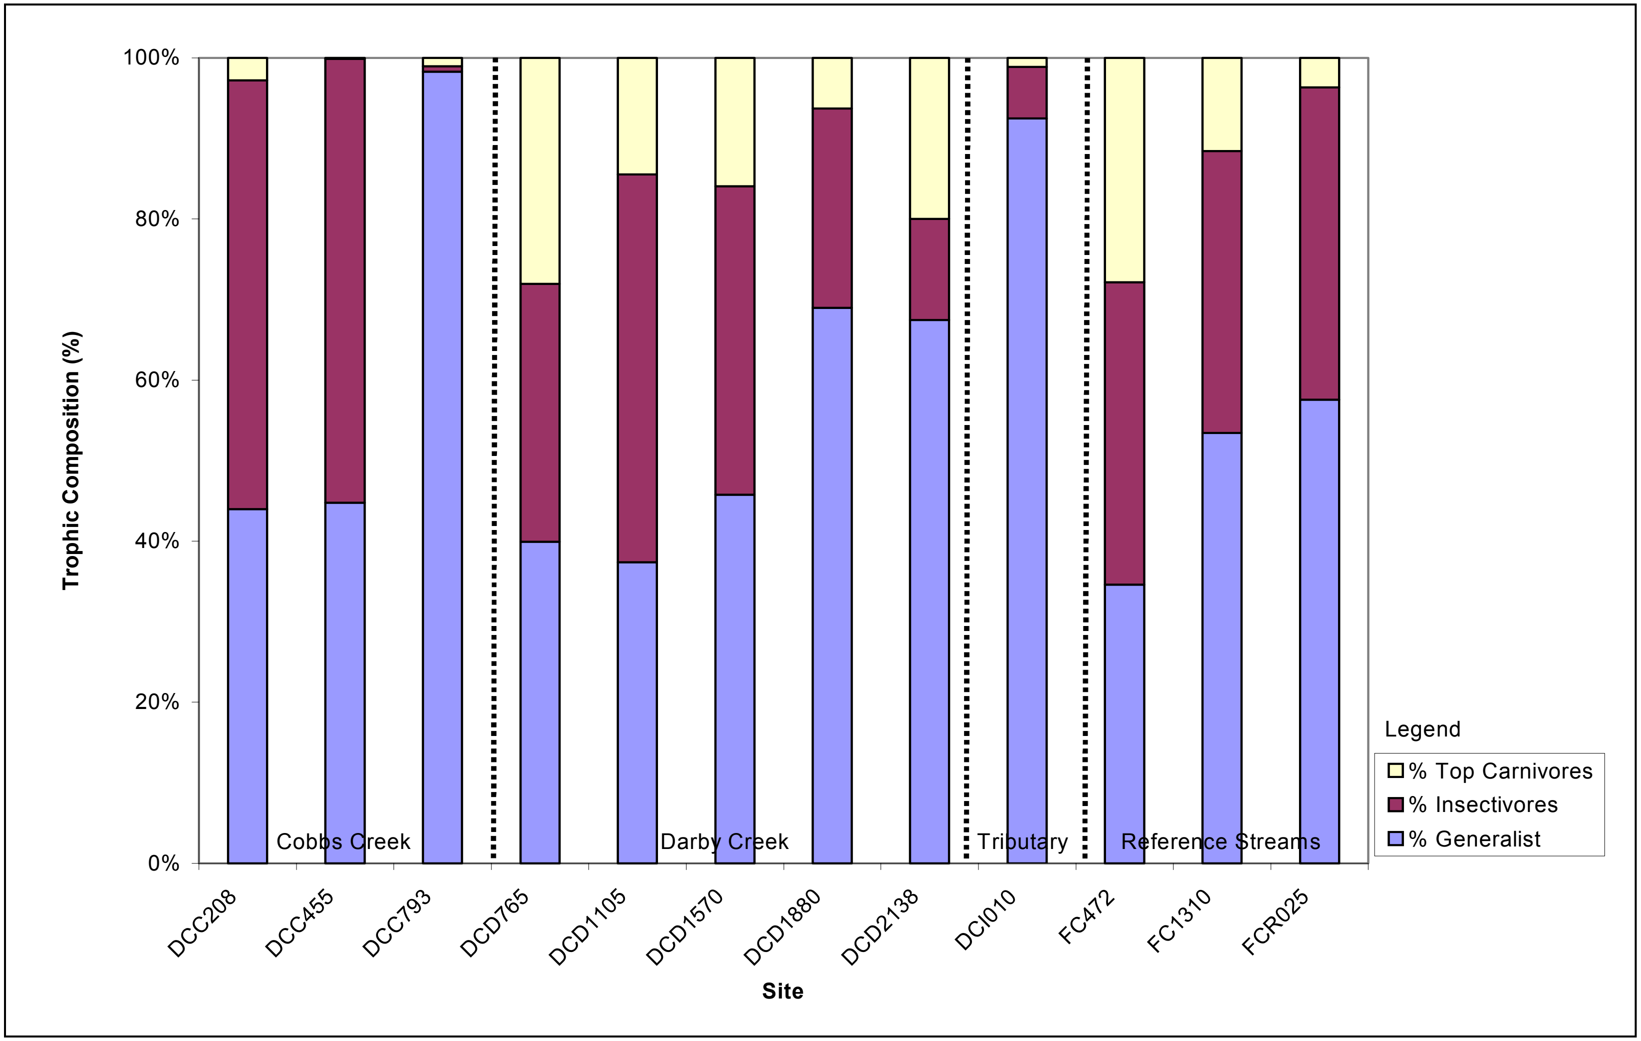

Figure 15. Trophic structure of fish assemblages in the Darby-Cobbs Watershed.

Relative abundance of insectivores decreases with degradation in response to availability of the insect supply, which reflects alterations of water quality and instream habitat (Daniels et al., 2002). Of particular concern was the absence of Longnose dace (*Rhinichthys cataractae*) in Darby-Cobbs Watershed. This benthic insectivore requires complex riffle systems of good quality and its complete absence in the watershed suggests impaired stream conditions. Though community composition varied between sites, the fish assemblage in Darby-Cobbs Watershed was skewed towards a tolerant, generalist feeding community.

Tolerance designations describe the susceptibility of a species to chemical and physical perturbations. Intolerant species are typically first to disappear following a disturbance (Barbour et al., 1999). Tolerant and moderately tolerant species composed 95% of the fish fauna in Darby-Cobbs Watershed (Figure 16). Cutlips minnow (*Exoglossum maxillingua*) and stocked trout (*Oncorhynchus mykiss, Salmo trutta, Salvelinus fontinalis*) were the only intolerant taxa found in the non-tidal sites. Eastern silvery minnow (*Hybognathus regius*) and Striped bass (*Morone saxatilis*) were additional intolerant species found in the tidal portions of the watershed. No more than one sensitive species was found at any given non-tidal site. Furthermore, all but two assessment sites were dominated by taxa tolerant of poor water quality. The non-tidal portion of Cobbs Creek was devoid of pollution-sensitive taxa. The relative low abundance of intolerant species implies a high level of disturbance that appears to increase upstream.

The Index of Biotic Integrity (IBI) is useful in determining long-term effects and coarse-scale habitat conditions because fish are relatively long-lived and mobile. A site with high integrity (i.e. high score) is associated with native communities that interact under natural community processes and functions (Karr 1981). Since biological integrity is closely related to environmental quality, assessments of integrity can serve as a surrogate measurement of health (Daniels et al., 2002). Mean IBI score for Darby-Cobbs Watershed was 31 (out of 50), placing it in the “fair” category (Figure 17). Skewed trophic structure and rare intolerant species are characteristics of a fish community in the “fair” category. The Modified Index of Well-Being and Shannon Diversity Index values, which are measures of diversity and abundance, decreased in an upstream direction. Overall, the more downstream sites had higher biological integrity than upstream sites.

5.2.2. Cobbs Creek Mainstem Sites

5.2.2.1. DCC208

In 1523.33 m^2 of stream surface area, a total of 1217 fish representing 13 species were collected during 80.95 minutes of electrofishing. DCC208 had the lowest abundance, biomass (9.50kg), density (0.8 fish/m^2), and standing crop (6.23g/m^2) in Cobbs Creek Watershed. Three species tolerant of poor stream conditions comprised over 80% of all fish collected, with Banded killifish (*F. diaphanus*) most abundant. Benthic insectivorous and intolerant species were absent from this monitoring location. Nearly

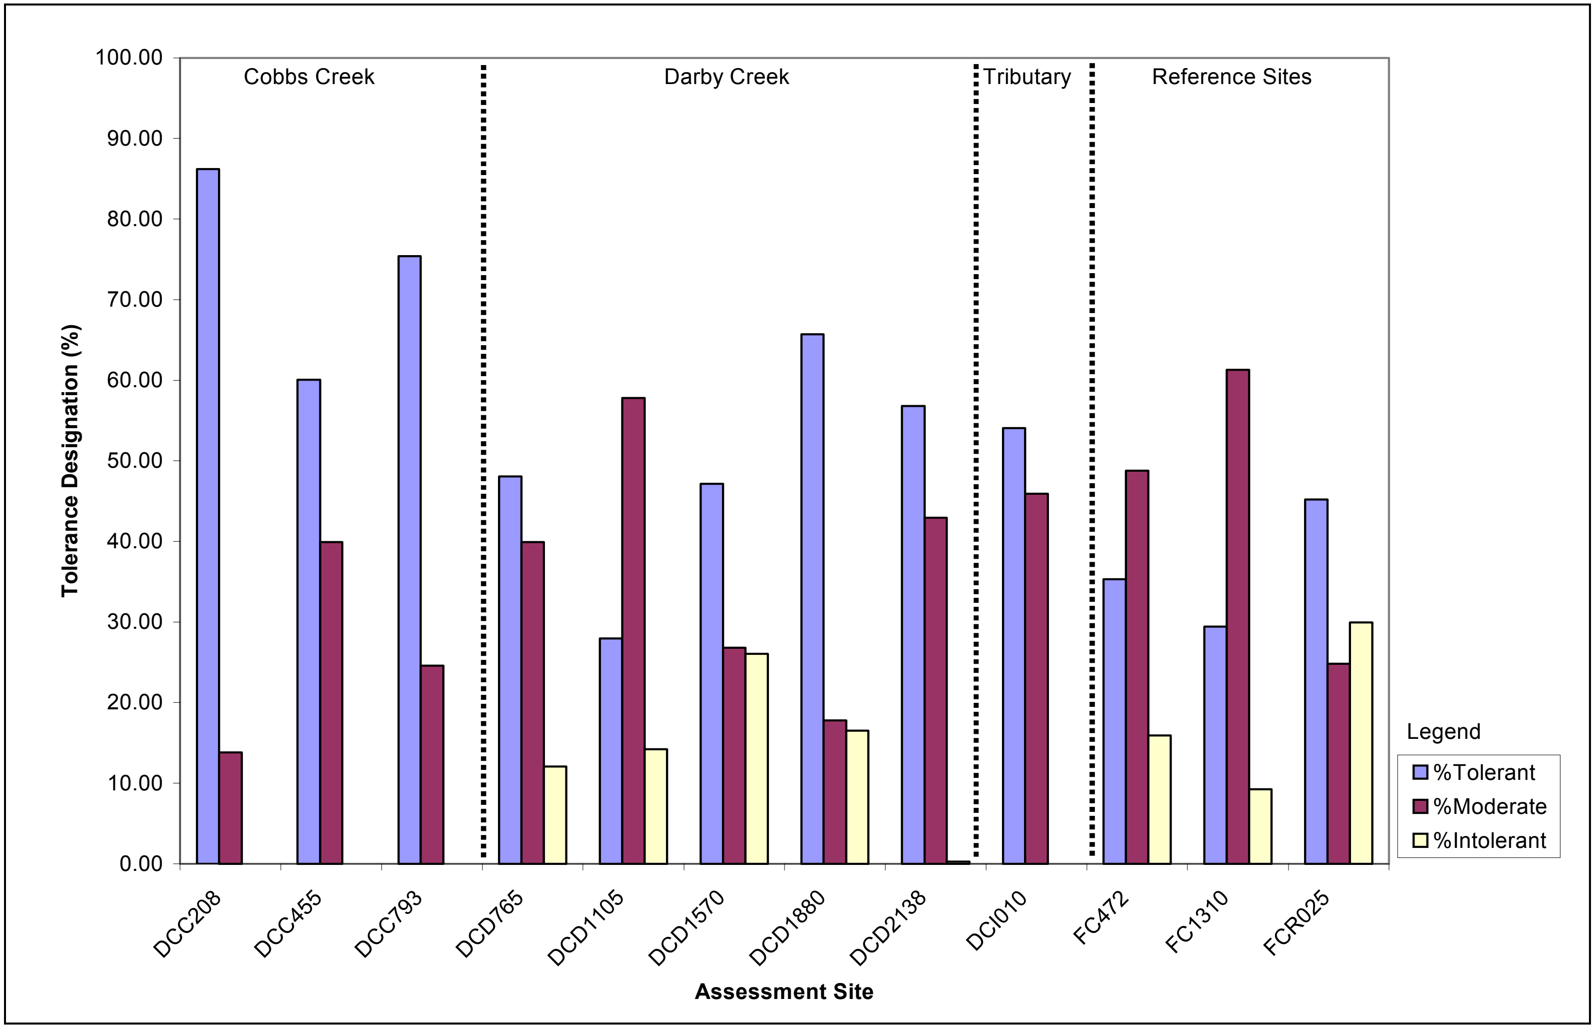

Figure 16. Pollution tolerance values at the monitoring sites in Darby-Cobbs Watershed.

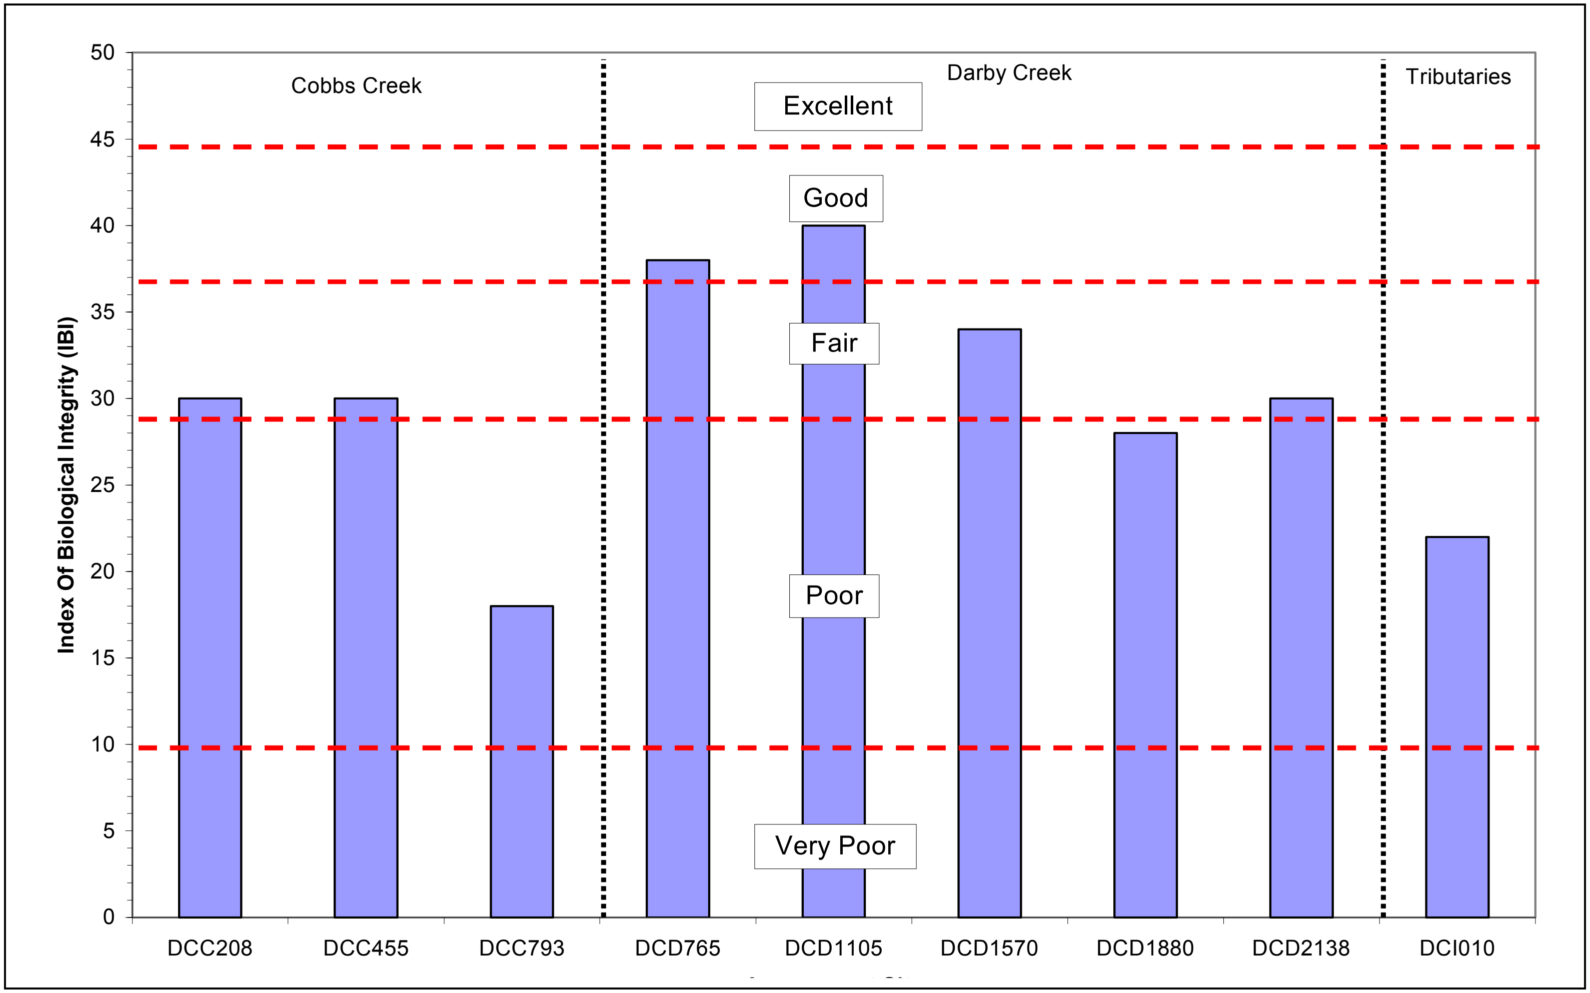

Figure 17. Index of Biological Integrity (IBI) scores at the nine assessment sites in Darby-Cobbs Watershed.

90% of the fish assemblage consisted of tolerant individuals and one single species accounted for 47% of all fish; three species contributed 68% of the total biomass at this location. The trophic composition was dominated by generalist feeders (44%) and insectivores (53%), with 3% top carnivores. The prevalence of tolerant taxa and unevenness of the assemblage indicated degraded stream conditions. The IBI score was 30 (out of 50), placing this site in the "fair" category. Absences of intolerant and sensitive species as well as a skewed trophic structure are characteristic of sites with fair biologic integrity. DCC208 had the lowest Modified Index of Well-Being value (9.51) of all main stem sites in the Darby-Cobbs Watershed and the Shannon Diversity Index (1.58) was well below reference condition values.

5.2.2.2. DCC455

A total of 1510 individuals of 17 species (including exotic and non-resident) yielded a biomass of 16 kg during 81 minutes of electrofishing. Based on a stream surface area of 1003 m^2, a density of 1.51 fish per m^2 and standing crop of 15.96 grams per m^2 were calculated. Of the 17 species collected at DCC455, four species accounted for 78% of the site's abundance and 86% of the total biomass. Banded killifish (*F. diaphanus*), a highly tolerant species, was most abundant (34%) and Brown bullhead (*Ameiuris nebulosus*) dominated the biomass (35%). Other common species were Mummichog (*F. heteroclitus*), Redbreast sunfish (*Lepomis auritus*), and Swallowtail shiner (*N. procne*). There were no intolerant taxa and benthic insectivorous species collected at this location; 60% of individuals were tolerant and 40% were moderately tolerant to pollution. The trophic composition was 55% insectivores, 45% generalist feeders, and less than 1% top carnivores.

The IBI score of 30 (out of 50) is characteristic of a "fair" quality fish assemblage. Since the IBI metric for total number of fish species excludes exotic and nonresident taxa, only 16 species were used to calculate the IBI score. This site had the highest Modified Index of Well-Being (11.13) and Shannon Diversity Index (1.94) for Cobbs Creek Watershed. However, these measures of abundance and diversity overestimate the quality of the assemblage because they do not account for the skewed trophic structure, lack of sensitive species, and elevated percentage of fish with disease and anomalies typically found in poor quality streams.

5.2.2.3. DCC793

DCC793 was the upstream-most fish assessment site within Cobbs Creek Watershed and located just upstream of the Philadelphia County line. This site had the greatest abundance and biomass, but the lowest diversity on the main stem of Cobbs Creek. The upstream site yielded 1907 individual fish of 12 species, accounting for 23.7 kg of biomass. Of 12 species collected at DCC793, 3 species comprised approximately 92% of all fish collected and 84% of the total biomass. Blacknose dace (*R. atratulus*), a tolerant species, was most abundant and accounted for more than half of the entire assemblage. Furthermore, no intolerant taxa were collected at DCC 793 and 98% of the assemblage was generalist feeders. Despite the highly skewed trophic structure (indicative of degraded stream conditions), this site had the greatest density (number of fish per unit area) and standing crop (biomass per unit area) in Cobbs Creek Watershed.

This site received an IBI score of 18 (out of 50), signifying a "poor" quality fish assemblage and therefore, poor environmental health. This was the lowest IBI score in Darby-Cobbs Watershed. In addition, nearly one third of assemblage had some type of disease or anomaly. The low values for the Modified Index of Well-Being (10.08) and Shannon Diversity Index (1.21) corroborate with the poor IBI score and represent an unhealthy stream reach.

5.2.3. Darby Creek Mainstem Sites

5.2.3.1. DCD765

Sampling at DCD765 took place several days following periods of rain. Discharge and stage height were slightly above normal, and may have accounted for reduced sampling efficiency. A total of 356 fish representing 18 species (including exotic and non-resident) were collected during 71.67 minutes of electrofishing in 1506.86 m^2 of stream surface area. This was the minimum number of fish collected at any site in Darby-Cobbs Watershed. Nevertheless, this site had good relative diversity and a balanced trophic structure. Trophic composition was evenly distributed, with 39% generalist feeders, 32% insectivores, and 28% top carnivores, representing the maximum percentage of top carnivores found at any site in the watershed. The most common fish were American eel (*Anguilla rostrata*), Cutlips minnow (*E. maxillingua*), and Redbreast sunfish (*L. auritus*), making up 58% of the fish assemblage. *A. rostrata* comprised 96% of the top carnivores and 41% of total biomass at DCD765. The presence of large American eels may have reduced the abundance of cyprinids and overall abundance through competitive exclusion or predation.

DCD765 received an IBI score of 38 (out of 50), placing it in the category of a "good" quality fish assemblage. The elevated percentage of intolerant individuals (12%) and low occurrence of DELT anomalies (5.9%) are characteristic of stream reaches with good biological integrity. The Modified Index of Well-Being (10.46) and Shannon Diversity Index (2.21), however, are relatively lower than expected in a "healthy" fish assemblage , and may be a result of decreased sampling efficiency due to high water velocities.

5.2.3.2. DCD1105

A total of 436 fish representing 17 species (including exotic, non-resident, stocked fishes) were collected during 75.33 minutes of electrofishing in 1450.67 m^2 of stream surface area. There were 2 benthic insectivorous species, 4 water column species, and only 1 intolerant taxa present at DCD1105. This site had the second lowest density and third lowest abundance of fish in Darby-Cobbs Watershed. Nonetheless, the small percentage of White suckers (3%) and a higher percentage of intolerant individuals (14%) are signs of a good quality fish assemblage. Also, this was one of only two sites with more moderately tolerant (58%) than tolerant (28%) fish. Functional feeding groups were well distributed between insectivores (48%), generalist feeders (37%) and top carnivores (15%).

The most common species included Swallowtail shiner (*N. procne*), Cutlips minnow (*E. maxillingua*), and Blacknose dace (*R. atratulus*), with American eel (*A. rostrata*) composing more than half of the biomass. This site had the highest IBI score in the Darby-Cobbs Watershed, with a value of 40 (out of 50). DCD1105 also received the highest Shannon Diversity Index value of 2.35. Based on the IBI score and Shannon Diversity Index, relative health of the fish assemblage at DCD1105 was the best in the watershed and characteristic of only slightly degraded streams.

5.2.3.3. DCD1570

The collection of 38 stocked trout (*Oncorhynchus mykiss* and *Salmo trutta*) from this site was the most in the watershed; however, the absence of juvenile trout suggests that there is no trout reproduction. Therefore, stocked trout were not included in several IBI metrics involving intolerant taxa and species richness. We collected 933 fish of 19 species (including exotic, non-resident, stocked fishes) during 87 minutes of electrofishing in 1208 m^2 of stream surface area. Of 19 species collected, six species accounted for 66% of all fish collected whereas four species comprised 87% of the total biomass. Blacknose dace (*R. atratulus*), a highly tolerant species, was most abundant (23%) and American eel (*A. rostrata*) was responsible for nearly half of the site's biomass. There were two benthic insectivorous species, four water column species, and only one intolerant species (*E. maxillingua*). DCD1570 had the greatest biomass (40.8 kg) and standing crop (biomass/m^2) of all Darby-Cobbs sites.

Biotic integrity of this site was "fair", receiving an IBI score of 34 (out of 50). Due to the high biomass and relative abundance, the Modified Index of Well-Being (10.46) and Shannon Diversity Index (2.27) overestimated the quality of the fish assemblage. This site was dominated by generalists feeders (46%) and had an elevated percentage of white suckers (12%), both signs of physical and chemical habitat deterioration (Barbour et al., 1999). Furthermore, this site had the greatest percentage of individual with DELT anomalies (43%) of all main stem sites in the watershed, suggesting possible subacute effects of chemical pollution.

5.2.3.4. DCD1880

The poor quality fish assemblage at this site was characterized by the high percentage of White suckers (15%), the dominance of generalist feeders (69%), lack of sensitive taxa, and high occurrence of individuals with DELT anomalies (25%). A total of 860 fish representing 22 species were collected at DCD1880; however, only 16 species were resident and non-stocked. Of 22 species collected, three species accounted for 72% of fish abundance and 74% of the total biomass (23.4 kg). Blacknose dace (*R. atratulus*), a highly tolerant species, comprised 41% of the fish assemblage and American eel (*A. rostrata*) was responsible for 37% of the site's biomass.

Tolerant taxa dominated this site and only one intolerant species (excluding stocked trout) was present. The Modified Index of Well-Being (11.21) and Shannon Diversity Index (1.91) values fell well below reference condition. The IBI score (28 out of 50) represented a fish assemblage of poor biological integrity. Local angler groups stock this portion of Darby Creek for an annual trout tournament and the potential effects of these introductions on native fish communities are uncertain.

5.2.3.5. DCD2138

Site DCD2138, positioned in a 2nd order reach of Darby Creek mainstem, was the uppermost site in Darby-Cobbs Watershed. This site had the lowest biomass and second lowest fish abundance in Darby Creek. A total of 375 individuals representing 12 species were collected during 70 minutes of electrofishing in 535.1 m^2 of stream surface area. Generalist feeders dominated this site (67%), but the percentage of top carnivores (20%) was much greater than expected for a stream this size. The piscivores, Rock bass (*Ambloplites rupestris*) and American eel (*Anguilla rostrata*), made up 78% of the biomass at this site. Furthermore, Blacknose dace (*R. atratulus*), a highly tolerant species, comprised 28% of the fish assemblage.

DCD2138 received an IBI score of 30 (out of 50), placing this site in the “fair” category. The Modified Index of Well-Being (10.26) value falls well below reference condition, but Shannon Diversity Index (2.12) is directly comparable to reference conditions. Over half of all individuals collected were tolerant and the fish assemblage was skewed towards a tolerant, generalist feeding community, suggesting a moderate level of chemical and/or physical perturbation.

5.2.4. Darby-Cobbs Tributary Sites

5.2.4.1. DCI010

This site was located on Indian Creek, a second order tributary to Cobbs Creek, and was the only tributary in which a fish assessment was conducted. Only six species were collected, compared to 18 species found at a second order reference stream. Species richness typically decreases with increased degradation. Common shiner (*L. cornutus*) and Blacknose dace (*R. atratulus*) were the most abundant species and White sucker (*C. commersoni*) constituted over half of the biomass. Intolerant taxa and benthic insectivorous species were absent. The trophic structure was biased towards generalist feeders (93%) and very few top carnivores were present. This site had the highest percentage of fish with disease and anomalies in Darby-Cobbs Watershed; more than half of all fish were affected. The extremely high incidence of DELT anomalies is symptomatic of a stressed community typically found downstream of point source pollution (Barbour et al., 1999).

Low species richness and composition scores combined with uneven trophic structure yielded an IBI score of 22 (out of 50), which is characteristic of a fish assemblage with “poor” biological integrity. To further support this point, DCI010 had the lowest

Modified Index of Well-Being (9.32) and second lowest Shannon Diversity Index (1.36) in the Darby-Cobbs Watershed. Also, this site had the maximum percentage of White suckers in the watershed (17%), indicative of degraded stream conditions.

5.2.5. Darby-Cobbs Tidal Sites

5.2.5.1. DCC037

Site DCC037 is located near the head of tide on the main stem of Cobbs Creek and was sampled at low to incoming tide. A total of 1710 individuals representing 25 species (including exotic and non-resident) were collected during 40.13 minutes of electrofishing in 1349.42 m^2 of stream surface area. This site had the greatest species richness, catch per unit effort (42.62 fish/min.) and second highest number of individuals collected in Darby-Cobbs Watershed. Despite the high diversity and abundance, two highly tolerant species, Banded killifish (*F. diaphanus*) and Mummichog (*F. hete*roclitus), comprised over 70% of the total fish assemblage. Furthermore, over 80% of all fish collected at DCC037 were tolerant of poor water quality, suggesting chemical and/or physical perturbation. It is important to note, however, that this is the only site in Cobbs Creek that contained an intolerant species (*Hybognathus regiu*s).

Due to the lack of tidal reference streams, an Index of Biotic Integrity (IBI) could not be determined. However, various metrics were used to estimate biological integrity. DCC037 had the highest percentage of top carnivores and the lowest percentage of individuals with disease, eroded fins, lesions, tumors, and anomalies (DELTA) in Cobbs Creek Watershed. Also, Modified Index of Well-Being (10.78) and Shannon Diversity Index (1.77) values indicate a fair quality fish assemblage.

5.2.5.2. DCD630

Site DCD630 is located near the head of tide on the main stem of Darby Creek and was sampled at low and incoming tide. A total of 1836 individuals representing 25 species (including exotic and non-resident) were collected during 47.34 minutes of electrofishing in 1366.7 m^2 of stream surface area. This site had the greatest species richness, catch per unit effort (42.62 fish/min.), density (1.34 fish/m^2), and number of individuals collected in the Darby Watershed. Despite high diversity and abundance, four species comprised over 70% of the total fish assemblage and 83% of total biomass. It is important to note, however, that this is the only site in Darby-Cobbs Watershed that contained two intolerant taxa (*Hybognathus regiu*s and *Exoglossum maxillingua*). Also, two benthic insectivorous species, five water column species and 11 cyprinid species were collected at DCD630.

Due to the lack of tidal reference streams, an Index of Biotic Integrity (IBI) could not be determined. However, various metrics were used to estimate biological integrity. Site DCC037 had the lowest proportion of generalist feeders (24%), most insectivores (68%), and lowest percentage of individuals with DELT anomalies in Darby-Cobbs Watershed. Also, this site had the highest Modified Index of Well-Being (11.78) in the watershed, indicating a good quality fish assemblage. DCD630 was only one of two sites that contained more moderately tolerant (62%) than tolerant (37%) fish.

5.3. Habitat Assessment

5.3.1. EPA Habitat Assessment Overview

Habitat impairments in Darby-Cobbs Watershed are numerous, mirroring those of other urban stream systems assessed by PWD. First and foremost, stream habitats within Darby-Cobbs Watershed are impaired due to effects of stormwater. Preponderance of impervious surfaces, particularly within Cobbs Creek Watershed, has diminished baseflow and caused small streams to exhibit increasingly “flashy” hydrographs in response to rain events (Appendix C). According to a baseflow separation analysis based on 27 years of flow data at USGS gauge 01475550, baseflow currently accounts for only 42% of mean total yearly flow from the Cobbs basin. In contrast, Darby Creek Watershed is less affected by impervious surfaces and has a yearly flow regime similar to the reference stream.

Exaggerated storm flows typical of urbanized watersheds result in erosion of banks and deposition of sediment in pools and on point bars. Many stream reaches in the watershed have been excessively overwidened and downcut; channels have been enlarged so severely that baseflow does not completely fill the channel or adequately cover riffle substrates. In many reaches, floodplain disconnection exists during almost all flow conditions. Due to ongoing erosion, nearly all stormwater forces are applied to a bare soil interface. Streambank erosion has also exposed sewer infrastructure (e.g., Manholes, interceptor sewers) increasing susceptibility of infrastructure to damage and leaks.

Fish and benthic macroinvertebrate sampling reinforced the view that stormwater flow is probably the most important factor shaping biological communities in most of the watershed. Stream organisms ill-adapted to extreme flows may be washed downstream and displaced from their optimum habitat. Erosion and sedimentation may decrease reproductive success of invertebrates and fish by washing away eggs, or alternately, covering eggs with sediment. Fish and benthic macroinvertebrate community responses to habitat modification were not consistent throughout the watershed. Serious effects were observed in Cobbs Creek and its tributaries, while upstream reaches of Darby Creek were similar in some aspects to reference conditions. Lower reaches of Darby Creek showed contrasting responses overall.

Common invertebrates of the most degraded portions of Cobbs and Lower Darby Creek have morphological or behavioral adaptations to increased stream velocities. Chironomid midges construct tubes made of silk that are firmly attached to stream substrates. The insect's body may be completely retracted within this protective tube. Similarly, hydropsychid caddisflies construct silk nets, which serve as refugia during exaggerated flow conditions. Free-living shredder taxa (e.g., case building caddisflies and tipulids) were not present at most degraded sites, and very few species with external gills were present.

Dominant fish in degraded reaches also exhibit morphological and behavioral adaptations to increased stream velocities. Blacknose dace and white suckers are generally more rounded in body cross-section (i.e., dorsoventrally flattened) than many other stream fish. This body shape may allow these fish to better hug the stream bottom or slope, thereby avoiding the highest velocities. American eels were dominant (in terms of biomass) at many sites. These fish have the ability to completely bury themselves in sediments, enter small crevices, and easily extract themselves from tight spaces by reversing their undulations and swimming backwards. American eels also have the advantage of reproducing at sea, only entering the watershed once they are able to swim freely. All other fish in the watershed are vulnerable to severe flows or smothering by silt during their embryo or larval stage.

Continuous DO and pH data suggest that periphyton biomass and community structure change fundamentally following severe storm events. Dense periphyton carpets are found in slower water throughout the watershed. While these algae have not been investigated taxonomically, filamentous greens (e.g., *Cladophora* sp.) appear to dominate the biomass of the periphyton climax community. Soil erosion and runoff, particularly during smaller storm events, may be a significant source of the phosphorus that drives these algal blooms.

Instream habitat was evaluated with EPA protocols at seventeen (n=17) sites targeted for benthic macroinvertebrate sampling. A much more detailed reach ranking survey, based in fluvial geomorphological principles, was conducted for Cobbs Creek, and West and East Indian Creeks in 2000. This document, entitled "Cobbs Creek Geomorphologic Survey-Level II: Guiding Principles for Fluvial Geomorphologic Restoration of Cobbs Creek" is available from PWD's Office of Watersheds.

5.3.2. Comparisons to Reference Site

Habitat features at Darby-Cobbs watershed sites were compared to those of the reference sites located in nearby Chester County. Mainstem and third order tributary sites were compared to French Creek reference sites, located in Coventry Township, Chester County, PA (Appendix A). Tributary sites, second order or less, were compared to Rock Run, a tributary to French Creek located in Coventry Township, Chester County, PA (Appendix A). Five Darby Creek sites had greater habitat scores than the reference site, indicating good habitat conditions along mainstem reaches of Darby Creek.

5.3.3. Factor Analysis

Principal components analysis (PCA) in Statistica (Statsoft, 1998) was used to reduce the number of variables needed to explain the variation between scores for 13 different habitat attributes among Darby-Cobbs sites. The first factor extracted accounted for 53% of the variance in the data matrix. Habitat attributes with high loading values for factor one included epifaunal substrate, velocity/depth regime, channel flow status, bank vegetative protection, and all pool attributes (Appendix E). The second factor extracted accounted for 19% of the variance, for a cumulative total of 72% variance explained. No habitat attributes showed high loading scores for factor two (Appendix E). An ordination plot of Darby-Cobbs sites and three reference sites showed the sites distributed widely across PCA axis one, with five highest-rated upstream Darby Creek sites grouped closely between French Creek and Rock Run reference sites.

Overall, the placement of sites along axis 1 correlated closely with total habitat scores and relative comparability to the reference sites (Figure 18). PCA axis 2 was not particularly useful, except for weak negative associations with channel alteration and riparian zone width and positive associations with frequency of riffles, sedimentation, and embeddedness.

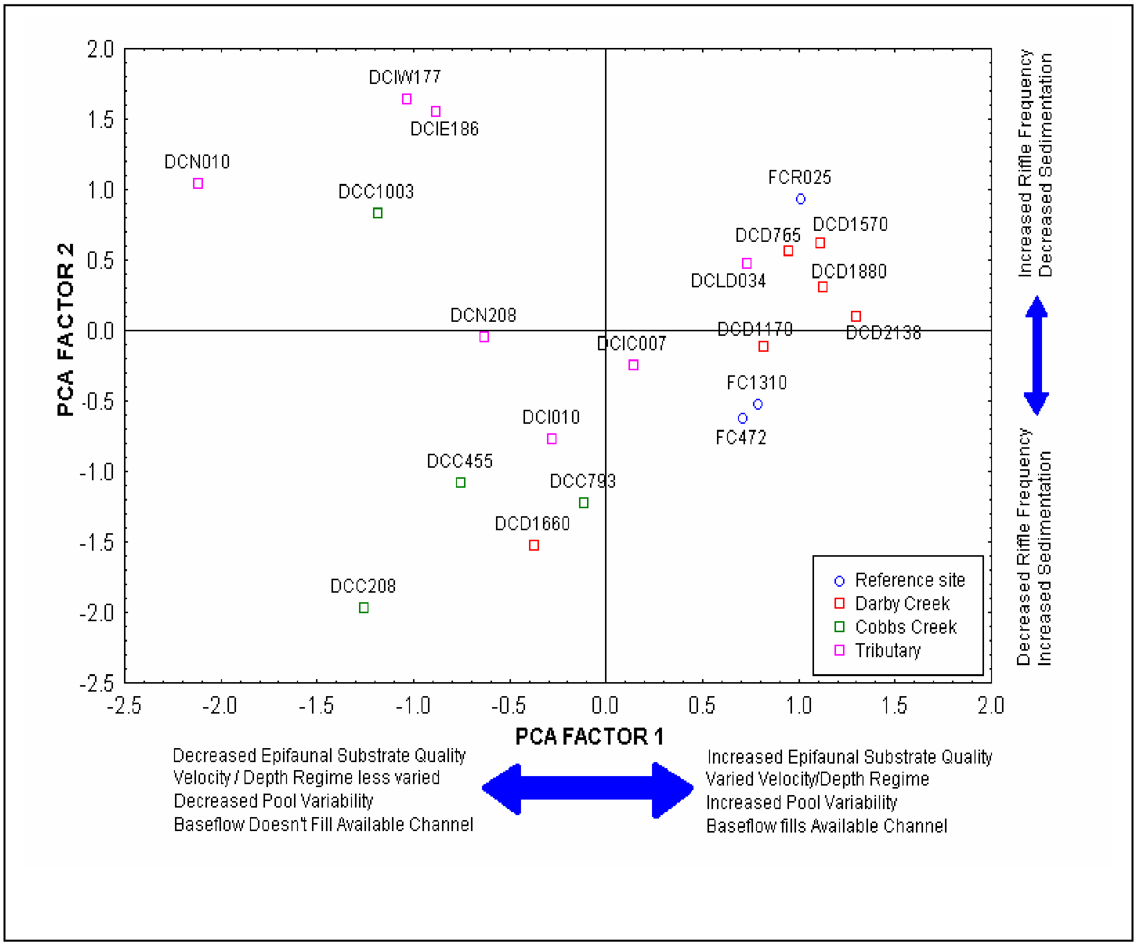

Figure 18. Principal Components Analysis ordination plot of 17 monitoring sites and 3 reference locations.

5.3.4. Individual Site Characterizations

5.3.4.1. Cobbs Creek Mainstem Sites

5.3.4.1.1. DCC208

Site DCC208 received a habitat assessment score of 127.5, and the habitat was deemed "partially supporting" (Figure 19). DCC208 was heavily impacted by sediment deposition (i.e., sand). The inorganic substrate of the site was 40% sand, and 60.0% of the macrohabitat was pools. Sedimentation, embeddedness, channel sinuosity, pool substrate, and epifaunal substrate all received marginal scores. These observations support the conclusion that the site was heavily impacted by stormwater. Poor scores were given for vegetative protection, bank stability and the left bank riparian zone. Overall habitat quality was marginal, with limited potential to support diverse aquatic communities.

5.3.4.1.2. DCC455

The habitat assessment score at site DCC455 was 142.5. This score represents a 75.2% comparison to the reference and classifies it as "supporting". DCC455 is just upstream of DCC208 and exhibited similar habitat impairments. The macrohabitat was a relatively even mix of pools, riffles and runs, but there was heavy sediment deposition throughout the stream reach (40% of substrate was sand). All of the habitat parameters were scored suboptimal or marginal. The stream banks were moderately stable, but were dominated by invasive emergent vegetation (Japanese knotweed). The riparian zone on the right bank was marginal due to areas mowed up to the stream bank. A strong sewage odor was present at the time of the habitat assessment.

5.3.4.1.3. DCC793

Site DCC793 received a habitat assessment score of 163.5, which represents an 86.3% comparison to the reference site ("supporting" designation). Macrohabitat at the site was well distributed among riffles, runs and pools, and the stream substrate was diversified, as well. Epifaunal substrate and available cover in the stream reach was optimal. The width of the riparian zone along the left bank was also favorable. Most other habitat features at DCC793 were suboptimal. Similar to other assessment sites on Cobbs Creek, moderate sand deposition was present throughout the stream reach. Most of the pools within the site were large and deep with a primarily sandy substrate. The riparian vegetative zone was much wider along the left bank of the stream than the right bank. Stability, however, was greatly reduced on the left bank where high flows had previously eroded much of the bank. The increased erosion of the left bank may be due to channel sinuosity at this location, which directs flow in that direction. Habitat at site DCC793 also may have been impacted by an exposed sewer line that crossed the stream at the upstream boundary of the assessment site.

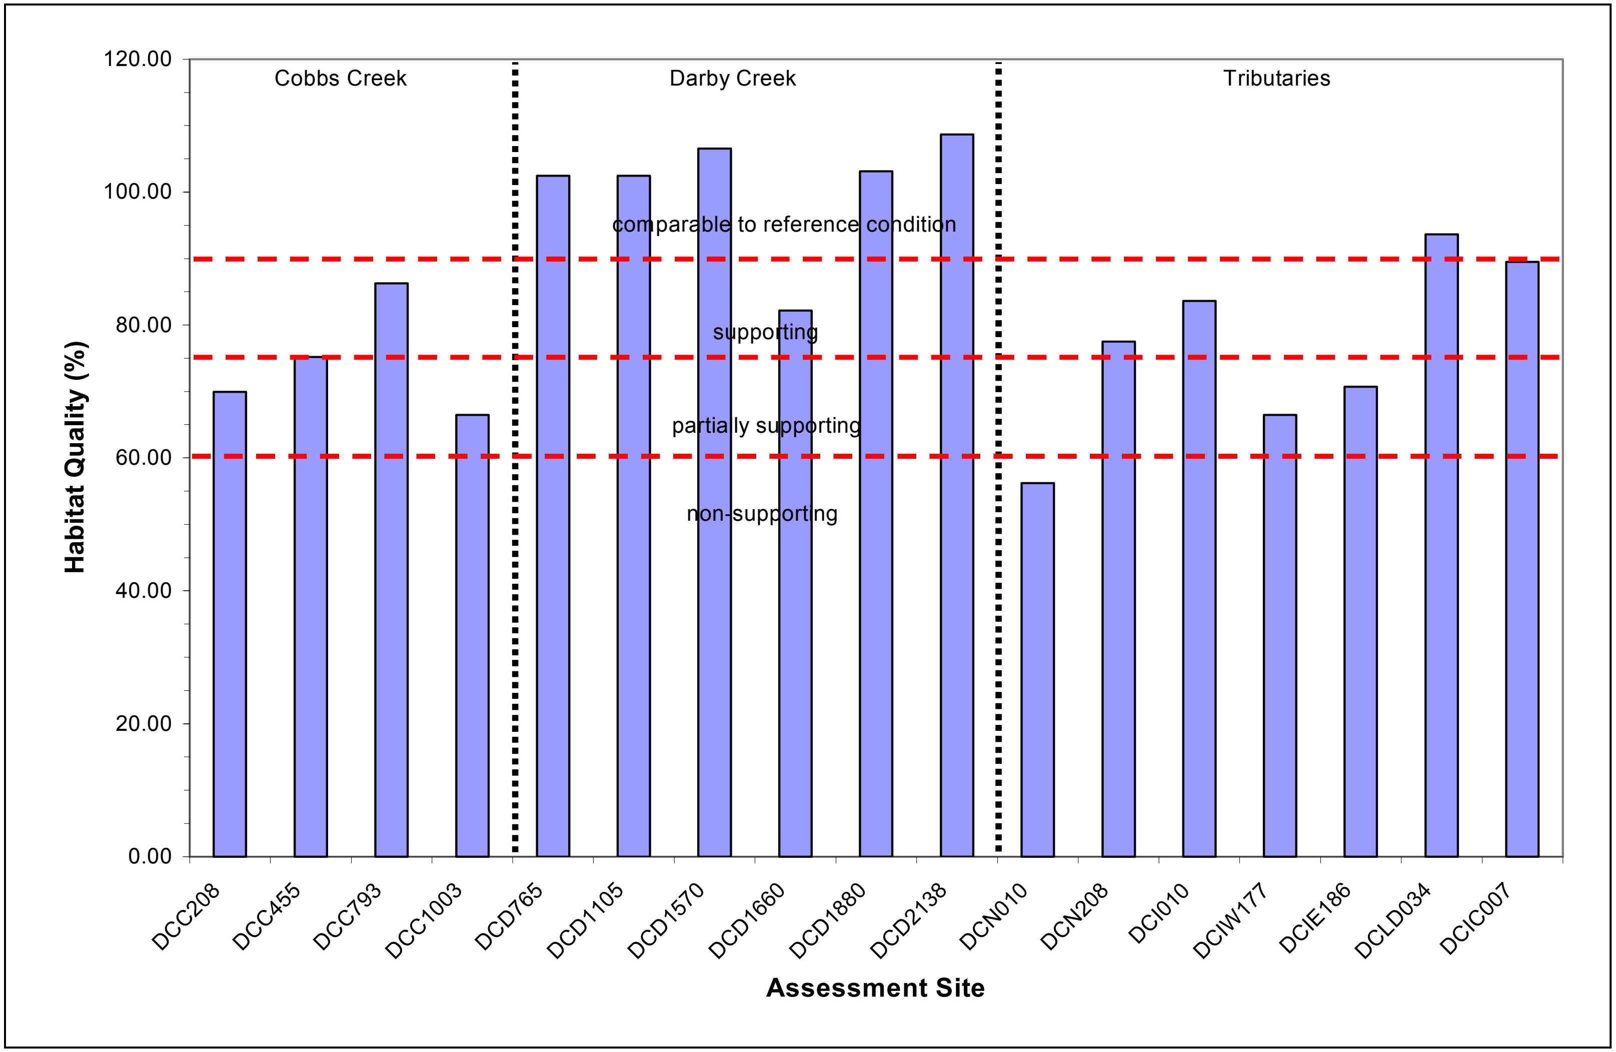

Figure 19. Habitat quality of 17 assessment sites in Darby-Cobbs Watershed. Values are represented as percent comparability to reference conditions.

5.3.4.1.4. DCC1003

Site DCC1003 received a habitat assessment score of 126.0. The site had the lowest score of all mainstem Cobbs Creek sites and was designated "partially supporting". The area surrounding the site was primarily residential with maintained lawns. The epifaunal substrate and available cover, pool substrate, and pool variability all received marginal scores. Evidence of heavy erosion was present throughout the site, and stream banks were moderately unstable. The riparian zone was insufficient, and vegetative protection was marginal. The stream was altered in areas by channelization, and the channel lacked sinuosity. The site appeared highly susceptible to erosion during periods of increased flow.

5.3.4.2 Darby Creek Mainstem Sites

5.3.4.2.1. DCD765

Site DCD765 received a habitat assessment score of 188.5, and the habitat was designated "comparable to reference" (102.4% comparison). Optimal habitat scores for epifaunal substrate and available cover, pool substrate characterization, pool variability, channel flow status, embeddedness, and velocity/depth regime all contributed to the site's excellent habitat score. The site also had an even combination of substrate components. All other condition categories were scored as suboptimal, except for the riparian vegetative zone width along the right bank, which was poor due to the presence of a mowed recreational area adjacent to the creek's right bank. A small area of stream bank was stabilized with rip-rap on the left bank. There was also moderate deposition throughout the stream reach.

5.3.4.2.2. DCD1105

The habitat assessment score of site DCD1105 was 188.5. This represents a 102.4 % comparison to the reference site and deems the habitat "comparable to reference". The habitat features of DCD1105 are very similar to that of DCD765. All of the habitat parameters were rated optimal or suboptimal except for the left bank riparian corridor, which received a marginal score due to an access road and mowed area that parallel the creek. The stream had an even distribution of macrohabitat types (i.e., pool, riffle, run). Both banks were relatively stable with decent vegetative protection.

5.3.4.2.3. DCD1570

Site DCD1570 received a habitat assessment score of 196.0, which represents a 106.5% comparison to the reference ("comparable to reference"). The macrohabitat at the site was primarily riffle (50%). The substrate components were mostly cobble and gravel (40% each), and there was light sand deposition. The predominant land use surrounding DCD1570 was forested area, but I-476 (i.e., the Blue Route) parallels the right bank of the stream. The highway was the main factor for the right bank's low riparian vegetative zone width score. DCD1570 had potential to be impacted by storm water run-off from the interstate highway. The channel sinuosity was marginal, but there were frequent riffles along the stretch.

5.3.4.2.4. DCD1660

The habitat score at DCD1660 was 156.5—an 82.2% comparison to the reference site ("supporting" designation). Most habitat parameters were scored suboptimal or marginal. Inorganic substrate was composed of 40% sand, and the site exhibited evidence of heavy sand deposition. The right bank at DCD1660 was moderately unstable, and the stream reach had low sinuosity. DCD1660 had the lowest habitat score of all mainstem Darby Creek sites.

5.3.4.2.5. DCD1880

Site DCD1880 received a habitat assessment score of 196.5, and the habitat was deemed "comparable to reference" (103.1% comparison). Most habitat attributes were scored optimal or suboptimal. The vegetative zone width on the left bank, however, was poor due to an adjacent pasture that was mowed close to the bank of the creek. An instream habitat restoration project was constructed upstream of the assessment site where submerged logs, snags and other stable habitat/fish cover features were installed along the banks to allow for greater colonization and maintenance of fish populations.

5.3.4.2.6. DCD2138

The habitat at site DCD2138 scored 207.0, and the site was designated "comparable to reference" (108.6% comparison). The site received the highest habitat score of all Darby-Cobbs assessment sites. DCD2138 is the farthest upstream assessment site on Darby Creek, and the site is located within a Brandywine Conservancy property. Habitat parameters were scored optimal or suboptimal. Macrohabitat types and inorganic substrate were both evenly distributed. Banks were stable, and a well-developed riparian corridor was present. Stable banks and not a lot of sedimentation suggest that the site had little impact from stormwater run-off and would have the potential to support a diverse biotic community.

5.3.4.3. Darby-Cobbs Tributary Sites

5.3.4.3.1. DCN010

Habitat assessment at site DCN010 returned a score of 106.5. The site was only 56.2% comparable to the reference site, and habitat was deemed "non-supporting". DCN010 had the lowest habitat score of all assessment sites. Field observations included a sewage odor and slightly turbid water. Inorganic substrate in the forms of boulder, cobble, and gravel was predominantly artificial (i.e. construction debris). The site was devoid of pools and had poor epifaunal substrate and available cover. Due to an overwidening of the stream channel, stream flow no longer reached the stream banks, and sediment bars were left exposed. The banks were moderately stable due to shoring structures (i.e. rip rap) and marginal vegetative protection.

5.3.4.3.2. DCN208

The assessment site at DCN208 scored 146.5 and was a 77.3% comparable to the reference site ("supporting" designation). Most habitat attributes were scored suboptimal or marginal. Field observations included heavy periphyton growth and a sewage odor emanating from the substrate. There was heavy local erosion with moderate sand deposition. Macrohabitat in the stream was predominantly riffle (50%), and substrate was evenly distributed. Suboptimal vegetative protection left the majority of the banks moderately unstable. Trees and Japanese knotweed were the predominant vegetation at DCN208.

5.3.4.3.3. DCI010

Site DCI010 received a habitat assessment score of 158.5, which classified the habitat as "supporting" (83.6% comparison). The site received suboptimal and marginal scores for most habitat condition parameters. Still, channel alteration at the site was optimal as the stream had retained a natural pattern and exhibited fair sinuosity. Cobble and sand dominated the substrate components, and evidence of erosion was moderate throughout the assessment site. The left bank was somewhat unstable, which could be a direct result of stormwater pulses.

5.3.4.3.4. DCIW177

Site DCIW177 received a habitat assessment score of 126.0. The habitat was designated "partially supporting", with a 66.5% comparison to the reference site. Most habitat parameters were scored suboptimal or marginal, with the exception of pool variability and riparian zone width which received "poor" scores. Pools composed only 20.0% of the macrohabitat type, and most of the pools present at DCIW177 were small and shallow. The riparian zone width was very much insufficient along both banks. Various sections of the stream bank within the assessment site were armored with rip-rap to protect against erosion. Excessive erosion rates in the stream segment may have been due to the lack of a satisfactory riparian area.

5.3.4.3.5. DCIE186

The assessment site at DCIE186 received a habitat assessment score of 134.0 which was a 70.71% comparison to the reference site ("partially supporting" designation). Frequency of riffles received an optimal score as riffles composed 50.0% of macrohabitat in the stream. All of the other habitat parameters were scored suboptimal or marginal. Lankenau Hospital is adjacent to the right bank of the assessment site and maintains a mowed field along this bank, decreasing the site's riparian vegetative zone score. Similar to West Branch Indian Run, only 20% of macrohabitat type was pools, and the pools at DCIE186 were all small and shallow.

5.3.4.3.6. DCLD034

The habitat assessment score at site DCLD034 was 177.5 and was 93.7% comparable to the reference site. Habitat conditions at the site were generally scored optimal or suboptimal. The stream segment had numerous riffles, and stream sinuosity was decent. There was moderate erosion along the stream banks and evidence of deposition in the pools. These latter attributes may be due to the lack of a sufficient riparian zone along the stream reach. The vegetative riparian buffers on both sides of the creek were less than desirable due to a maintained field cut short along both banks. The riparian zone width received a marginal score despite the "comparable to reference" designation of the site.

5.3.4.3.7. DCIC007

Site DCIC007 received a habitat assessment score of 170.5, which resulted in a "supporting" designation (89.5% comparison). Vegetative protection on both banks was scored optimal. Vegetation disruption was not evident, and banks were well covered with trees and understory shrubs. Most habitat parameters, however, were scored as suboptimal or marginal. The site was adversely affected by sediment deposition in the form of sand and by moderate erosion.

5.3.5. Habitat Suitability Indices

5.3.5.1. Overview

Habitat Suitability Indices (HSI) developed by The U.S. Fish and Wildlife Service (USFWS) were applied to sites in Darby-Cobbs Watershed targeted for fish sampling. These models integrate the expected effects of a variety of environmental, physicochemical, and hydrological variables on representative native species, as well as species of special environmental or economic concern. As stream restoration activities recommended under Target B of the watershed management plan are implemented, these indices will allow for habitat improvements to be measured quantitatively. Because freshwater fish communities are shaped by myriad inter-related environmental and ecosystem interactions and stressors (e.g., habitat degradation, flow modification, predation, competition, disease, invasive species, toxic substances, prey population dynamics, etc.), beneficial effects of habitat restoration may be obscured by other factors. Numeric HSI allow for habitat to be evaluated independently of these confounding factors.

While it may be possible to model habitat suitability for most (or even all) species found in a waterbody, this level of analysis is probably unnecessary. Habitat requirements of many species are so poorly understood that HSI have not been developed or are only generally applicable. Furthermore, many groups of species (e.g., sunfish) share many habitat requirements, obviating the need to model habitat suitability for each individual species. Best results may be obtained when HSI of a small number of sensitive, recreationally-sought, or economically important species of interest are considered.

5.3.5.2. HSI Model Selection

HSI models for seven species were selected for Darby-Cobbs Watershed. Models were chosen to reflect the range of habitat types and attributes needed to support healthy, naturally-reproducing native fish communities and provide recreational angling opportunities in non-tidal portions of the watershed. Five native minnow species were selected for HSI analysis: Blacknose dace (*Rhinichthys atratulus*), Common shiner (*Luxilis cornutus*), Creek chub (*Semotilus atromaculatus*), Fallfish (*Semotilus corporalis*), and Longnose dace (*Rhinichthys cataractae*). Of these, *R. cataractae* is not known to occur in Darby-Cobbs Watershed. However, this species' known affinity for stable, high quality riffle habitats is reflected in its HSI, prompting inclusion in the analysis as an important indicator of those macrohabitat features. The Longnose dace HSI may be considered a surrogate indicator of habitat suitability for other riffle species (e.g., darters) for which no HSI are available.

Two centrarchid fish, Redbreast sunfish (*Lepomis auritus*), and Smallmouth bass (*Micropterus dolomieu*), were included in the analysis. These species are tolerant of warmer water temperatures and require extensive slow, relatively deep water (i.e., pool) habitats with appropriate cover or structure to achieve maximum biomass. While black basses (*M. dolomieu* and its congener *M. salmoides*) are not native to southeastern Pennsylvania, they occupy the top carnivore niche and are among the most sought-after freshwater game fish in water bodies where they occur. Moreover, the only other large-bodied piscivores known to occur in non-tidal portions of Darby-Cobbs Watershed are American eels, native catadromous fish for which no HSI has been developed, and three salmonids (Rainbow trout, *Oncorhynchus mykiss*; Brown trout, *Salmo trutta*; and Brook trout, *Salvelinus fontalis*), "coldwater" species, maintained in the watershed solely through stocking.

5.3.5.3. Smallmouth Bass HSI Model

The small number of *M. dolomieu* (n=10) collected from non-tidal reaches of Darby-Cobbs watershed hindered data analysis. However, mean HSI score of three Darby Creek sites where these fish were collected was 0.82, while mean HSI score of the 6 sites where fish were not collected was 0.61. Sites where fish were collected had higher HSI scores than sites where fish were not collected in all cases. Correlations between HSI score and Smallmouth bass abundance and biomass were weak, largely due to lack of data. Results of HSI analyses (Table 10) corroborated findings of other research, particularly general habitat and continuous water chemistry analyses.

Table 10. Smallmouth bass HSI individual variable scores, total HSI score and fish data by site.

Habitat Variable	DCC208	SI	DCC455	SI	DCC793	SI	DCD765	SI	DCD1170	SI	DCD1570	SI	DCD1880	SI	DCD2138	SI	FC472	SI

No smallmouth bass were collected from Cobbs Creek. Sites DCC208 and DCC455 had the lowest HSI scores in the watershed and were limited by dissolved oxygen concentration, cover, and pool substrate composition (Table 10). Site DCC793 was limited by stream gradient and depth of pools, indicating unsuitably high stream velocities in pool habitats. Sites in Cobbs Creek generally exhibited unsuitable characteristics (e.g., lack of cover, decreased substrate size, or increased velocity) in pool habitats; these factors force bass to expend more energy acquiring food. Competition from American eels and the frequency and magnitude of severe storm flow conditions cannot be discounted as factors making Cobbs Creek less suitable for Smallmouth bass.

Ten smallmouth bass individuals were collected from the three downstream-most sites within the non-tidal portion of Darby Creek watershed. The lack of Smallmouth bass at upstream sites is to be expected, as this species requires deeper, calmer water than is typically found in first- or second-order stream sites. It should be noted that Darby Creek watershed is generally less affected by urbanization than Cobbs creek watershed, and has more of its historic tributaries intact. Stream order and river mile-based comparisons between the two watersheds are probably not very meaningful. Within Darby Creek watershed, sites where Smallmouth bass were not collected had, in some cases, pool structure, substrate size and or cover numerically similar to downstream sites, suggesting that distribution may be related stream size.

Like most centrarchids, Smallmouth and Largemouth basses are able to acclimate to brief periods of suboptimal dissolved oxygen concentration. With few exceptions, such as sites in which DO concentrations may frequently drop below 3mg/l for extended periods, or sites in which spawning substrates are chronically anoxic with Hydrogen sulfide (H_2S) present, Smallmouth bass distributions are probably not strongly governed by DO concentrations. Furthermore, many centrarchid species' thermal preferenda are higher than temperatures typical of 2nd to 4th order streams in southeast PA. Most species are known to reach their maximum size in the non-temperate Southern U.S., growing fastest in lentic habitats where conditions are suitable for growth year-round and specific management techniques are employed. HSI model temperature output (Table 10) reflects the fact that optimum temperatures are seldom reached in Southeastern PA.

Stream restoration activities that increase the amount of instream and overhanging cover, or activities that create, expand or improve pool habitats probably will result in increased habitat suitability for Smallmouth bass. Re-meandering of the stream channel, installation of flow diverters such as rock vanes and J-hooks, as well as the creation of undercut banks through log sill cribbing and cantilevered banks should also enhance habitat for Smallmouth bass and forage fish by establishing low velocity refugia during storms.

Infrastructure assessments, inspections, and dry weather pollution source trackdown activities will likely reduce the severity of water quality (i.e., DO and pH related) impacts on HSI scores at some sites, particularly DCC208 and DCD765. It is unlikely that habitat impairment due to frequent water level fluctuations and the effects of erosion and sedimentation will be ameliorated in the near future without significant investments in streambank restoration and basin-wide implementation of stormwater BMPs.

5.3.5.4. Redbreast Sunfish HSI Model

As a generalist species, Redbreast sunfish (*Lepomis auritus*) are adaptable to a range of habitat attributes and may feed opportunistically upon a variety of prey types. Most SI variable expressions in this species' HSI include a large range of highly suitable values (or large area "under the curve"). HSI scores (Table 11) did not generally correlate well with observed *L. auritus* abundance or biomass. Limiting factors included pH, vegetative cover, temperature, and substrate-related variables, but the discriminatory power of the HSI was probably limited by lack of variability among sites.

Site DCC793 received the highest HSI score in the watershed, yet only 1 Redbreast Sunfish was collected at this site. DCC793 was the only site in the watershed that had a sizeable population of Pumpkinseed sunfish (*L. gibbosus*). At most other sites, Redbreast sunfish were more abundant than other sunfish species, though a longitudinal trend in sunfish species diversity increasing from downstream to upstream was observed in Darby Creek. Sunfish species' habitat needs are generally similar; there was no obvious explanation for the change in species relative abundance. Somewhat better correlations resulted from comparison of a modified version of the HSI to grouped *Lepomis* spp. abundance and biomass (Table 12).

pH limitation was indicated at sites DCD765 and DCC208, where pH fluctuations due to algal activity occasionally result in pH >9.0. The Redbreast sunfish HSI model was probably not designed to be used with the least suitable value picked from a continuous database. Because fish can avoid areas of unsuitable pH when they occur infrequently, it would be more suitable for the model to account for how frequently unsuitable pH conditions occur (e.g., take the 90th percentile value, disregard outliers, etc.).

Likewise, summer temperature during spawning may poorly reflect habitat suitability for this species. The HSI was developed for an industrial cooling water investigation in the southern U.S.; temperature parameters should not be expected to be "optimal" in the temperate northeast. Fish collected at upstream sites with less suitable spawning temperatures may spawn at warmer downstream locations or in sunnier, sandy backwaters that are not accounted for in the data.

Observations made during electrofishing surveys suggested that Redbreast sunfish (and congeneric sunfishes) are most frequently found associated with cover, which can be difficult to measure quantitatively. Cover measurements included in the Redbreast Sunfish HSI were normalized to a scale of 0-25 from EPA Habitat assessment variable 1: Epifaunal Substrate and Available cover (Section 5.3.1.). As most sites in Darby-Cobbs Watershed are known to be deficient in vegetative cover, the "% vegetative cover" variable was estimated as half this normalized Epifaunal substrate value (e.g., EPA Epifaunal Substrate and Available Cover score =20, HSI Cover % =25, HSI vegetative cover % = 12.5.)

EPA habitat assessment techniques may not be most appropriate to habitat investigations for this species. For example, the EPA habitat technique stipulates that "transitional and new fall" woody debris (e.g., tree limbs and branches) should be disregarded. However, this type of cover is often quite common (and largely beneficial) in urbanized streams that have forested margins and eroding banks, such as Cobbs and Darby Creeks. Though "transitional and new fall" woody debris may not be permanent at a site, it may persist for a year or more, particularly when aggregations form along stream margins. The microhabitat within an aggregation of this woody debris is very complex when compared to most types of permanent hard cover, and qualitative observations during electrofishing surveys suggest that tree limbs and branches are beneficial and a preferred cover type for many fish.

Of course, large aggregations of woody debris may threaten the structural integrity of bridges, culverts and other infrastructure. One of the chief functions of PWD's Waterways Restoration Unit (WRU) is to remove this type of debris. As stream segments are restored, a careful balance should be struck between cleaning the stream of trash and debris and overzealous elimination of beneficial natural habitat features. Another excellent solution to this problem is the selective installation of staked or cabled trees and large tree limbs, Christmas tree bundles, willow stakes, root wads, and, in still water, manufactured fish habitat structures.

5.3.5.5. Blacknose Dace HSI Model

The Blacknose Dace HSI model produced fair results. Site DCC793 had the highest HSI score in the watershed (0.85), as well as the greatest abundance and largest biomass. Sites DCC208 and DCD765 scored 0.15, and (respectively) had the lowest and second lowest abundance and biomass in the watershed. Aside from these extreme values, the HSI model was not a good predictor of Blacknose dace abundance or biomass (Table 13). The Blacknose dace is classified as a tolerant fish. In fact, along with *C. commersoni*, *A. rostrata*, and *Fundulus* spp., Blacknose dace is one of the most common piscine inhabitants of degraded streams in southeast PA. Despite its tolerance of degraded stream conditions, the species' HSI model is quite complex- it includes 16 raw variables, six life requisite components, as well as limiting and compensatory mechanisms.

Limiting variables identified by the model included stream width, stream margin substrate composition, and pool substrate composition. As some of these variables were estimated, results of the HSI model are only as good as the estimates. The model was found to be too sensitive in the range of stream gradient values observed and was adjusted slightly to exclude these effects, which would have been limiting at 5 of 9 sites. While greater stream gradients may be preferred, this species is routinely collected in sites of lower gradient. An overall pattern of increasing abundance from downstream to upstream was evident.

Blacknose dace is a stocky fish, moderate in body form and somewhat rounded (dorsoventrally flattened) in comparison to other, more vertically compressed minnows.

Hydrodynamics may play a part in its adaptability to a variety of flow conditions and, in part, explain its abundance at degraded sites that are periodically exposed to intense scouring flows. Other minnow species may not be as well adapted at surviving these types of flows. As stormwater BMPs and streambank restoration proceed under Target B of the watershed management plan, perhaps these hydrologically-impaired sites will begin to support more diverse fish communities rather than being dominated by three or four tolerant species.

5.3.5.6. Creek Chub HSI Model

The Creek Chub HSI model produced satisfactory results overall. Sites where no fish were collected had the lowest HSI scores in the watershed (Table 14). The site with the highest HSI score had the greatest abundance and biomass in the watershed. While biomass increased at all sites as HSI scores increased, and abundance showed the same pattern in 8 of 9 cases, the HSI model's scale of resolution was greatly compacted. Five sites had HSI scores between 0.80 and 0.88, while the two lowest scores were 0.4 and 0.69. When the lowest score corresponding to zero fish collected was taken as the origin rather than (0,0), the strongest correlations between (log-transformed) HSI scores and fish biomass and abundance were observed (R^2 values 0.94 and 0.93, respectively).

With 20 habitat and water quality variables and 5 life requisite components, the Creek Chub HSI model was most complex of the models used. As many water quality variables returned optimum suitability values (i.e., SI= 1.0), and most had limited discriminatory power, the model could be made simpler without sacrificing predictability. It is likely that if a smaller number of critical habitat variables were focused on, the model could have better resolution over a larger scale of final HSI scores.

5.3.5.7. Common Shiner HSI Model

Common shiner HSI model output was not very useful. Much like the Redbreast sunfish model, the SI variables used are general in nature, and contain a large range of suitable values (Redbreast sunfish and Common shiners are both considered generalist species). With the exception of two sites that were severely limited by a single SI variable (pH at site DCD765 and % pools at site DCD2138), SI variable attributes of most sites were very similar and the resulting HSI scores were also similar, ranging from 0.80 to 0.93 (Table 15). If the influence of a single low pH value and the smaller proportion of pools at these sites were disregarded, all sites would have HSI scores within this narrow range.

Common shiner abundance and biomass were fairly similar at all sites with the exception of DCC793, where a much greater number were collected. Perhaps the most interesting finding with regard to Common shiners was the greatly reduced average size of individual fish collected at site DCC455 compared to other sites.

5.3.5.8. Fallfish HSI Model

Interpretation of Fallfish HSI model output was hindered by a lack of data; only 19 individuals were collected in total. Only one individual was collected in the Cobbs Creek sub-basin (site DCC793). The Fallfish HSI model is one of the simplest HSI models available, considering only six variables. Furthermore, as applied to the Darby-Cobbs Watershed, only five variables were considered because it was not possible to convert modern NTU turbidity data to JTU data. Differences between sites were not very large for most of the remaining five variables (Table 16).

Substrate type, however, is an important factor because Fallfish construct and spawn over gravel nest structures. Fallfish males push and carry gravel and smalls stones to create a nest pile which may be quite large. Following a spawning episode, eggs are buried, after which additional material may be added to the nest structure and the process repeated. Similar egg burying behavior is practiced by other minnow species (e.g., Cutlips minnow, Creek chub). Since developing eggs rely on oxygen exchange through interstitial spaces, clean, oxygenated gravel is necessary. Several phenomena arising from urbanization may reduce spawning success of these species.

Increased stream velocities resulting from increased impervious cover may be severe enough to damage or completely scour away nest structures. Alternately, nests built in depositional areas may become silted over, smothering eggs. Substrates may contain significant amounts of dead and decaying organic matter or be inhabited by other aerobic and chemosynthetic microbial communities. If oxygen-depleting biochemical processes within the sediments outpace re-oxygenation, or if the overlying water itself is low in dissolved oxygen, eggs may die. Decreased reproductive success may partially explain the very low abundance of Fallfish and complete absence of Cutlips minnow in the Cobbs Creek basin.

While Fallfish HSI model applicability was very limited, the biogeography of Fallfish and other egg-burying cyprinids may be helpful in identifying macro-scale impairments to run and pool stability, as well as the oxygen state and suitability of stream substrates for not only their eggs, but sediment dwelling benthic invertebrates as well. Site-specific conclusions should be avoided, however, because fish are mobile and may be collected far away from their spawning sites.

5.3.5.9. Longnose dace HSI Model

Longnose dace HSI model output predicted that water temperatures in all Cobbs Creek sites and site DCD765 would preclude survivorship of naturally reproducing population of Longnose dace (Table 17). Other sites were severely limited by stream velocity. Though the model requires average stream velocity data, it might be more appropriate to consider only riffle velocity, as sites chosen for fish surveys in Darby-Cobbs were selected based on a relatively even mix of macrohabitat features. If surveys were

conducted strictly for riffle dwelling species such as Longnose dace, the average depth would be much smaller and average velocity would be much higher for a given "site".

The Longnose dace HSI model was applied to Darby-Cobbs Watershed despite the fact that this species was not collected from the watershed in the 2003 fish survey. A review of historical fish distribution records conducted for the Fairmount Park Commission by researchers at the Academy of Natural Sciences indicates that this species has never been recorded from the watershed. Longnose dace are, however, present in other streams in the Delaware and Schuylkill drainages. This species is considered a riffle specialist, feeding and spawning in fast water in higher gradient, clear and cool streams. High Longnose dace HSI scores may thus indicate favorable riffle conditions, not only for this species, but for a variety of other riffle dwellers, including sensitive macroinvertebrate bioindicator taxa.

5.4. Chemical Assessment

5.4.1. Overview

Discrete (fixed interval) chemical sampling was conducted weekly under a variety of conditions (e.g., wet weather, ice) that may have influenced results of many chemical and water quality analyses. For example, instream measurements of dissolved oxygen and grab samples taken for fecal coliform analyses may exhibit great variability in response to environmental conditions. The former is dependent on time of day and sunlight intensity, while the latter may vary with rainfall. For this reason, results of discrete chemical sampling are most useful for characterizing dry weather water quality under Target A of the Watershed Management Plan. Target C and indicator 9 of the Watershed Management Plan were specifically targeted by PWD's Wet Weather Monitoring Program and Continuous Water Monitoring Program, respectively.

Much of Darby-Cobbs Watershed is served by a combined sewer system. Wet weather overflows at CSO structures periodically cause releases of combined sewage to streams. Effects of these releases may extend beyond the times when rain is falling or overflows are occurring. CSO discharges, even when infrequent, may thusly be a significant factor in shaping a stream's water quality. Philadelphia's streams can not be expected to meet water quality criteria during wet weather (Target C) unless CSO discharges are addressed and stormwater is treated. Conversely, combined sewer systems may be more efficient than separate sewer systems at capturing (diverting) pollutants from small, diffuse, and/or periodic sources (e.g., very small storms, gradual snowmelt, car and equipment washing, intentional dumping in storm drains).

Many watersheds in developed and developing areas are poorly protected from surface runoff from landscapes, golf courses, industrial areas, etc., which may introduce nutrients to the stream. A wide buffer of riparian vegetation around the stream can intercept and filter this runoff, reducing nutrient concentrations before they reach the stream. Another important benefit of streamside vegetated buffer zones, especially those with mature trees, is shading. Beyond direct influences of shading on algal biomass, primary productivity and amplitude of diel fluctuations in dissolved oxygen, shading reduces temperature effects, thereby affecting dissolved oxygen levels indirectly. Though only 9% of the Cobbs Creek watershed is forested, nearly all this forest land lies within stream corridors.

Additionally, suburban and urban landscapes, such as the Darby Cobbs Watershed, abound in potential point and non-point sources of organic, thermal, microbial, and heavy metal pollution. Acute and chronic effects of these pollutants on stream habitats and organisms are difficult to quantify.

5.4.2. Indicator 7: Bacteria

Fecal coliform bacteria concentration is positively correlated with point and non-point contamination of water resources by human and animal waste and is used as an indicator of poor water quality (Indicator 7 of the Watershed Management Plan). PADEP has established a maximum limit of 200 colony forming units, or “CFUs,” per 100ml sample during the period 05/01-9/30, the “swimming season” and a less stringent limit of 2000CFUs/100ml for all other times. It should be noted that the state criterion is based on the geometric mean of five consecutive samples collected over a 30-day period. As bacterial concentrations can be significantly affected by rain events and otherwise may exhibit high variability, individual samples are not as reliable as replicate or multiple samples taken over a short period.

Based on data from numerous sources (PADEP, EPA, USDA-NRCS, volunteer and non-profit organizations, etc.), it appears likely that many, if not most, southeastern PA streams would be found in violation of water quality criteria given sufficient sampling effort. PWD has expended considerable resources toward documenting concentrations of fecal coliform bacteria and *E. coli* in Philadelphia's watersheds. The sheer amount of data collected allows for more comprehensive analysis and a more complete picture of the impairment than does the minimum sampling effort needed to verify compliance with water quality criteria. In keeping with the organizational structure of the watershed management plan, fecal coliform bacteria analysis has been broken into dry (Target A) and wet weather (Target C) components, defined by a period with at least 48 hours without rain as measured at the nearest gauge in PWD's rain gauge network.

5.4.2.1. Target A: Dry Weather Fecal Coliform Bacteria

All individual dry weather samples collected from Darby-Cobbs Watershed during the non-swimming season (n=18) showed fecal coliform bacteria concentration well below the water quality criterion of 2000CFU/100ml. But geometric means of fecal coliform concentration at all sites exceeded water quality criteria during the swimming season (Table 18 and Figure 20). Samples from sites DCI010, DCC208, and DCC455 on 6/12/03 were likely affected by a leaking sewer. The sewer leak was subsequently detected by PWD biologists conducting a fish assessment downstream. Geometric means of fecal coliform from these sites would be 366, 324 and 696, respectively, with these samples omitted.

With the exception of intense sampling upstream and downstream of a point source, surface water grab samples do not usually allow one to determine the source(s) of fecal contamination. Recent research has shown that fecal coliform bacteria may adsorb to sediment particles and persist for extended periods in sediments (VanDonsel, et al. 1967, Gerba 1976). Presence of bacterial indicators in dry weather may thus more strongly reflect past wet weather loadings than dry weather inputs (Dutka and Kwan, 1980). Clearly, there exist several possible sources of fecal coliform bacteria within the watershed, all or combinations of which may be acting within different spatial and

temporal dimensions. PWD is piloting a Bacterial Source Tracking (BST) program that may eventually be useful in identifying the sources of fecal coliform bacteria collected in dry weather. Of particular interest is the relative proportion of the total bacterial load from human sources vs. domestic and wildlife animal sources.

5.4.2.2. Target C: Wet Weather Fecal Coliform Bacteria

Surface water grab samples (n=54) were collected at nine sites throughout Darby- Cobbs Watershed during or within 48 hours of wet weather as part of PWD's 2003 fixed interval (weekly) discrete chemical sampling program. Results of weekly discrete fecal coliform bacteria concentration analysis appear in Table 19. An additional 130 automatic sampler composite samples were collected from 5 sites during two individual wet weather events as part of PWD's intensive wet weather monitoring program. Hydrograph-matched scatterplots of fecal coliform bacteria concentration at each site for each event appear in (Appendix F). The data from these events is summarized in Tables 20 and 21.

Not surprisingly, wet weather fecal coliform bacteria concentration is elevated significantly at each site compared to dry weather concentrations. Both Cobbs and Darby Creeks exhibited a typical pattern of fecal coliform bacteria concentration increasing at downstream locations. Though all sites sampled probably could be in violation of state fecal coliform bacteria standards (e.g., many samples in excess of 1000 CFU/100ml, more than 10% of samples in excess of 400CFU/ml), Cobbs Creek and its tributaries within Philadelphia (i.e., Naylors Run and the Indian Creeks) appear more severely affected than suburban Delaware County sites.

5.4.3. Indicator 8: Metals

Metals occur in all natural waters in varying concentrations due to runoff, erosion, atmospheric deposition, and interactions with streambed geological features. However, because certain metals may be toxic even in very small concentrations, toxic metals concentrations are included in the CCIWMP (indicator 8). Darby Creek Watershed (32.3 river miles including Darby Creek, Hermesprota Creek, Muckinipattis Creek, Stony Creek, Langford Run, and Whetstone Run) was listed by PADEP in 1996 as impaired due to metals in urban runoff/storm sewers, though individual segments were not identified. Cobbs Creek watershed (24.8 river miles, including Indian creek) was listed by PADEP in 2002 as impaired due to urban runoff/storm sewers and municipal point sources, but cause(s) of the impairment were not identified.

Metals of concern (e.g., lead, chromium, cadmium, copper, and zinc) were most often undetectable or present in minimal concentrations in water samples taken in 2003 from Darby-Cobbs watershed. However, increases in concentration during rainfall were observed for copper, iron, and lead. Though water column toxic metal concentrations may be generally small, many metals readily adsorb to sediment particles, interact with organic molecules, or otherwise precipitate or become deposited or incorporated into stream sediments. Since most aquatic organisms either inhabit sediments or feed upon benthic invertebrates, possible toxic effects may not be reflected by water column concentrations alone.

Calcium and magnesium concentrations of Darby-Cobbs watershed were not unusual, keeping with the predominant rock types in the watershed (schists and gneiss). As the major divalent cations in surface water, Calcium and Magnesium are used to compute hardness (expressed as mg/l $CaCO_3$). This is an important parameter, because toxicity of other metals generally has an inverse relationship with hardness. Most EPA and PADEP toxic metal water quality criteria are currently defined as linear regression equations that account for observed decreases in toxicity as hardness increases. Each sample metal concentration is evaluated against the criterion as calculated with sample hardness. Furthermore, two water quality criteria exist for each toxic metal, criteria continuous concentration (CCC) and criteria maximum concentration (CMC); these criteria address chronic and acute toxicity, respectively. Dry weather water samples were compared to CCC and wet weather samples were compared to CMC.

PADEP dissolved metal criteria are based on EPA toxic metals standards originally developed for total recoverable metals. Though these criteria have been modified to include a conversion factor for use with dissolved metals data, actual dissolved metal concentrations cannot be predictably determined as a proportion of total recoverable metals concentrations. Solubility of metals in natural waters varies with other environmental variables. Because of the degree to which metals may adsorb to sediment and form complexes with organic particles, it is likely that actual water column dissolved metal concentrations in Darby-Cobbs Watershed are smaller than those predicted using these conversion factors. To assess the effects of using these conversion factors, total recoverable metal concentrations were compared to both dissolved and total recoverable criteria.

5.4.3.1. Target A: Dry Weather Metals Concentrations

With the exception of copper, metals concentrations were relatively small in dry weather (Table 22). Cadmium and Chromium were not detected in any of 69 dry weather samples from Darby-Cobbs Watershed. Lead was detected in only 3 samples, 2 from site DCC208 and one from site DCC455; only one of these three detections was a possible violation of the dry weather (continuous) criterion (CCC) for lead. Aluminum and zinc were detected in approximately two thirds of dry weather samples. Aluminum concentrations were consistently small, the maximum value was less than 50% of the CMC and the mean concentration was less than 10% of the CMC (no CCC has been established for aluminum). Zinc concentrations were typically 10% or less of the CCC. Copper was detected in all dry weather samples; three samples may have exceeded the CCC. While standards for each sample vary with hardness, many samples had copper concentration at 50% or more of the CCC. Based on ICP-MS performance on individual check standards, reporting limits for some metals were higher than 1µg/l on some occasions.

Table 22. Metal concentrations collected during dry weather in Darby-Cobbs Watershed.

Metal	non-detects	Max	Min	Arithmetic Mean	Std. Dev.	Geometric Mean	WQ Violations
Aluminum	16	0.363	0.015	0.067	0.053	0.055	N/A
Cadmium	69	N/A	N/A	N/A	N/A	N/A	0
Calcium	0	52.0	24.0	34.89	6.573	34.311	N/A
Chromium	69	N/A	N/A	N/A	N/A	N/A	0
Copper	0	0.020	0.002	0.006	0.004	0.006	3
Iron	4	0.785	0.052	0.196	0.113	0.171	0
Lead	66	0.007	0.002	0.004	0.003	0.003	1
Magnesium	0	19.320	11.700	14.945	1.510	14.781	N/A
Manganese	3	0.142	0.010	0.033	0.024	0.027	0
Zinc	19	0.084	0.002	0.017	0.017	0.012	0

Water column total recoverable metals concentrations often do not accurately reflect bioavailability of toxic constituents and cannot be expected to reliably predict effects along and among stream sediments. Much recent research has been focused on metals toxicity and studies have focused on determination of toxic constituents of sediments themselves; toxic constituents of interstitial waters; re-suspension of toxicants by storm flows, recreational use, or bioturbation by benthic biota; controlled laboratory testing with experimental organisms; *in-situ* toxicity investigations; and development and refinement of sediment toxicity models.

EPA has begun the process of revising water quality criteria for toxic metals to incorporate the considerable body of research that has been conducted since the original criteria were published. These new criteria more appropriately reflect the chemical behavior of toxicants in surface waters and account for their bioavailability. For example, cupric ions (Cu^{2+}) have been recognized as the major cause of copper toxicity (Sunda and Guillard 1976; Sunda and Hansen 1979). However, complexes formed through ligand bonding with inorganic and organic molecules may reduce free copper concentrations by three or more orders of magnitude (Morel & Hering 1993) through competition for ligand bonding sites. EPA's draft copper water quality standard (2003) incorporates the Biotic Ligand Model (DiToro et al., 2001) and more reliably predicts the toxic effects of copper concentrations than linear regression equations that consider only hardness as a covariable.

5.4.3.2. Target B: Wet Weather Metals Concentrations

Wet weather metals concentrations were generally greater than concentrations in dry weather; the incidence of possible water quality violations was much higher overall in wet weather than in dry weather. For example, metals that may have violated water quality criteria only in wet weather included aluminum, cadmium, manganese, and zinc. Possible violations of copper and lead criteria were more frequent in wet weather as well. Hydrograph-matched scatterplots of toxic metal concentrations appear in (Appendix G).

While surface runoff undoubtedly contributes to increases in wet weather metals concentrations, it is likely that re-suspension of metals associated with sediments contributes to excursions from water quality criteria.

5.4.4. Indicator 9: Dissolved Oxygen Concentration

Continuous monitoring Sondes at sites within Darby-Cobbs Watershed measured, among other parameters, water column dissolved oxygen (DO) concentration. DO concentrations often strongly reflect autotrophic community metabolism and in turn, affect the heterotrophic community structure as a limiting factor for numerous organisms. Because sufficient DO concentration is critical for fish, amphibians, crustacea, insects, and other aquatic invertebrates, DO concentration is used as a general indicator of a stream's ability to support a balanced ecosystem. The Pennsylvania Department of Environmental Protection (PADEP) has established criteria for both instantaneous minimum and minimum daily average DO concentration. Criteria are intended to be protective of the types of aquatic biota inhabiting a particular lake, stream, river, or segment thereof.

All water chemistry monitoring sites within Darby-Cobbs Watershed, with the exception of DCD1660, are designated as Warm Water Fisheries (WWF). Site DCD1660, and all segments of Darby Creek north of PA Rte. 3 (West Chester Pike) are designated a Trout Stocking Fishery (TSF). PADEP water quality criteria require that minimum DO levels in WWF not fall below 4.0 mg O_2/L and that daily averages remain at or above 5.0 mg O_2/L. A Trout Stocking Fishery such as DCD1660 has more stringent DO standards to support more sensitive stocked salmonid fish species from February 15 to July 31 each year. During this period, a minimum daily DO average of 6.0 mg O_2/L is required, and allowable DO instantaneous minimum is 5.0 mg O_2/L. For the remainder of the year, TSF criteria align with WWF standards. These regulations, along with corresponding temperature criteria, form the foundation of stream protection in general and allow for propagation and maintenance of healthy fish communities.

Combinations of natural and anthropogenic environmental factors may affect DO concentration. Autotrophic and heterotrophic organisms are influenced by nutrient concentrations, solar radiation, temperature, and other environmental factors. Daily fluctuations of oxygen in surface waters are due primarily to the metabolic activity of these organisms. If temperature alone influenced DO concentration, saturation would increase at night, when water temperature drops, and decrease during the day as the water warms. Because the watershed is generally dominated by biological activity, the reverse occurs: DO concentrations in Darby-Cobbs Watershed rise during the day when autotrophic organisms are photosynthesizing and decrease at night when community respiration is the dominant influence. Another factor in the amount of oxygen dissolved in the water is re-aeration (diffusion of atmospheric oxygen). Barometric pressure, surface area, turbulence and oxygen saturation deficit influence the amount of oxygen transferred to the stream from the atmosphere. Effects of re-aeration tend to augment or diminish (rather than shift or change) effects of stream metabolism.

Stream sites that support abundant algal growth often exhibit dramatic diel fluctuations in dissolved oxygen concentration. Algal photosynthesis infuses oxygen during the day (often to the point of supersaturation), while algae and heterotrophic organisms remove oxygen throughout the night. These sites are more susceptible to oxygen deficits on cloudy days when the amount of photosynthesis is limited by sunlight and community respiration dominates system activity.

DO fluctuations were more pronounced at some sites than at others, due in part to specific placement of the continuous monitoring instrument (Sonde) at each site. When interpreting this continuous DO data, one must keep in mind that the instrument can only measure dissolved oxygen concentration of water in direct contact with the DO probe membrane. Furthermore, to obtain the most accurate readings of DO, probes should be exposed to flowing water or probes themselves must be in motion. Local microclimate conditions surrounding the probe and biological growth on the probe itself may also contribute to errors in measurement. It is possible for Sondes situated in subtly different areas of the same stream site to exhibit marked differences in DO concentration due to flow, shading, and local microclimate differences. Sonde measurements of DO concentrations during the summer period (8/14/03-9/14/03) are depicted in figures 21 thru 25.

The Sonde located at DCC208, for example, is located in a pool upstream of a dam. Additionally, the Sonde at DCC208 is not shaded. Deep pools, slower stream velocity, and ample sunlight provide excellent conditions for algal growth which are reflected in diel DO fluctuations (Figure 21). DCD765 is another site in which the Sonde is only

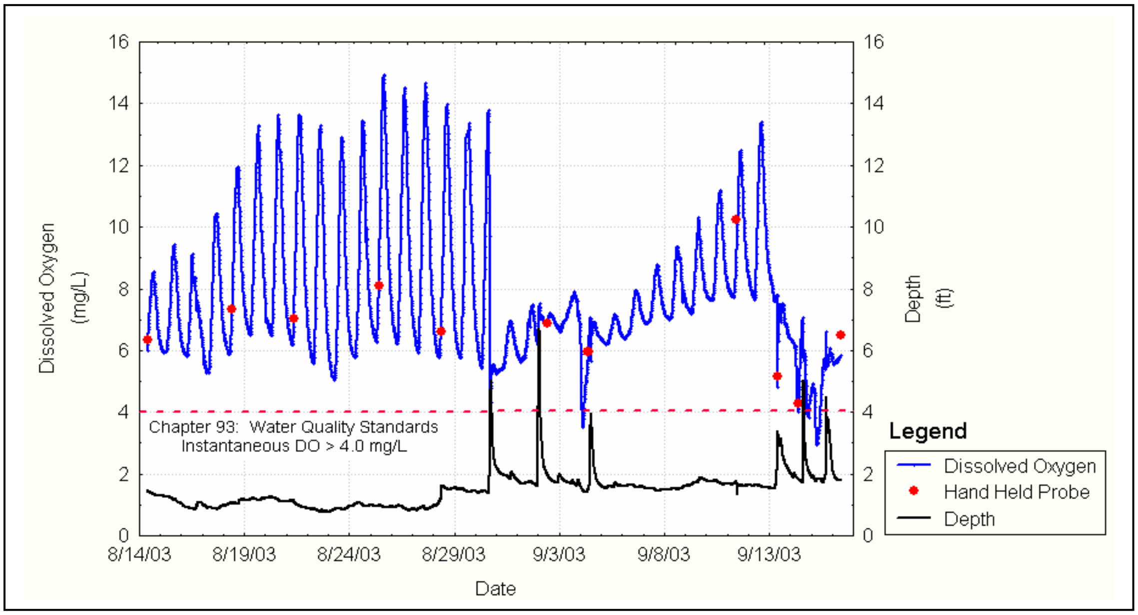

Figure 21. Continuous measurements of dissolved oxygen at DCC 208.

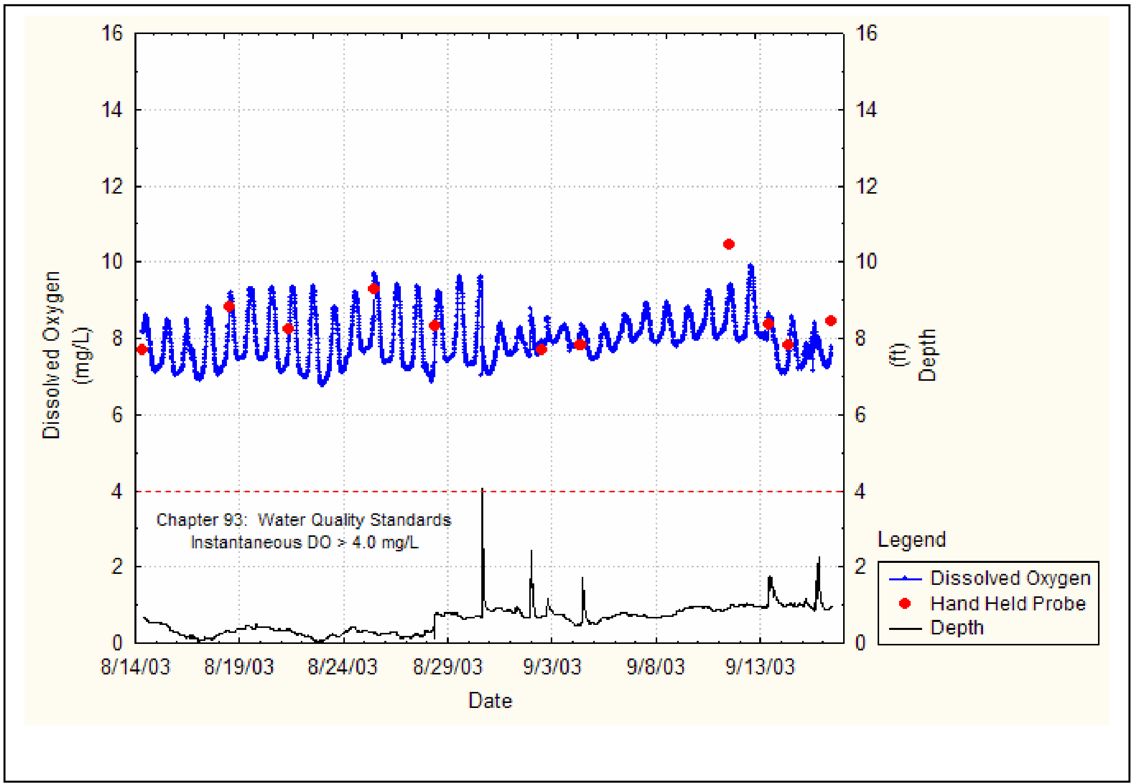

Figure 23. Continuous measurements of dissolved oxygen at DCC 770.

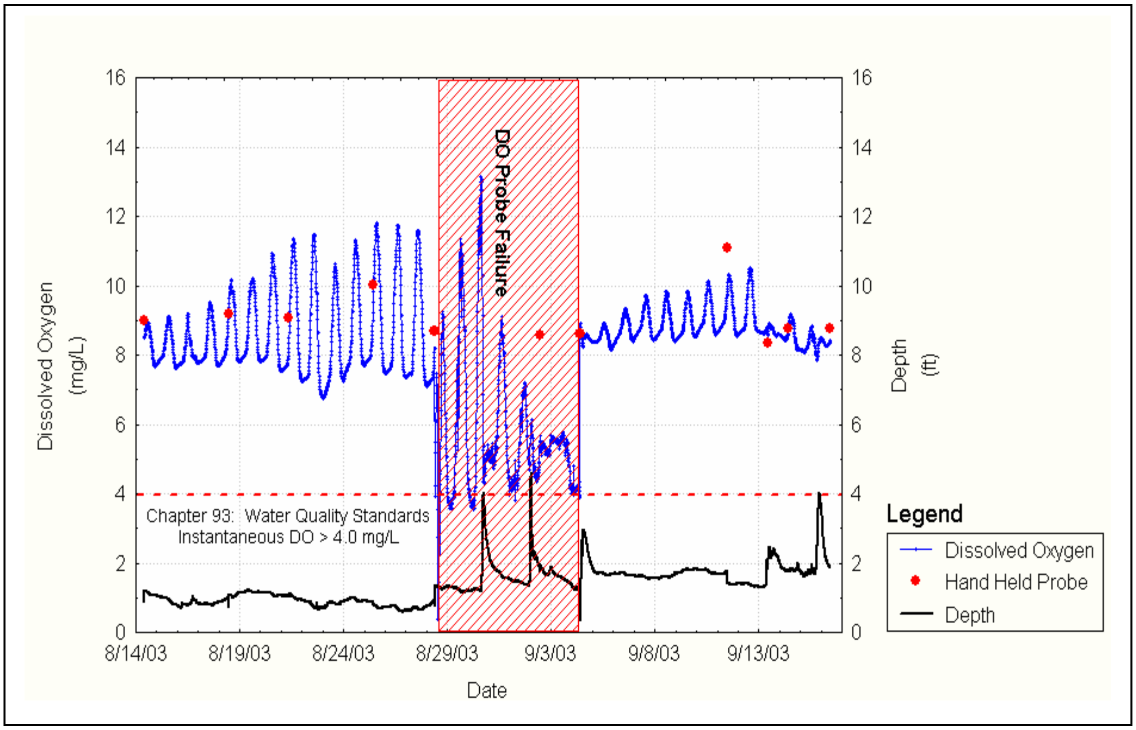

Figure 24. Continuous measurements of dissolved oxygen at DCD 765.

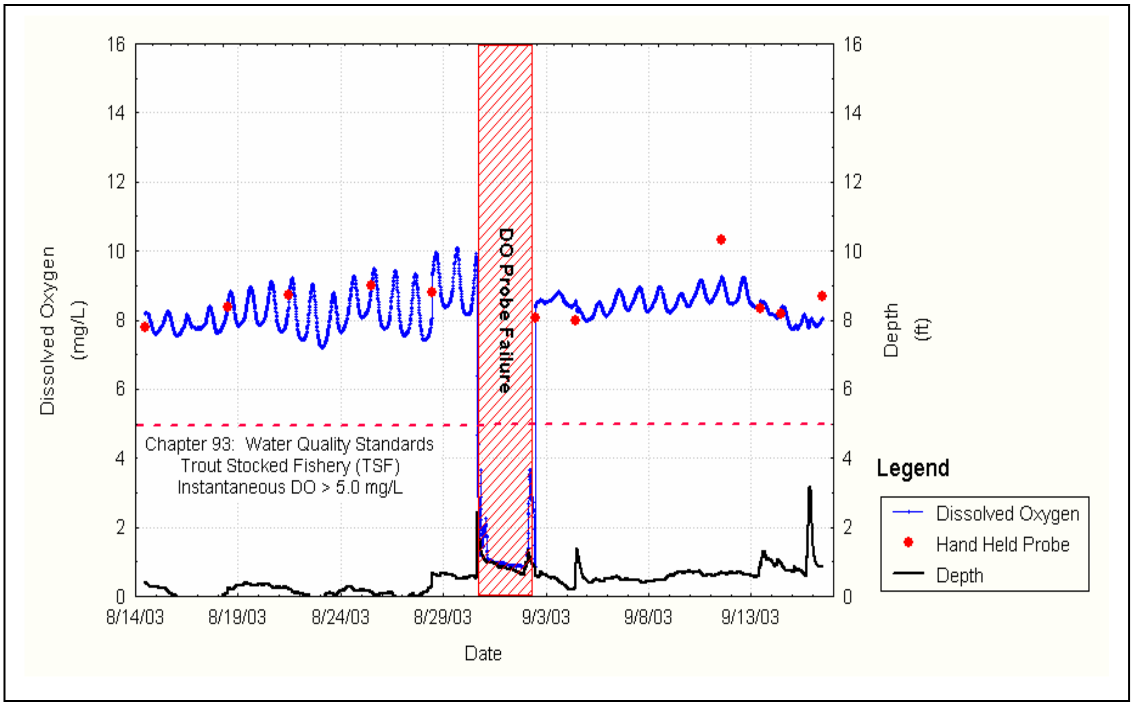

Figure 25. Continuous measurements of dissolved oxygen at DCD 1660.

partially shaded. While not as large as DCC208, the amplitude of DO fluctuations exceeded 3 mg/L at this site. In contrast, the Sonde at DCD1660 is located under a bridge in shallow water. While not measured quantitatively, it is likely that algal periphyton density was smaller at this site; resulting diel fluctuations are damped in comparison to sites exposed to more sunlight (Figure 25). Sondes at sites DCC455 and DCC770 are in areas that are mostly shaded (Figures 22 and 23, respectively).

Two separate rain events occurred during the period of Sonde deployments in Darby-Cobbs Watershed. During and following the rain events, DO concentrations decreased considerably. Following sloughing of algal periphyton (benthic algae, biofilm, *aufwuchs*), the stream exhibits effects of diminished productivity. An August 30, 2003 rain event demonstrated this phenomenon at all five continuously monitored sites. DCC208 is the only site in which DO suppression violated the state water quality standards for instantaneous dissolved oxygen. Site DCC208, as discussed earlier, has many site-specific attributes that result in dense algal periphyton communities. These same factors also make it more difficult to measure DO concentrations with veracity. (DO probe failure occurred at two sites during this rain event. Cleaning of debris from DO probes, in both cases, corrected the problem in time to record a period of diminished productivity due to sloughing at these sites). Following the disturbance, autotrophic communities became reestablished, as evidenced by the return of normal, exaggerated diel fluctuations in DO concentration.

5.4.5. pH

Continuous monitoring through the use of Sondes on the Darby and Cobbs Creeks recorded pH values at each of five sites. pH is a measure of acidity, or the concentration of hydrogen ions in a solution. In natural waters, the balance between acidity and alkalinity is determined by concentrations of various dissolved compounds, salts and gases and typically remains near neutral, or pH 7. Fluctuations in pH can occur in freshwater systems as a result of natural and anthropogenic influences. Interplay between inorganic carbon species, known as the bicarbonate buffer system, generally maintains pH within a range suitable for aquatic life.

The bicarbonate buffer system is a function of the equilibrium relationship between carbon dioxide (CO_2) and carbonic acid (H_2CO_3), as well as bicarbonate (HCO_3^-) and carbonate (CO_3^{2-}) ions. In natural waters, the predominant source of hydrogen ions is carbonic acid. Biochemical metabolism of carbon throughout the day continually shifts the equilibrium equation, causing fluctuations in pH. As plants and algae consume carbon dioxide during photosynthesis, carbonic acid dissociates to replenish the CO_2 and maintain equilibrium. Decreasing carbonic acid concentrations cause elevated pH. As photosynthetic rates decline after peak sunlight hours, respiratory activities of aquatic biota replenish carbon dioxide to the system, decreasing pH. Acidity in Darby-Cobbs watershed is chiefly determined by this metabolic activity; the watershed is not heavily influenced by bedrock composition, groundwater sources or anthropogenic inputs, such as acid mine drainage.

Water quality criteria established by PADEP regulate pH to a range of 6.0 to 9.0 in Pennsylvania's freshwater streams. pH values between 6 and 9 units do not negatively affect stream biota. Organisms can be indirectly affected by pH due to its influences on the dissociation of many compounds, such as ammonia. As pH increases, a greater fraction of ammonia N is present as unionized NH_3 (gas). For example, ammonia is ten times as toxic at pH 8 as at pH 7. Extreme pH values may increase dissociation of or general toxicity of other constituents. For example, pH levels affect the bioavailability of metals (e.g., copper), which have individually regulated criteria established by PADEP.

Continuous pH data was discretized to 15 min intervals and plotted against time and stream depth. Figures 26 through 30 depict pH trends at each of five continuously-monitored sites on the Darby-Cobbs watershed, including the large diel pH fluctuations that accompany highly productive sites with abundant periphytic algae. Community metabolism regulates the extent of pH fluctuations. Environmental conditions, including ample sunlight, led to a dense autotrophic community at sites DCC208 and DCD765, which exhibited greater diel pH fluctuations than the other monitored sites; these sites also generally came closest to and occasionally violated water quality criteria by exceeding pH 9.0 (Figures 26 and 29, respectively). pH at shadier sites (i.e., DCC770, DCC455 and DCD1660) is probably less influenced by metabolic activity, and oscillations in pH appear noticeably damped as a result.

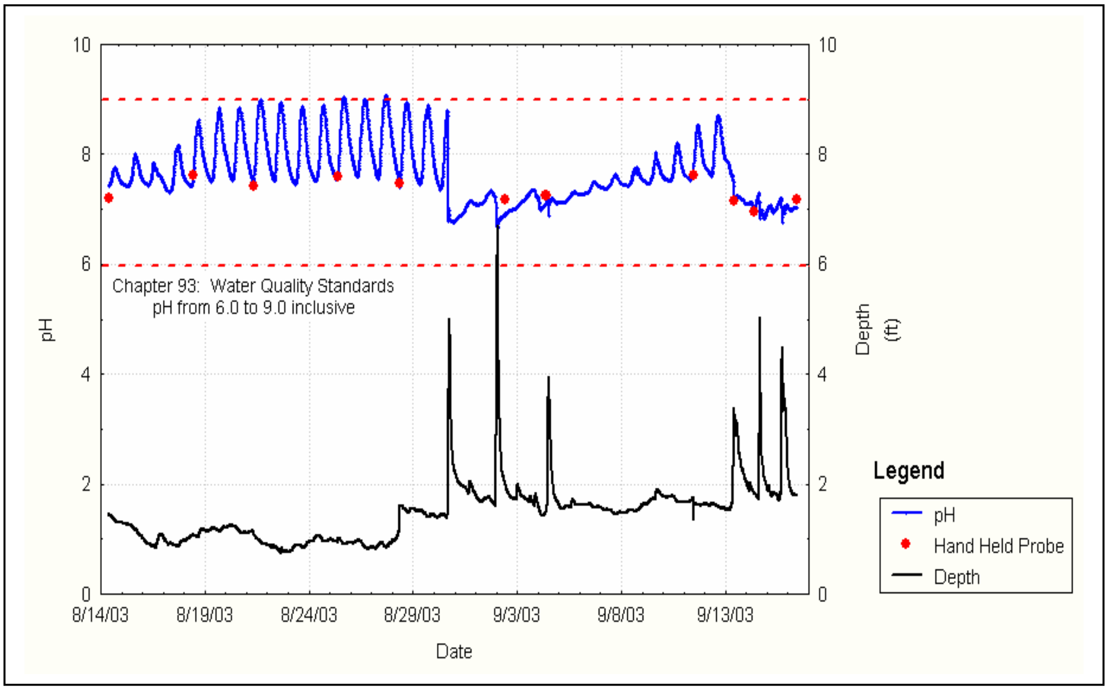

Figure 26. Continuous measurements of pH at DCC 208.

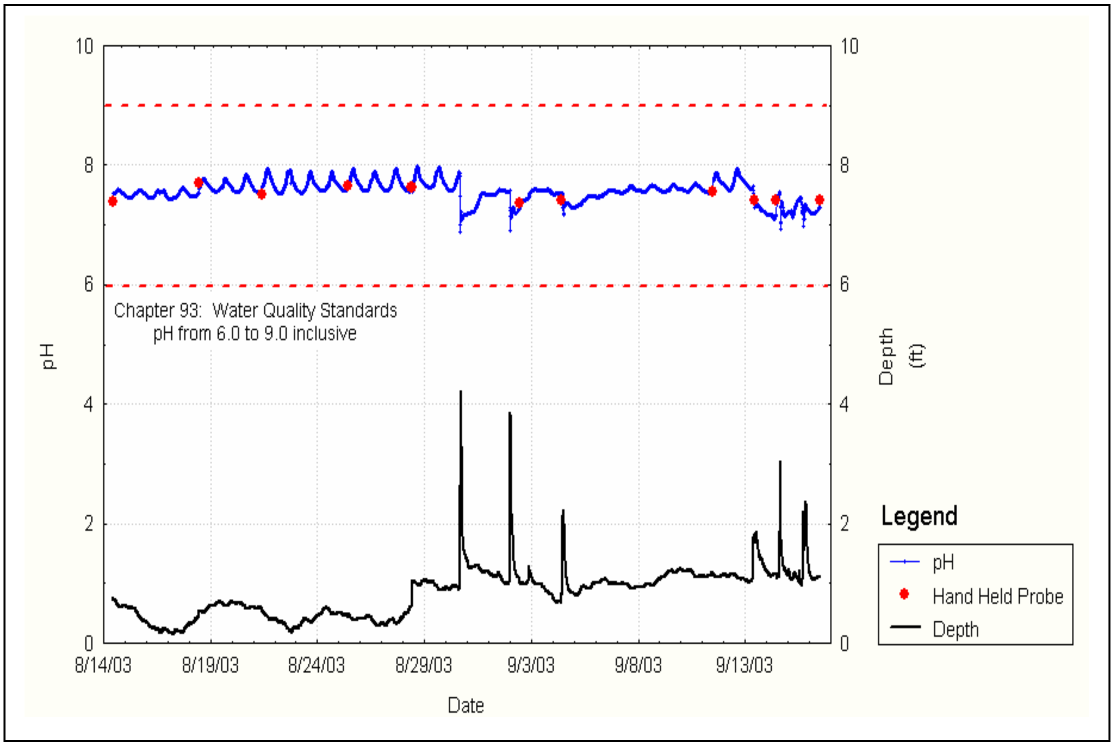

Figure 27. Continuous measurements of pH at DCC 455.

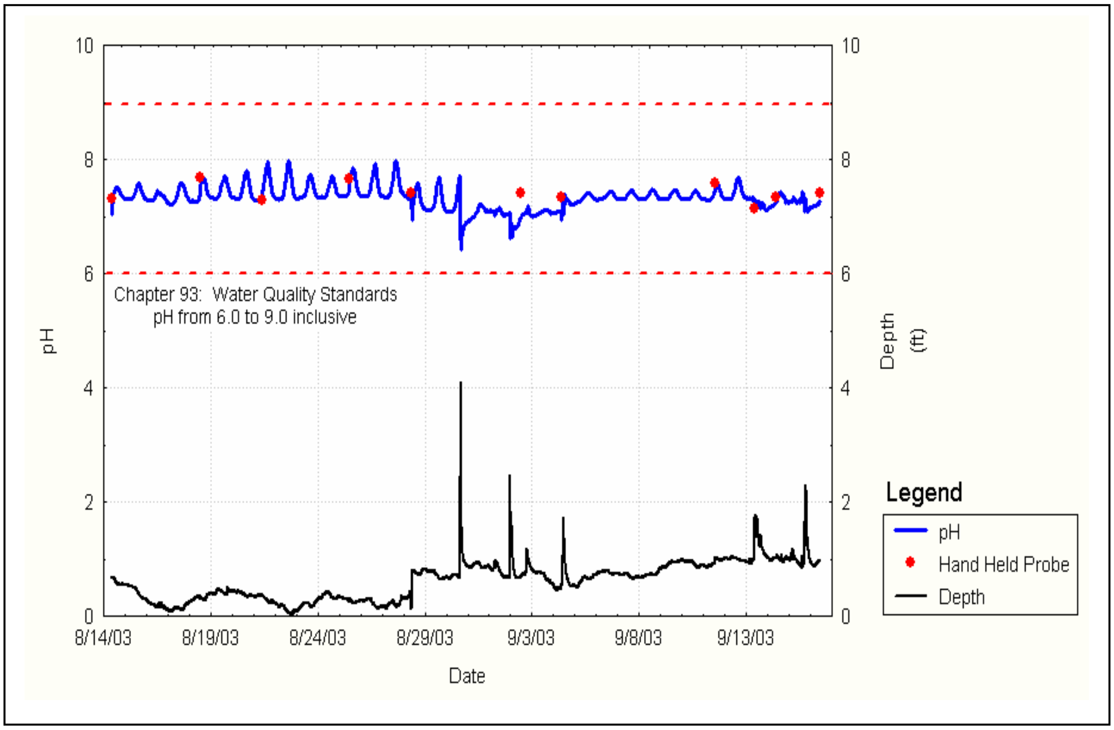

Figure 28. Continuous measurements of pH at DCC 770.

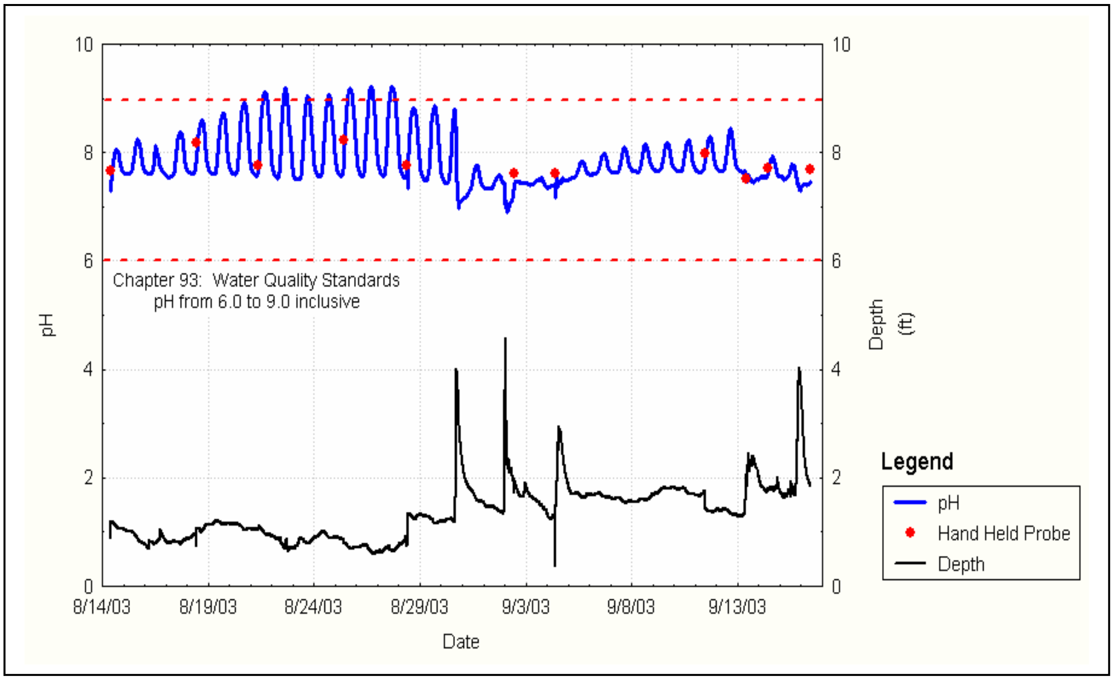

Figure 29. Continuous measurements of pH at DCD 765.

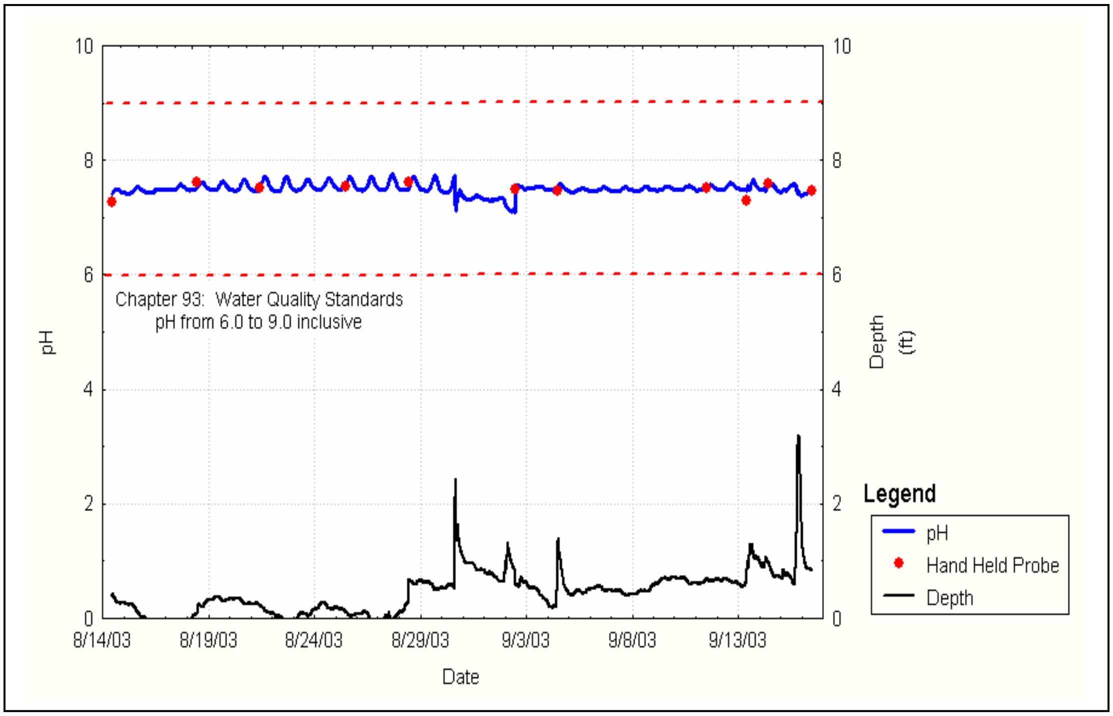

Figure 30. Continuous measurements of pH at DCD 1660.

Two separate rain events occurred during the period of Sonde deployments in Darby-Cobbs Watershed. Increased velocities and larger flows during wet weather swept away attached algae, macrophytes and suspended periphyton. Figures 26 through 30 demonstrate that without autotrophs to reduce carbon dioxide through photosynthesis, pH levels remain steady. The autotrophic community recovers from this disturbance over subsequent weeks and pH gradually returns to normal fluctuations at each site. Decreased pH levels during and following wet weather events did not violate minimum pH standards.

5.4.6. Specific Conductance

Specific conductance is a measure of waters' ability to pass electrical current and is an approximate predictor of total dissolved ions in solution. This measure is often used to monitor changes in water chemistry. Daily fluctuations in specific conductance result from biological activity changes that occur throughout the day. Sites DCC208 and DCD765 experienced more pronounced daily changes in specific conductance due to the presence of a denser biological community (Figures 31 and 34, respectively). Other factors affecting specific conductance include rain events, which decrease conductivity due to dilution of stream water by storm water and increases in total ionic strength due to application of de-icing compounds and road salts during cold weather. Following a large rain event, dissolved ion concentrations may remain below normal baseflow concentrations for more than a week as the stream's natural chemistry gradually reestablishes itself.

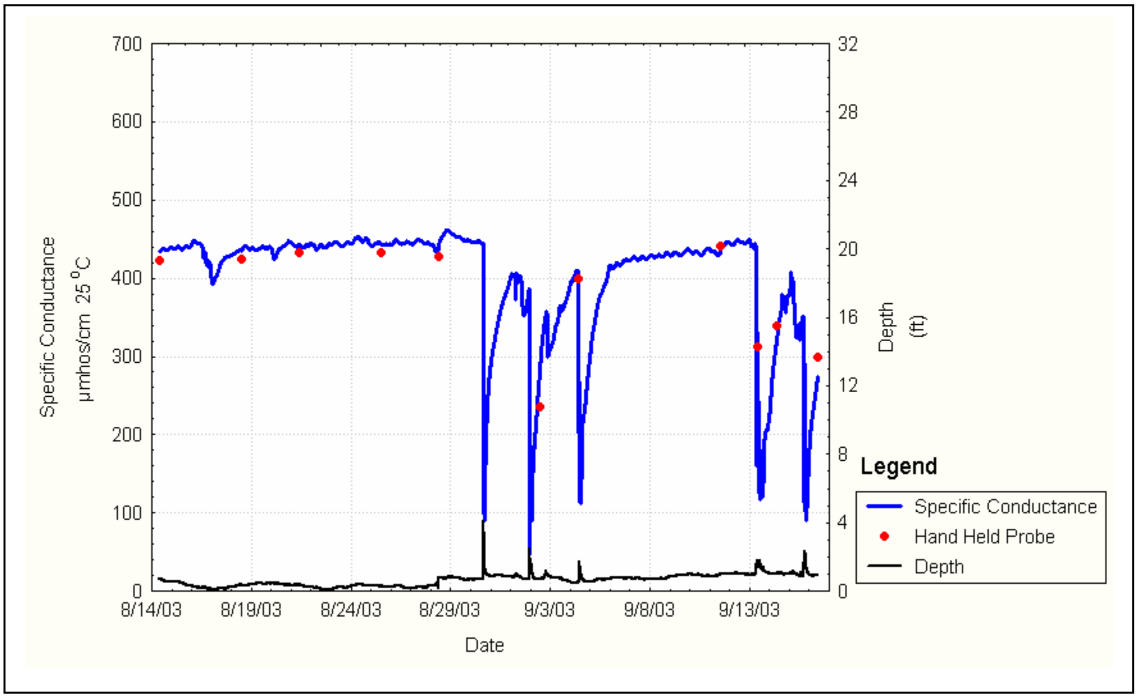

Figure 33. Continuous measurements of Specific Conductance at DCC 770.

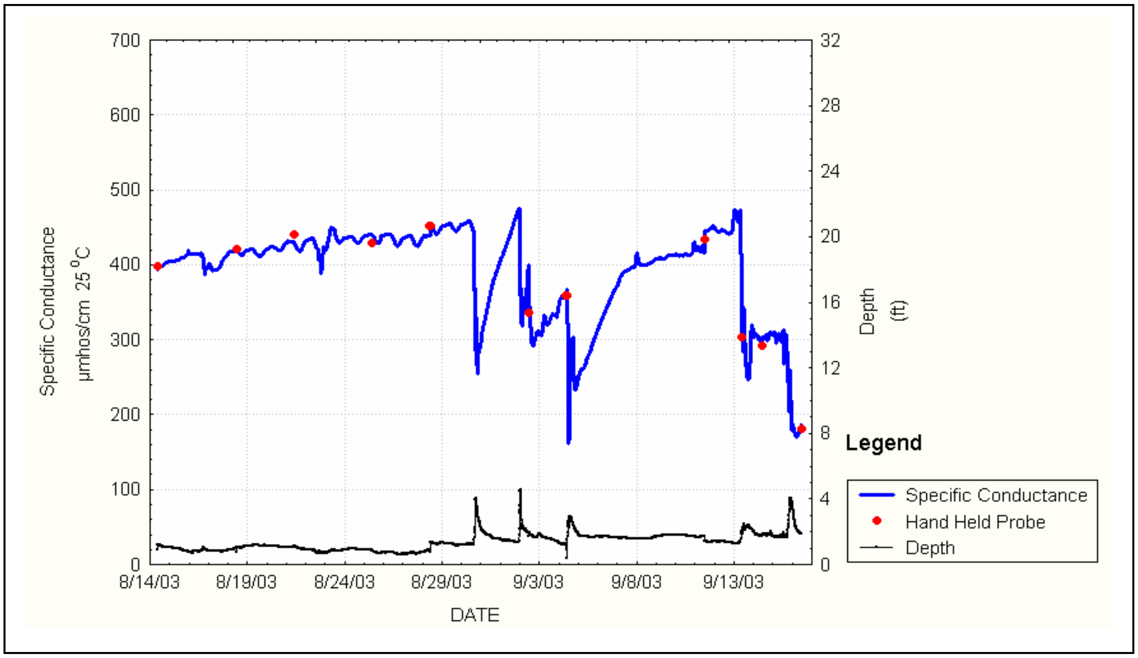

Figure 34. Continuous measurements of Specific Conductance at DCD 765.

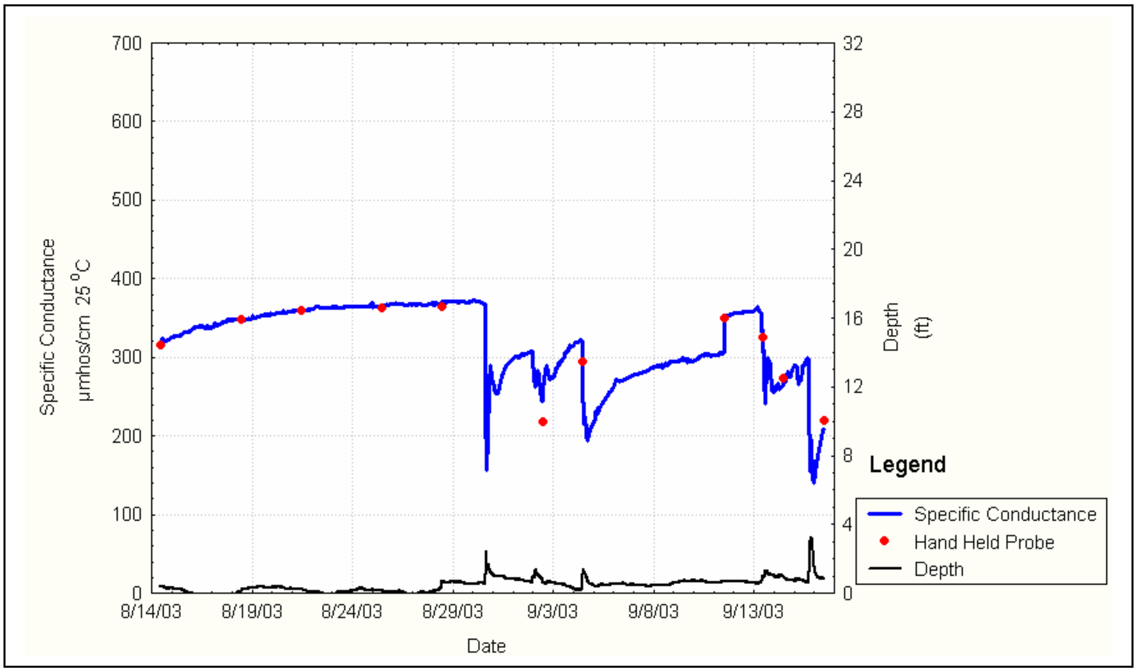

Figure 35. Continuous measurements of Specific Conductance at DCD 1660.

5.4.7. Temperature

The role of temperature in shaping aquatic communities cannot be understated. With the exception of birds and mammals, all freshwater aquatic organisms are poikilotherms ("cold-blooded"). Unable to regulate body temperature through metabolism, these organisms must select suitable temperature conditions within their habitats. PADEP has established temperature criteria for the waters of the commonwealth, largely to delineate areas requiring more stringent thermal protection for naturally-reproducing populations of sensitive ("cold water") fish species, recreationally-sought salmonids, in particular. Temperature criteria also serve to protect aquatic life from increases in temperature from industrial activity (e.g., cooling water). Darby-Cobbs Watershed does not support natural populations of coldwater fish, and is not known to be significantly affected by discharges of cooling waters.

Many water bodies that cannot support natural populations of cold water fish do have adequate thermal protection to maintain hatchery-raised adult trout. Segments of Darby Creek watershed north of PA Rte 3 (West Chester Pike) are so protected and are designated a trout stocking fishery (TSF); the remainder of Darby-Cobbs watershed is designated a warmwater fishery (WWF). Thermal maxima for sites in Darby Cobbs Watershed, as measured with continuous water quality monitoring equipment, never exceeded State water quality standards (Figures 36 through 40). Changes in temperature of 2°C or more were observed at most sites on a number of occasions; however, changes of this magnitude occurred in dry and in wet weather.

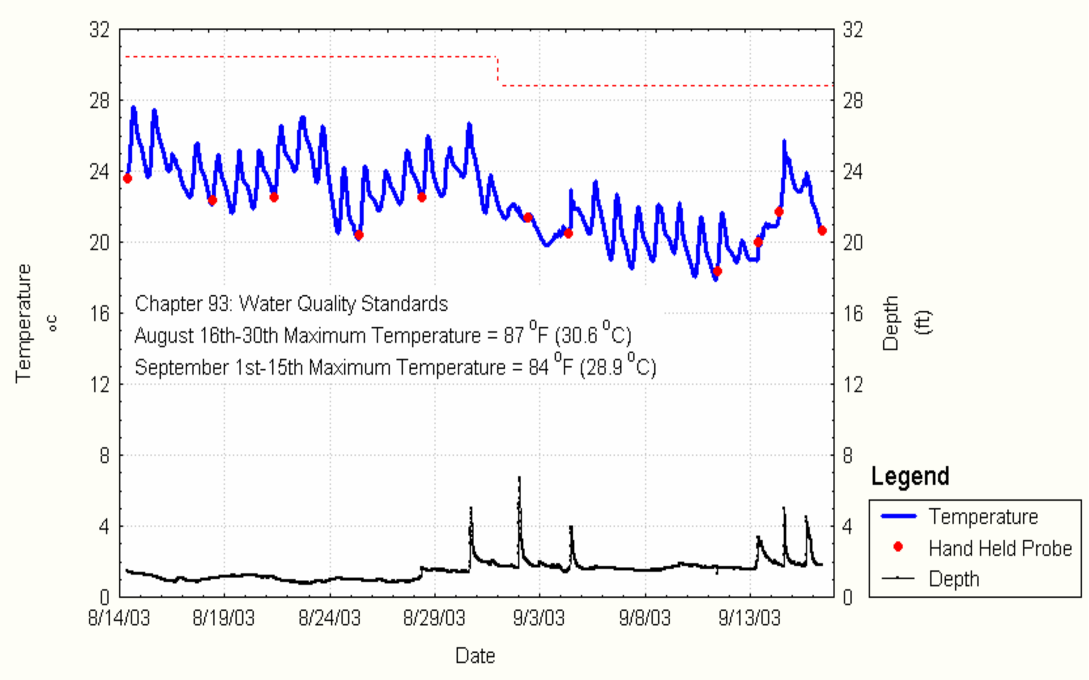

Figure 36. Continuous measurements of temperature at DCC 208.

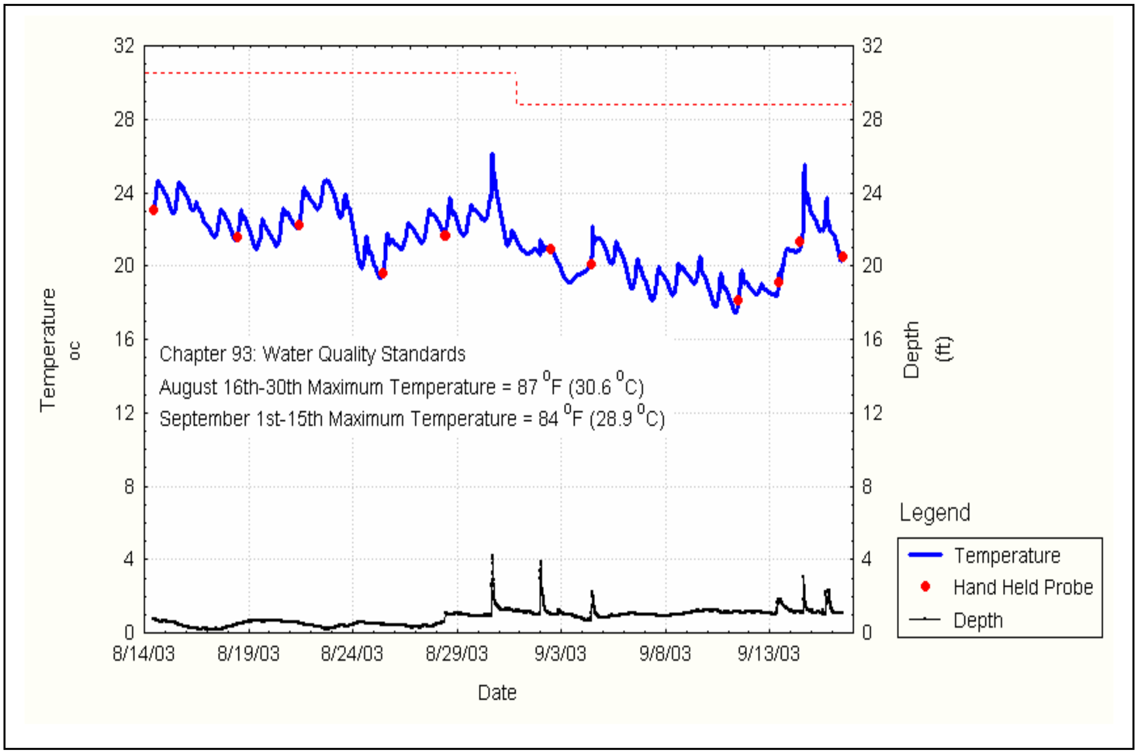

Figure 37. Continuous measurements of temperature at DCC 455.

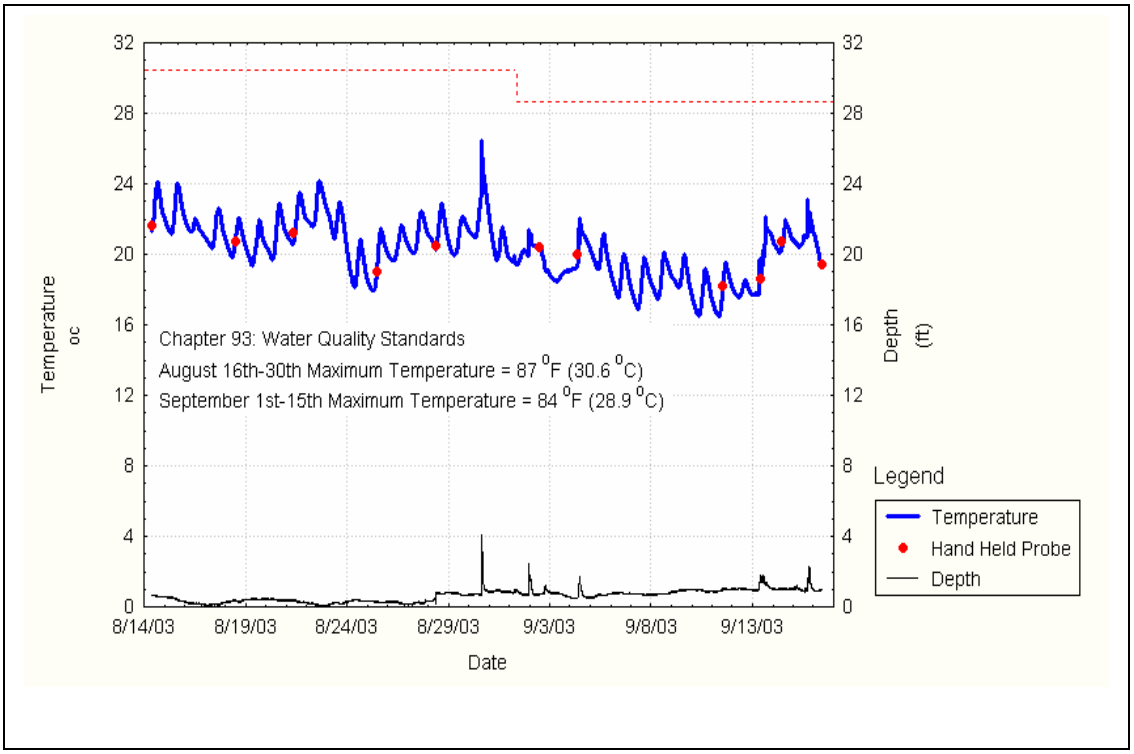

Figure 38. Continuous measurements of temperature at DCC 770.

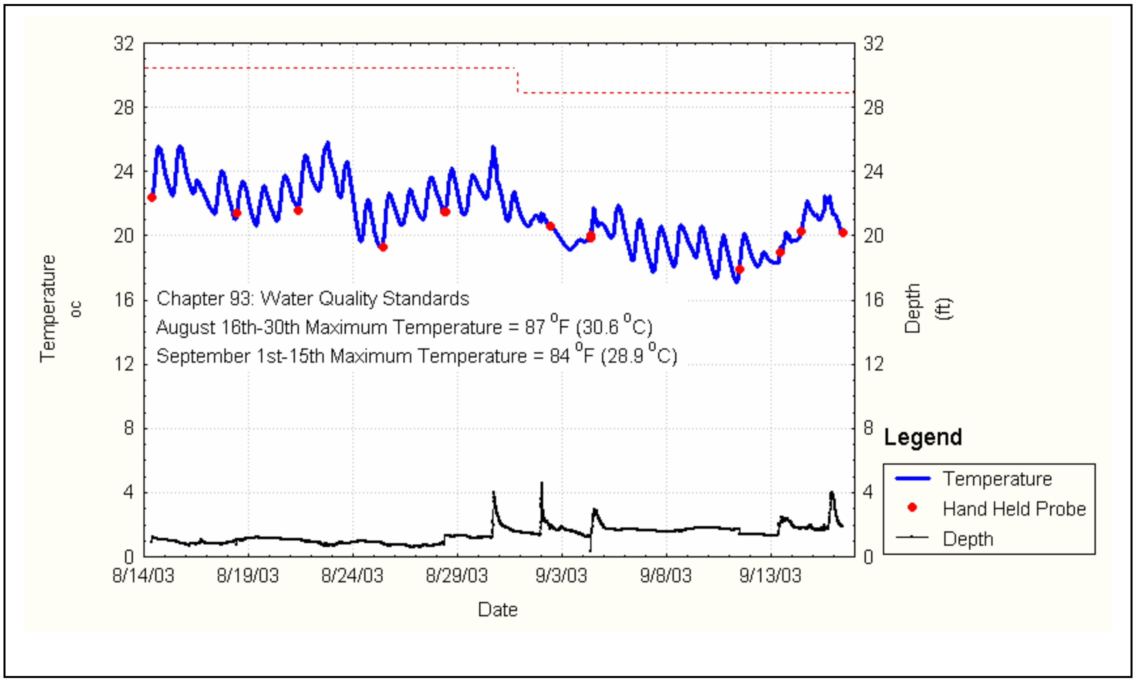

Figure 39. Continuous measurements of temperature at DCD 765.

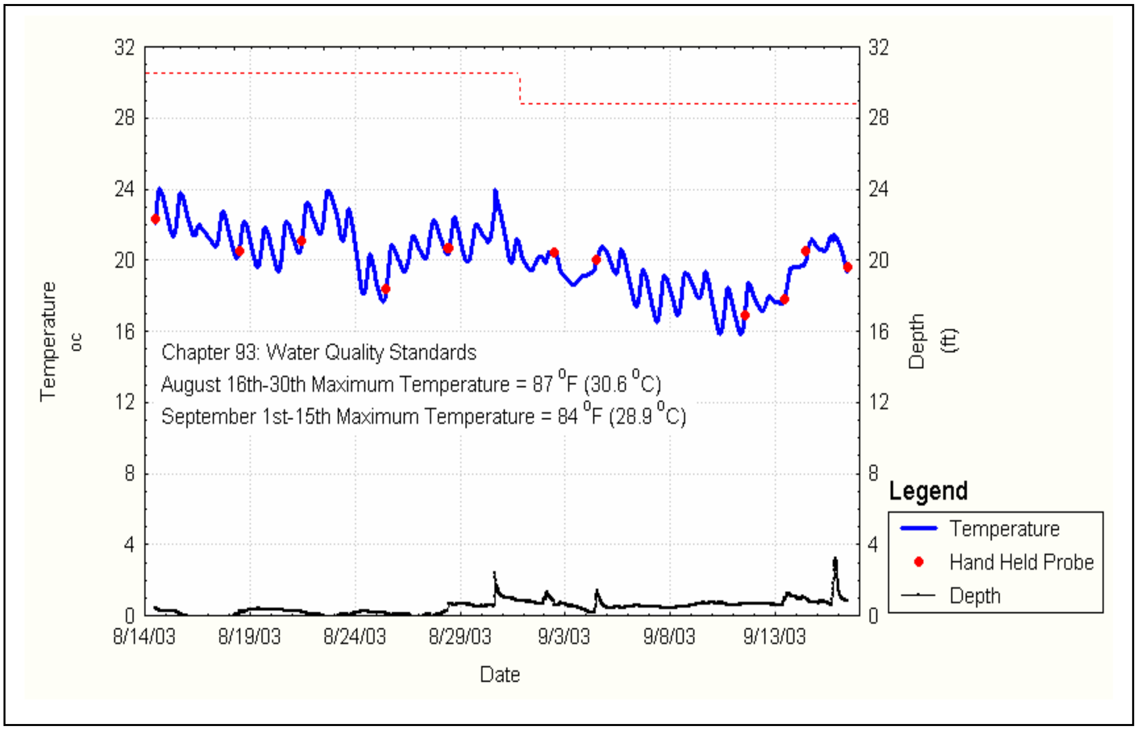

Figure 40. Continuous measurements of temperature at DCD 1660.

In addition to limiting effects of lethal and sublethal temperatures on fish survival, temperature regime has myriad implications for aquatic communities. These effects are discussed in greater detail in Section 5.3.5. (Habitat Suitability Indices).

5.4.8. Nutrients

Universally applicable minimum nutrient criteria for protecting water resources are difficult to establish. Furthermore, determining unimpaired, or “natural” nutrient conditions for streams in the Piedmont and Eastern Coastal Plain regions of Pennsylvania is made difficult by extensive land development and preponderance of agricultural land use. EPA has proposed nutrient criteria for protection of aquatic life in rivers and streams; though nutrient management strategies formulated to prevent (or reverse) eutrophication of one water body may not be appropriate for other water bodies. When a water body has been identified as nutrient impaired, thorough nutrient investigations may be conducted to determine Total Maximum Daily Loads (TMDLs) of pollutants that a water body can assimilate.

With the exception of ammonia, PADEP does not currently have aquatic life-based nutrient criteria, only a limit on oxidized inorganic nitrogen (i.e., nitrate and nitrite) that is intended to protect public water supplies. Elevated nutrient concentrations have been identified as the principal cause of nuisance algal blooms that may cause taste and odor problems in treated drinking water. A small number of algal taxa are known to produce toxins that represent a human, livestock, or wildlife health risk. While such effects are serious where and when they occur, increased biomass of naturally occurring attached periphyton algae communities is a far more widespread phenomenon that may negatively affect water quality. Data from minimally impaired sites in PADEP & EPA water quality databases have been included with Darby-Cobbs Watershed nutrient data for comparison where appropriate and/or applicable.

5.4.8.1. Nutrients: Nitrogen species

Surface water samples were analyzed for nitrate (NO_3), nitrite (NO_2) and ammonia nitrogen (NH_3-N) concentration. The Kjeldahl method of determining total organic N was also applied. All N species may be naturally present in aquatic systems; however, elevated levels of N are indicative of both point and non-point sources of pollution. Nitrate and ammonia (specifically ammonium ions, $NH4^+$) are the forms of N most useful to stream producers such as green plants, algae and cyanobacteria. Naturally occurring chemical reactions and metabolic activities of common bacteria (e.g., *Nitrosomonas*, *Nitrobacter*) are responsible for altering the ratio of inorganic N species in freshwater systems. In the presence of oxygen, ammonia is converted first to nitrite, then to nitrate (nitrification). Efficiency of the reactions in which ammonia N is converted to oxidized forms is dependent on environmental conditions (i.e., temperature, pH and dissolved oxygen concentration).

Though deep stagnant water is present in a few locations, particularly in pools behind dams and in "plunge pools", most of Darby-Cobbs Watershed consists of shallow, well mixed and (at a minimum, partially) oxygenated stream segments. Inputs of organic matter and inorganic N, particularly concentrated inputs from SSOs and CSOs, may tax dissolved oxygen levels and result in violations of water quality standards. These effects are most severe in summer, when the rate of N-oxidizing reactions is fastest, dissolved oxygen capacity of stream water is reduced, instream biomass is high, and baseflow may be at or near yearly minimum.

5.4.8.2. Nitrite

As an intermediate product in the oxidation of organic matter and ammonia to nitrate, nitrite is seldom found in unimpaired natural waters in great concentrations provided that oxygen and denitrifying bacteria are present. Nitrite was never detected in any 2003 samples from Darby Creek or Naylors Run regardless of weather conditions, but was detected in 21 of 100 wet weather samples and 3 of 69 dry weather samples from Cobbs Creek. Observed wet-weather nitrite concentrations are likely due to CSO/SSO discharge and runoff. On 6/12/03, nitrite was detected during dry weather at sites DCI010, DCC455 and DCC208. The inability to detect nitrite at site DCC770 and observed pattern of longitudinally diminishing concentrations (from upstream to downstream) suggested a point source, later determined to be a leaking sewer. PADEP has established a maximum limit of 10mg/l for total nitrate and nitrite N. Nitrite concentrations in Darby-Cobbs watershed never exceeded nitrate concentrations, and were never responsible for water samples exceeding this criterion.

5.4.8.3. Nitrate

Concentrations of nitrate are often greatest in watersheds impacted by (secondary) treated sewage and agricultural runoff, but elevated nitrate concentrations in surface waters may also be attributed to runoff from residential and industrial land uses, as well as atmospheric deposition and precipitation (e.g., HNO_3 in acid rain). Nitrate is a less toxic inorganic form of N than ammonia and serves as an essential nutrient for photosynthetic autotrophs. Availability of inorganic N can be a growth-limiting factor for producers, though usually only in oligotrophic (nutrient-poor) lakes and streams or acidic bogs.

According to US EPA's nutrient criteria database, samples collected from unimpaired surface waters in the eastern coastal plain region of Pennsylvania had mean nitrate concentration of 1.9mg/l (n = 786). The 75th percentile seasonal median nitrate + nitrite concentration in EPA ecoregion IV, sub region 64 watersheds was 2.9mg/l. Close examination of nitrate data collected from southeastern PA streams by PWD and PADEP showed at least some nutrient impaired streams could be assigned to one of two broadly defined categories- streams in which nitrate concentrations increase due to runoff, and streams in which nitrate concentrations are elevated during baseflow conditions and diluted by stormwater. The former stream type is characteristic of agricultural regions, while the latter is characteristic of streams affected by wastewater effluent.

PADEP has established a maximum limit of 10mg/l for total nitrate and nitrite N, but this limit is based on protection of drinking water and cannot reasonably be expected to prevent eutrophication of natural water bodies. No sites in Darby-Cobbs Watershed violated water quality criteria- the watershed is not affected by treated wastewater effluent, does not contain extensive areas of agricultural land use, and has not been listed as nutrient impaired by PADEP under section 303d of the Clean Water Act. However, all sites in Darby-Cobbs have mean nitrate concentration >1.5mg/l and would be considered "eutrophic" under the stream trophic classification system of Dobbs (1998).

During wet weather, nitrate concentrations were generally diluted; nitrate concentration was significantly higher (t-test, $p<0.05$) in dry weather at five of nine sites in Darby Cobbs Watershed (Figure 41). While nitrate concentrations were similar among Darby Creek sites, Cobbs Creek sites showed nitrate concentration decreasing in a downstream direction, suggesting uptake by producers, dilution as link magnitude increases, or denitrification by bacteria under anoxic conditions, where they exist. Indian Creek Watershed had the highest mean nitrate concentration of all sites. Land use in the Indian Creeks' basins includes golf courses as well as areas where resident Canada geese congregate; topography is steep upstream of the sampling site.

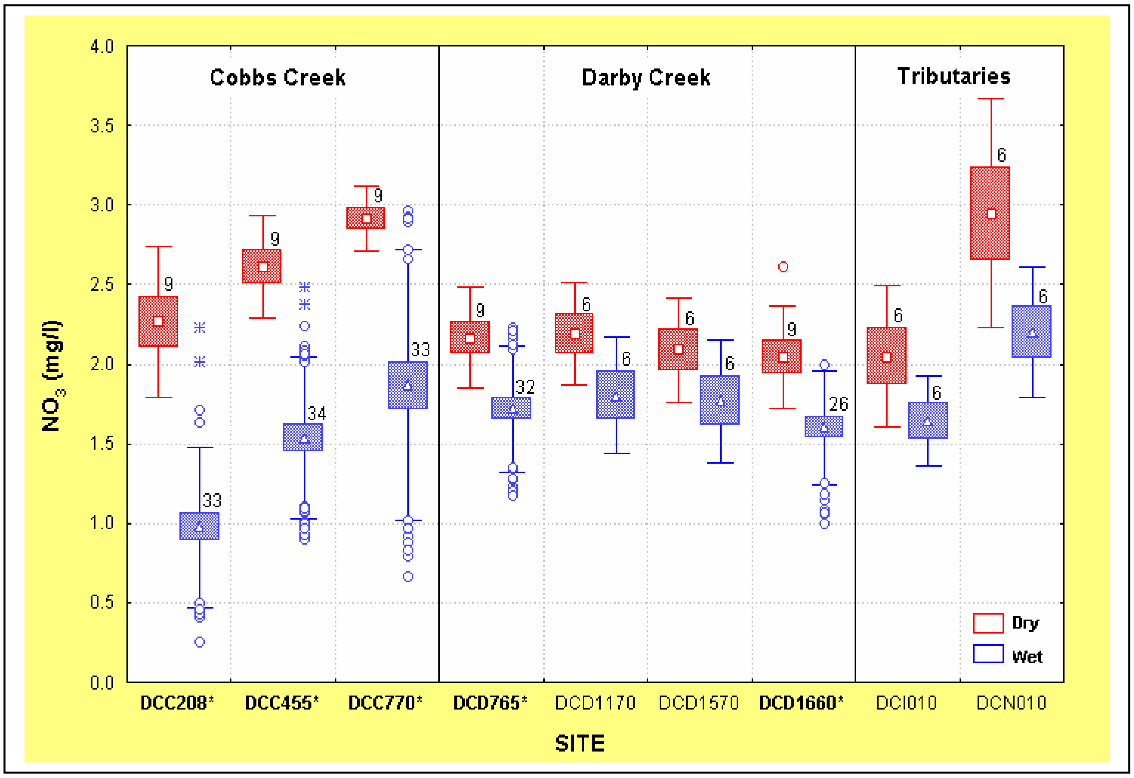

Figure 41. Dry and wet weather nitrate concentrations at the 9 monitoring sites

5.4.8.4. Ammonia

Ammonia, present in surface waters as un-ionized ammonia gas (NH_3), or as ammonium ion (NH_4^+), is produced by deamination of organic nitrogen-containing compounds, such as proteins, and also by hydrolysis of urea. Secondary treatment, as practiced in most modern sewage treatment facilities, removes dissolved organic compounds, effectively reducing ammonia concentrations in both the effluent and the receiving stream. In the presence of oxygen, ammonia is converted to nitrate by a pair of bacteria-mediated reactions, together known as the process of nitrification.

Overall, Darby Cobbs Watershed sites had relatively low ammonia concentration; 95 of 208 discrete grab samples (45%) taken in 2003 had ammonia concentration below detection limits. Mean ammonia concentration was highest at site DCI010, but this value was artificially high due to a sewage leak during dry weather on 6/12/03 (0.907mg/l). Wet weather impacts on ammonia concentration were most noticeable at Cobbs Creek sites DCC208 and DCC455 (Figure 42), which are likely affected by CSO discharge. Ammonia impacts from wet weather event 1 appeared more severe than from event 2.

PADEP has established maximum total ammonia nitrogen standards for the waters of the Commonwealth, but each sample must be compared individually to a standard that integrates sample temperature and pH to account for dissociation of ammonia in water. Higher temperatures and more alkaline pH allow more ammonia to be present in the toxic, unionized form. Total ammonia nitrogen concentration was above 1.0mg/l in only 1 of 208 samples, a wet weather sample from site DCC208. Despite pH values that occasionally exceeded 8.0, no violations of ammonia water quality standards were observed. However, continuous water quality monitoring instruments recorded pronounced fluctuations in pH at sites DCD765 and DCC110 due to algal blooms. It is likely that if ammonia nitrogen were present during periods of upper-range pH violations (i.e., measurements greater than 9.0), its toxicity would be high.

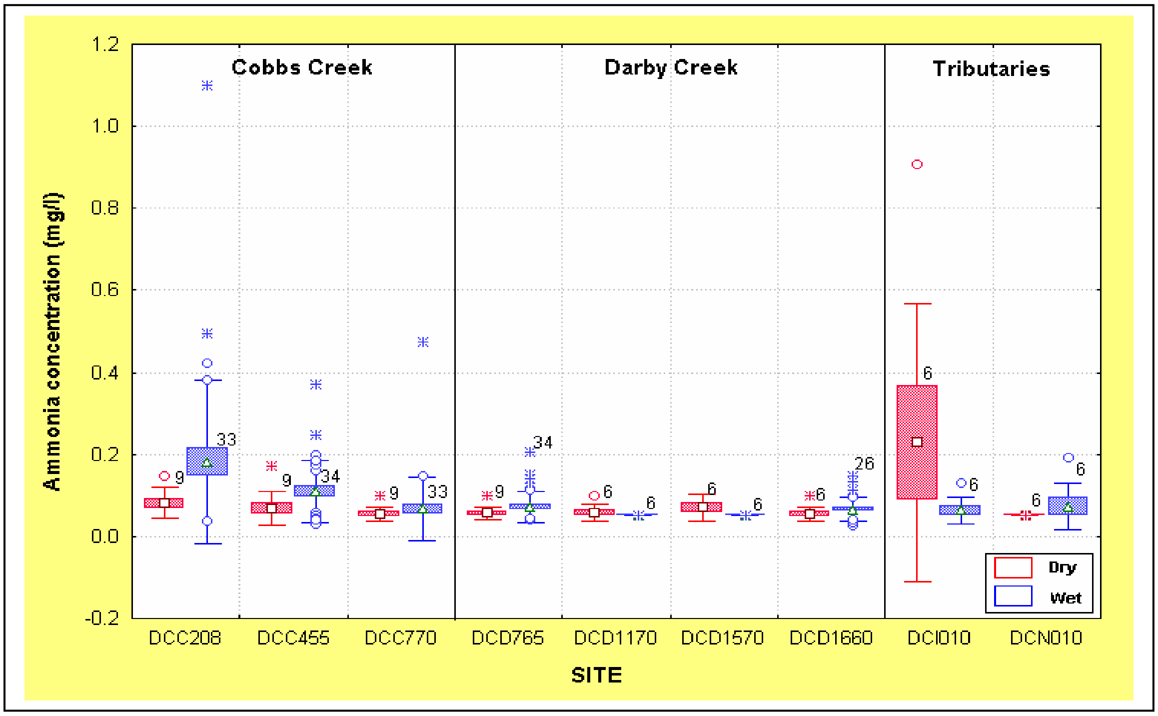

Figure 42. Dry and wet weather ammonia concentrations at the 9 monitoring sites.

5.4.8.5. Total Kjeldahl Nitrogen (TKN)

TKN provides an estimate of the concentration of organically-bound N, but the test actually measures all N present in the trinegative oxidation state. Ammonia must be subtracted from TKN values to give the organically bound fraction. TKN analysis also does not account for several other N compounds (e.g., azides, nitriles, hydrazone); these compounds are rarely present in significant concentrations in surface waters. Two outliers were excluded from the data analysis and graphics- these samples were collected from sites DCI010 and DCC455 during a sewer leak 6/12/03. TKN concentrations from these two sites were much greater than other dry weather samples and correspond with abnormally large concentrations of other parameters that serve as indicators of sewage contamination, (i.e., fecal coliform and *E.coli* bacteria, nitrate, ammonia, etc.) observed at these sites on this date.

Every site but DCC208 had TKN concentration less than the reporting limit of 0.3mg/l on at least one occasion. All sites experienced increases in TKN concentration during wet weather, but this phenomenon was more pronounced at Darby Creek sites. Increases during wet weather can probably be attributed to organic compounds in stormwater runoff, breakdown products of accumulated streamside (allochthonous) plant material, re-suspended organic sediment particles, and displaced (sloughed) algae. Much of the TKN present during larger flows in Darby-Cobbs Watershed may reach the Delaware estuary still in an organically-bound state.

5.4.8.6. Phosphorus

Phosphorus, like nitrogen, is a macronutrient (element required by plants in relatively large amounts); P concentrations are often correlated with algal density and are used as a primary indicator of cultural eutrophication of water bodies. Phosphorus readily adsorbs to soil particles and is generally less mobile in soils than nitrogen compounds. Potential non-point sources of P are decomposing organic matter in or near the stream, runoff from industrial parks, agriculture and residential areas, and inorganic P adsorbed to soil particles that are washed into the stream by erosive forces. In fact, soil erosion may be the greatest source of P in some portions of Darby-Cobbs watershed. Point sources of P include CSO and SSO discharges; though infrequent, they contribute large amounts of phosphorus where and when they occur.

Total P includes some smaller fraction of P that is considered to be bioavailable, or readily usable by stream producers. Bioavailable P (BAP) includes soluble reactive P (SRP) and, depending on other factors, some portion of particulate inorganic P. Furthermore, some producer taxa can obtain P through production of endogenous alkaline phosphatases. Nutrient dynamics and the effects of P limitation have been studied extensively in limnetic systems, but care should be taken when applying conclusions from phytoplankton dominated systems (i.e., lakes) to small streams. For example, in periphyton dominated streams, nutrients may be re-mineralized and recycled many times within the biofilm.

Stream producers in Darby-Cobbs Watershed are exposed to flow and a somewhat constant rate of nutrient delivery, albeit one that is punctuated with episodic inputs of greater P concentration due to runoff and erosion. These inputs, however, are coupled with physical disturbances (e.g., hydraulic shear stress, other abrasive forces, reduced light availability). These stressors respond to changes in flow in a non-linear fashion. Many taxa have the ability to store intercellular reserves of inorganic nutrients ("luxury consumption") when concentrations exceed immediate demands. It is thus very difficult to estimate the concentration of P available to stream producers and draw conclusions about stream trophic status from the (usually limited) data available.

Nevertheless, stream nutrient criteria have been proposed. For example, New Jersey's Department of Environmental Protection (NJDEP) has established a criterion of 0.10mg/l total P for streams and rivers and 0.05mg/l total P for lakes and their tributaries. USEPA has suggested the use of ecoregion-specific criteria based on the 75th percentile of total P concentration in unimpacted reference streams, or, in the case of insufficient reference stream data, the 25th percentile of TP for all streams in the ecoregion. For the ecoregion that includes Darby-Cobbs Watershed, this criterion is (0.14) mg/l. Dobbs (1998) suggested that the mesotrophic/eutrophic boundary for TP is 0.07mg/l.

Total P concentration was used in analysis of Darby-Cobbs Watershed because orthophosphate (PO_4) concentrations were nearly always below reporting limits. Two data points from 6/12/03 at sites DCI010 and DCC455 were excluded from the analysis, because TP concentrations at these sites (0.22 and 0.130 mg/l, respectively) were likely influenced by a sewer leak in the immediate area. This sample from DCI010 was also the only dry weather sample in which PO_4 was detected (0.149mg/l).

5.4.8.7. *Phosphorus Concentration: Dry Weather*

Darby Creek sites generally had less TP in dry weather than Cobbs Creek sites (Figure 43). Overall, 77% of Darby Creek dry weather samples had total P concentration below the reporting limit of 0.05mg/l, while only 21% of Cobbs Creek sites had dry weather TP concentration below reporting limits. Though only two samples were above reporting limits, greatest mean total P concentration in dry weather (0.106 mg/l) was observed at site DCI010, which is located downstream of golf courses and areas where resident Canada geese congregate. Excluding samples below reporting limits, the watershed overall had mean dry weather TP concentration of 0.073mg/l, which is below NJDEP's criterion, approximately half the proposed EPA criterion, and slightly greater than the mesotrophic-eutrophic boundary concentration proposed by Dobbs (1998).

5.4.8.8. *Phosphorus Concentration: Wet Weather*

Total P concentrations were significantly higher in wet weather than in dry weather at sites DCC208, DCC455, DCC770, and DCD767 (student's t-tests, $p<0.05$) (Figure 43). Total P concentrations were also higher at all other sites, but statistical power was limited

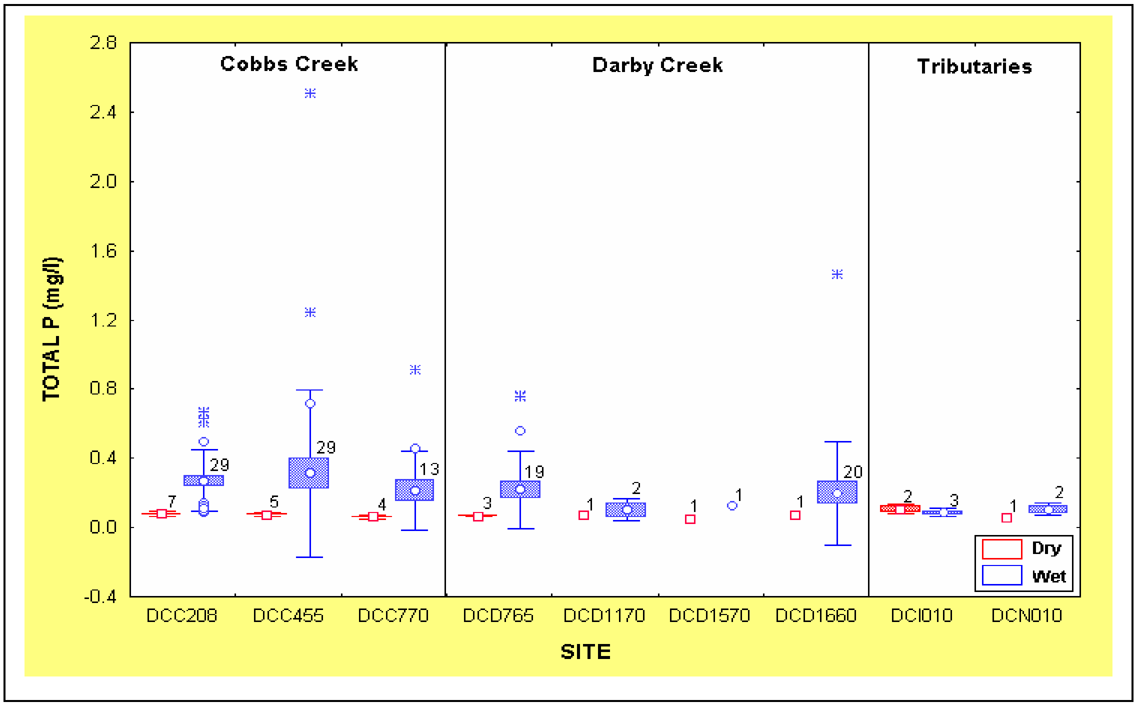

Figure 43. Dry and wet weather total phosphorus concentrations at the 9 monitoring sites.

with too few samples exceeding reporting limits. Despite greater total P concentrations in wet weather, PO_4 concentrations never exceeded reporting limits in wet weather, indicating that the majority of P within the watershed is adsorbed to sediment particles or organically-bound and is not immediately usable by stream producers. The degree to which wet weather P becomes bioavailable to stream producers depends on a variety of factors. Organically-bound macronutrients probably become transported out of the system (loading to the Delaware Estuary) during larger flows; P appears to be no exception.

5.4.8.9. Dry Weather N:P Ratios

Estimates of dry weather total N:P nutrient ratios were hindered by the number of samples with nitrite, total phosphorus, ammonia and/or TKN values below reporting limits. Only 3 of 69 samples could have nutrient ratios estimated directly. To generate a greater number of N:P ratio estimates, a value equal to half the reporting limit was substituted for all parameters with sample concentration less than the reporting limit (Figure 44). However, because of the lower reporting limit for total P, these values probably greatly overestimated N:P ratio. A more unorthodox comparison of NO_3 vs. actual TP observations was also used in an attempt to better estimate the relative proportions of these two nutrients (Figure 44). In any case, all sites within the watershed appear strongly P-limited.

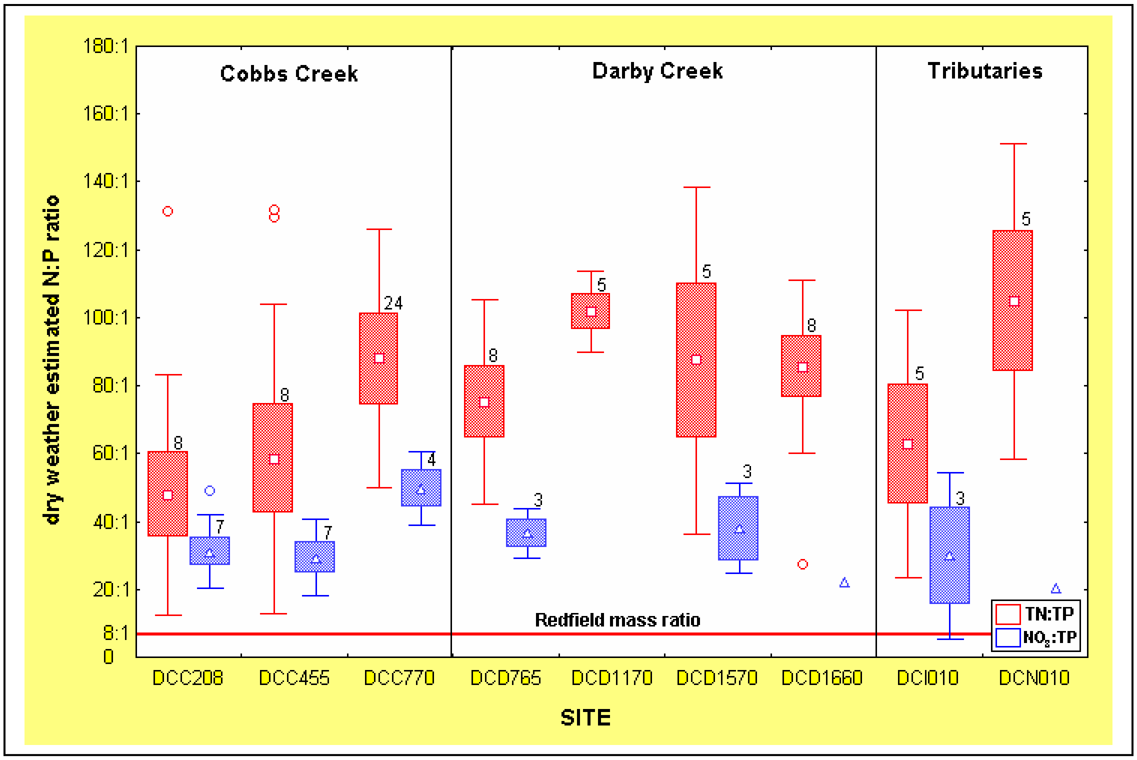

Figure 44. Estimated dry weather N:P ratios at the 9 monitoring sites.

5.4.8.10. Stream Nutrient Concentrations: Flow Implications

Stream nutrient concentrations in Darby-Cobbs Watershed are dynamic, often increasing in wet weather due to CSO discharge, runoff, and erosion. But concomitant increases in physical stressors probably impose limits on the degree to which stream producers can take advantage of these increased concentrations. Particle size selection, traditionally related to flow by entrainment velocity curves, may determine the effective P loading for a given sediment load. Smaller particles, due to their greater relative surface area, can adsorb relatively more P than larger particles. Smaller particles are also generally more readily eroded and entrained in stormwater flow than larger particles.

Smaller storm events in Darby-Cobbs Watershed probably contribute more to eutrophication than larger events. For example, if smaller sediment particles adsorb more P than larger particles as has been suggested, P loading becomes less efficient as larger particles are entrained in runoff. As shear stresses increase, streambank materials comprise a greater proportion of the sediment load. These particles are likely more similar to the soil parent material (i.e., lower in P concentration than more superficial soils layers that tend to incorporate more organic material). As flows increase, a greater proportion of the total load is transported out of the system, a greater proportion of the total nutrient load is inaccessible to producers, and much of the photosynthetic biomass (filamentous green algae and their associated epiphytes in particular) may be sloughed away and transported out of the system.

In areas served by combined sewers, the relative impact of small, intense storms is magnified. CSO discharge is minimally diluted by stormwater in the initial overflow phase, or "first flush". If nutrients present in these overflows can become deposited along with sediment or rapidly taken up by stream producers, discharges of short duration, particularly in which shear stresses do not result in major sloughing of algal communities, may have far-reaching consequences for stream nutrient dynamics and aquatic biota. A greater benefit may result from reducing frequency, number, and volume of small CSO discharges rather than attempting to capture releases from larger events.

SECTION 6: INDICATOR STATUS UPDATE

6.1. Overview

An important component of the Comprehensive Characterization Report is to provide concise updates on the biological, chemical and physical conditions within the Darby-Cobbs Watershed. Indicator status updates derived from this report will be used as a tool for identifying spatial and temporal trends of a particular stream reach or for the entire watershed. Moreover, indicators defined in the Cobbs Creek Integrated Watershed Management Plan will serve as benchmarks for future restoration projects. The indicators addressed in this report are as follows:

- Indicator 3: Stream Channels and Aquatic Habitat
- Indicator 5: Fish
- Indicator 6: Benthos
- Indicator 7: Effects on Public Health (Bacteria)
- Indicator 8: Effects on Public Health (Metals and Fish Consumption)
- Indicator 9: Effects on Aquatic Life (Dissolved Oxygen)

6.2. Indicator 3: Stream Channels and Aquatic Habitat

Indicator 3 of the Cobb Creek Integrated Watershed Management Plan stresses the importance of physical habitat features that will support healthy fish and benthic communities. As described in Section 5.3.1. EPA Habitat Assessment, thirteen habitat variables, ranging from instream parameters to riparian health, were compared against reference conditions to obtain an overall habitat integrity score.

In 2003, habitat at 17 sites throughout the Darby-Cobbs Watershed was surveyed by PWD staff biologists. Monitoring locations along Darby Creek mainstem received consistent scores, ranging from the highest value, “Comparable to Reference Conditions”, to the next incremental level, “Supporting” (Figure 45). Similarly, two tributary sites, Little Darby Creek and Ithan Creek, received ratings of “Comparable to Reference Conditions”.

In contrast to Darby Creek, habitat values along Cobbs Creek and its tributaries were less desirable. Of the four main stem locations, two sites received “Supporting” while the remaining two locations were designated as “Partially Supporting” (i.e., marginal). Naylor’s Run, a 2nd order tributary to lower Cobbs Creek, received rankings of “Supporting” in the upper portion and “Non-Supporting” near the confluence with Cobbs Creek. Similarly, sites on the east and west branches of Indian Creek were determined to be only “Partially Supporting” of aquatic communities.

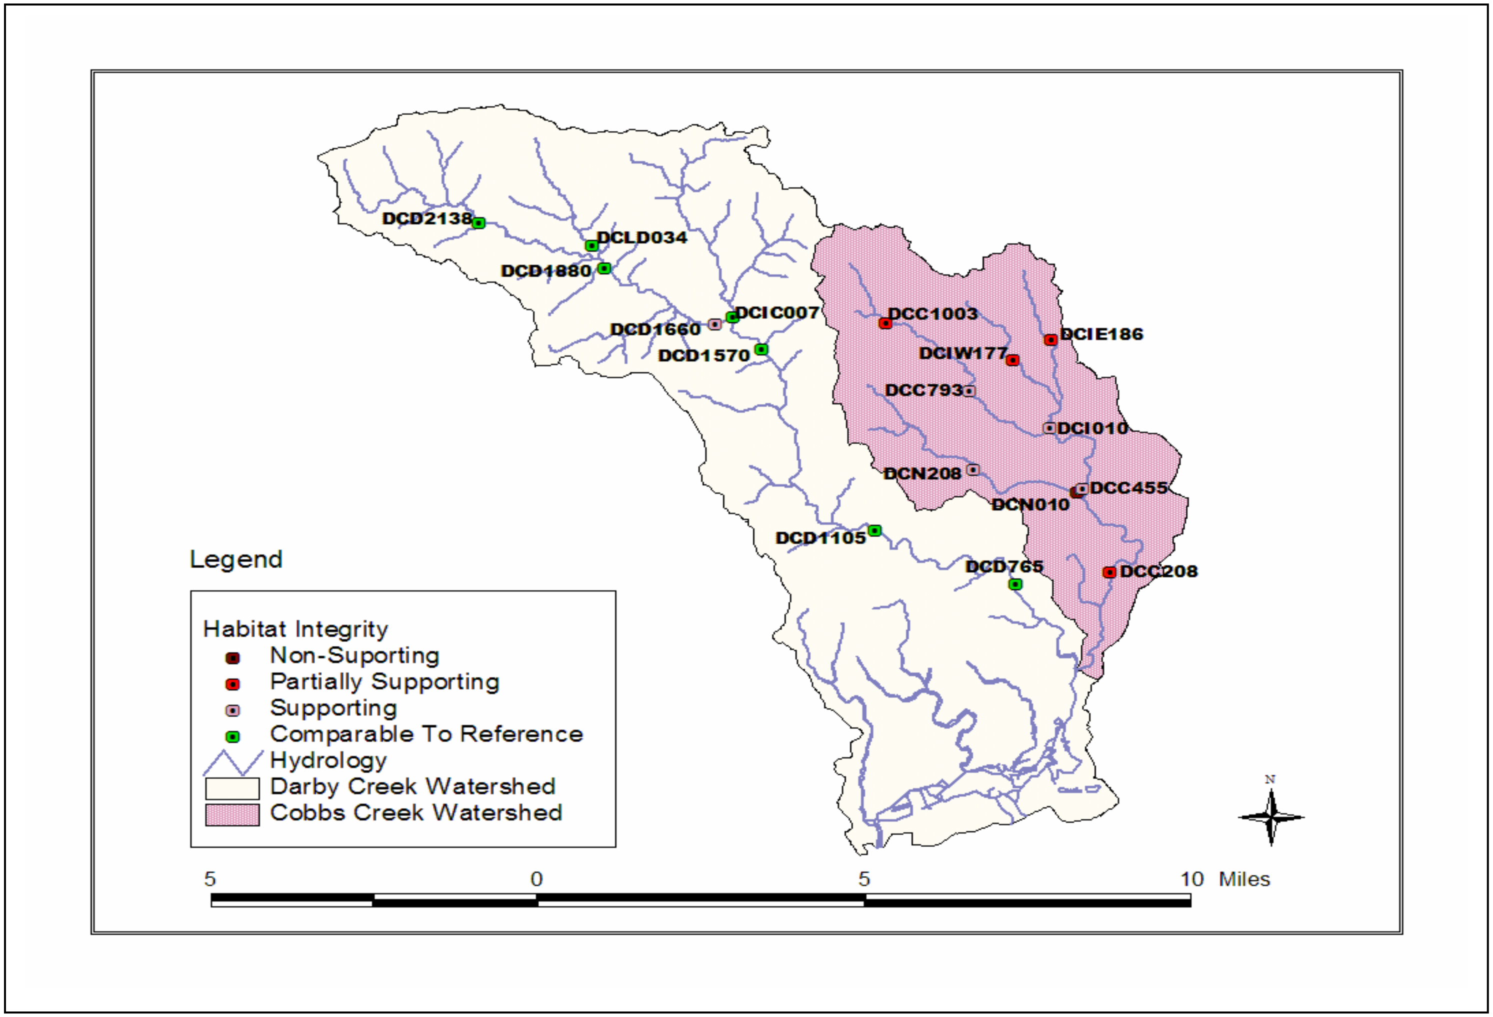

Figure 45. Stream channels and aquatic habitat indicator status update.

6.3. Indicator 5: Fish

During 1999, three surrogate indicators were used to define the integrity of fish communities in the Cobbs Creek Basin. Relative abundance (i.e., density), pollution tolerance and number of native species provided a semi-quantitative measurement of fish assemblage health. With the development of ecoregion-specific metrics, PWD has substituted the past indicators with the Index of Biological Integrity (IBI), a multi-metric approach that characterizes fish community health at a particular stream reach or at the watershed scale (Section 4.2.4. Fish IBI Metrics).

Fisheries data collected in 2003 revealed IBI scores varying among watersheds and spatially along the river continuum. More specifically, downstream sites on Darby Creek received scores of "good", while upstream locations were designated as "fair" or "poor" (Figure 46). Greater diversity, the presence of pollution-intolerant fish species and variation in trophic levels were among the major reasons for higher IBI scores in downstream portions of Darby Creek. Conversely, sites in Cobbs Creek received IBI scores in the "fair" to "poor" categories. Although fish density was generally greater in Cobbs Creek, community structure consisted of pollution-tolerant taxa with generalist feeding strategies.

After a thorough review of historical and recent data compiled on Cobbs Creek (i.e., 1999 and 2003), it is evident that active restoration strategies must be implemented and monitored over time to measure the efficacy of planned habitat restoration projects, as defined in the Darby-Cobbs Integrated Watershed Management Plan.

6.4. Indicator 6: Benthos

Benthic macroinvertebrate monitoring occurred at 17 sites in Darby-Cobbs Watershed during 2003. Similar to the 1999 sampling effort, Rapid Bioassessment Protocol III (RBP III) was chosen as the approved method for assessing the condition of the macroinvertebrate community in Darby-Cobbs Watershed.

The assessment conducted in 2003 reconfirmed findings of the Pennsylvania Department of Environmental Protection (PADEP) and Philadelphia Water Department (PWD). Benthic impairment in Cobbs Creek was omnipresent; stream designations ranged from "moderately impaired" to "severely impaired" (Figure 47). Darby Creek monitoring sites received the same designations, with the exception of one upstream site which scored as "slightly impaired".

The severity of impairment throughout Darby-Cobbs Watershed suggests that attaining healthy benthic communities in mainstem localities and associated tributaries is not a feasible option at this time. Habitat restoration, flow attenuation and active re-introduction (i.e., "invertebrate seeding") may be the only solutions to ensure a viable benthic community within this watershed.

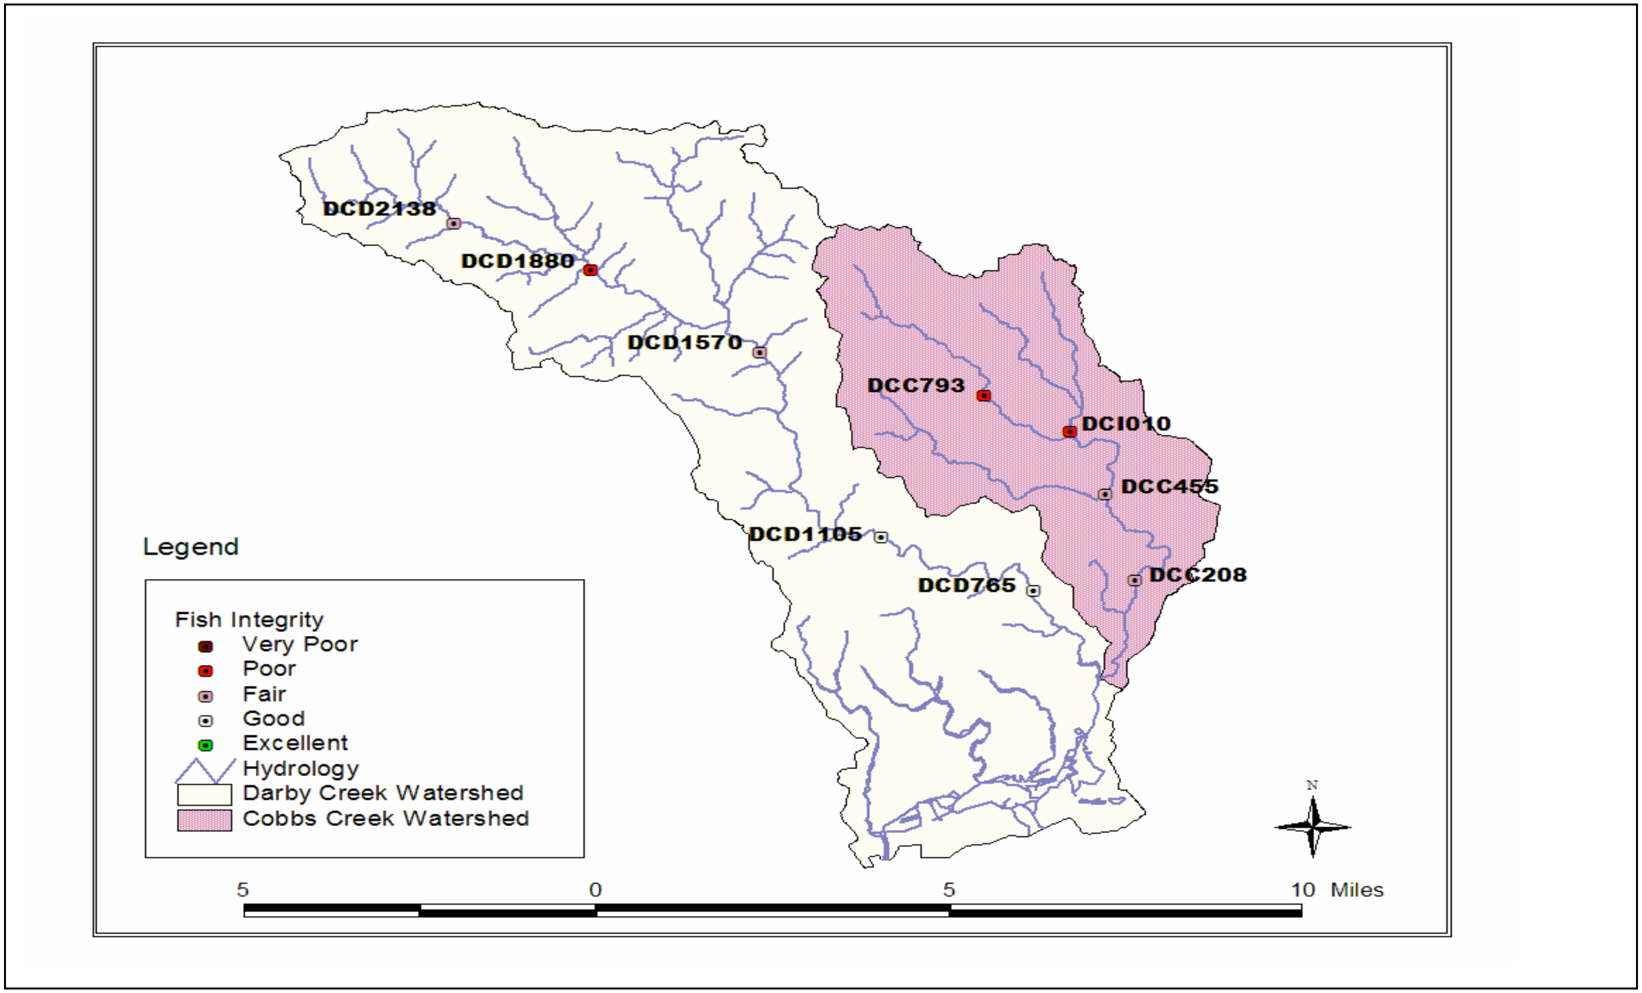

Figure 46. Fish indicator status update.

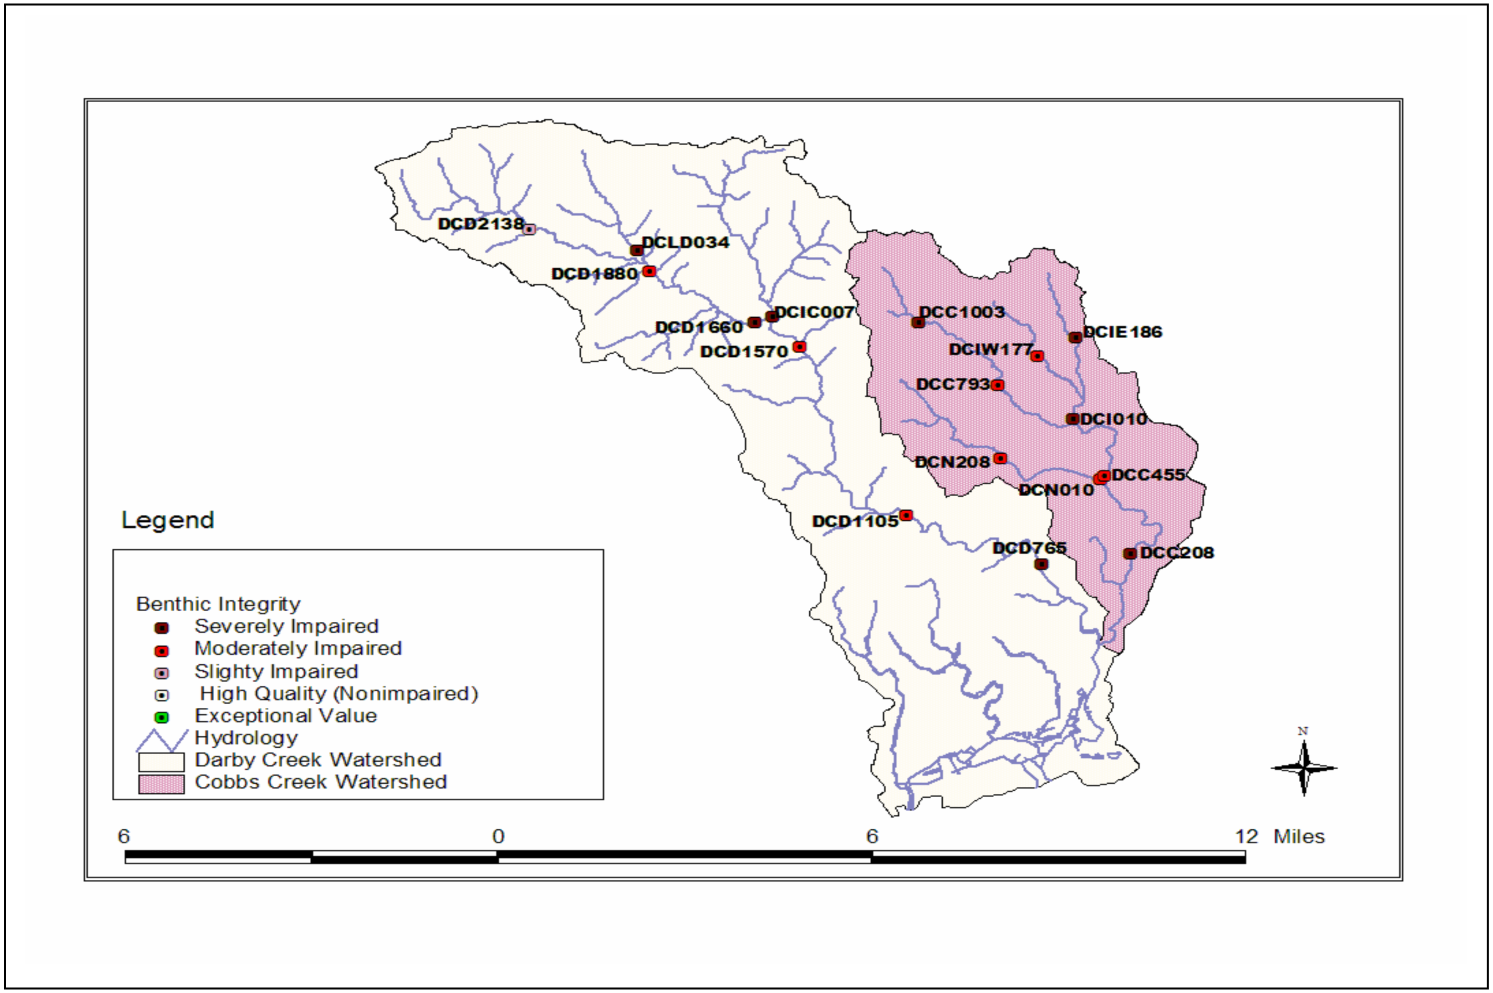

Figure 47. Benthic indicator status update.

6.5. Indicator 7: Public Health Effects (Bacteria)

Based on Pennsylvania's water quality criteria, the maximum fecal coliform concentration during the swimming season (i.e., May 1 through September 30) shall not exceed a geometric mean of 200 CFU per 100 ml for five nonconsecutive samples. During the remainder of the year, the maximum fecal coliform level should be equal to or less than a geometric mean of 2000 CFU per 100 ml based on five consecutive samples collected on different days.

During 2003, discrete chemical samples were taken at nine sites in Darby-Cobbs Watershed. Sampling events occurred at each site at weekly intervals for one month during three separate seasons (n= 12 sampling events per site). In addition, wet weather samples were collected during two runoff-producing storm events. Geometric means of fecal coliform concentrations were calculated during wet and dry periods for each site and compared to the appropriate standard.

Similar to 1999 and 2000 water quality sampling, mean concentration of fecal coliform during dry weather exceeded standards at all sites in Darby-Cobbs Watershed. In general, 33.3 % of all sites along Darby Creek mainstem met water quality standards during dry weather in 2003 (Figure 48). Geometric means calculated for Darby Creek sites revealed that values were generally between 2 to 4 times the season standards (i.e., 200 CFU/100 ml or 2000 CFU/100 ml) (Figure 49). In Cobbs Creek, sites DCI 010 and DCC 208 met water quality standards in 50.0 % and 33.3 % of the samples, respectively. Upstream and midstream sites (DCC 770 and DCC 455) had less desirable results, with standards being met only 22% of the time. No samples taken on Naylor's Run (DCN 010) met water quality standards during the swimming and non-swimming seasons.

Wet weather sampling results showed concentrations of fecal coliform exceeding water quality standards at all sites in Darby-Cobbs Watershed (Figure 50). Thirty-three percent of samples at Darby Creek sites met standards while only 16.7% of samples in Cobbs Creek were below water quality standards. Moreover, fecal coliform concentrations were between 2 to 10 times greater than standard values in Darby Creek (i.e., 400-2000 CFU/100 ml during the swimming season). Similarly, mean concentrations of fecal coliform were greater than the water quality standard but varied spatially along the river continuum (Figure 51). For example, concentrations at the upstream location (DCC 770) were between 2 to 10 times the standard limit and increased steadily until values reached between 50 to 200 times (i.e., 10,000-40,000 CFU/100 ml) the water quality standards at Site DCC 208. Similarly, concentrations of fecal coliform at tributary locations (i.e., DCN 010 and DCI 010 ranged between 2,000 to 10,000 CFU/100 ml during wet conditions.

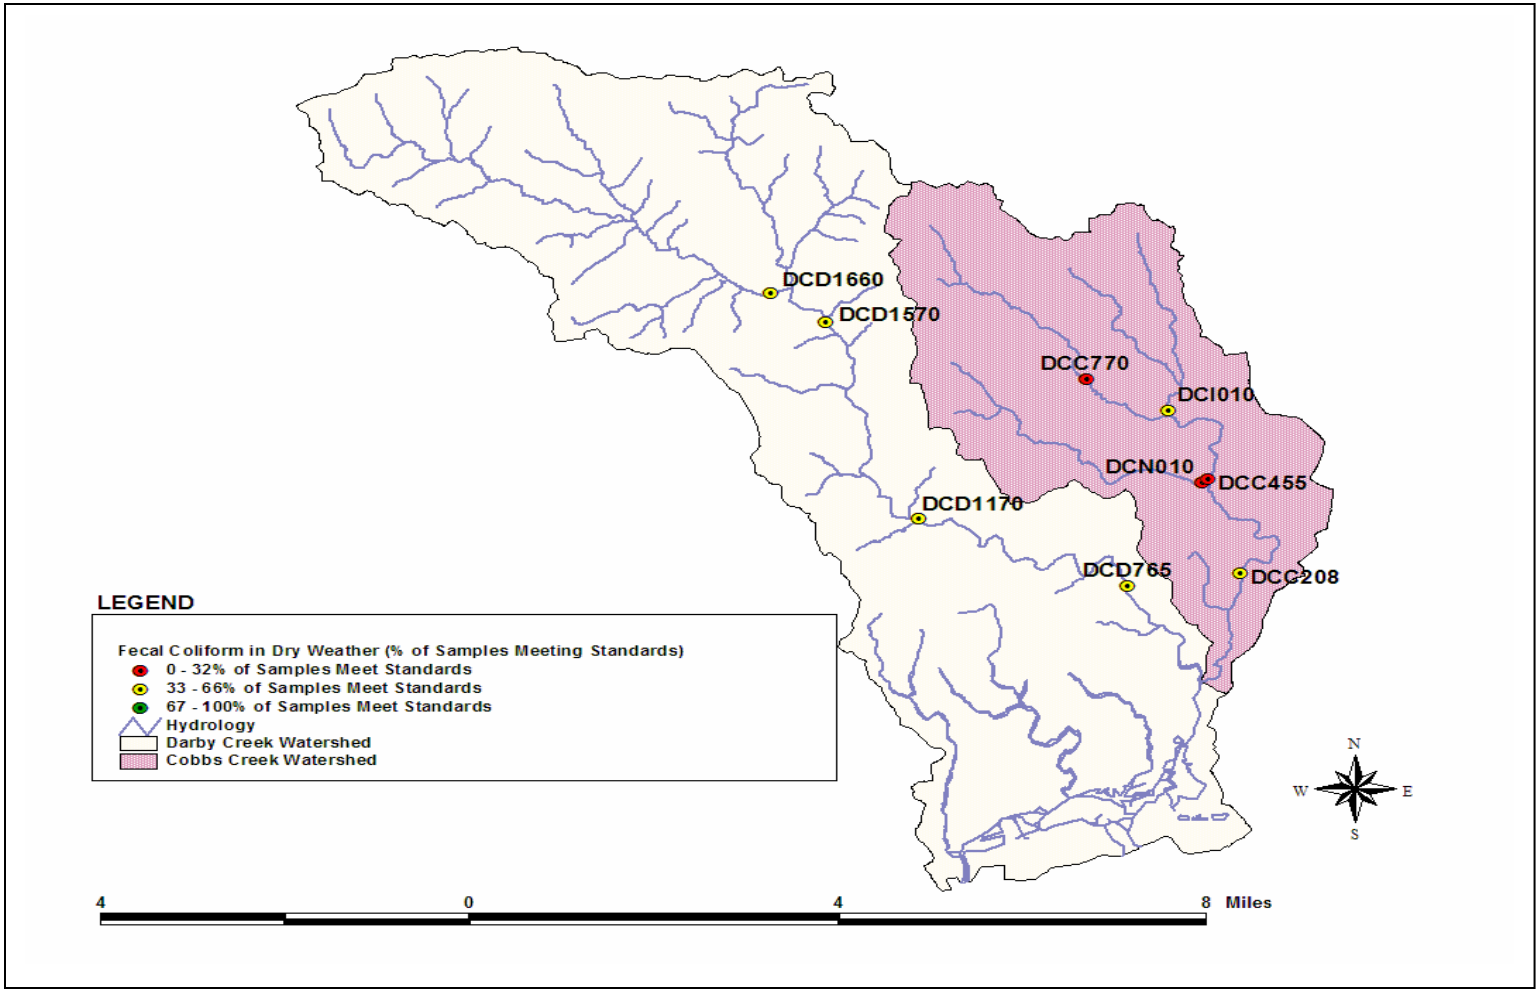

Figure 48. Dry weather fecal coliform indicator status update.

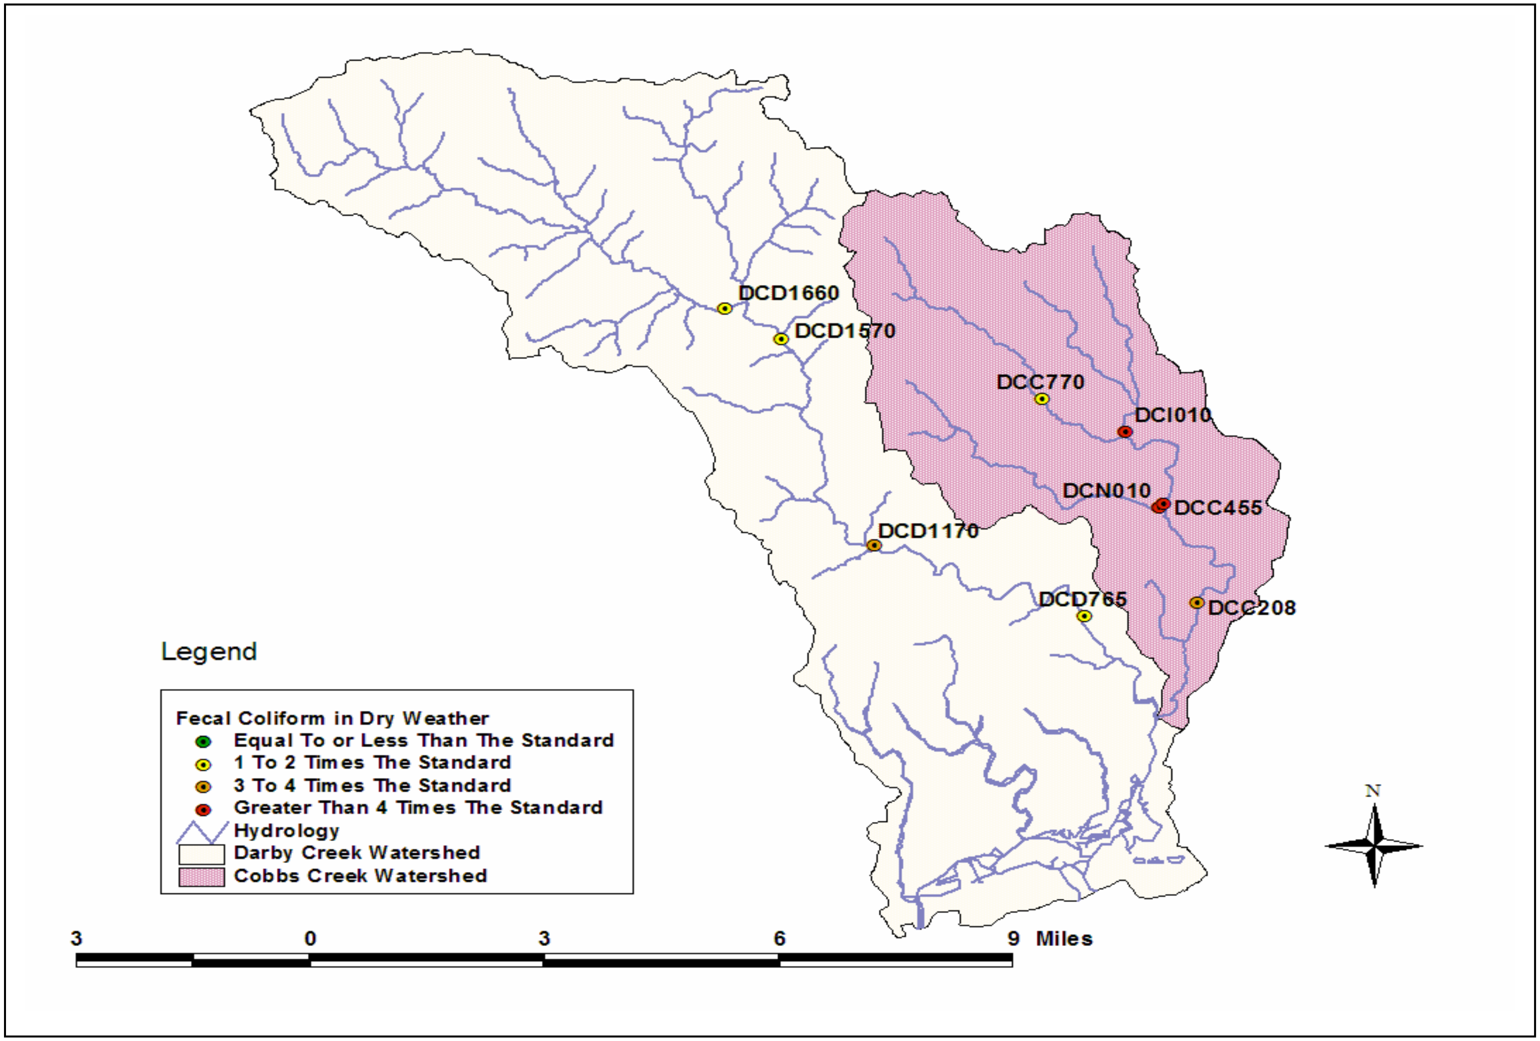

Figure 49. Geometric means of fecal coliform concentrations in dry weather

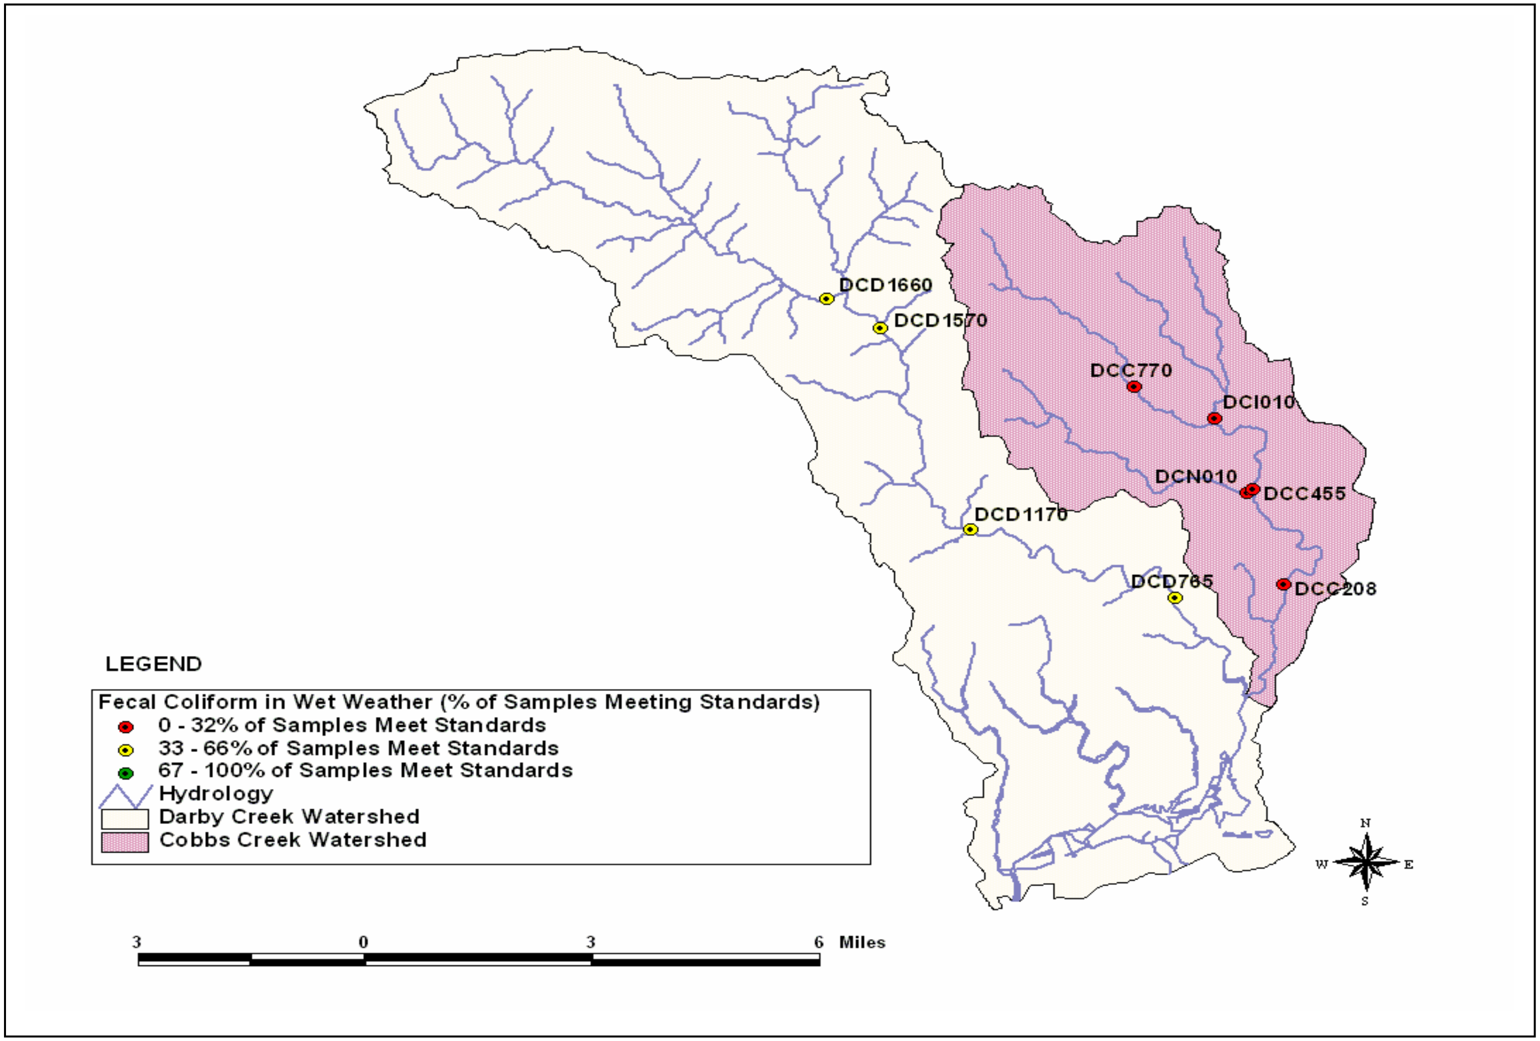

Figure 50. Wet weather fecal coliform indicator status update.

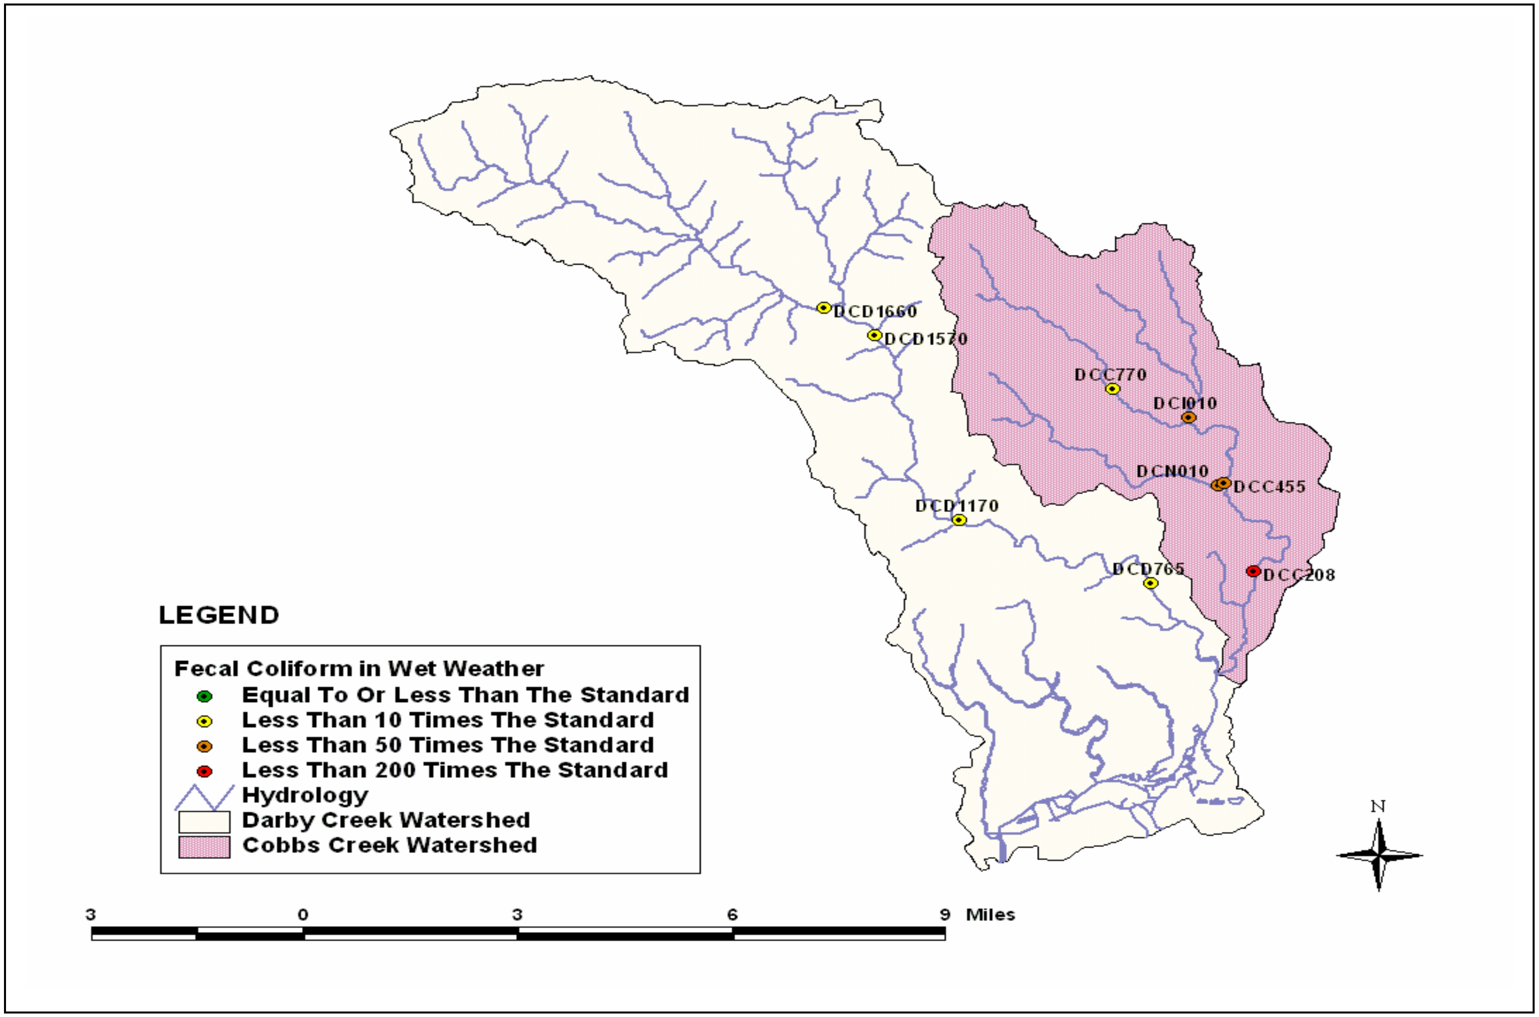

Figure 51. Geometric means of fecal coliform concentrations in wet weather.

6.6. Indicator 8: Public Health Effects (Metals and Fish Consumption)

Relatively small amounts of certain toxic compounds can kill aquatic life through acute poisoning, while chronic levels may be harmful to developmental stages of fish and macroinvertebrates. For example, bioaccumulation of toxins in fish may have a profound effect on fecundity and may also pose a threat to humans who regularly consume fish.

The established indicator measures the percent of cadmium, chromium, copper and zinc samples meeting state standards at various sites in Darby-Cobbs Watershed. In 2003, PWD scientists collected 48 samples at each site for Cd, Cr, Cu and Zn during dry and wet weather. An additional 48 to 56 samples were collected at each site during two wet-weather targeted events.

Results suggest standards intended to protect aquatic life were met at all locations during dry-weather in 2003 with the exception of copper in the upper reach of Darby Creek (Figure 52). Conversely, wet-weather exceedances were omnipresent on both the Darby Creek and Cobbs Creek (Figure 53). Of the metals, aluminum and copper generally exceeded standards more than 10 % of the time, while chromium and lead samples were greater than Pennsylvania's water quality criteria between 2% - 10% of the time.

6.7. Indicator 9: Aquatic Life Effects (Dissolved Oxygen)

During 2003, automated water quality monitors (i.e., Sondes) were deployed in Darby-Cobbs Watershed at three locations in Cobbs Creek and two locations in Darby Creek. Sondes were deployed for approximately one month, recording dissolved oxygen concentrations (mg/L) every 15 minutes. In total, approximately 792 hours of data were recorded at each site between 8/14/03-9/16/03.

Continuous data in from two Darby Creek sites indicated that DO concentrations did not fall below the instantaneous concentration standards (i.e., 5 mg/l in the upstream location and 4 mg/l in lower Darby Creek) (Figure 54). Similar results were observed in the upper reaches of Cobbs Creek (DCC 770). At site DCC 455, dissolved oxygen concentrations fell below the 4 mg/l limit less than one percent of the total recorded data. At site DCC 455, however, dissolved oxygen levels violated water quality criteria approximately 2.9 % of the time.

A probable explanation for this occurrence is the high level of algal activity as a result of stagnant flow, nutrient inputs and lack of forest canopy in this vicinity. As indicated in the Darby-Cobbs Integrated Watershed Management Plan, plans to increase stream velocity, such as dam removal and physical restoration, and increased vegetative protection will potentially eliminate the large diurnal DO swings associated with an overabundance of primary producers in downstream of Cobbs Creek sites.

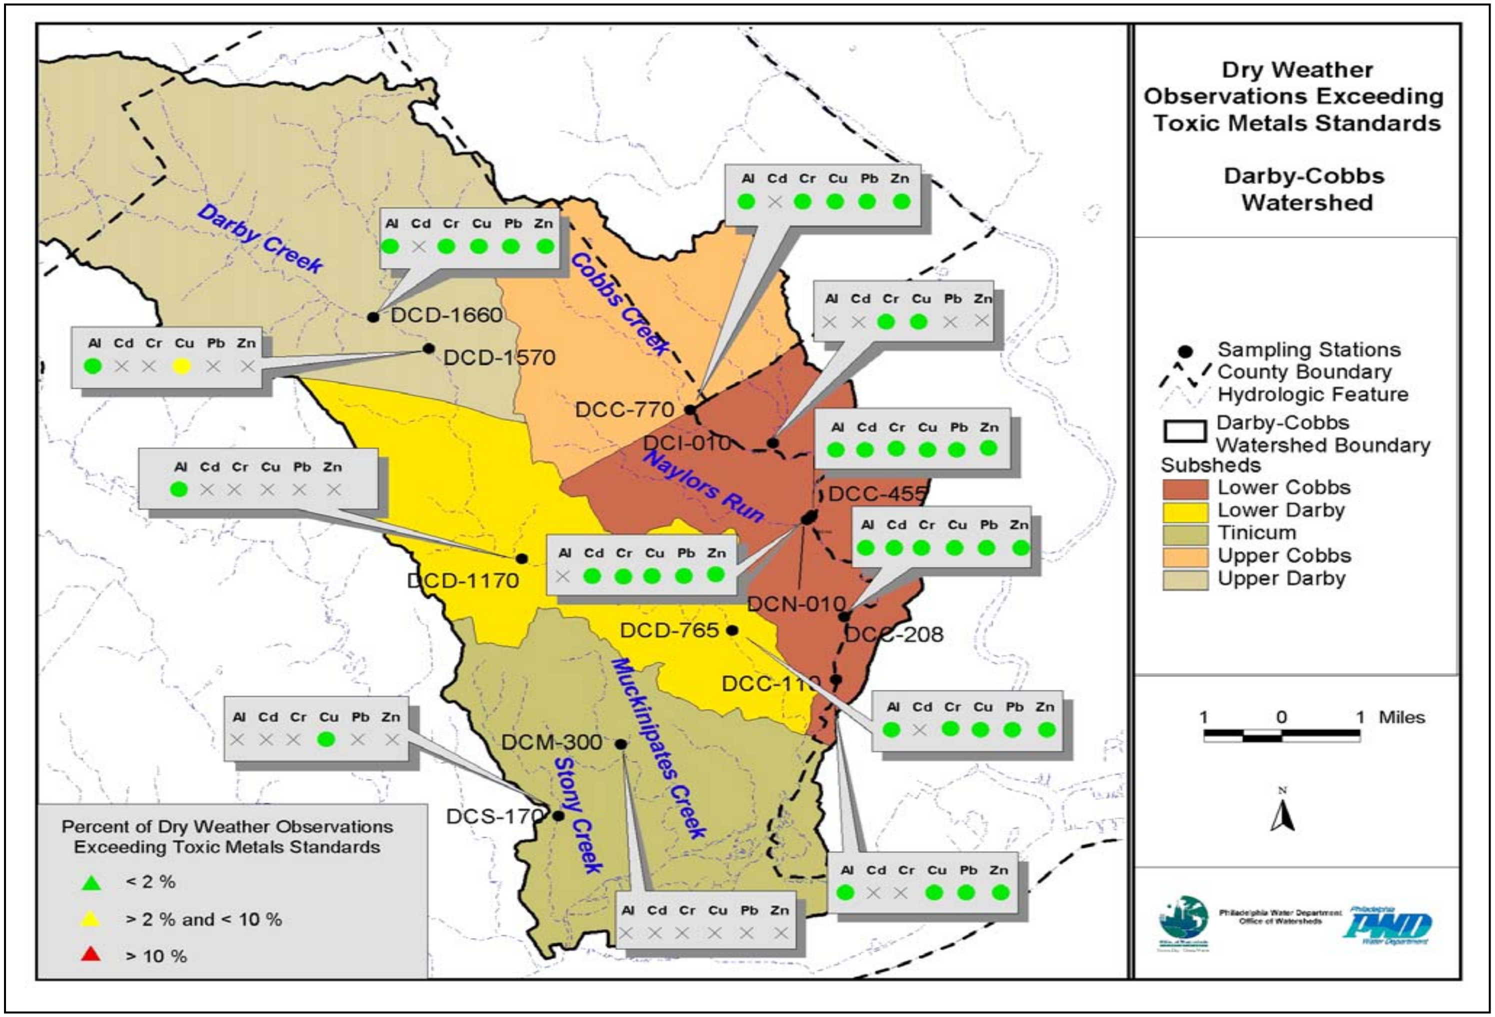

Figure 52. Dry weather metals indicator status update.

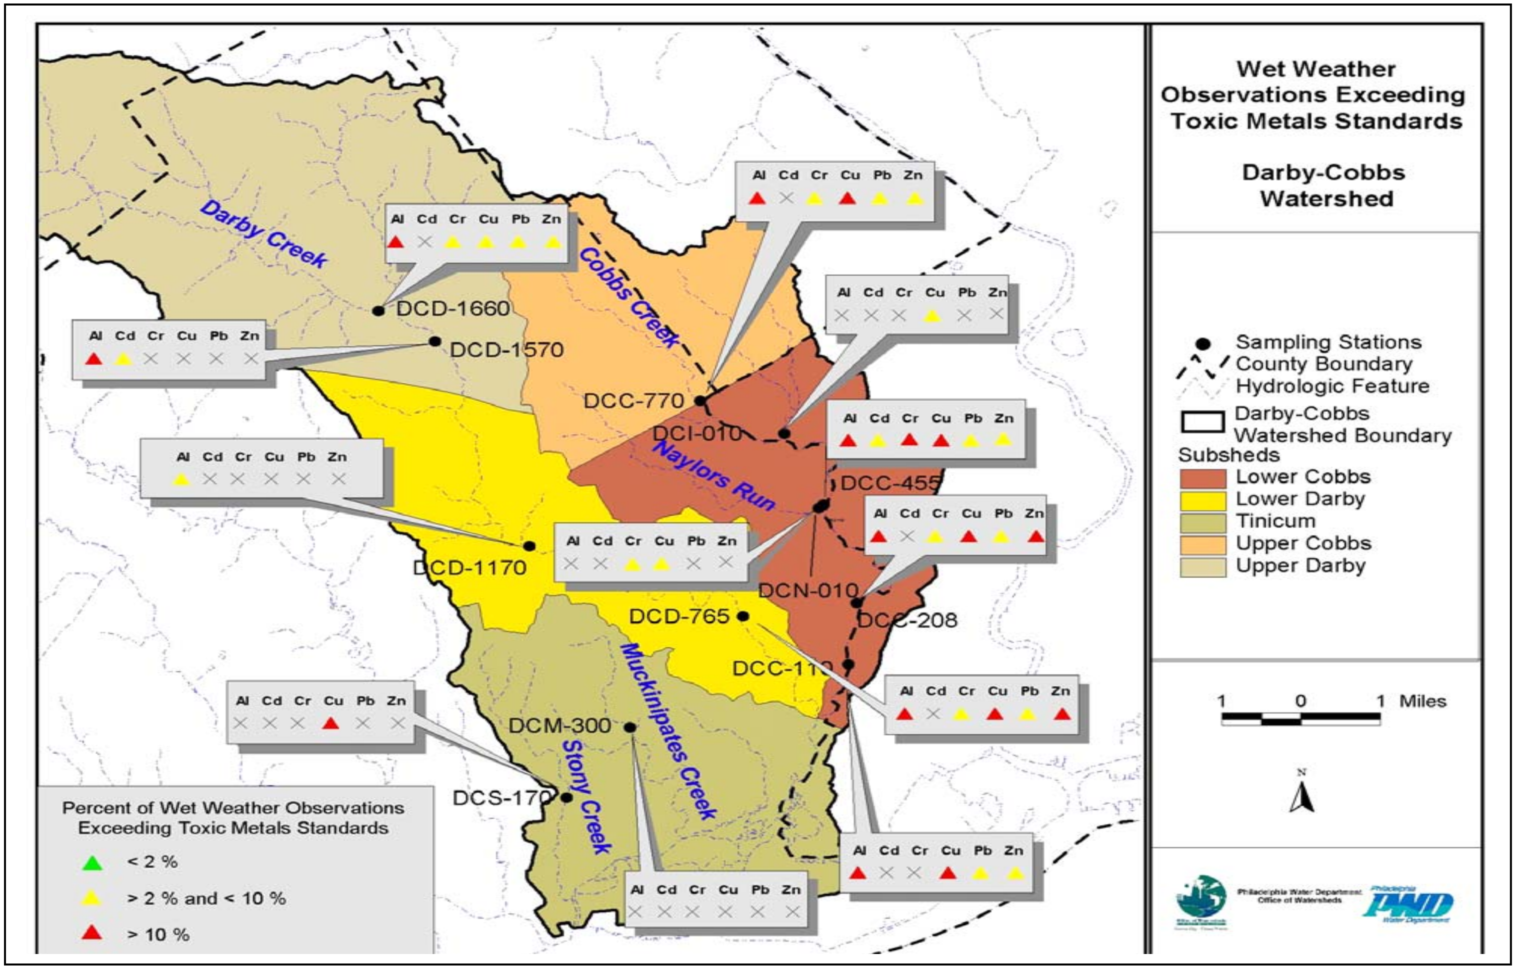

Figure 53. Wet weather metals indicator status update.

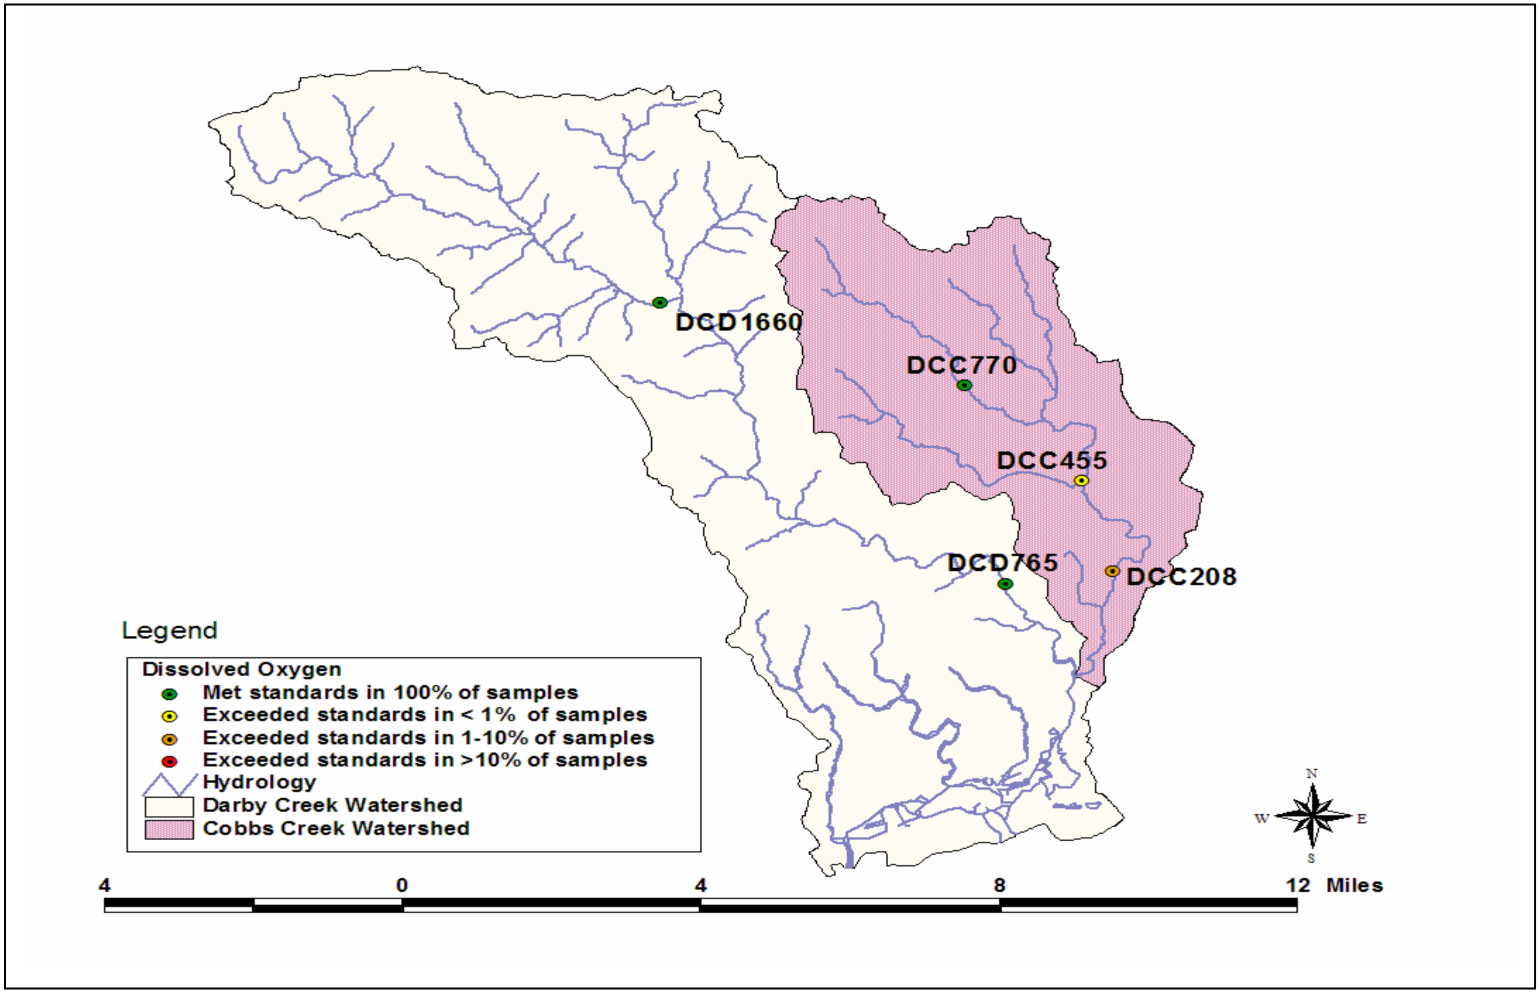

Figure 54. Dissolved oxygen indicator status update.

SECTION 7: EXECUTIVE SUMMARY

Problems faced by the Darby-Cobbs Watershed stem from many sources, but succinctly, the watershed suffers from excess land development and urbanization. These effects are evident in the physical habitat, and reflected by biological communities and water quality samples collected from the watershed. Though numerous impairments exist, habitat modification and physical disturbances stand out as the most important factors, underlying all other biological impairments. Healthy ecosystems cannot exist without healthy habitats.

With impervious cover contributing in excess of 30% of the land area in many subsheds, stormwater flows have de-stabilized much of the stream channels of the watershed. Many first order tributaries have been lost. Urbanization promotes a cumulative, self-reinforcing pattern of streambank erosion. As stream channels become physically larger and further disconnected from their historic floodplains, more stormwater forces are restricted to the stream channel, where compromised, heavily eroded banks are least suited to dissipate them.

Widespread urbanization, as present in the Cobbs Creek Watershed, magnifies flow modification by decreasing infiltration and groundwater recharge- establishing a hydrologic pattern of "feast or famine". Presently, baseflow accounts for only 42% of total mean annual flow in the Cobbs basin. Effects of urbanization and physical habitat degradation were evident in biomonitoring data, but these effects were more severe in Cobbs Creek Watershed. The Cobbs Creek Integrated Watershed Management Plan (CCIWMP) outlines several options for detaining, infiltrating, and treating stormwater to reduce its impact on the stream channel and aquatic habitats. The watershed cannot be restored without addressing these stormwater impacts.

Sunlight provides most energy to the Darby-Cobbs Watershed. Attached algae and aquatic mosses are the primary producers, and constitute the base of the aquatic ecosystem. Algae were not generally observed to grow to nuisance levels, with the possible exception of slow water areas behind dams and other obstructions. Continuous water quality monitoring and field observations at some sites suggest that periphytic algae are responsible for pronounced diurnal fluctuations in dissolved oxygen (DO) concentration and pH that may stress natural fish and invertebrate communities. Algal community structure and biomass also change drastically at some sites due to scouring storm events.

It is expected that activities recommended under Target B of the CCIWMP (i.e., streambank restoration, dam removal and modification, and re-engineering of slow water areas and scour pools) will greatly reduce the amount of stream area subject to severe DO and pH fluctuations. Identification and correction of dry weather sewage inputs, as required by existing regulations, should also help reduce nutrient inputs that drive algal production. Riparian shading reduces both algal biomass potential and the magnitude of DO fluctuations, but riparian zone management must balance stream shading needs with allowing enough light penetration to support a multi-tiered native plant community. If stream habitat is restored and dissolved oxygen conditions are favorable, invertebrate and fish communities can be restored as well.

Invertebrate communities in Darby-Cobbs Watershed sampled in 2003 generally indicated impairment when compared to reference conditions, but this impairment was more severe in Cobbs Creek than in Darby Creek. Most sites showed a simplified invertebrate community dominated by chironomid midges and net spinning caddisflies- moderately tolerant invertebrates with generalized food requirements. These invertebrates can resist scouring and frequent disturbance of their habitat by firmly attaching themselves to stream substrates with silk. Free-living active invertebrates, predators, sensitive species, and invertebrates with feathery external gills were rare at some Darby Creek sites and completely absent from most Cobbs Creek sites and tributaries. The role of sediment toxicity or anoxia on invertebrate communities remains unknown, but water chemistry samples from some sites showed that concentrations of metals of concern (e.g., copper, lead, aluminum, iron, and zinc) may exceed state water quality criteria.

Fish assessments generally mirrored results of the macroinvertebrate study, with most sites exhibiting less diversity and specialization than fish communities found at reference sites. As a whole, the watershed was dominated by a small number of moderately tolerant species with generalized feeding habits and life history strategies. Fish species that have been shown to be tolerant of habitat degradation and food source limitation were dominant, while species that have specialized habitat, food or reproductive needs were largely missing from the Cobbs Creek basin. The most important species (in terms of biomass) was American eel, a species that spawns in the ocean, can tolerate extreme flows, and epitomizes the term "generalist feeder". Though upper reaches of Darby Creek watershed support a put-and-take trout fishery, fishery restoration plans for the watershed as a whole must be realistic in view of the watershed's "warmwater" designation and the immutable constraints of climate, geology and geography. Temperature and DO regime are ultimately and absolutely bound by these constraints.

Water quality investigations documented many violations (or in the case of toxic metals, possible violations) of state water quality criteria, particularly in wet weather. Combined sewers periodically release a mixture of raw sewage and stormwater to many areas of Darby-Cobbs Watershed. Damaged, improperly sized, or choked sanitary sewers and illicit connections may also release raw sewage to the watershed. Because much of Darby-Cobbs Watershed is not meeting state water quality standards for fecal coliform bacteria during dry weather, investigation and abatement of dry weather sewage sources is one of the most important components of Target A of the CCIWMP. Streams must be safe during the times when people are most likely to come in contact with them. Dry weather source trackdown is the most cost effective step toward meeting water quality standards during dry weather.

However, research shows that fecal coliform bacteria may persist for extended periods of time in stream sediments. It is possible that the effects of periodic wet weather CSO discharge may be long-lasting and cause some streams to have "background" fecal coliform concentrations in excess of water quality standards even once dry weather sources are eliminated. Wildlife and domestic animals are also sources of fecal coliform bacteria that cannot be overlooked. Reducing wet weather sewage sources is the goal of The City of Philadelphia's CSO Long Term Control Plan (LTCP). Over the next two years PWD is committed to a 20% reduction in CSO volume citywide.

These CSO reductions may be realized through a number of technologies, but it is imperative that the chosen solution (or solutions) address the actual cause of impairment. For example, small storm events likely contribute maximally to nutrient enrichment and algal blooms, as the relative proportion of sanitary sewage is largest and physical stresses due to sloughing and turbidity are smallest. While large storm events cause a greater amount of nutrients to be passed through the system, sloughing and turbidity reduce the ability of the algal community to take advantage of these nutrients. The greatest improvements may arise from prioritizing, controlling, and eliminating sources of nutrients when and where conditions are favorable for algae.

Recognition of the need to protect people from water and sewage-borne diseases and parasites has extricated us from the "dark ages" of public health, spawning regulations and the technical innovations needed to meet them. As our knowledge of threats to people and the natural environment grows, water quality regulations are under continuous revision. Unfortunately, scientific research and environmental regulations often outpace practical implementation of corrective measures.

The current state of the Darby-Cobbs Watershed is the product of more than a century of neglect and abuse, and correcting these problems will require an enormous commitment. Furthermore, this effort will take many years and cost millions of dollars. As a group of engineers and scientists in the service of the public, the Philadelphia Water Department is working to ensure that Philadelphia's watershed improvements are cost-effective and based on sound science. We believe that the ideas and options presented in the Cobbs Creek Integrated Watershed Management Plan represent reachable goals and provide a road map for attaining those goals.

Cobbs Creek Integrated Watershed Management Plan

Darby-Cobbs Watershed Partnership Mission Statement

"To improve the environmental health and safe enjoyment of the Darby-Cobbs watershed by sharing resources through cooperation of the residents and other stakeholders in the watershed. The goals of the initiative are to protect, enhance, and restore the beneficial uses of the Darby-Cobbs waterways and riparian areas. Watershed management seeks to mitigate the adverse physical, biological, and chemical impacts of land uses as surface and groundwater are transported throughout the watershed to the waterways."

Executive Summary

Foreword

This plan presents a logical and affordable pathway to restore and protect the beneficial and designated uses of the waters of the Cobbs Creek basin. Based on extensive physical, chemical and biological assessments, the plan explores the nature, causes, severity and opportunities for control of water quality impairments in the Cobbs Creek watershed. The primary intent of the planning process, as articulated by the stakeholders, is to improve the environmental health and safe enjoyment of the Cobbs watershed by sharing resources and through cooperation among residents and other stakeholders in the watershed. The goals of the initiative are to protect, enhance, and restore the beneficial uses of the Cobbs waterways and its riparian areas. The plan recommends appropriate remedial measures for the Cobbs Creek basin, provides a financial commitment to initiate the implementation of the plan, and seeks to provide the impetus for stakeholders of the Darby basin to follow suit.

The Darby-Cobbs Watershed Partnership worked with the Philadelphia Water Department to complete a comprehensive, multi-year watershed assessment covering the Darby, Cobbs, and Tinicum sub-basins (see Figure E-1). Results of the watershed-wide assessment suggests that at some times during dry weather periods, bacteria contamination of the Cobbs's waters prevents the achievement of water quality standards that would support swimming or other forms of primary contact recreation in the creek. Also, stream aesthetics, accessibility and safety are compromised due to illegal litter and dumping, trash from stormwater discharges, and bank deterioration along the stream corridors. Existing aquatic and riparian habitat, degraded by urban runoff, limit the diversity of fish and benthic life and prevent the development of healthy living resources conditions necessary to support recreational activities such as fishing. Wet weather water quality is limited by bacteria discharged from combined and separate storm sewers. High rates of urban runoff cause flood flows that erode the stream banks and bottoms and expose and compromise utility infrastructure.

The good news is that measurable progress can be made towards restoring the legislated designated beneficial uses of the stream. To this end, this plan provides an investment strategy for achieving definable levels of environmental return in the Cobbs Creek basin. It is estimated that significant progress towards improving the areas of environmental concern discussed above can be made for an investment of less than $100 per household per year over a 20-year horizon. The plan proposes that the other municipalities in the Cobbs basin make similar financial commitments to implementation that will ensure the restoration and preservation of the waters that flow from and through their communities, shaping their quality of life along the way. A significant portion of this funding is directed towards work that reflects the widely recognized national need to renew our water resources infrastructure. These efforts basically are things that should be done anyway. It is proposed that a combination of Federal, state, local government, and private funding be brought to bear to implement this plan. The Philadelphia Water Department expended over $1 million in the development of the plan, and will commit $2 million per year or more towards implementing its recommendations over the next 20 years. The plan proposes that the other municipalities in the Cobbs basin make similar financial commitments to implementation that will ensure the restoration and preservation of the waters that flow from and through their communities.

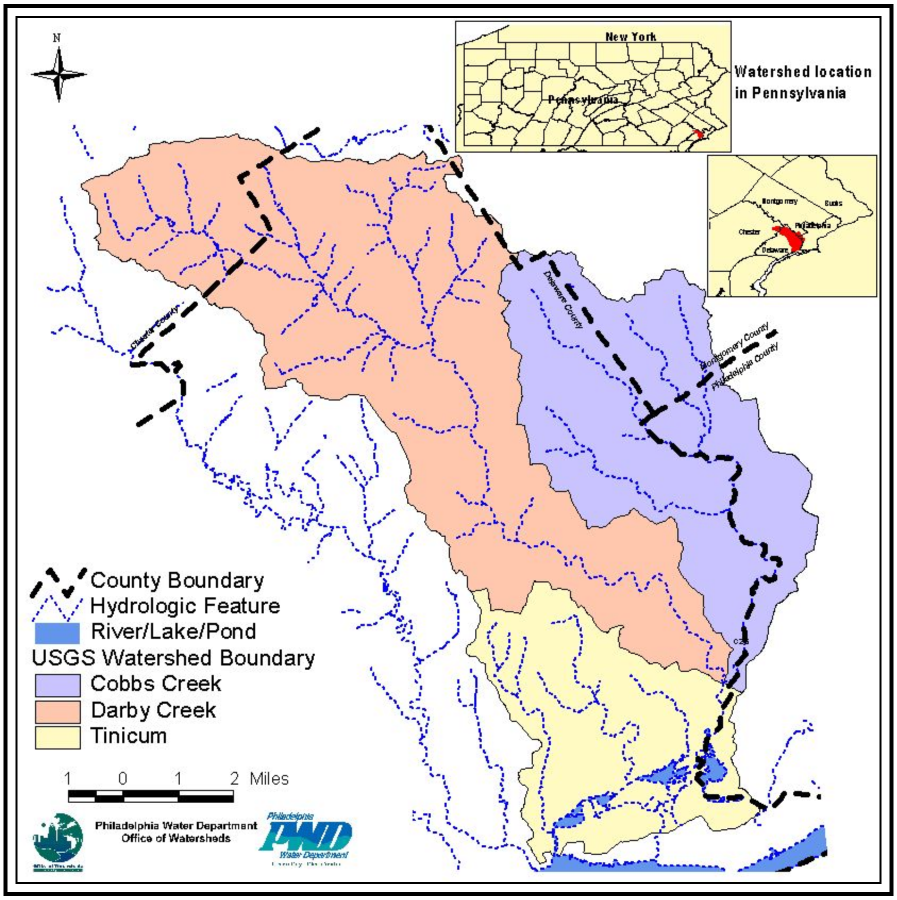

Figure E-1: Darby-Cobbs Watershed. This plan summarizes the results of watershed assessment activities in the Darby, Cobbs, and Tinicum basins. Detailed planning, alternatives analysis, and recommendations are provided for the Cobbs basin. The plan recommends appropriate measures for the Cobbs Creek basin and seeks to provide an example for stakeholders in the Darby and Tinicum basins to follow.

Introduction

Stewardship of a river must be built around the needs of the community. It will grow by making visible the critical way the health of the watershed is integral to basic quality of life issues. Once the seeds of stewardship have been planted, members of the community can be recruited to take action in protecting their watershed. In 1999, The Philadelphia Water Department (PWD) acted as the municipal sponsor of the Darby-Cobbs Watershed Partnership, an exciting and groundbreaking effort to connect residents, businesses and government as neighbors and stewards of the watershed. Since then, the Partnership has been active in developing a vision for the watershed and guiding and supporting subsequent planning activities within both the Darby and Cobbs sub-watersheds.

PWD, with the support of the Darby-Cobbs Watershed Partnership, has just completed a multi-year watershed planning effort to restore the Cobbs Creek Watershed to one that can boast fishable, swimmable and enjoyable streams. The planning process and implementation recommendations are contained in the recently completed Cobbs Creek Integrated Watershed Management Plan (CCIWMP). This executive summary presents the major findings of the CCIWMP.

Background

The Darby-Cobbs Watershed Partnership first worked with PWD to complete a comprehensive, multi-year watershed assessment covering the Darby, Cobbs, and Tinicum drainage basins (see Figure E-1). The assessment provides a snapshot of current conditions in the watershed, and lays the groundwork for the development of more detailed plans to improve conditions in each of the sub-basins within the Darby-Cobbs watershed. With portions of the Cobbs Creek watershed served by combined sewers, and with significant interest from the Partnership in improving water quality and riparian habitat conditions, PWD then took the next step by leading the development of the CCIWMP. During the stakeholder process, the Pennsylvania Environmental Council drafted a resolution for the partnership to establish common ground for municipal coordination required for the plan to be successful. The resolution and its signatories are reprinted below.

Partnership Resolution

Whereas, the Darby Creek watershed and its tributaries, the largest of which is the Cobbs Creek, constitute an important natural resource by providing aquatic and terrestrial habitat, an important cultural and historical resource with many key sites throughout the watershed, an important recreational resource providing fishing opportunities, and parkland for exploration and relaxation; and

Whereas, the Darby Creek and its tributaries have been degraded by development and historical absence of municipal stormwater management controls contributing to damaging floods, extensive erosion and low flows in times of drought; and

Whereas, the Pennsylvania Department of Environmental Protection has determined through its biological assessment process that the water quality of certain segments of the Darby Creek and its tributaries have become impaired; and

Whereas, various studies are underway to guide conservation and improvement of the Darby Creek including a Rivers Conservation Management Plan (under the auspices of the Darby Creek Valley Association), a Stormwater Management Plan prepared pursuant to the Stormwater Management Act of 1978; and

Whereas, cooperative action taken in coordination with municipalities and citizens located both up and downstream in the watershed is the key to enhancing the value of the Darby Creek for all its residents; and

Whereas, the Darby-Cobbs Watershed Partnership was created to serve that purpose and provides a structure for watershed-based planning and action to conserve and to improve the environmental health and safe enjoyment of the watershed; and

Whereas, the Darby-Cobbs Watershed Partnership will work to eliminate the impairment of the stream segments and restore the watershed to its unimpaired state for uses so designated by the Department of Environmental Protection.

Therefore, it is resolved that the «Governing_Body» does hereby declare support for the Darby-Cobbs Watershed Partnership and act freely to join as a Watershed Partner,

Furthermore, the «Governing_Body» does resolve to appoint a liaison who will participate in the Partnerships' conservation planning and action programs and will regularly (at the discretion of this body) provide reports on the Partnerships' activities.

Resolution Signatories

Counties:	Chester, Delaware, Philadelphia
Municipalities:	Colwyn Borough, East Lansdowne Borough, Folcroft Borough, Lansdowne Borough, Marple Township, Newtown Township, Radnor Township, Ridley Township, Sharon Hill Borough, Tinicum Township, Upper Darby Township, Lower Merion Township, Springfield Township, City of Philadelphia

With the addition of this plan, the watershed communities now have a blueprint for restoring this urban stream into a community asset, while making significant progress toward improving water quality during both dry and wet weather.

The primary intent of the plan, as articulated by the stakeholders, is to mitigate wet weather impacts caused by urban stormwater runoff and combined sewer overflow (CSO), identify ways to improve water quality, aesthetics, and recreational opportunities in dry weather; and restore living resources in the stream and along the stream corridor. PWD placed a high priority on the development of the CCIWMP because it represents one of the three major components of the City of Philadelphia's CSO Long Term Control Plan (LTCP) strategy. This component entails a substantial commitment by the City to watershed planning to identify long term improvements throughout its watersheds, including any additional CSO controls that will result in an improvement to water quality and, ultimately, the attainment of water quality standards.

PWD was not alone in this planning effort. Significant support from other agencies helped to fund various pieces of the plan in order to better integrate the planning effort with other regulatory programs. The USEPA provided funding under a Section 104(b)(3) Water Quality Cooperative Agreement, money that helped PWD to develop the modeling framework that underlies much of the analysis in the plan. USEPA also provided Wetland Program Grant money to help assess existing wetlands within Cobbs Creek and provide basic data for developing wetland restoration projects. PADEP provided funding, through a Growing Greener Grant, to partially fund stream assessment and restoration along a stretch of Cobbs Creek near Marshall Road. Through Act 167 money, PADEP also funded PWD modeling and analysis to support stormwater planning. Finally, initial planning efforts and the development of planning goals, embodied in a Rivers Conservation Plan, were funded by PA-DCNR.

At the outset, there was insufficient physical, chemical, and biological information on the nature and causes of water quality impairments, sources of pollution, and appropriate remedial measures for the Cobbs Creek. The lack of information made it impossible to determine what needed to be done for additional CSO control or control of other wet weather sources throughout the watershed. Lack of sufficient information is not unique to Cobbs Creek. In fact recognition of this deficiency, especially with respect to the effects of wet weather discharges and receiving water dynamics, has increased nationwide and led to a broader recognition of the need for watershed-based planning and management to properly define water quality standards and goals.

The USEPA Long Term Control Planning Guidance suggests that the sources of watershed pollution and impairment, in addition to CSOs, are varied and include other point source discharges; discharges from storm drains; overland runoff; habitat destruction; land use activities, such as agriculture and construction; erosion; and septic systems and landfills. The Guidance notes that the major advantage in using a watershed-based approach to develop a LTCP is that it allows the site-specific determination of the relative impacts of CSOs and non-CSO sources of pollution on water quality.

Plan Goals

Considerable stakeholder input towards developing watershed goals was sought from the beginning of this planning effort. Stakeholder input was primarily organized through the Partnership, which reached consensus on a set of planning goals and objectives. In addition, the plan sought to integrate goals derived from other relevant regulatory programs and plans to more fully achieve the ideal of integrated water resource planning. The resulting integrated planning goals, and their relation to the major regulatory programs, are summarized in Table E-1.

Table E-1 Regulatory Support for Stakeholder Goals for the Cobbs Creek Watershed

Goal Description	Act 167 Stormwater	Act 537 Sewage Facilities	TMDL Program	NPDES Stormwater	CSO Program	RCP
Streamflow and Living Resources. Reduce the impact of urbanized flow on the living resources to meet designated uses	x					x
Stream Habitat and Aquatic Life. Improve stream habitat and indices of aquatic integrity.			x	x	x	x
Stream Channels and Banks. Reduce streambank and stream channel deposition and scour to protect and restore the natural functions of aquatic habitat and ecosystems, streambanks, and stream channels.	x					x
Flooding. Decrease flooding.	x					x
Water Quality. Improve dry and wet weather stream quality.		x	x	x	x	x
Pollutant Loads. Decrease pollutant loads to surface waters.		x	x	x	x	x
Stream Corridors. Protect and restore stream corridors, buffers, floodplains, and natural habitats including wetlands.						x
Quality of Life. Enhance community environmental quality of life.	x	x	x	x	x	x
Stewardship. Foster community stewardship.				x	x	x
Coordination. Improve inter-municipal, inter-county, state-local, and stakeholder cooperation and coordination on a watershed basis.	x		x	x	x	x

Planning Approach

Once the Partnership had established the goals and objectives for the CCIWMP, a planning approach was designed to achieve the desired results through a cooperative effort between Philadelphia and the other watershed municipalities. The approach has four major elements:

- Data collection, organization and analysis
- Systems description
- Problem identification and development of plan objectives
- Strategies, policies and approaches

Figure E-2 summarizes the primary steps of the planning process. The right column shows the sections of the plan relevant to each step in the planning process.

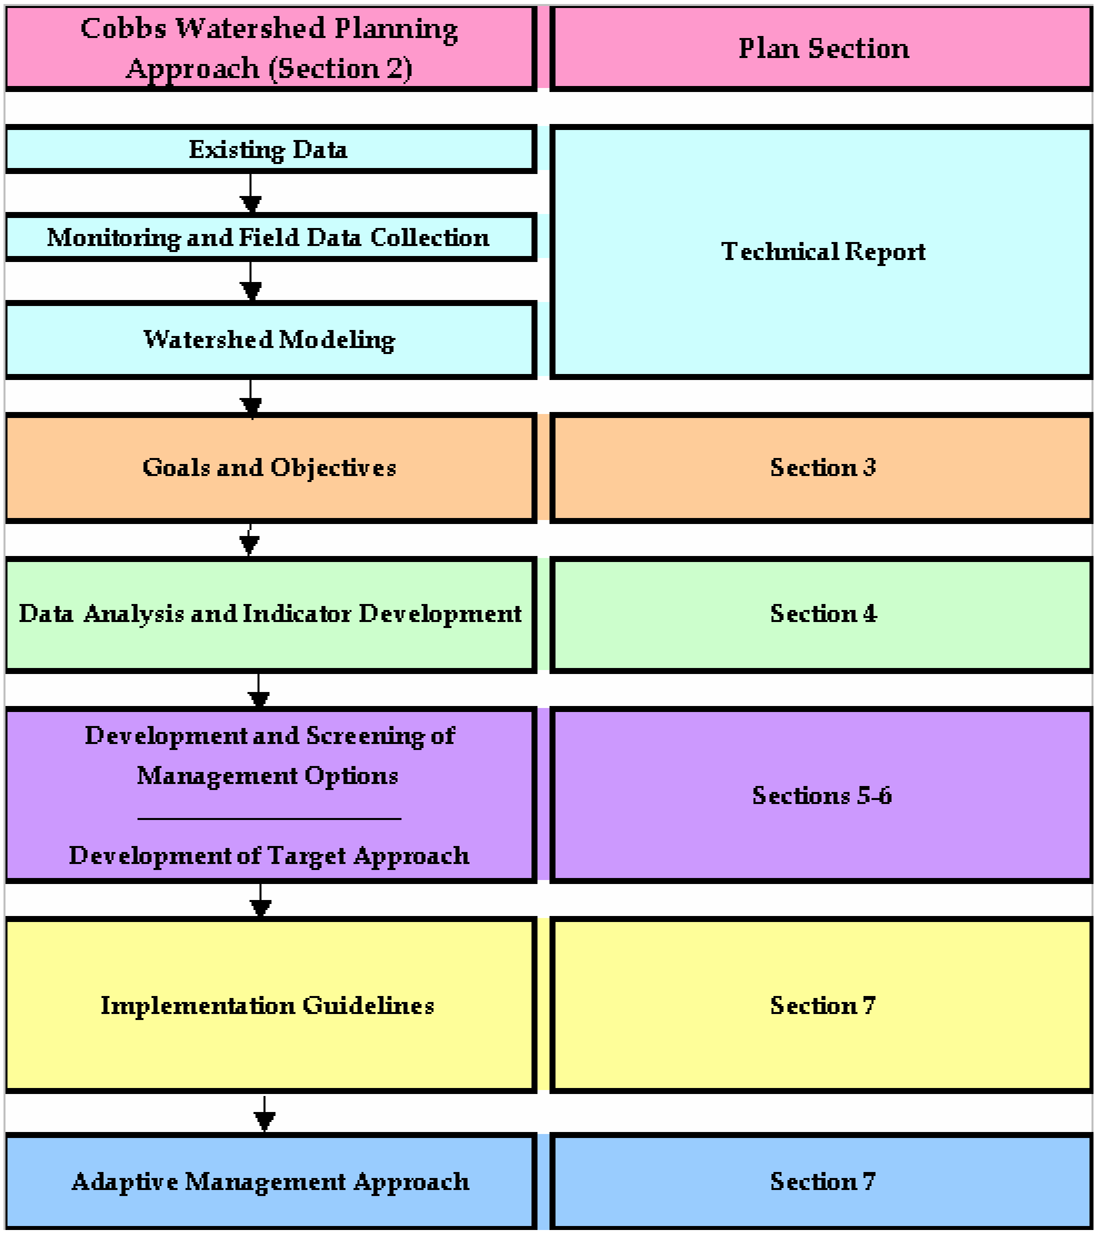

Figure E-2: Cobbs Planning Approach

Watershed Status and Problem Identification

An important aspect of the watershed management plan is a basic description of existing conditions within the watershed and streams. To accomplish this, a series of indicators were developed to represent the results of the data collection efforts and the data analysis and modeling. An indicator is a measurable quantity that characterizes the current state of at least one aspect of watershed health. The indicators were selected for their potential use both in assessing current conditions and assessing future progress in improving conditions.

Through the extensive field studies, modeling, and data analysis, the highest priority problems in the Cobbs Creek were identified, and the means for addressing the problems were developed. Given that the Cobbs Creek watershed is a highly urbanized watershed with both CSOs and significant stormwater flows, some of the highest priority problems included:

Dry Weather Water Quality and Aesthetics

- Water quality concerns including high fecal coliform during dry weather
- Dry weather sewage flows in separate sewered areas
- Trash-filled, unsightly streams that discourage residential use.
- Safety concerns along streams and stream corridors

Healthy Living Resources

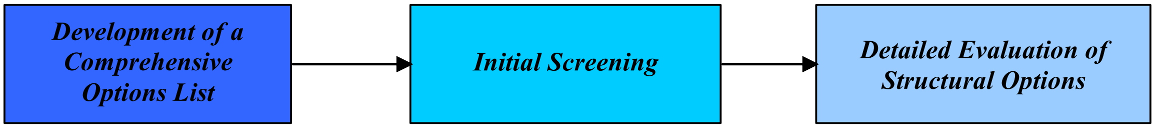
- Degraded aquatic and riparian habitats
- Limited diversity of fish and benthic life
- Periodic, localized occurrences of low dissolved oxygen primarily associated with plunge pools and areas of stagnant water behind dams
- Utility infrastructure threatened by bank and streambed erosion
- Limited public awareness and sense of stewardship for Cobbs Creek

Wet Weather Water Quality and Quantity

- Water quality concerns including high fecal coliform during wet weather, and nutrients and metals during wet weather flows
- CSO impacts on water quality and stream channels
- Little volume control and treatment of stormwater flows in separate sewered areas

Development and Screening of Management Options

Lists of management measures, called options, were developed to address the identified problems and to meet each of the goals and objectives established for the Cobbs Creek watershed. Only those options deemed feasible and practical for Cobbs Creek were considered in the final list of management options. Options were developed and evaluated in three steps:



Since the plan cannot prescribe actions to be undertaken by all the participants in the planning process, recommendations and guidelines for implementation were developed. Modeling and other analyses were used to develop six alternatives, each with a different approach and cost to achieve the goals and objectives. From an analysis of these six alternatives, the final recommendations were made.

Implementation Approach

In developing watershed management alternatives and discussing goals and objectives with stakeholders, it became clear that implementation could best be achieved by defining three distinct targets to meet the overall plan objectives. Two of the targets (A and B) were defined so that they could be fully met with a limited set of options that are fully implemented. For the third target (C), it was agreed to set interim objectives, recommend measures to achieve the interim objectives, implement those controls, and monitor and reassess the effectiveness of the plan in meeting the objectives.

TARGET A: Dry Weather Water Quality and Aesthetics

The first target is to meet water quality standards in the stream during dry weather flows. Target A was defined for Cobbs Creek with a focus on trash removal and litter prevention, and the elimination of sources of sewage discharge during dry weather.

TARGET B: Healthy Living Resources

Improvements to the number, health, and diversity of the benthic invertebrate and fish species in the Cobbs Creek will require investment in habitat improvement and measures to provide the opportunity for organisms to avoid high velocities during storms. Improving the ability of an urban stream to support viable habitat and fish populations must focus primarily on the elimination or remediation of the more obvious impacts of urbanization on the stream. These include loss of riparian habitat, eroding and undercut banks, scoured streambed or excessive silt deposits, channelized and armored stream sections, trash buildup, and invasive species.

TARGET C: Wet Weather Water Quality and Quantity

The third target is to restore water quality to meet fishable and swimmable criteria during wet weather and address flooding issues. Improving water quality and flow conditions during and immediately following storms is the most difficult target to meet in the urban environment. The only rational approach to achieve this target must include stepped implementation with interim targets for reducing wet weather pollutant loads and stormwater flows, along with monitoring for the efficacy of control measures.

Initial load reduction targets for parameters such as stormwater flow, metals, total suspended solids, and bacteria were set in conjunction with the stakeholders. Based on preliminary work by PWD, 20% reductions are a challenging but achievable interim target.

Implementation Guidelines

All measures or options were thoroughly screened and evaluated using a variety of approaches, including modeling, cost-effectiveness screening, and the use of a computerized multi-criteria evaluation tool. This resulted in the selection of only those options appropriate and deemed effective for the particular conditions found in the Cobbs Creek watershed. The implementation guidelines seek to present the options in such a way that each major stakeholder or responsible party understands what is expected. The guidelines are designed such that, if implementation follows the recommendations, all plan objectives associated with Targets A and B will be fully met, and the interim objectives for Target C will be met or exceeded.

In the plan, options are fully described, and the expected level of implementation is provided. Where possible, the locations where implementation is expected are also indicated. Implementation guidelines are presented in this executive summary in a series of tables. First, options are grouped by the party responsible for implementation. Second, options are grouped according to their applicability to the implementation targets. Finally, tables of planning level costs are provided.

Recommendations by Responsible Party

These summary tables present the recommended actions grouped according to the agency or organization primarily responsible for implementation. Tables E-2 through E-4 present the recommended actions for Philadelphia, Delaware, Montgomery, and Chester Counties; and PADEP.

Table E-2 Philadelphia Actions

Action	Where	When
Pet Waste, Litter, and Dumping Ordinances	Watershed-wide	Short-term
Public Education	Watershed-wide	Short-term
School-Based Education	All schools	Short-term
Public Participation and Volunteer Programs	Watershed-wide	Short-term
Inspection and Cleaning of Combined Sewers	Watershed-wide	Short-term
Combined Sewer Rehabilitation	Combined-Sewered Areas	Medium-term
Stream Cleanup and Maintenance	Cobbs Creek within or along City boundary	Short-term
Enhancing Stream Corridor Recreational and Cultural Resources	Along the stream corridor	Medium-term
Bed Stabilization and Habitat Restoration	Cobbs Creek 40%, West Indian Creek 44%	Short-term
Bank Stabilization and Habitat Restoration	Middle section of Cobbs Creek	Short-term
Channel Realignment and Relocation	Cobbs Creek, East and West Indian Creek	Short-term
Plunge Pool Removal	CSO and stormwater outfalls	Short-term
Improvement of Fish Passage	Woodland Avenue dam	Short-term
Wetland Creation	Riparian corridor	Short-term
Invasive Species Management	Riparian corridor	Short-term
Reforestation	Riparian corridor	Short-term
Requiring Better Site Design in Redevelopment	Watershed-wide	Short-term
Stormwater and Floodplain Management	Watershed-wide	Short-term
Post-Construction Stormwater Runoff Management	Municipalities required to do Phase II permit	Short-term
Sanitary Sewer Overflow Detection	Separate-Sewered Areas	Short-term
Sanitary Sewer Overflow Elimination: Structural Measures	Separate-Sewered Areas	Medium-term
CSO Control Program	Philadelphia combined sewer system	Short-term
Catch Basin and Storm Inlet Maintenance	All inlets	Short-term
Street Sweeping (Philadelphia Streets Department)	Streets and Parking Lots	Short-term
Responsible Landscaping on Public lands	Green space	Short-term
Responsible Bridge and Roadway Maintenance	Roadways and bridges	Short-term
Reducing Effective Impervious Cover through Better Site Design	Watershed-wide	Long-term
Increasing Urban Tree Canopy	Watershed-wide	Medium-term
Porous Pavement and Subsurface Storage	Parking lots watershed-wide	Long-term
Green Rooftops	Appropriate public buildings chosen by PWD	Medium-term
Capturing Roof Runoff in Rain Barrels or Cisterns	Homes where dry wells are not feasible	Medium-term
Maintaining/Retrofitting Existing Stormwater Structures	Watershed-wide	Short-term
Retrofitting Existing Sewer Inlets with Dry Wells	Inlets in combined-sewered areas	Long-term
Residential Dry Wells, Seepage Trenches, and Water Gardens	Homes and schools watershed-wide	Long-term
Bioretention Basins and Porous Media Filtration	Watershed-wide	Long-term
Treatment Wetlands: Onsite and Regional	Riparian corridor	Medium-term
Monitoring and Reporting	Watershed-wide	Ongoing

Table E-3 Delaware and Montgomery County Municipality Actions

Action	Where	When
On-Lot Disposal (Septic System) Management	All areas with septic systems	Short-term
Pet Waste, Litter, and Dumping Ordinances	Watershed-wide	Short-term
Public Education	All Cobbs Creek municipalities	Short-term
School-Based Education	All schools	Short-term
Public Participation and Volunteer Programs	All Cobbs Creek municipalities	Short-term
Capacity Management Operation and Maintenance	Separate-Sewered Areas	Short-term
Inspection and Cleaning of Sanitary Sewers	Separate and Combined Sewered Areas	Short-term
Sanitary Sewer Rehabilitation	Separate-Sewered Areas	Medium-term
Illicit Discharge, Detection, and Elimination (IDD&E)	All areas with a storm or combined sewer.	Short-term
Stream Cleanup and Maintenance	Cobbs Creek within or along City boundary	Short-term
Enhancing Stream Corridor Recreational and Cultural Resources	Along the stream corridor	Medium-term
Bed Stabilization and Habitat Restoration	Cobbs Creek 40%, West Indian Creek 44%	Short-term
Bank Stabilization and Habitat Restoration	Middle section of Cobbs Creek	Short-term
Channel Realignment and Relocation	Cobbs Creek, East and West Indian Creek	Short-term
Plunge Pool Removal	CSO and stormwater outfalls	Short-term
Improvement of Fish Passage	Woodland Avenue dam	Short-term
Wetland Creation	Riparian corridor	Short-term
Invasive Species Management	Riparian corridor	Short-term
Reforestation	Riparian corridor	Short-term
Requiring Better Site Design in Redevelopment	Watershed-wide	Short-term
Stormwater and Floodplain Management	Watershed-wide	Short-term
Post-Construction Stormwater Runoff Management	Municipalities required to do Phase II permit	Short-term
Sanitary Sewer Overflow Detection	All areas with separate sewers	Ongoing program
Reduction of Stormwater Inflow and Infiltration to Sanitary Sewers	Separate-Sewered Areas	Medium-term
Catch Basin and Storm Inlet Maintenance	All inlets	Ongoing program
Street Sweeping	Streets and Parking Lots	Short-term
Responsible Landscaping on Public lands	Green space	Short-term
Responsible Bridge and Roadway Maintenance	Roadways and bridges	Short-term
Reducing Effective Impervious Cover through Better Site Design	Watershed-wide	Long-term
Increasing Urban Tree Canopy	Watershed-wide	Medium-term
Porous Pavement and Subsurface Storage	Parking lots watershed-wide	Long-term
Capturing Roof Runoff in Rain Barrels or Cisterns	Homes where dry wells are not feasible	Medium-term
Maintaining/Retrofitting Existing Stormwater Structures	Watershed-wide	Short-term
Residential Dry Wells, Seepage Trenches, and Water Gardens	Homes and schools watershed-wide	Long-term
Bioretention Basins and Porous Media Filtration	Watershed-wide	Long-term
Treatment Wetlands: Onsite and Regional	Riparian corridor	Medium-term
Monitoring and Reporting	Watershed-wide	Ongoing

Table E-4: PADEP Actions

Action	Where	When
Industrial Stormwater Pollution Prevention	Industrial sites	Short-term
Construction Stormwater Pollution Prevention	Construction sites	Short-term
Pollution Trading	To be determined	Long-term
Use Review and Attainability Analysis	To be determined	Short-term
Stewardship/Advocacy of Watershed Management Plan	Watershed-wide	Short-term
Watershed-Based Permitting	To be determined	Medium-term
Monitoring and Reporting	Watershed-wide	Ongoing

Recommendations by Implementation Target

Another way to summarize the recommendations is to list options by the target they are designed to address. This grouping by implementation target is shown below. If implementation occurs according to the guidelines in the plan, Targets A and B will be fully met, and implementation of options to meet Target C will results in a more than 20% reduction in wet weather flow volume and pollutant loading.

Target A : Dry Weather Water Quality and Aesthetics

Regulatory Approaches

AR1 On-Lot Disposal (Septic System) Management
AR2 Pet Waste, Litter, and Dumping Ordinances

Public Education and Volunteer Programs

AP1 Public Education
AP2 School-Based Education
AP3 Public Participation and Volunteer Programs

Municipal Measures

AM1 Capacity Management Operation and Maintenance (CMOM)
AM2 Inspection and Cleaning of Combined Sewers
AM3 Sanitary Sewer Rehabilitation
AM4 Combined Sewer Rehabilitation
AM5 Illicit Discharge, Detection, and Elimination (IDD&E)
AM6 Stream Cleanup and Maintenance

AO1 Enhancing Stream Corridor Recreational and Cultural Resources

AMR Monitoring and Reporting

Target B : Healthy Living Resources

Channel Stability and Aquatic Habitat Restoration

BM1 Bed Stabilization and Habitat Restoration
BM2 Bank Stabilization and Habitat Restoration
BM3 Channel Realignment and Relocation
BM4 Plunge Pool Removal
BM5 Improvement of Fish Passage

Lowland Restoration and Enhancement

BM6 Wetland Creation
BM7 Invasive Species Management

Upland Restoration and Enhancement

BM8 Biofiltration
BM9 Reforestation

BMR Monitoring and Reporting

Target C : Wet Weather Water Quality and Quantity

Regulatory Approaches

Zoning and Land Use Control

CR2 Requiring Better Site Design in Redevelopment

CR3 Stormwater and Floodplain Management
CR4 Industrial Stormwater Pollution Prevention
CR5 Construction Stormwater Pollution Prevention
CR6 Post-construction Stormwater Runoff Management
CR7 Pollution Trading
CR8 Use Review and Attainability Analysis
CR9 Watershed-Based Permitting

Municipal Measures

CM1 Sanitary Sewer Overflow Detection
CM2 Sanitary Sewer Overflow Elimination: Structural Measures
CM3 Reduction of Stormwater Inflow and Infiltration to Sanitary Sewers
CM4 Combined Sewer Overflow (CSO) Control Program
  - Nine Minimum Controls
  - Long Term CSO Control Plan
  - Watershed-Based Planning

CM5 Catch Basin and Storm Inlet Maintenance
CM6 Street Sweeping
CM7 Responsible Landscaping Practices on Public Lands
CM9 *R*esponsible Bridge and Roadway Maintenance

CMR Monitoring and Reporting

Stormwater Management

Source Control Measures

CS1 Reducing Effective Impervious Cover Through Better Site Design
CS2 Increasing Urban Tree Canopy
CS3 Porous Pavement and Subsurface Storage
CS4 Green Rooftops
CS5 Capturing Roof Runoff in Rain Barrels or Cisterns

Onsite and Regional Stormwater Control Facilities

CS6 Maintaining/Retrofitting Existing Stormwater Structures
CS8 Retrofit of Existing Sewer Inlets with Dry Wells
CS9 Residential Dry Wells, Seepage Trenches, and Water Gardens
CS12 Bioretention Basins and Porous Media Filtration
CS13 Treatment Wetlands: Onsite and Regional

Planning Level Cost Tables

Planning-level costs have been developed for the majority of the options being recommended. Because costs are highly dependent on site specific conditions as well as the extent that implementation occurs, costs are only approximate. These costs are useful, however, in providing order of magnitude funding needs, and also, as a comparison to potential costs associated with more traditional approaches to CSO control, such as large scale storage tanks designed to reach the 85% capture goal.

Planning level costs are provided for each of the options discussed under the three Targets. In many cases, the cost is left blank. This means that costs are not applicable because they are relatively small, or the option would be implemented by existing municipal staff and do not represent an additional cost.

The mix of structural BMPs and implementation percentages in this section are suggested as a feasible plan that will equal or exceed the 20% discharge reduction target. The exact mix of BMPs implemented in each area of the watershed will be determined by local municipalities or by a government or institutional body to be chosen at a later time.

Tables E-5 and E-6 provide costs for implementation to meet Targets A and B. Table E-7 provides costs for non-structural measures aimed at meeting Target C. Table E-8 provides cost estimates for structural measures designed to meet Target C (when combined with the measures in Table E-9). PWD costs are separated from outside agency costs (primarily municipalities) by apportioning costs based on ownership of facilities or simply by the relative areas of the watershed within and outside of Philadelphia City limits. Cost ranges are provided based on the costs associated with the various alternatives that were evaluated. Actual costs are expected to fall within the range, and will depend on the exact mix of options ultimately implemented.

“Cost per acre” values are provided in Table E-9 as a simple measure of the way costs are apportioned in the table.

The affordability of the costs associated with this plan was also analyzed. The results of this analysis are presented in Table E-10 for Philadelphia and for the combined suburban communities comprising the remainder of the watershed. For Philadelphia, the affordability calculation indicates that the incremental cost of the Cobbs improvements would be approximately $10 per household per year, representing 0.03% of median household income. For the combined suburban communities the cost would be $90 per household per year, representing 0.14% of the weighted median household income for those areas. Both of these values are well within USEPA affordability guidelines, and represent relatively limited increases in the current rates being paid for water, sewer, and stormwater in Philadelphia. These calculations represent incremental costs. The overall impact on affordability would need to be evaluated in the context of all the programs comprising water quality improvement within a given community. For example, residents of Philadelphia will ultimately help pay for management programs in five or more watersheds. Residents of the smaller communities may only pay for this one program. Because residents of Philadelphia will ultimately pay for improvements in a number of watersheds, the total cost per household in Philadelphia likely will be similar to the cost for households in the suburban communities.

Tables E-11 and E-12 provide data to assist communities outside Philadelphia in placing projected CCIWMP costs in a local context. Table E-11 expresses estimated costs for communities per acre and per household inside the watershed boundaries; Table E-12 presents costs within the boundaries of all municipalities that intersect the watershed. These cost tables are but one illustration of a possible cost distribution, and are provided to aid municipalities in deciding what funding and institutional mechanisms may be most appropriate given local conditions.

Table E-5 Planning-level Cost Estimates for Target A Options

	Total		Philadelphia		Other Counties	
	Annual Cost	One-Time	Annual Cost	One-Time	Annual Cost	One-Time
Regulatory Approaches						
AR2 On-Lot Disposal (Septic System) Management	$75,000				$75,000	
AR2 Pet Waste, Litter, and Dumping Ordinances[1]						
Public Education and Volunteer Programs	$615,000		$276,000		$340,000	
Municipal Measures						
AM1 Capacity Management Operation and Maintenance (CMOM)[2]						
AM2 Inspection and Cleaning of Combined Sewers	$2,000,000	$21,120,000	$896,000	$8,448,000	$1,104,000	$12,672,000
AM3 Sanitary Sewer Rehabilitation[2]						
AM4 Combined Sewer Rehabilitation[2]						
AM5 Illicit Discharge, Detection, and Elimination (IDD&E)		$22,500,000		$10,125,000		$12,375,000
AM6 Stream Cleanup and Maintenance	$66,000	$31,000	$33,000	$15,000	$33,000	$15,000
AO1 Enhancing Stream Corridor Recreational and Cultural Resources[1]						
AMR Monitoring and Reporting[3]						
Total Cost for Target A Options	$2,756,000	$43,651,000	$1,205,000	$18,588,000	$1,552,000	$25,062,000
Cost per acre for Target A Options	$190	$3,070	$340	$5,220	$150	$2,360

1 - already in place in most locations, or costs difficult to quantify
2 - costs included in option AM2
3 - monitoring and reporting costs not included in this table

Table E-6 Planning-level Costs for Target B Options

	Total		Philadelphia		Other Counties	
	Annual Cost	One-Time	Annual Cost	One-Time	Annual Cost	One-Time
Channel Stability and Aquatic Habitat Restoration[1]	$33,000	$26,400,000	$16,500	$13,200,000	$16,500	$13,200,000
BM1 Bed Stabilization and Habitat Restoration[2]						
BM2 Bank Stabilization and Habitat Restoration[2]						
BM3 Channel Realignment and Relocation[2]						
BM4 Plunge Pool Removal[2]						
BM5 Improvement of Fish Passage		$130,000		$130,000		
Lowland Restoration and Enhancement

Section 1: Background

The integrated watershed management plan, developed by the Darby-Cobbs Watershed Partnership, is based on a carefully developed approach to meet the challenges of watershed management in an urban setting. It is designed to meet the goals and objectives of numerous, water resource related regulations and programs, and draws from the similarities contained in many watershed-based planning approaches authored by DEP and EPA. Its focus is on attaining priority environmental goals in a phased approach by making use of the consolidated goals of the numerous existing programs that directly or indirectly require watershed planning.

1.1 What is a Watershed and Why a Plan?

A watershed is a natural formation including land and communities connected by water (Figure 1). Simply said, the health of a stream depends on the quality of the land surrounding it, which in turn relies on the people charged with the care for that land. How do you care for an urban watershed? By addressing practices of the past, including paving the land and piping the stormwater, which took place as the area was urbanized. These practices were deemed an important step in development at the time, but they have had a devastating impact on the natural environment. As scientific knowledge and values have changed over time, the maintenance of both a vibrant community and healthy natural resources can be achieved, and the two can reinforce one another.

To address the impacts of past development on Cobbs Creek, we must define and understand the problems in the watershed. To this end, extensive physical, chemical and biological assessments were carried out, coupled with interaction with stakeholders. These activities helped to define and focus planning objectives and form the basis for the entire planning effort. Our plan explores the nature, causes, severity and opportunities for control of water quality impairments in the Cobbs Creek watershed. The primary intent of the plan, as articulated by the stakeholders, is to improve the environmental health and safe enjoyment of the Cobbs watershed by sharing resources and through cooperation among residents and other stakeholders in the watershed. The goals of the initiative are to protect, enhance, and restore the beneficial uses of the Cobbs waterways and its riparian areas, goals that are currently only partially being addressed by a number of programs. A piecemeal approach through a variety of regulatory programs dealing separately with stormwater quantity, water quality, impacts to streams from sanitary and combined sewers, and wetland protection has proven to be ineffective and inefficient in dealing with the problems associated with urban streams. Integrated planning is the preferred approach.

An integrated watershed management plan is a long-term action plan designed to achieve the twin goals of a healthy community and healthy natural resources. An integrated plan embraces the laws designed to save streams, preserves the streams' ecology, and enhances the parkland and riparian buffers that shelter these streams. This plan reaches out to propose municipal action working in concert with conservation planning that strives to ensure that growth and redevelopment within the watershed proceeds with particular care to the environment. Most importantly, the plan incorporates a diversity of people who live, work, and dream in all areas of the watershed. People provide the catalyst for change, the energy to create the plan, and the vigilance to sustain the plan. These people, the stakeholders, become the watershed's guardians – the keepers of the integrated plan.

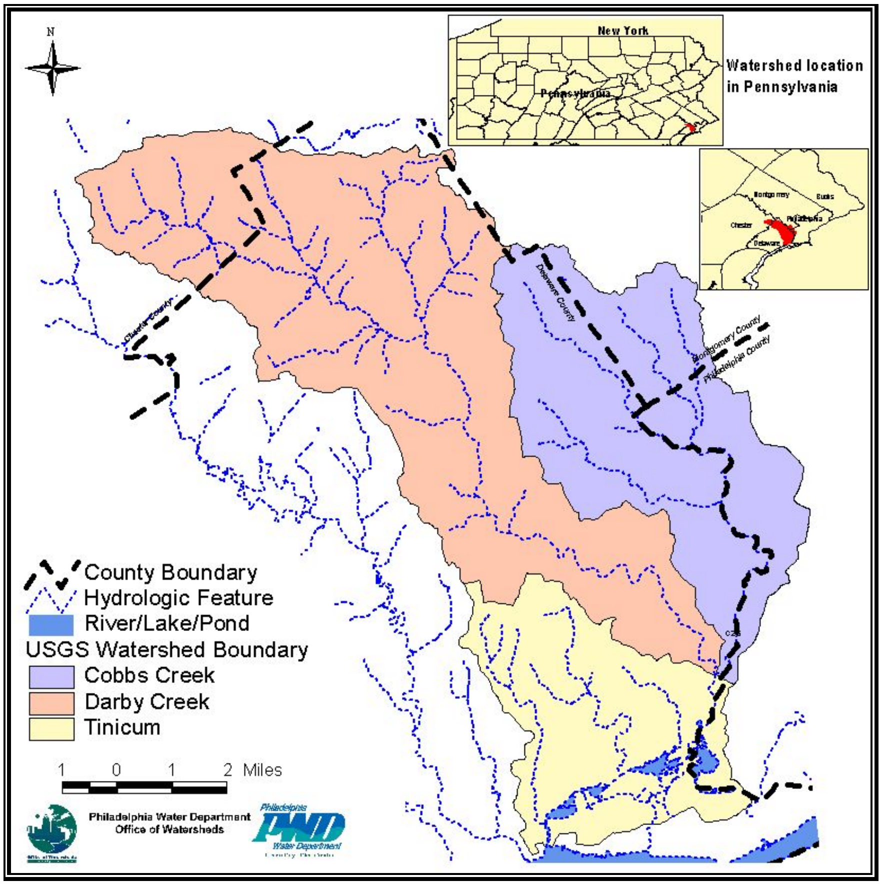

Figure 1-1 Darby-Cobbs Watershed

1.2 Brief History of the Darby-Cobbs Creek Watershed

The history of Cobb's Creek watershed is typical of many similar watersheds on the borders of Philadelphia County--a progression from natural fields and woodlands inhabited only by native peoples, to an agricultural and industrial era fueled by the energy of European immigrants, which eventually gave way to population pressures as open lands were developed into densely-built residential neighborhoods.

Before the beginning of European exploration and immigration, the area was home to Native Americans, particularly the Lenni Lenape tribe. They used Cobb's Creek (which they knew as "Karakung") and its surrounding tributaries and lands for fishing, hunting, transportation, and rudimentary agriculture.

Dutch, Swedish and finally the dominant English Quaker immigrants settled the area beginning in the mid-17th century. Marshes were diked or drained both for health reasons, and to provide dry ground for pastures or growing hay for sale. Streams were diverted into man-made millraces to provide power for a growing number of small mills. These Europeans began what became the wholesale clearing of woodland in the watershed, both to open up farming and pasture lands and to provide lumber for buildings in the growing city of Philadelphia. By the mid-18th century, these "plantations," as farmsteads were then known, were probably the most common landscape feature in and around the City.

It is likely that the removal of forests led to increased runoff and stream flows during storms, and increased sedimentation and erosion. But the actual historical effect of these and other man-made changes in the watershed on the aquatic and terrestrial life is difficult to quantify.

The oldest mill in Philadelphia, built by the Swedish settlers on Cobb's Creek in 1642, stood just upstream from where Woodland Avenue now crosses the creek, and subsequent mills on this site used water power to grind flour into the early 20th century. By the 19th century there were dozens of water-powered mills along Cobb's Creek and its major tributaries, Naylor's Run and Indian Creek. Besides the usual saw, grist and snuff mills, in the early 1800s a thriving gunpowder manufacturing center was located along the creek, in Haverford Township. Keystone Paper Mill stood at the confluence of Indian Creek and Cobb's Creek, and near 63rd and Market, in Millbourne Borough, the Millbourne Flour Mill of the Sellers family stood for more than 100 years. Numerous textile mills existed in the watershed, with clusters of factories in the Angora section of West Philadelphia (near 60th Street and Baltimore Avenue), the Cardington neighborhood of Upper Darby (where Marshall Road crosses the creek), and in the Haddington neighborhood of Philadelphia, where the east and west branches of Indian Creek joined (now Morris Park, at the intersection of 69th Street and Haverford and Lansdowne Avenues). Water used in various industrial processes, such as paper-making and textile dyeing and bleaching, was dumped directly back into the creek, untreated, which certainly had an adverse affect on water quality and aquatic life.

The wholesale transformation of the watershed, from mostly open space with scattered villages and small industrial centers into a mostly-developed residential area, began in the latter part of the 19th century. One factor in this change was the completion of the Mill Creek sewer in West Philadelphia. Entering Philadelphia at 63rd Street and City Avenue, Mill Creek cut a diagonal five-mile valley through West Philadelphia before emptying into the Schuylkill River at 43rd Street. In some places 35 or 40 feet below the current street levels, the creek served as an impediment to development, which tended to stop at its eastern edge. Encapsulation of this creek in a combined sewer, begun in 1869 and completed about 1895, and the subsequent filling and leveling of the valley, allowed the grid of rowhouse development to continue unimpeded toward Cobbs Creek, the City's western edge.

A second important factor in the watershed's transformation was the construction of the Market-Frankford Elevated Railroad. Begun in 1906 and completed by 1908, this line allowed quick access into the city for suburban dwellers, and greatly spurred residential construction in the western parts of Philadelphia and eastern Delaware County. In 1932, a newspaper article stated that more than half of West Philadelphia's 90,000 homes had been built after the El project began. The same article noted that by that time Upper Darby's population had mushroomed to 60,000, with much of that growth coming after 1920.

This rampant development contributed to the degradation of the stream quality in several ways. A number of Cobbs Creek tributaries were completely obliterated, the largest being Thomas Run, which once ran from about 53rd and Walnut streets to Cobbs Creek at about 60th Street; today it runs only underground, in a combined sewer. Thousands of feet of Naylor's Run were channeled into underground culverts to facilitate commercial and residential development in the filled land above the pipes. A massive increase in impervious surfaces in the watershed meant that runoff was reaching the creek more quickly, leading to higher storm flows, increased erosion and scouring of the stream bed.

Furthermore, sewers from the new neighborhoods in the watershed emptied directly into the creek and its tributaries, polluting the water with raw sewage. By 1914 Philadelphia had constructed an interceptor sewer which kept wastes from within its boundaries from entering the creek, but it took decades more before communities in neighboring Delaware and Montgomery counties did the same.

By the 1930s, most of the mills had left the watershed, leaving abandoned buildings as the main reminder of the area's once-thriving industrial heritage. Residential development continued to spread, with large sections of Overbrook Park in Philadelphia built up after World War II, and development continuing into Haverford and Lower Merion Townships in the 1950s and 1960s, although at a considerably lower density. In more recent times, polluted stormwater runoff and inadequate drainage systems, leaking and inadequate septic tanks, lack of open space and adequate recreation, illegal dumping, and an array of other urban ills have also taken their toll on the quality of human and natural life in the watershed.

On the bright side, beginning in the mid-19th century, a number of cemetery companies began buying up large tracts of the watershed, establishing Mt. Moriah, Fernwood, Holy Cross, and Arlington cemeteries. As the farmsteads in the watershed, one by one, were transformed into residential neighborhoods, these cemeteries served to preserve hundreds of acres of open space by keeping them out of the hands of developers.

The creation of Cobbs Creek Park and Morris Park in Philadelphia, in the beginning of the 20th century, also managed to preserve hundreds of acres of open space, and saved Indian Creek from being buried in an underground sewer, as is shown on various planning maps of the era.

Plans for an expressway up the Cobbs Creek valley (I-695), which would have begun at I-95 near Essington and connected with another expressway at Whitby Avenue in West Philadelphia, were finally killed in the mid-1970s, with the money diverted into mass transit projects.

For more historical information on Cobbs Creek see http://www.sewerhistory.net

1.3 Comprehensive Planning and the Regulatory Framework

Water Resource Management in Urban Streams

In many states, numerous federal and state regulations and programs are aimed at improving the water quality and flow patterns in urban streams, while at the same time reducing flooding. Pennsylvania is no exception; the USEPA and the Pennsylvania Department of Environmental Protection (PADEP) have a complex regulatory framework for managing water resources with frequently overlapping demands and requirements. There are several major regulatory programs that contain significant elements related to watershed management in the Cobbs Creek watershed. These are:

- Pennsylvania Title 25, Chapter 93 Water Quality Standards Regulations
- the Total Maximum Daily Load (TMDL) process to improve water quality on impaired streams and water bodies
- the Phase I and Phase II stormwater regulations to control pollution due to stormwater discharges from municipal stormwater systems
- the stormwater management PA Act 167 to address management of stormwater runoff quantity particularly in developing areas
- PA Act 537 sewage facilities planning to protect and prevent contamination of groundwater and surface water by developing proper sewage disposal plans
- EPA's Combined Sewer Overflow (CSO) Control Policy to minimize mixed sewage and stormwater overflowing directly into streams

Each of these regulatory programs supports very specific aspects of water resources management. The specific nature of the regulations sometimes negates the ability of a regulatory program to deal comprehensively with a water quality issue that benefits from more than one of these programs. For the development of this integrated plan, these regulations provide guidelines that are transformed into a series of planning objectives within the watershed management planning process.

These objectives then lead directly to the selection of watershed management options to address the stakeholder-defined goals for environmental quality. In this manner, the plan makes requests of each of these programs to go beyond their programmatic requirements and begin to represent their outcome within the context of the watershed plan goals.

Pennsylvania Title 25, Chapter 93 Water Quality Standards Regulations

Water quality criteria are the numeric concentrations, levels or surface water conditions that need to be maintained or attained to protect existing and designated uses of a stream. They are designed to protect the water uses appropriate to each stream. The streams are classified in Pennsylvania in Chapter 93, Title 25 of the Pennsylvania Code.

Usually the most sensitive of these protected uses are generally water supply, recreation and fish consumption, and aquatic life related. Therefore, criteria designed to protect these uses will normally protect the other uses listed in Chapter 93.

The designated uses for the non-tidal portion of Cobbs Creek include all the state-wide uses plus migratory fishes as shown below:

Symbol	Designated Use
	Aquatic Life
WWF	Warm Water Fishes
MF	Migratory Fishes
	Water Supply
PWS	Potable Water Supply
IWS	Industrial Water Supply
LWS	Livestock Water Supply
AWS	Wildlife Water Supply
IRS	Irrigation
	Recreation
B	Boating
F	Fishing
WC	Water Contact Sports
E	Esthetics

The regulations state that water may not contain substances attributable to point or non-point source discharges in concentration or amounts sufficient to be inimical or harmful to the water uses to be protected or to human, animal, plant or aquatic life.

Impairment Designations and the TMDL Process

Water quality standards provide the target against which the water quality in Cobbs Creek is measured. If water quality standards are not being met, and technology based controls of point and non-point sources are not sufficient to meet the standards, then the load of pollutants must be reduced. Section 303(d) of the Clean Water Act (CWA) and the USEPA's Water Quality Planning and Management Regulations (40 CFR Part 130) provide a framework for reducing pollutant loads based on calculation of Total Maximum Daily Loads (TMDLs). TMDLs are the sum of individual waste load allocations (point sources) and load allocations (non-point sources) plus a margin of safety. They establish a link between water quality standards and water quality based controls. The objective of TMDLs is to allocate allowable loads among different pollutant sources so that the appropriate control actions can be taken and water quality standards achieved.

The basic steps in the water quality based approach to TMDLs include:

- Identification of the water quality-limited waters and the quality parameters of concern
- Prioritizing the locations by ranking and targeting
- Establishing the TMDL
- Implementing the control actions
- Assessment of the control actions

Pennsylvania has listed water quality-limited waters according to point and non-point sources for toxic, conventional (BOD, TSS, fecal coliform, oil and grease), and non-conventional (ammonia, chlorine, and iron) pollutants. Streams that are listed under Section 303(d) of the CWA are particularly targeted for improvement (PADEP, 2004). The Cobbs Creek watershed is within Subbasin 03G, which also includes Crum Creek, Ridley Creek, and Chester Creek watersheds. Within the Cobbs watershed, the following stream segments are listed as impaired.

- The lower 10.09 miles of Darby Creek and 3.55 miles of unnamed tributaries are impaired due to habitat modification, siltation, and water/flow variability from urban runoff and from storm sewers.
- The entire 18.75 miles of Cobbs Creek and unnamed tributaries within the watershed are impaired due to urban runoff/storm sewers and habitat modification.

The next step in the statewide TMDL process includes prioritization of the list and the development of TMDLs for high-priority water bodies. It is this phase of the TMDL process that is of interest to the integrated watershed planning process.

Prioritization must take into account the severity of the pollution and the designated uses of the water body. It should consider the following:

- Risks pertaining to human health and aquatic life
- Degree of public interest and support
- Recreational, economic, and aesthetic importance

- Vulnerability or fragility of the aquatic habitat
- New permit applications for discharges or revisions to existing permits
- Court orders and decisions
- National policies and priorities

TMDL development requires the quantification of pollutant sources and the allocation of maximum discharge loads to contributing point and non-point sources in order to attain water quality standards. TMDLs are best developed on a watershed basis in order to efficiently and effectively manage the quality of the water. The TMDL process may be developed using a phased approach that includes monitoring requirements and it generally includes the following five activities:

- Selection of the pollutants
- Evaluation of the water body's assimilative capacity
- Assessment of the pollutants discharged from all sources
- Predictive analysis of the water body's response to pollution and determination of the total allowable pollutant load
- Allocation (with a margin of safety) of the allowable pollutant load among the different sources

The National Pollutant Discharge Elimination System's (NPDES) permitting process is used to implement control measures to limit effluent from point sources. In the case of non-point sources, state and local laws can be used to implement best management practices (BMPs), as well as Section 319 state management programs. These programs must be coordinated in order to effectively achieve the required non-point source reductions.

NPDES Stormwater Rules

In response to the 1987 Amendments to the Clean Water Act (CWA), the Environmental Protection Agency (EPA) developed Phase I of the NPDES Stormwater Program in 1990. Phase I required NPDES permits for all stormwater discharging from storm sewers (MS4s) of medium and large urban areas (UAs) with populations of 100,000 or more. It also required permits from eleven categories of industrial activity, including construction activities that disturb five or more acres of land. Permit coverage can be either under an individually tailored NPDES permit (used by MS4s and some industrial facilities) or a general NPDES permit (used by most industrial facilities and construction sites).

Phase II of the NPDES Stormwater Program was published in November 1999. The Phase II Regulation requires NPDES permit coverage - mostly under general permits - for stormwater discharges from most small-urbanized areas (small MS4s) and construction activities that disturb from 1 to 5 acres of land. A list of affected communities has been published in the Federal Register.

There are a minimum of six control measures that communities must implement as part of a municipal stormwater management program whose goal is Phase II compliance. These are:

1. Public Education and Outreach

Distributing educational materials and performing outreach to inform citizens about the impacts polluted stormwater runoff discharges can have on water quality.

2. Public Participation and Involvement

Providing opportunities for citizens to participate in program development and implementation, including effectively publicizing public hearings and/or encouraging citizen representatives to be part of a stormwater management panel.

3. Illicit Discharge Detection and Elimination

Developing and implementing a plan to detect and eliminate illicit discharges to the storm sewer system. Includes the developing of a system map as well as informing the community about hazards associated with illegal discharges and improper waste disposal.

4. Construction Site Runoff Control

Developing, implementing, and enforcing an erosion and sediment control program for construction activities that disturb one or more acres of land (controls could include for example, silt fences and temporary stormwater detention ponds).

5. Post Construction Runoff Control

Developing, implementing, and enforcing a program to address discharges of post-construction stormwater runoff from new development and redevelopment areas. Applicable controls could include preventative actions such as protecting sensitive areas (e.g. wetlands) or the use of structural BMPs such as grassed swales or porous pavement.

6. Pollution Prevention/Good Housekeeping

Developing and implementing a program with the goal of preventing or reducing pollutant runoff from municipal operations. The program must include municipal staff training on pollution prevention measures and techniques (e.g., regular street sweeping, reduction in the use of pesticides or street salt, or frequent catch-basin cleaning).

The EPA has listed the following municipalities within the Darby-Cobbs watershed for inclusion in the Phase II program. The permit cycle for these permits starts in 2003.

Aldan Borough, Clifton Heights Borough, Collingdale Borough, Colwyn Borough, Darby Borough, Darby Township, East Lansdowne Borough, Easttown Township, Folcroft Borough, Glenolden Borough, Haverford Township, Lansdowne Borough, Lower Merion Township, Marple Township, Millbourne Borough, Morton Borough, Narberth Borough, Newtown Township, Norwood Borough, Prospect Park Borough, Radnor Township, Ridley Park Borough, Ridley Township, Rutledge Borough, Springfield Township, Tinicum Township, Tredyffrin Township, Upper Darby Township, Upper Darby Township, Yeadon Borough.

Act 167 Stormwater Management Act of 1978 (32 PS § 680.3.)

The Stormwater Management Act 167 is administered by PADEP and is designed to address the inadequate management of accelerated stormwater runoff resulting from development. The plan must address a wide range of hydrologic impacts due to development on a watershed basis, and include such considerations as tributary timing, flow volume reduction, base flow augmentation, water quality control, and ecological protection. Watershed runoff modeling is usually a critical component of the study, with modeled hydrologic responses to 2, 5, 10, 25, 50, and 100-year storms.

The primary purposes of the act are to:

- Encourage planning and management of stormwater runoff
- Authorize a comprehensive program of stormwater management designed to preserve and restore the flood carrying capacity of Commonwealth streams;
- Preserve natural stormwater runoff regimes
- Protect and conserve groundwater

The act requires that each county--in consultation with affected municipalities --prepare and adopt a stormwater management plan for each watershed that falls wholly or partially within the county. The act focuses on reduction of stormwater runoff quantities, rather than on water quality. Each stormwater plan will include, but is not limited to:

- A survey of existing runoff characteristics in small as well as large storms, including the impact of soils, slopes, vegetation and existing development;
- A survey of existing significant obstructions and their capacities;
- An assessment of projected and alternative land development patterns in the watershed, and the potential impact of runoff quantity, velocity, and quality;
- An analysis of present and projected development in flood hazard areas, and its sensitivity to damages from future flooding or increased runoff;
- A survey of existing drainage problems and proposed solutions;

- A review of existing and proposed stormwater collection systems and their impacts;
- An assessment of alternative runoff control techniques and their efficiency in the particular watershed;
- An identification of existing and proposed state, federal, and local flood control projects located in the watershed and their design capacities;
- A designation of those areas to be served by stormwater collection and control facilities within a ten-year period;
- An estimate of the design capacity and costs of such facilities;
- A schedule and proposed methods for financing the development, construction and operation of the facilities;
- An identification of the existing or proposed institutional arrangements to implement and operate the facilities;
- An identification of floodplains within the watershed;
- Standards for the control of stormwater runoff from existing and new development which are necessary to minimize dangers to property and life;
- Priorities for implementation of action within each plan; and
- Provisions for periodically reviewing, revising and updating the plan.

After adoption and approval of a stormwater plan, the location, design, and construction within the watershed of stormwater management systems, flood control projects, subdivisions and major land developments, highways, and transportation facilities must all be conducted in a manner consistent with the approved plan.

As noted above, beginning in 2003, municipalities within the Cobbs Creek watershed also will have to obtain a NPDES permit for separate storm sewer systems. PADEP has developed a Protocol which meets the six Minimum Control Measures required of municipal permittees under the Phase II NPDES Stormwater Regulations (40 CFR §§ 122.26 – 123.35). If an MS4 municipality commits to implementing the provisions of the Protocol for any Minimum Control Measure (e.g., Construction Site Runoff Control), it does not need an independent review and approval of its stormwater management program by DEP for that Minimum Control Measure. The federal regulations also allow DEP and MS4 municipalities to use existing qualifying state and local programs to satisfy any of the NPDES General Permit requirements of MS4s. The Pennsylvania Stormwater Management Act ("Act 167") is an existing qualifying program, and integrating the planning required for Act 167 with the planning required to meet the six Minimum Control Measures is a logical approach to take. An integrated Act 167 Plan is presently under preparation for the Darby-Cobbs Creek watershed by Delaware County with assistance from Philadelphia, Chester, and Montgomery Counties.

Act 537 Sewage Facilities Planning

Act 537, enacted by the Pennsylvania Legislature in 1966, requires that every municipality in the state develops and maintains an up-to-date sewage facilities plan. The act requires proper mapping, assessment, and planning for future needs of all types of sewage facilities. In addition, this program provides requirements for the permitting of individual and community on-lot disposal systems, and uniform standards of design.

The main purpose of a municipality's sewage facilities plan is to ensure that the sewage collection and treatment systems have adequate capacity to convey present and future to sewage flows to a wastewater treatment facility. The planning process also requires correction for existing sewage disposal problems including malfunctioning on-lot septic systems, overloaded treatment plants or sewer lines, and improper sewer connections. The program is also designed to prevent future sewer problems and to protect the groundwater and surface water of the locality and specifically requires in-stream water quality to be evaluated during the planning process. To meet these objectives, PADEP uses the Official Sewage Planning requirements of Act 537 that prevent and eliminate pollution of the waters of the Commonwealth by coordinating planning for the sanitary disposal of sewage with a comprehensive program of water quality management.

Official plans contain comprehensive information, including:

- The location of treatment plants, main intercepting lines, pumping stations and force mains, including their size, capacity, point of discharge and drainage basin served.
- Descriptions of problems with existing sewerage facilities and operation and maintenance requirements
- Planning objectives and needs
- Physical description of planning area
- Evaluation of existing wastewater treatment and conveyance systems
- Evaluation of wastewater conveyance and treatment needs

Combined Sewer Overflow (CSO) Control Policy

EPA's CSO Control Policy, published in 1994, provides the national framework for regulation of CSOs under NPDES. The policy guides municipalities and state and federal permitting agencies in meeting the pollution control goals of the CWA in as flexible and cost-effective a manner as possible. As part of the program, communities serviced by combined sewer systems are required to develop long-term CSO control plans (LTCPs) that will result in full compliance with the CWA, including attainment of water quality standards.

As the first step under the CSO policy, nine minimum technology-based controls are required; these are measures that can reduce the prevalence and impacts of CSOs and that are not expected to require significant engineering studies or major construction.

- Proper operation and regular maintenance programs for the sewer system and the CSOs;
- Maximum use of the collection system for storage;
- Review and modification of pretreatment requirements to assure CSO impacts are minimized;
- Maximization of flow to the publicly owned treatment works for treatment;
- Prohibition of CSOs during dry weather;
- Control of solid and floatable materials in CSOs;
- Pollution prevention;
- Public notification to ensure that the public receives adequate notification of CSO occurrences and CSO impacts; and
- Monitoring to effectively characterize CSO impacts and the efficacy of CSO controls.

In the longer term, the CSO policy includes four requirements to ensure that the CSO systems meet the pollution control goals and local environmental objectives in a cost-effective manner:

- Clear levels of control to meet health and environmental objectives;
- Flexibility to consider the site-specific nature of CSOs and find the most cost-effective way to control them;
- Phased implementation of CSO controls to accommodate a community's financial capability; and
- Review and revision of water quality standards during the development of CSO control plans to reflect the site-specific wet weather impacts of CSOs.

One of the three major components of the City of Philadelphia’s CSO Long Term Control Plan (LTCP) strategy involves a substantial commitment by the City to watershed planning to identify long term improvements throughout its watersheds, including any necessary additional CSO controls, that will result in further improvements in water quality and, ultimately, the attainment of water quality standards. The need for this watershed initiative is rooted in the fact that insufficient physical, chemical and biological information currently existed on the nature and causes of water quality impairments, sources of pollution, and appropriate remedial measures. Because of this deficiency, at the time the CSO LTCP was developed, it was impossible to determine what needed to be done for additional CSO control or control of other wet weather sources throughout the watershed. This deficiency, especially with respect to the effects of wet weather discharges and receiving water dynamics, was increasingly recognized nationwide and led to a broader recognition of the need for watershed-based planning and management to properly define water quality standards and goals. The PWD suggested in its LTCP that the National CSO Policy, state and federal permitting and water quality management authorities, cities, environmental groups, and industry, recognized that effective long-term water quality management could be accomplished only through watershed-based planning.

The CSO Control Policy acknowledges the importance of watershed planning in the long term control of CSOs by encouraging the permit writer "... to evaluate water pollution control needs on a watershed management basis and coordinate CSO control efforts with other point and nonpoint source control activities" (1.B). The watershed approach is also discussed in the section of the CSO Control Policy addressing the demonstration approach to CSO control (II.B.4.b; and Chapter 3 of the USEPA Guidance for Long Term Control Planning), which, in recommending that NPDES permitting authorities allow a demonstration of attainment of WQS, provides for consideration of natural background conditions and pollution sources other than CSOs.

The EPA Long Term Control Planning Guidance suggests that EPA is committed to supporting the implementation of a comprehensive watershed management approach. EPA has convened a Watershed Management Policy Committee, consisting of senior managers, to oversee the reorientation of all EPA water programs to support watershed approaches.

Of particular importance to CSO control planning and management is the NPDES Watershed Strategy. This strategy outlines national objectives and implementation activities to integrate the NPDES program into the broader watershed protection approach. The Strategy also supports the development of basin management as part of an overall watershed management approach

The Long Term Control Planning Guidance suggests that the sources of watershed pollution and impairment, in addition to CSOs, are varied and include other point source discharges; discharges from storm drains; overland runoff; habitat destruction; land use activities, such as agriculture and construction; erosion; and septic systems and landfills. The benefits to implementing a watershed approach are significant and include:

- Consideration of all important sources of pollution or impairment
- Clearer definition of water quality benefits resulting from a given level of CSO reduction
- Greater flexibility to reflect the site-specific nature of CSO discharges
- Greater cost effectiveness (through coordination of monitoring programs, for example)

- Fostering of prevention as well as control
- Fairer allocation of resources and responsibilities.

The Guidance notes that the major advantage in using a watershed-based approach to develop an LTCP is that it allows the site-specific determination of the relative impacts of CSOs and non-CSO sources of pollution on water quality. For some receiving water reaches within a watershed, CSOs could well be less significant contributors to non-attainment than stormwater or upstream sources. In such cases, a large expenditure on CSO control could result in negligible improvement in water quality.

The EPA LTCP Guidance outlines a conceptual framework for conducting CSO planning in a watershed context (Figure E-1). The approach is intended to identify CSO controls for each receiving water segment based on the concepts of watershed management and use attainability. The Cobbs watershed planning approach outlined in this document is conceptually identical. It moved from data collection through analysis and modeling to arrive at a set of recommended measures or options designed to meet the goals and objectives agreed upon through the stakeholder process. Figure E-1 also identifies the section of the the Watershed Management Plan that documents each step in the process.

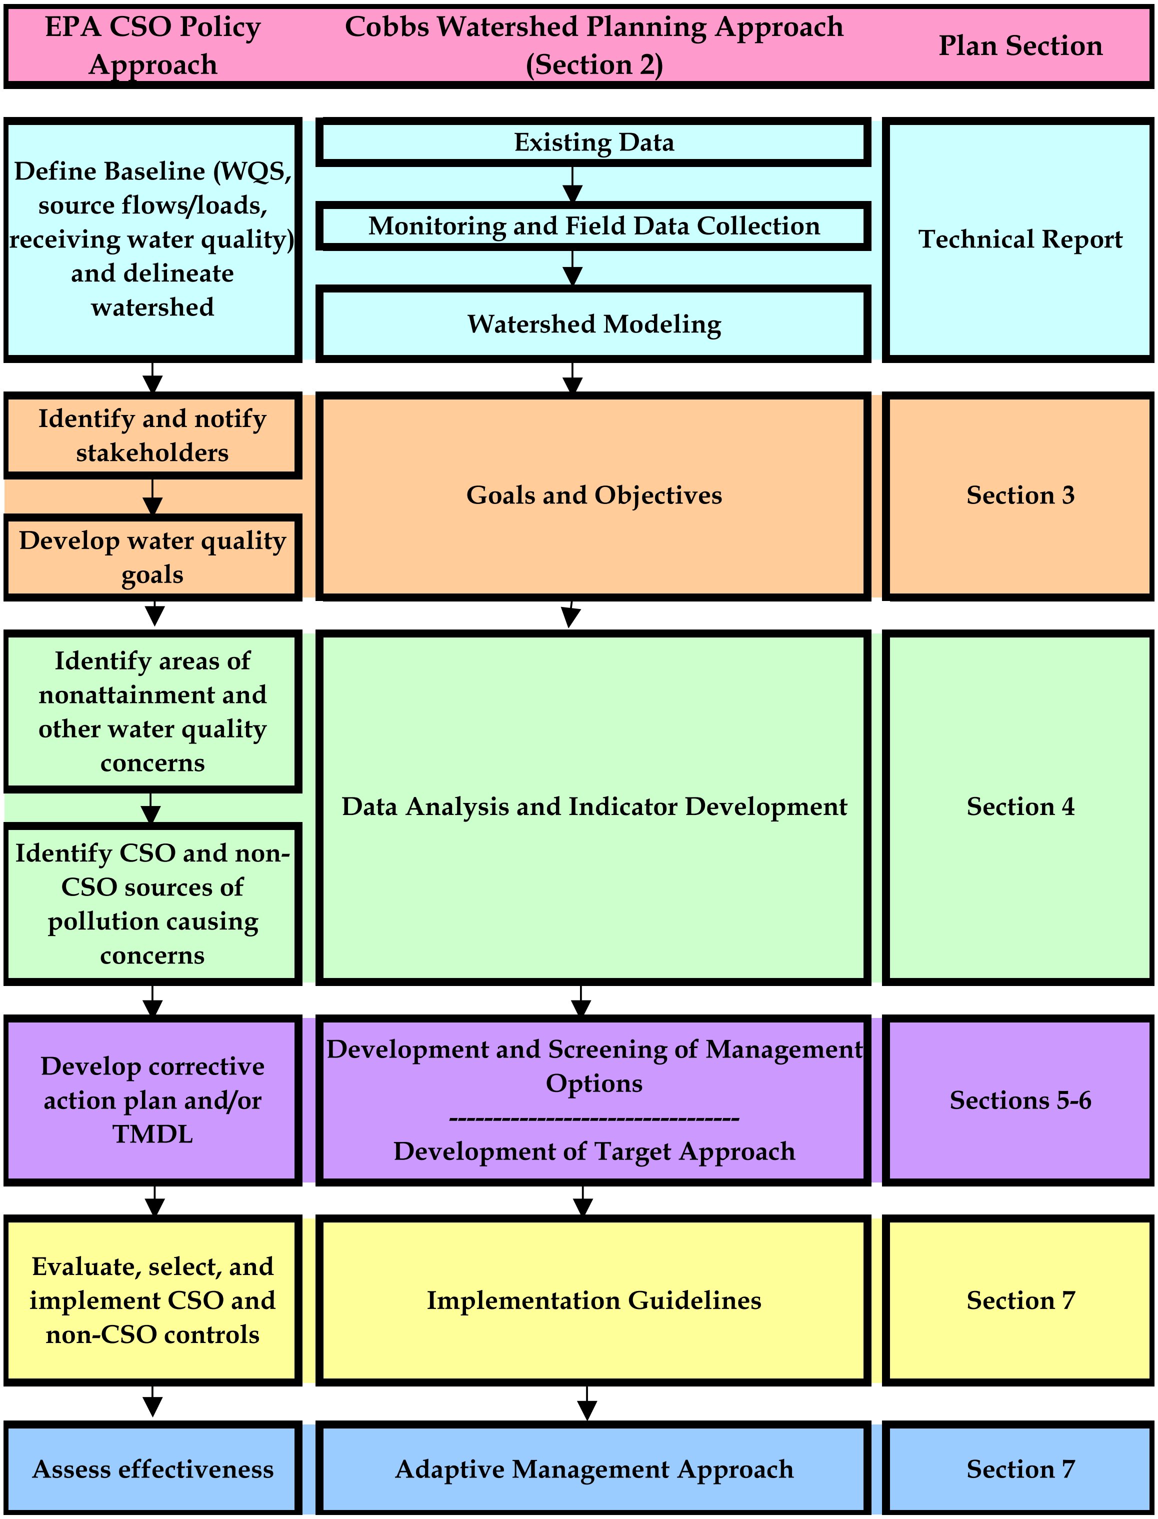

Figure 1-2: Cobbs Planning Approach

Watershed-Based CSO Control Planning Approach for a Receiving Water Segment – from USEPA Guidance for Long Term Control Plan (1995)

1.4 Overlapping Aspects of Regulatory Programs

Integrated watershed planning includes various tasks, ranging from monitoring and resource assessment to technology evaluation and public participation. The scope and importance of each task varies for each watershed, depending on the site-specific factors such as the environmental features of the watershed, regulatory factors such as the need to revise permits or complete TMDLs, available funding, extent of previous work, land use, and the size and degree of urbanization of watershed.

There are numerous activities required under each of the five programs mentioned above. Table 1-1 gives an overview of the types of activities required under each program, and Table 1-2 gives an overview of the types of data needed for each activity. Both tables highlight the fact that the task completed or the data collected under one program is often identical or very similar to the work done under other programs. It is clear that significant savings can be achieved through coordination of the programs and the development of one comprehensive plan for a watershed that meets all five program needs.

Table 1-1 Overview of Planning Tasks Required by Watershed Programs

Planning Tasks	Act 167 Stormwater	Act 537 Sewage Facilities	TMDL Program	NPDES Stormwater	CSO Program	RCP

Watershed-based planning is now the preferred approach on both the federal and state level. General water quality and water quantity goals have been established at a state level, and the next step is to develop specific goals for each watershed. Table 1-3 shows the watershed planning goals for Cobbs Creek and how they correspond to many of the overlapping goals of the five major regulatory programs.

Table 1-3 Overview of the Statement of Goals of the Watershed Programs

Goal Description	Act 167 Stormwater	Act 537 Sewage Facilities	TMDL Program	NPDES Stormwater	CSO Program	RCP
Streamflow and Living Resources. Reduce the impact of urbanized flow on the living resources to meet designated uses	x					x
Stream Habitat and Aquatic Life. Improve stream habitat and indices of aquatic integrity.			x	x	x	x
Stream Channels and Banks. Reduce streambank and stream channel deposition and scour to protect and restore the natural functions of aquatic habitat and ecosystems, streambanks, and stream channels.	x					x
Flooding. Decrease flooding.	x					x
Water Quality. Improve dry and wet weather stream quality.		x	x	x	x	x
Pollutant Loads. Decrease pollutant loads to surface waters.		x	x	x	x	x
Stream Corridors. Protect and restore stream corridors, buffers, floodplains, and natural habitats including wetlands.						x
Quality of Life. Enhance community environmental quality of life.	x	x	x	x	x	x
Stewardship. Foster community stewardship.				x	x	x
Coordination. Improve inter-municipal, inter-county, state-local, and stakeholder cooperation and coordination on a watershed basis.	x		x	x	x	x

1.5 PADEP's Watershed Based Planning Approach

The approach and specific tasks behind the Cobbs watershed management plan are intended to meet the needs of the five major programs discussed above. The watershed based planning process utilizes a "Plan-Do-Check-Review" methodology that establishes environmental goals and identifies parameters or indicators with which to measure progress toward those goals. The three Commonwealth-wide environmental goals established are: (1) "sustain, conserve, protect, enhance and restore Pennsylvania's environment, natural resources, and ecological diversity"; (2) "reduce, towards the ultimate goal of eliminating, harmful effects from environmental contaminants and conditions"; and (3) "engage all Pennsylvanians as active and informed stewards of the environment." Problems requiring attention in the Darby, Crum, Ridley, Chester and Cobbs watersheds are outlined in the PADEP's Watershed Restoration Action Strategy (WRAS). WRAS also includes budget allocations for some organizations involved in restoration of the Darby-Cobbs watershed (PADEP, 2002).

The watershed based planning process is intended to:

1. Characterize the condition of the environment by evaluating data sources (i.e., establish a "baseline");
2. Identify possible causes of any impaired conditions;
3. Allow PADEP and stakeholders to develop objectives and activities intended to address the causes in order to improve the existing environmental conditions;
4. Measure progress of activities by using selected indicators to effectively track changes in the environment, and make adjustments to activities as necessary; and
5. Integrate the other planning programs within the watershed based planning program framework.

The Cobbs planning approach seeks to integrate sound science and stakeholder consensus-building to develop an effective plan. The approach is designed to satisfy each of the five elements of the watershed based planning process.

1.6 Other Relevant Programs

Other programs, both regulatory and non-regulatory, influence the watershed management planning approach and are briefly described under this section.

Rivers Conservation Program

One significant non-regulatory program is the Department of Conservation and Natural Resources' (PA-DCNR's) Rivers Conservation Program (RCP), which was developed to conserve and enhance stream resources by implementing locally initiated plans.

The program provides technical and financial assistance to municipalities and stream support groups for the conservation of local streams. Generally the RCP plan intends to assess the cultural and historic resources of a stream corridor, identify potential threats and recommend restoration/maintenance options. It involves the statement of goals to be accomplished and the listing of recommendations for the development and implementation of the plan.

The goals and recommendations from an RCP can be an important building block for a comprehensive watershed management plan (WMP). The programs are similar in structure and approach; they have the same geographic scope, require overlapping data collection, and involve the statement of goals and listing of recommendations. However, the RCP is narrower in scope than the WMP and focuses more on quality of life along the stream corridor rather than on regulatory compliance.

Sanitary Sewer Overflow (SSO) Policy

Requires revisions to the NPDES permit regulations to improve the operation of municipal sanitary sewer collection systems, eliminate the occurrence of sewer overflows, and provide more effective public notification when overflows do occur.

PADEP On-Lot Sewage Disposal Regulations

Require local agencies to administer a permitting program for the installation of on-lot sewage disposal systems.

PENNVEST State Revolving Fund Program

Provides funding for sewer, stormwater, and water projects throughout the Commonwealth.

Delaware River Basin Commission (DRBC) Programs

Regulate both groundwater and surface water use for withdrawals greater than 100,000 gpd based on average 30-day use in a large portion of the study area, which drains to the Delaware River

Delaware Valley Regional Planning Commission (DVRPC) Programs

Address transportation, land use, and environmental protection issues in addition to economic development. Also provide services in planning analysis, data collection, and mapping.

PADEP Greenways Program

An Action Plan for Creating Connections is designed to provide a coordinated and strategic approach to creating connections through the establishment of greenways in the State.

CWA Section 104(b)(3) Program

Promotes the coordination and acceleration of research, investigations, experiments, training, demonstrations, surveys, and studies relating to the causes, effects, extent, prevention, reduction and elimination of pollution.

CWA Section 208 Wastewater Planning

Intended to encourage and facilitate the development and implementation of area-wide waste treatment management plans.

CWA Section 319(b) Non-point Source Management Program

Designed to address mine drainage, agricultural runoff, construction/urban runoff, hydrologic and habitat modifications, on-lot wastewater systems, and silviculture.

1.7 Regulatory Agency and Stakeholder Partnerships

In 1999, PWD acted as the municipal sponsor of the Cobbs Watershed Partnership, an exciting and groundbreaking effort to connect residents, businesses and government as neighbors and stewards of the watershed. PWD hired the Pennsylvania Environmental Council (PEC), a well-respected, non-profit institution with a reputation for supporting watershed-based, holistic planning in the form of smart growth planning. PEC pulled together a diverse representation of the watershed – municipalities, "friends" groups, educators, citizens, agencies, and watershed organizations – for the first partnership meeting.

Meetings during the first year were devoted to general education about watershed concepts, about soliciting the visions and concerns of participants as they related to their communities' environmental health and to the creation of three subcommittees to assist in managing the groundwork required for foundation of a watershed management plan. Minutes from these meetings are available at http://www.phillywater.org/Darby-Cobbs under Partnership Involvement.

A steering committee was recruited, representing municipalities that already had some form of watershed planning under way, to develop the road map and timeline for the tackling of a watershed management plan. The steering committee assisted with the selection of topics to be covered, reviewed the technical data and suggested public education/outreach tasks, and helped select the plan's goals and objectives.

The technical committee was open to all members of the partnership; ultimately, participants consisted mainly of local, state, and federal government agencies. This committee reviewed the technical documents produced by PWD, including a watershed reconnaissance of past and existing water quality studies, a current water quality sampling and modeling report, a sediment pollutant loading report, and a bioassessment summary. This technical data is essential for justifying and prioritizing the goals and objectives of the watershed management plan.

The public participation committee, also open to all partnership members, largely consists of watershed organizations, educators, residents, and educational non-profits. The committee established a number of projects to raise general awareness about watershed issues and to recruit further partnership membership. Projects included: a watershed wide survey, press conferences, a state of the watershed report, teacher training workshops, and the development of a watershed video.

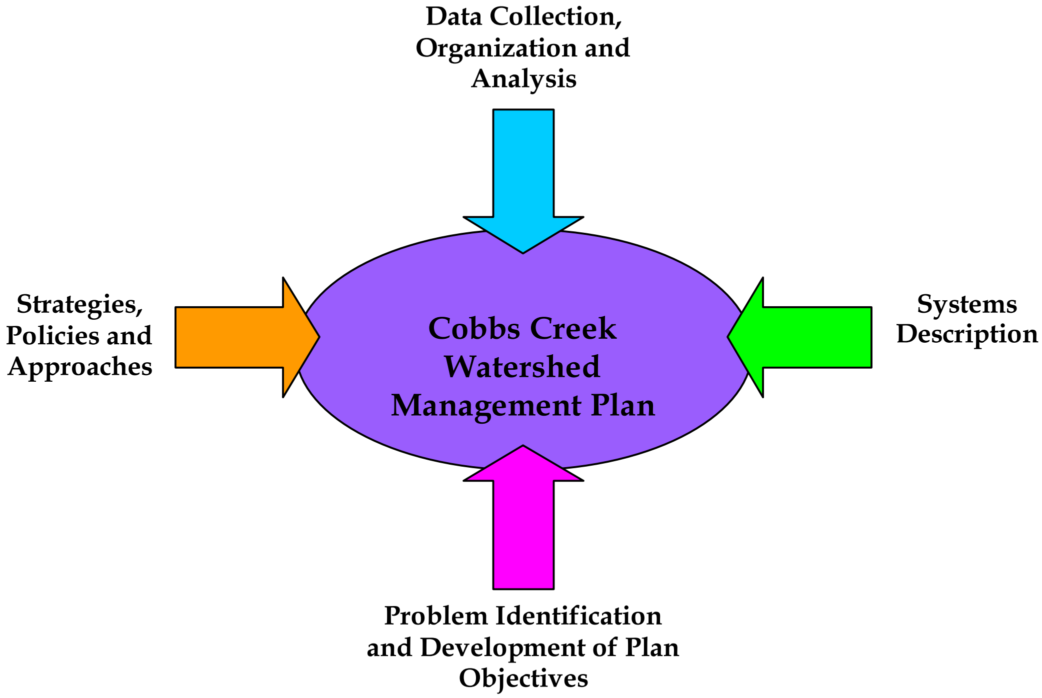
The partnership selected and prioritized the goals and objectives of the watershed management plan. Their role will continue as the recommendations of the plan are implemented in the coming years.

Section 2: Integrated Watershed Management for the Cobbs Watershed

Section 2.1 describes the general approach to watershed planning that serves as the framework for the Cobbs Creek watershed plan. The approach developed by the Darby-Cobbs Watershed Partnership for the Cobbs integrated watershed plan adopts the general approach discussed in Section 2.1 and includes many of the activities included in Philadelphia's Long Term Combined Sewer Overflow Control Plan. Section 2.2 describes the specific activities carried out to complete the plan.

2.1 General Planning Approach

The recommended approach for the Cobbs Creek watershed management plan coordinates each of the five programs discussed on Section 1.3. It has four major elements, each with multiple tasks specific to the planning efforts within the sub-basin of the Cobbs Creek watershed.



Data Collection, Organization and Analysis

The initial step in the planning process is the collection and organization of existing data on surface water hydrology and quality, wastewater collection and treatment, combined sewer overflows, stormwater control, land use, stream habitat and biological conditions, and historic and cultural resources. In addition, existing rules, regulations, and guidelines pertaining to watershed management at federal, state, basin commission, county, and municipal levels also are examined for coherence and completeness in facilitating the achievement of watershed planning goals.

Data is collected by many agencies and organizations in various forms, ranging from reports to databases and Geographic Information System (GIS) files. Field data collection efforts are undertaken early in the study once data gaps are identified.

Systems Description

The planning approach for an urban stream must focus on the relationship between the natural watershed systems (both groundwater and surface water) and the constructed systems related to land use that influence the hydrologic cycle, such as water supply, wastewater collection and treatment, and stormwater collection. A critical step in the planning process is to examine this relationship in all its complexity and to explore the adequacy of the existing regulatory structure at the federal, state, county, and municipal level to properly manage these natural and anthropogenic systems. In urban watersheds, the natural systems are, by definition, influenced by the altered environment, and existing conditions reflect these influences. It is not, however, always obvious which constructed systems are having the most influence, and what that influence is. Analyzing and understanding the water resources and water supply/wastewater/stormwater facilities and their interrelationship provides a sound basis for subsequent planning leading to the development of a realistic set of planning objectives. Concise descriptions of each of the constructed systems are presented, and a series of indicators that adequately describe the watershed and stream characteristics are identified and measured.

Problem Identification and Development of Plan Objectives

Existing problems and issues related to water quality, stream habitat, and streamflow related to the urbanization of the watershed can be identified through analyses of:

- Prior studies and assessments
- Existing data
- New field data
- Stakeholder input

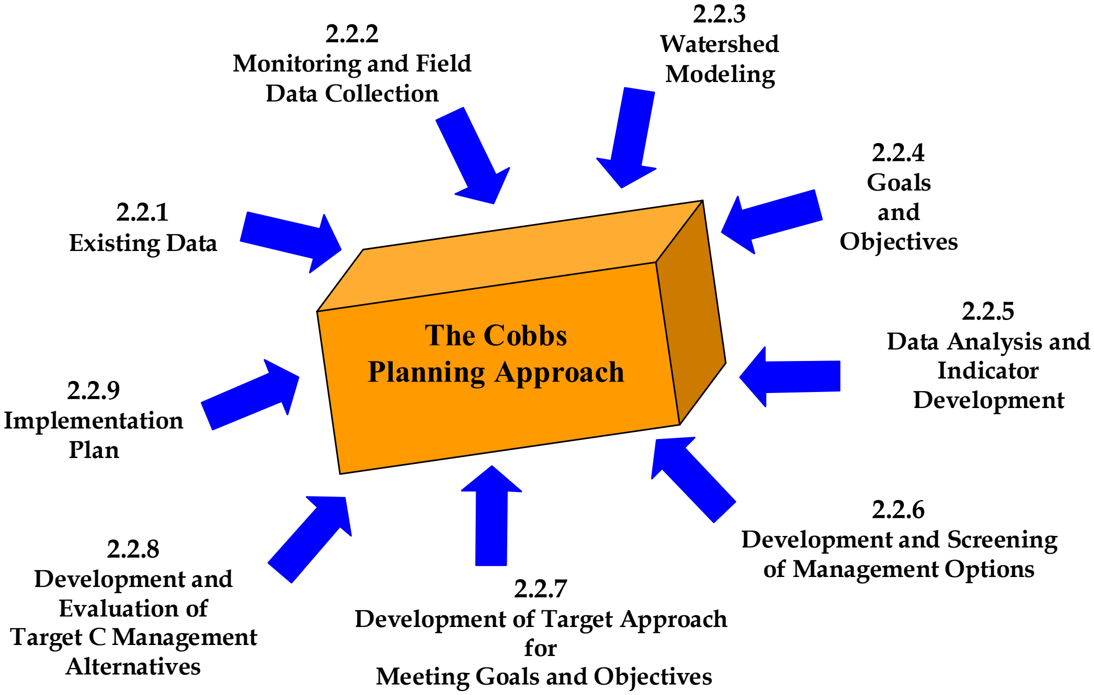
Problems and issues identified through data analysis must be compared with problems and issues brought forward by stakeholders. An initial list of problems and issues then are transformed into a preliminary set of goals and objectives. These goals and objectives may reveal data gaps and may require additional data collection and analysis. Ultimately, with stakeholder collaboration, a final list of goals and objectives is established that truly reflects the conditions of the watershed. These goals and objectives must be prioritized by the stakeholders based on the results of the data analysis.

The priority of objectives becomes the basis for developing planning alternatives. Potential constraints on implementation require that the objectives be broken down into phased targets, in which alternatives are developed to meet interim objectives.

In this way, the effectiveness of implementation can be monitored, and targets adjusted, as more is learned about the watershed, its physical characteristics, and evolving water quality regulations.

Strategies, Policies and Approaches

Once end targets and interim targets are established, with a clear list of associated planning objectives based on sound scientific analysis and consensus among stakeholders, effective sets of implementable management alternatives are developed to meet the agreed upon targets and objectives. These alternatives are a combination of options that may include suggested municipal actions, recommendations on water supply and wastewater collection system improvements, potential measures to protect water quality from point sources, best management practices for stormwater control, measures to control sanitary and combined sewer overflows, changes to land use and zoning, stream channel and streambank restoration measures, etc. These are combined in a coherent fashion within the context of the watershed-wide management alternatives. The alternatives then are evaluated based on cost, effectiveness in achieving priority objectives, and implementation feasibility. The plan ultimately should provide an implementation process to achieve the stated objectives over a specified period of time.



2.2 The Cobbs Planning Approach

The approach and specific tasks for the Cobbs Creek watershed management plan are intended to meet the criteria of the five major programs discussed in Section 1.3 as well as fit with PADEP's watershed based planning program approach.

In order to establish environmental goals and identify the indicators that measure progress toward these goals, the Cobbs planning strategy utilizes the "plan-do-check-review" methodology of the watershed based planning process. To satisfy the five elements included in this procedure, the Cobbs planning process moved from data collection and analysis to plan development in an organized manner, with constant interaction with the established stakeholder groups. The primary data collection, analysis, and technical planning activities of the Cobbs watershed management plan are outlined below, and the stakeholder process is discussed in Section 3.

2.2.1 Existing Data

PWD assembled relevant existing data and information collected in the past by other agencies and by prior studies. Several types of geographic and physical data were collected.

Geographic and Demographic Data. The base map for the project study area was prepared from U.S. Census Bureaus TIGER (Topologically Integrated Geographic Encoding and Referencing) database. These files contain local and state political boundaries, rivers and waterways, roads and railroads, and census block and block group boundaries for demographic analysis.

Meteorological Data. In addition to U.S. Census data, meteorological data was gathered to analyze streamflow responses to seasonal changes, climate variation, and storms, and to model stormwater flows. Long-term rainfall data were obtained from the National Oceanic and Atmospheric Administration's (NOAA) rainfall gage at the Philadelphia International Airport. This gage has over 100 years of hourly precipitation data, from January 3, 1902 through the present. In addition to this long-term rainfall gage, the PWD CSO Program has over 10 years of 15-minute rainfall data from 24 City rain gages. There are six of these gages in the vicinity of the Cobbs Creek watershed. The available rainfall data for each gauge is summarized in Table 2-1, and Figure 2-1 shows their locations. Data from each gage were analyzed for accuracy and completeness, and the data were subjected to statistical analyses to check for changes in the gage location or physical layout, as well as to explore correlations among gages to identify potential over-or under-catch trends.

Table 2-1 Rainfall Data Available for the Cobbs Creek Watershed Gages

Gauge Name	Available Data
RG-01	1991 - 2002
RG-02	1990 - 2002
RG-06	1991 - 2002
RG-09	1990 - 2002
RG-22	1990 - 2002
RG-23	1992 - 1998, 2001 - 2002

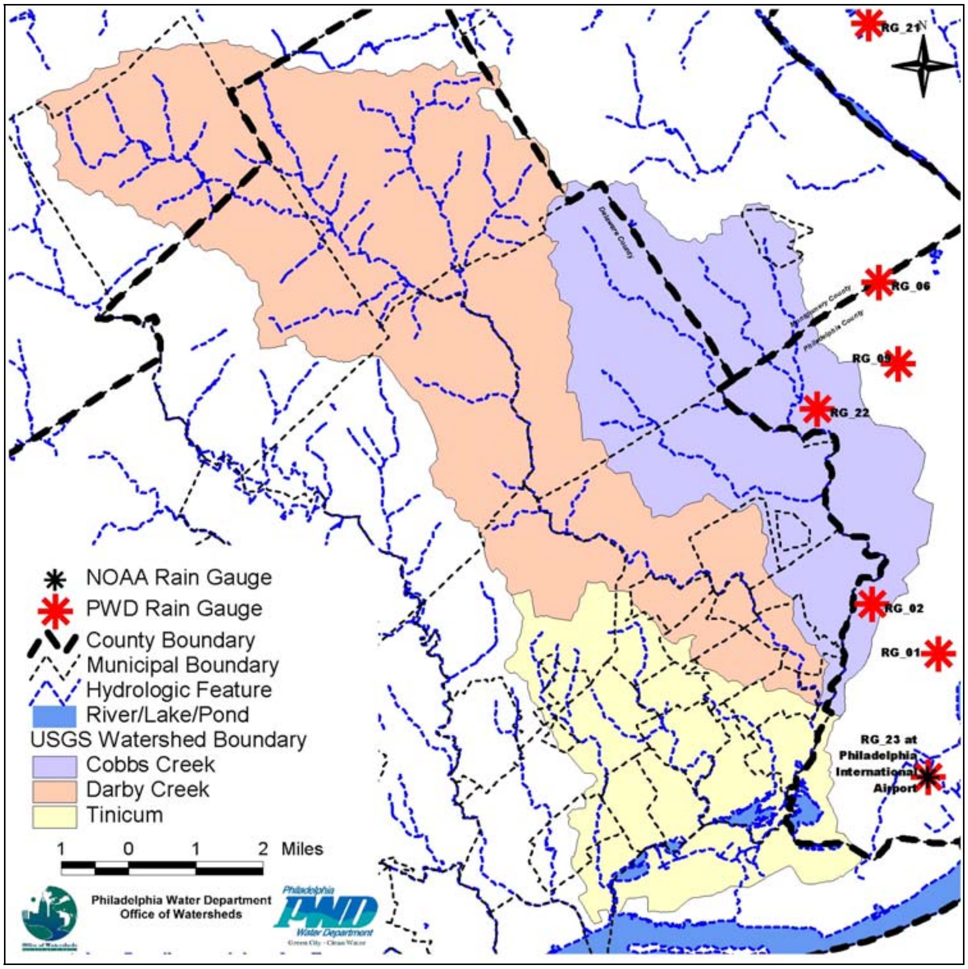


Figure 2-1 City Rain Gages in or near the Watershed

Land Use. Land use information for the Cobbs Creek watershed was obtained from the Delaware Valley Regional Planning Commission (DVRPC) for the counties of Chester, Delaware, Montgomery, and Philadelphia. The DVRPC land use maps are based on aerial photography from March through May of 1995. For a more useful representation of the existing land use information for hydrologic analyses, resulting in a land use map with 20 different categories shown in Figure 2-2.

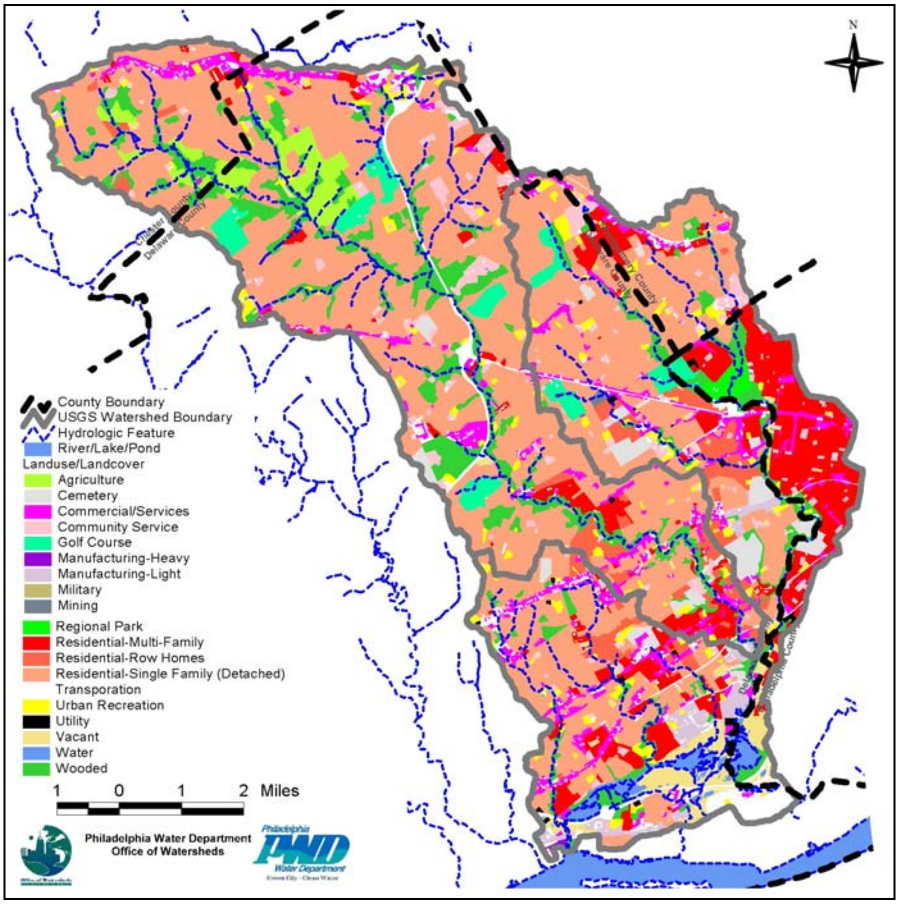

Figure 2-2 DRVPC Land Use Map for the Darby-Cobbs Creek

Streamflow. During the 1960's, the United States Geological Survey (USGS), in cooperation with PWD, established streamflow-gaging stations at six locations in the Darby-Cobbs Creek watershed. While only one of these gages still is active today, the two to three decades of historic record they provided is invaluable in characterizing the hydrologic response of the watershed. The locations of the gages are presented on Figure 2-3 and listed in Table 2-2. Daily streamflow records from the gages were analyzed, and baseflow separation performed to identify patterns along the stream of baseflow and stormwater runoff. The results of these analyses are presented in Section 4.

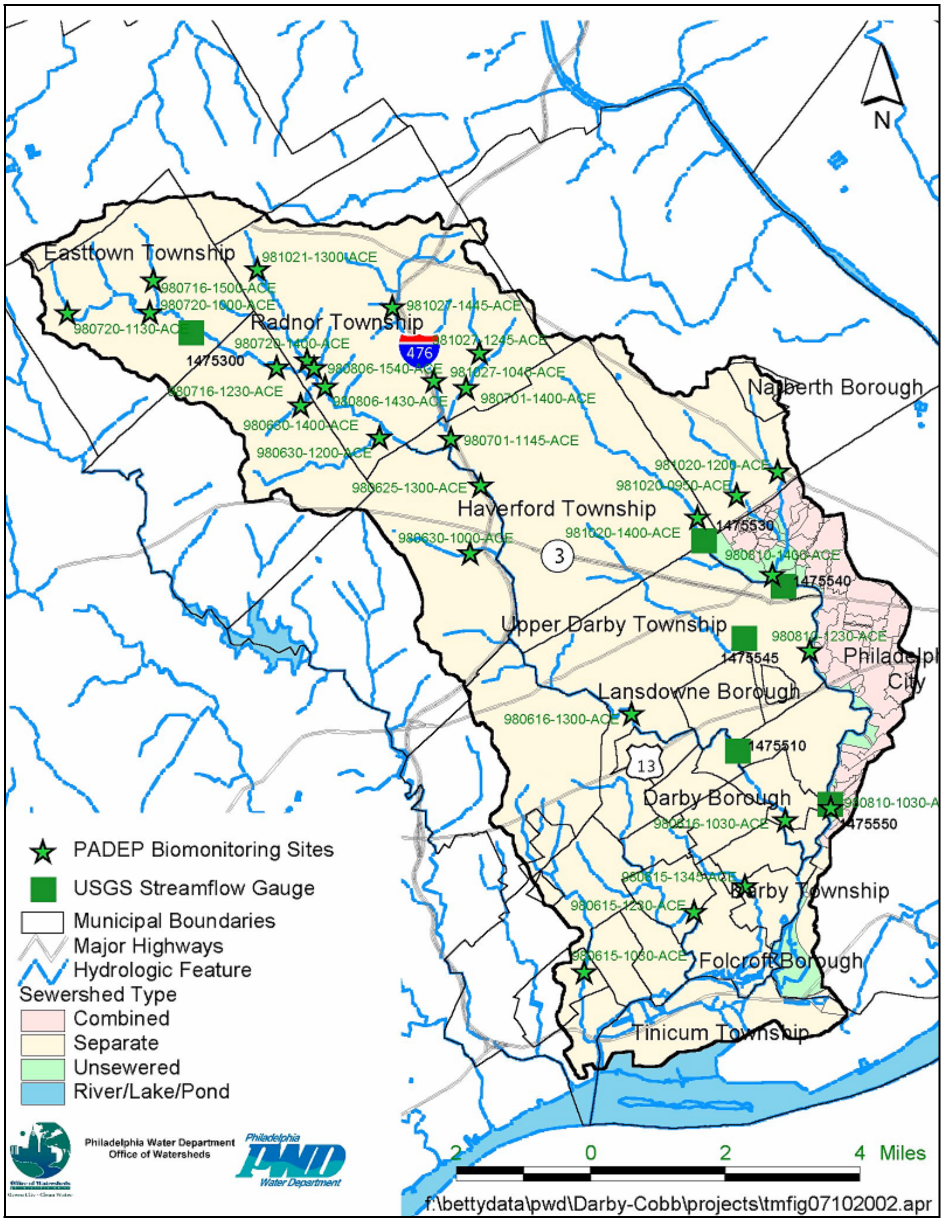

Figure 2-3 USGS Streamflow Gages

Table 2-2 USGS Gages and Periods of Record

Station ID	Location	Quality Data	Streamflow Data
01475300	Darby Creek At Waterloo Mills Near Devon, Pa.		4/28/1972-9/30/1994, 6/28/1996-present
01475510	Darby Creek Near Darby, Pa.		2/1/1964-10/3/1990
01475530	Cobbs Creek At U.S. Highway No. 1 At Phila., Pa.	1/1/1965-3/3/1980	10/1/1964-9/30/1981
01475540	Cobbs Creek Below Indian Creek Near Upper Darby, Pa.	10/10/1967-2/7/1973	10/1/1964-6/30/1973
01475545	Naylor Creek At West Chester Pike Near Phila., Pa.		6/1/1972-10/20/1978
01475550	Cobbs Creek At Darby, Pa.	11/9/70-3/3/80	1/1/1964-10/3/1990

Water Quality. In the early 1970's, the Philadelphia Water Department began a study in cooperation with the U.S. Geological Survey titled, "Urbanization of the Philadelphia Area Streams." The purpose of this study was to quantify the hydrology and pollutant loading of Philadelphia's streams, and possibly relate the degradation in water quality to urbanization. Two of the stations sampled for the study were in the Cobbs Creek watershed at USGS gaging locations: Station 12, Cobbs Creek at U.S. Route 1, and Station 15, Cobbs Creek at Darby. Monthly discrete water quality samples were collected at each site and analyzed for conductivity, BOD_5, total phosphate, ammonia, nitrite, nitrate, and fecal coliform. The program collected about 10 years of monthly samples. The majority of the data currently available from STORET, USEPA's water quality database, were collected as part of this study.

Stream Assessment and Biological Data. Some stream assessment data for the Cobbs watershed were also available. The Philadelphia Academy of Natural Sciences collected stream morphology data for four streams in the Cobbs Creek watershed in August 1998. The data were collected in Fairmount Park for Indian Run, Indian Creek, Bocce Tributary, and Cobbs Tributary 3. The data provide information about streambed slope, cross-sectional properties, and sediment grain size distribution.

At the request of PWD, PADEP performed a biological assessment of the non-tidal portions of the Cobbs Creek watershed. For the assessment, 28 stations were chosen that represent the watershed, based upon land use and stream order. Each station was evaluated using the Rapid Bio-assessment Protocol and USEPA's habitat assessment methods. The assessments occurred between June and late October in 1998. The decisions to consider a station impaired or unimpaired were based upon the quality and quantity of habitat and macroinvertebrates.

2.2.2 Monitoring and Field Data Collection

To supplement existing data, PWD's Office of Watersheds (OOW) conducted an extensive sampling and monitoring program to characterize conditions in the Darby-Cobbs Creek watershed. The program was designed to document the condition of aquatic resources, to provide information for the planning process needed to meet regulatory requirements imposed by EPA and PADEP, and to monitor long term trends as implementation of the plan proceeds.

Water Quality Sampling

Three types of water quality sampling were carried out by PWD for the Cobbs Creek. Figure 2-4 presents the locations of each sampling site along the creek during an initial assessment. Discrete sampling was performed weekly from May through July 1999 at each of the locations. Wet weather sampling involved the collection of discrete samples before and during a wet weather event, allowing the characterization of water quality responses to stormwater runoff and sanitary and combined sewer overflows. Of the ten sampling events, four are considered wet weather events. The third type of sampling was continuous monitoring, carried out by introducing YSI 6600-01 Sondes, shallow depth continuous water quality monitors, and probes that record dissolved oxygen, pH, and turbidity. The equipment was deployed to three locations periodically for a number of days to collect continuous data samples and observe water quality fluctuations.

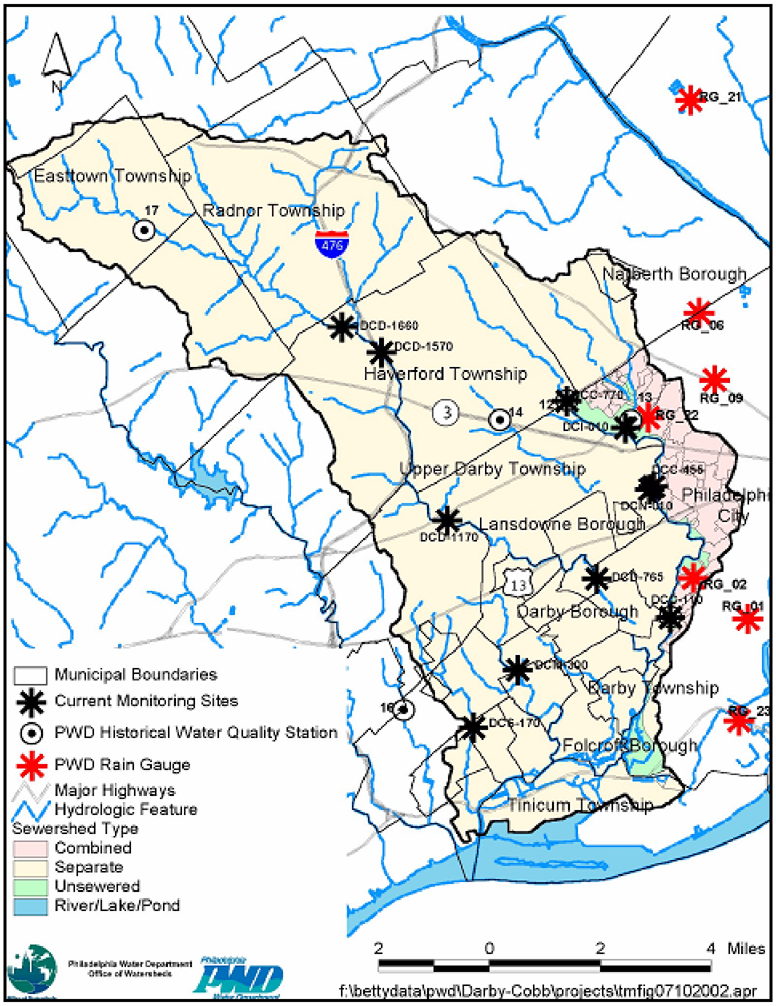

Figure 2-4 Ten Water Quality Monitoring Locations

Biological Monitoring

Biological monitoring is a useful means of detecting anthropogenic impacts to the aquatic community. Resident biota (e.g. benthic macroinvertebrates, fish, periphyton) in a water body are natural monitors of environmental quality and can reveal the effects of episodic and cumulative pollution and habitat alteration (Plafkin et. al. 1989, Barbour et al. 1995). The Philadelphia Water Department's Office of Watersheds and Bureau of Laboratory Services, along with the Philadelphia Academy of Natural Sciences and the Pennsylvania Department of Environmental Protection have been developing a preliminary biological database to assess the aquatic integrity of the Darby-Cobbs watershed. Macroinvertebrate and ichthyfauna monitoring was conducted at specific locations within the Cobbs Creek watershed.

Geographical Information Systems (GIS) databases and watershed maps were constructed to provide accurate locations of the sampling sites.

An ichthyfauna (fish) assessment occurred at five sampling stations on Cobbs Creek; three on the mainstem, and two on the smaller tributaries: West Branch Indian Creek and Naylor's Run. Six metrics were used to assess the quality of the fish assemblages in Cobbs Creek.

1. Species richness
2. Species diversity
3. Trophic composition relationships
4. Pollution tolerance levels
5. Disease and parasite abundance/severity
6. Introduced (exotic) species

In addition to the fish assessment, the results of a PADEP Rapid Bioassessment Protocol (RBP) assessment of seven sites in the Cobbs Creek watershed were also compiled. PADEP biologists used a combination of habitat and biological assessments to evaluate the Cobbs Creek under the Unassessed Waters Program. Biological surveys included kick screen sampling of benthic macroinvertebrates, which were identified by family and by their tolerance to pollution. Benthic macroinvertebrates mainly are aquatic insect larvae that live on the stream bottom. Since they are short-lived and relatively immobile, they reflect the chemical and physical characteristics of a stream and chronic sources of pollution. The biological integrity and benthic community composition was determined using USEPA guidelines for RBP III.

Upon completion of the total biological scoring, each site was compared to a reference site according to its drainage area and geomorphological attributes. The two reference sites chosen were Broad Run (located at the intersection of Chestnut Lane and Broad Run Road, West Bradford Township, Chester County) and French Creek (located at Coventry Road Bridge, South Coventry Township, Chester County). The comparison of the biological assessment of each site with the reference site was designed to create a baseline for monitoring trends in benthic community structure that might be attributable to improvement or worsening of conditions over time. Several Biological Condition Categories were developed:

- Non-impaired
- Slightly impaired
- Moderately impaired
- Severely impaired

Habitat Assessment

Habitat assessments evaluate how deeply the stream substrate is embedded, the degree of streambank erosion, the condition of riparian vegetation, and the amount of sedimentation. Data from the PADEP surveys were available for both the Darby and Cobbs Creeks. Habitat assessments at seven sites were completed based on the Stream Classification Guidelines for Wisconsin (Ball, 1982) and Methods of Evaluating Stream, Riparian, and Biotic Conditions (Platts et al., 1983). Reference conditions were used to normalize the assessment to the Cobbs Creek (mainstream) "best attainable" situation. Habitat parameters were separated into three principal categories to characterize the site:

- Primary or microscale habitat
- Secondary or macroscale habitat (stream channel)
- Tertiary or riparian and bank structure

Resource based Habitat Suitability Indices (HSI) were developed to add aquatic life-based habitat and flow requirement criteria to the watershed assessment. HSIs integrate the expected effects of a variety of physicochemical and hydrological variables on a target species of environmental or economic concern. Data are used to construct sets of suitability index curves, each of which relates a habitat parameter to its suitability for the species of interest. Curves rate habitat variables on a scale of 0 to 1.0, and were developed to measure food and cover, water quality, and reproduction (e.g. substrate type, percent pools, percent cover, depth of pools, pH, DO, turbidity, temperature).

Fluvial Geomorphological Assessment

For the Cobbs Creek watershed, Philadelphia performed a fluvial geomorphic assessment and baseline determination of stream stability. The measurement of geomorphic parameters and physical and hydraulic relationships were performed at both Level I and Level II of the Rosgen classification methodology (D.L. Rosgen Applied River Morphology 1996).

Level I: Desktop survey was desktop delineation of the stream using generalized major stream types based on available topographic information, geological maps, soils maps, and aerial photographs. The purpose of the inventory was to provide an initial framework for organizing and targeting subsequent field assessments of important reaches where problems are known to occur or are anticipated to occur. Available topographic information, geological maps, soils maps, and aerial photographs were reviewed.

Level II: Reach stream survey was performed for approximately 30 miles of the highest order streams and tributaries within the Cobbs Creek watershed. Field teams of two stream surveyors walked along the designated lengths of each stream and tributary and estimated several parameters related to channel morphology:

- Bankfull Elevation
- Bankfull Width
- Entrenchment Ratio range
- Width/Depth ratio range
- Sinuosity range
- Channel Slope range
- Channel Materials (pebble count)
- Meander Pattern

2.2.3 Watershed Modeling

An important tool for developing the watershed plan is a hydrologic and hydraulic model of the stream and stormwater system. In most streams in the eastern US, stormwater flows can range from less than 30% of total annual streamflow in less-developed watersheds to over 70% in highly urbanized settings. Modeling of stormwater flows is, therefore, a critical component of a watershed management plan. The model should, at a minimum, be built to provide storm-by-storm flows to the streams as well as estimates of pollutant loads carried by the stormwater reaching the streams.

A Stormwater Management Model (SWMM) was built for the entire Cobbs Creek watershed. SWMM is a comprehensive set of mathematical models originally developed for the simulation of urban runoff quantity and quality in storm, sanitary, and combined sewer systems. The model subdivides the watershed into approximately 100 subwatersheds and estimates flow and pollutant loading from each land use type within each of the subwatersheds. It simulates the hydraulics of combined sewers, the open channel of the creek itself, and the floodplain. Thus, the model is useful for simulation of stormwater runoff quantity and quality, combined sewer overflow, and streamflow. The model was calibrated by comparing stormwater runoff to estimated runoff, calculated through hydrograph separation at USGS gage 01475550, on Cobbs Creek upstream of the confluence with Darby Creek. Model simulations included:

- Existing conditions using a long-term rainfall record from Philadelphia Airport
- Annual average pollutant loads for key pollutants found in stormwater. The list of pollutants includes parameters such as nitrate and phosphorus, total suspended solids, heavy metals, BOD, and DO
- Numerous simulations to test the effectiveness of various BMPs within the Cobbs Creek watershed. Effectiveness was judged based on reductions in stormwater discharges, CSOs, and reduced pollutant loading during wet weather

- Simulations of six potential mixes of BMPs to assess the overall effectiveness of alternative watershed management plan approaches to achieving plan objectives

The model results also helped identify areas where stormwater runoff or pollutant loads are particularly high and in need of control. Model flow results, in combination with the results of the fluvial geomorphic assessment, provided excellent tools for identifying areas of the watershed that are undergoing stormwater-related stress and an efficient way of developing alternative integrated watershed management approaches, particularly with regard to the Wet Weather Target C objective.

2.2.4 Goals and Objectives

Early in the planning process, project goals and objectives were developed in conjunction with the stakeholders. In general, goals represent consensus on a series of "wishes" for the watershed. Ten project goals were established that represent the full spectrum of goals from all the programs relevant to the watershed (e.g. River Conservation Plan, TMDL programs, Act 167 Stormwater Plans etc.) A significant effort was made to consolidate the various goals into a single, coherent set that avoids overlap and is organized into clear categories.

Once the preliminary set of goals was developed, a series of associated objectives was developed. Objectives translate the "wishes" into measurable quantities; indicators are the means of measuring progress toward those objectives. This relationship is the link between the more general project goals and the indicators developed to assess the watershed and to track future improvement.

The preliminary planning goals and objectives were presented to stakeholders for initial review. However, the final, prioritized goals and objectives were subjected to final review and approval when the data analysis and modeling work were complete.

2.2.5 Data Analysis and Indicator Development

An important aspect of a watershed management plan is a basic description of existing conditions within the watershed and streams. To accomplish this, a series of indicators were developed to represent the results of the data collection efforts and the data analysis and modeling. An indicator is a measurable quantity that characterizes the current state of at least one aspect of watershed health. Every indicator is directly linked to one or more project objectives. Thus, they serve to describe the current conditions, and provide a clear method of monitoring progress and achievement of objectives as management alternatives are implemented over time. This approach was fashioned after the watershed based planning approach program.

The indicators selected for their potential use both in assessing current conditions, as well as assessing future progress in improving conditions, are shown below.

The Land Use and Stream Health Relationship

Indicators	
1	**Land Use and Impervious Cover**
2	**Streamflow**
3	**Stream Channels and Aquatic Habitat**
4	**Restoration Projects Lists of completed, in progress, and planned projects**
5	**Fish**
6	**Benthos**

Water Quality

Indicators	
7	**Effects on Public Health (Bacteria)**
8	**Effects on Public Health (Metals and Fish Consumption)**
9	**Effects on Aquatic Life (Dissolved Oxygen)**

Pollutants and Their Sources

Indicators	
10	**Point Sources**
11	**Non-point Sources**

The Stream Corridor

Indicators	
12	**Riparian Corridor**
13	**Wetlands and Woodlands**
14	**Wildlife**
15	**Flooding**

Quality of Life

Indicators	
16	**Public Understanding and Community Stewardship**
17	**School-Based Education**
18	**Recreational Use and Aesthetics**
19	**Local Government Stewardship**
20	**Business and Institutional Stewardship**
21	**Cultural and Historic Resources**

2.2.6 Development and Screening of Management Options

Clear, measurable objectives provided the guidance for developing options designed to meet the project goals. A management option is a technique, measure, or structural control that addresses one or more objectives (e.g., a detention basin that gets built, an ordinance that gets passed, an educational program that gets implemented).

The following example clarifies the difference among a goal, an objective, and a management option.

Goal: improve water quality

Objective: maintain dissolved oxygen levels above 5 mg/L

Management Option: eliminate deep, poorly mixed plunge pools where low DO is detected

Lists of management options were developed to meet each of the goals and objectives established for the Cobbs Creek watershed. Only those options deemed feasible and practical were considered in the final list of management options. Options were developed and evaluated in three steps:

1. ***Development of a Comprehensive Options List.*** Virtually all options applicable in the urban environment were collected. These options were identified from a variety of sources, including other watershed plans, demonstration programs, regulatory programs, the literature, and professional experience.
2. ***Initial Screening.*** Some options could be eliminated as impractical for reasons of cost, space required, or other considerations. Options that already were implemented, were mandated by one of the programs, or were agreed to be vital, were identified for definite implementation. The remaining options were screened for applicability to Cobbs Creek. This was accomplished by developing a database and creating every possible combination of options. These were scored based on their relative cost and the degree to which they met the project objectives. Only the most cost-effective options were considered further.
3. ***Detailed Evaluation of Structural Options.*** Structural best management practices for stormwater and combined sewage were subjected to a modeling analysis. Effects on runoff volume, overflow volume, peak stream velocity, and pollutant loads were evaluated at various levels of coverage.

The initial screening looked at the cost effectiveness of over 20 options for controlling stormwater using an automated database approach. The intent was not only to look at each option by itself, but also to assess the effectiveness of each option in combinations with other options. Figure 2-5 shows that the database developed over one million possible combinations of the options, and scored each for their cost effectiveness.

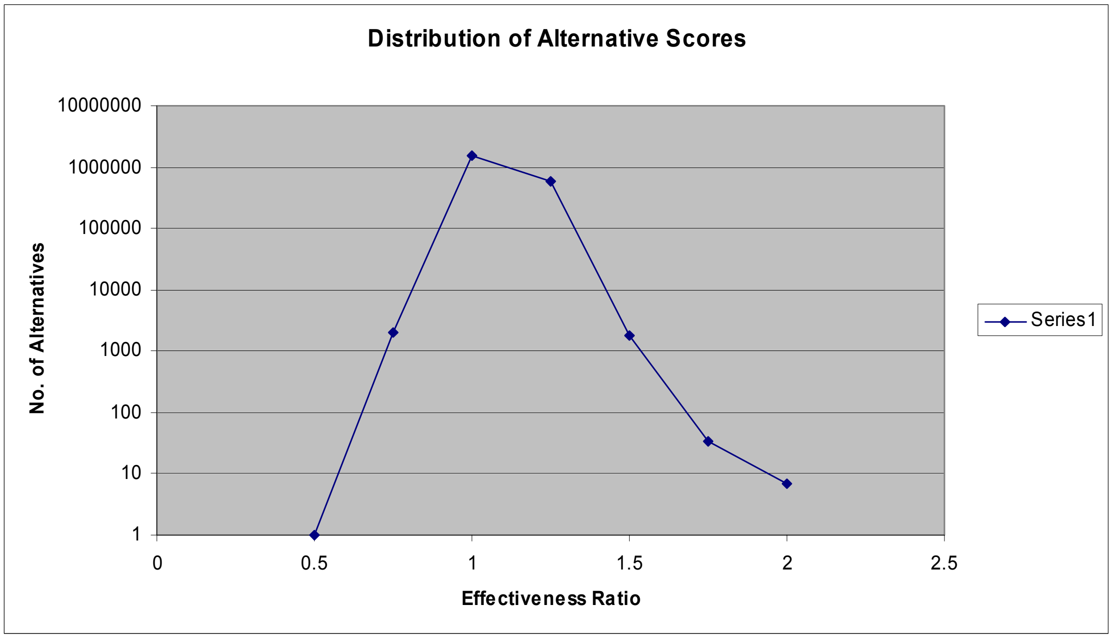

Figure 2-5 Distribution of Effectiveness Scores for Combined Options

The decision to include an option in the final set of alternatives was based on how well it performed in the cost-effectiveness evaluation, both as a stand-alone option, and also in combination with other options.

Detailed evaluation of structural options (step 3) used the SWMM model to assess the effectiveness of each option and by performing a planning-level cost estimate of each option. All options that had an effect on CSOs or stormwater-related pollutant loads were modeled at several degrees of implementation using the SWMM model. Graphs of effectiveness versus degree of implementation were developed, and the results then were combined with more careful cost estimates to provide guidance on selecting effective options or combinations of options.

The modeling and other analyses resulted in six alternatives selected for full evaluation.

2.2.7 Development of Target Approach for Meeting Goals and Objectives

In developing watershed management alternatives and discussing goals and objectives with stakeholders, it became clear that implementation could best be achieved by defining three distinct targets to meet the overall plan objectives. Two of the targets were defined so that they could be fully met with a limited set of options that are fully implemented. The third target fit better with the “plan-do-check-review” methodology of the watershed based planning process. In other words, it was agreed to set interim objectives, recommend measures to achieve the interim objectives, implement those controls to achieve these objectives, and reassess the capability to meet the objectives, or agree to raise the bar to more complete achievement of the final objectives.

Targets are defined here as groups of objectives that each focus on a different problem related to the urban stream system. They can be thought of as different parts of the overall goal of fishable and swimmable waters through improved water quality, more natural flow patterns, and restored aquatic and riparian habitat.

By defining these targets, and designing the alternatives and implementation plan to address the targets simultaneously, the plan will have a greater likelihood of success. It also will result in realizing some of the objectives within a relatively short time frame, providing positive incentive to the communities and agencies involved in the restoration, and more immediate benefits to the people living in the watershed.

The targets for the Cobbs Creek watershed management plan are defined as follows.

TARGET A: Dry Weather Water Quality and Aesthetics

Target A was defined for Cobbs Creek with a focus on trash removal and litter prevention, and the elimination of sources of sewage discharge during dry weather. Streams should be aesthetically appealing (look and smell good), be accessible to the public, and be an amenity to the community. Access and interaction with the stream during dry weather has the highest priority, because dry weather flows occur about 60-65 % of the time during the course of a year on the Cobbs Creek. These are also the times when the public is most likely to be near or in contact with the streams. The water quality of the stream in dry weather, particularly with respect to bacteria, should be similar to background concentrations in groundwater.

In many urban streams, monitoring indicates that the water quality rarely meets the water quality standard for bacteria, and exhibit occasional DO problems, even during baseflow or dry weather conditions. Thus, the first target focuses on dry weather water quality, coupled with the visual aesthetics of the stream, primarily the removal of trash and the elimination of illegal dumping so often associated with degraded, urban waterways. The first target also includes a range of regulatory and nonstructural options that address both water quality and quantity concerns. Because the options under consideration are aimed at the total elimination of dry weather sources of trash and sewage, all options related to this target were included in the implementation plan.

TARGET B: Healthy Living Resources

Based on the results of the water quality monitoring, habitat assessment, and biological monitoring, water quality was not identified as the primary cause of the low diversity and impaired nature of the fish population in the stream. Improvements to the number, health, and diversity of the benthic invertebrate and fish species in the Cobbs Creek need to focus on habitat improvement and the opportunity for organisms to avoid high velocities during storms. Fluvial geomorphological studies, wetland and streambank restoration/creation projects, and stream modeling should be combined with continued biological monitoring to ensure that correct procedures are implemented to increase habitat heterogeneity within the aquatic ecosystem.

Improving the ability of an urban stream to support viable habitat and fish populations focuses primarily on the elimination of remediating the more obvious impacts of urbanization on the stream. These include loss of riparian habitat, eroding and undercut banks, scoured streambed or excessive silt deposits, channelized and armored stream sections, trash buildup, and invasive species. The primary tool to accomplish this target is stream restoration. Restoration focuses on improving channel stability, improving instream and riparian habitat, providing refuges for fish from high velocity conditions during storms, and managing land within the stream corridor. Restoration strategies include:

- Bank stabilization, including boulder structures, bioengineering, root wads, plantings, and log and woody structures
- Bed stabilization, including rock/log vanes with grade control, rock/log cross vanes, and using naturally occurring boulders and bedrock
- Realignment & relocation, used only on severely degraded stream sections
- Dam and debris removal
- Reforestation, with priority to floodplains, steep slopes, and wetlands
- Invasive species management to increase biodiversity
- Wetland creation, often used in conjunction with stream realignment to improve floodplain areas subject to annual flooding
- Forest preservation
- Fish holding areas, with low to no current zones created to provide fish with places to hold position during high flows

Stream restoration measures to meet this target were identified, and all options required to meet the target are planned for implementation.

TARGET C: Wet Weather Water Quality and Quantity

The third target is to restore water quality to meet fishable and swimmable criteria during wet weather. Improving water quality and flow conditions during and after storms is the most difficult target to meet in the urban environment. Because wet weather conditions on Cobbs Creek occur to some degree about 35-40% of the time during the year, measures to improve wet weather quality have a somewhat lower priority than measures designed to address dry weather water quality. During wet weather, extreme increases in streamflow are common, accompanied by short-term changes in water quality. Stormwater generally does not cause immediate DO problems, but sampling data indicate that concentrations of some metals (such as copper, lead, and zinc) and bacteria do not meet water quality standards during wet weather. These pollutants are introduced by both stormwater and wet weather sewage overflows (CSOs and SSOs).

A comprehensive watershed management approach must also address flooding issues. Where water quality and quantity problems exist, options may be identified that address both. Any BMP that increases infiltration or detains flow will help decrease the frequency of damaging floods; however, the size of such structures may need to be increased in areas where flooding is a major concern. Reductions in the frequency of erosive flows and velocities also will help protect the investment in stream restoration made as part of the second target (B).

Target C must be approached somewhat differently from Targets A and B. Full achievement of this target means meeting all water quality standards during wet weather, as well as eliminating all flooding. Meeting these goals will be difficult. It will be expensive and will require a long-term effort. The only rational approach to achieve this target must include stepped implementation with interim targets for reducing wet weather pollutant loads and stormwater flows, along with monitoring for the efficacy of control measures.

Initial load reduction targets for parameters such as metals, total suspended solids (TSS), and bacteria were set in conjunction with the stakeholders. Based on preliminary work by PWD, 10-20% reductions are a challenging but achievable initial interim target.

It is expected that changes to the approach, and even to the desired results, will occur as measures are implemented and results are monitored. This process of continually monitoring progress and adjusting the approach is known as *adaptive management*. The NPDES permit programs for stormwater and CSO outfalls can lead to a cycle of monitoring, planning, and implementation that helps define a time frame to this process.

2.2.8 Development and Evaluation of Target C Management Alternatives

An alternative for meeting Target C, or wet weather water quality objectives, is a group of options designed to meet the established interim target of 10-20% reduction in stormwater flows and/or pollutant loading. For example, a management alternative might consist of a combination of all the following options:

- Establishing a program of uniform and coordinated municipal stormwater ordinances
- Installing rain barrels on 20% of the homes

- Installing porous pavement with underground stormwater storage in half of the parking lots in the watershed
- Developing a public education program

The results of the options screening and evaluation process discussed in Section 2.2.6 were used to assemble Target C alternatives. To develop a management alternative, options are grouped as to maximize effectiveness, minimize cost, and avoid combinations of options that conflict with each other (e.g. two options designed to occupy the same space or utilize the same pipe). Target C alternatives were developed based on unifying approaches such as minimum cost, BMPs on public property and BMPs on private property.

2.2.9 Implementation Guidelines

Six alternatives, each including a package of options to address all three targets, were evaluated using a multi-criteria evaluation program called EVAMIX. The program is designed to evaluate the alternatives against a series of criteria weighted according to priority by the stakeholders. The evaluation, along with the many individual SWMM model simulations, provided significant insight into the best approaches to meeting Target C objectives. The draft implementation plan developed provided:

- Specific recommendations and a schedule for meeting Target A objectives
- Specific recommendations and a schedule for meeting Target B objectives
- Guidance on which BMPs or mixes of BMPs were most effective in Cobbs Creek for meeting Target C objectives.
- Guidance on the needed degree of implementation to achieve Target C objectives
- Guidance on areas of the watershed where BMPs would be most effective
- Recommendations on Target C options for the CSO areas, and recommendations for Target C options for separate storm sewer areas

Section 3: Goals and Objectives

Developing a focused and prioritized list of goals (general) and objectives (specific, measurable) is critical to a successful planning process. Goals and objectives need to be:

- initially developed by stakeholders and regulatory agencies,
- analyzed and informed by the watershed data collection, analysis, and modeling carried out by the project team,
- finalized by the project team and prioritized by the stakeholders.

3.1 Stakeholder Goal Setting Process

Considerable stakeholder input towards developing watershed goals was sought from the beginning of this planning effort. Responses were summarized, and additional stakeholder input organized through further contacts with the stakeholders. The mission statement for the Darby-Cobbs Watershed Partnership planning effort, as well as related goals from other programs were developed by the stakeholders and are listed here.

Darby-Cobbs Partnership Mission Statement

To improve the environmental health and safe enjoyment of the Darby-Cobbs watershed by sharing resources through cooperation of the residents and other stakeholders in the watershed. The goals of the initiative are to protect, enhance, and restore the beneficial uses of the Darby-Cobbs waterways and riparian areas. Watershed management seeks to mitigate the adverse physical, biological, and chemical impacts of land uses as surface and groundwater are transported throughout the watershed to the waterways.

Goals of Related Studies and Programs

Other studies already have provided a list of goals. Generally the goals in this section are those identified through the rivers conservation planning process, supplemented by those goals that are required as a result of various environmental regulatory requirements. Additional goals identified in the Darby-Cobbs stakeholder meetings also were included once consensus was established. Existing goals included:

- Aquatic life designated use attainment goal (warm water fishery)
- Public health: contact recreation (bacteria, noxious plants)
- Aesthetics: visual and olfactory conditions (noxious plants, bank erosion, litter, odor, etc.)
- Riparian corridors
- Wetlands, woodlands & meadows
- Wildlife
- Act 167 plan goals
- Act 537 goals
- TMDL-related goals
- NPDES program goals (including stormwater management and CSO control)
- Environmental Futures Program goals
- River conservation plan goals

3.2 Consolidated Watershed Planning Goals and Objectives

The large list of goals from the existing stakeholder process needed to be organized. This was accomplished by consolidating goals from various sources into a coherent set for the integrated plan. Other considerations included stakeholders' desire to restore the living resources, and the steering committee preference for achieving goals through innovative, land-based, low-impact, and cost-effective management options. Consensus was reached eventually around the following ten goals. Under each goal, more specific objectives are listed.

1. **Streamflow and Living Resources.** Reduce the impact of urbanized flow on the living resources.
   1.1. Increase baseflow as a percentage of total flow.
   1.2. Increase groundwater recharge.
   1.3. Prevent increases in the stormwater flow peaks in future development/redevelopment areas.
   1.4. Reduce directly connected impervious cover in developed areas. Reduce the rate of growth in directly connected impervious cover in areas with new development.
   1.5. Based partially on Act 167 stormwater planning, revise municipal codes to encourage new development and redevelopment of existing, vacant, and abandoned lands using techniques that help reach stormwater and erosion control objectives.

2. **Stream Habitat and Aquatic Life.** Improve stream habitat and indices of aquatic integrity.
    2.1. Improve stream habitat to restore selected living resources to a pre-development condition.
    2.2. Improve quantitative measures of fishery health.
    2.3. Improve quantitative measures of benthic invertebrate quality.
    2.4. Adapt or develop quantitative measures of attached algae to assess current stream conditions.
    2.5. Improve migratory fish passage.

3. **Stream Channels and Banks.** Reduce streambank and stream channel deposition and scour to protect and restore the natural functions of aquatic habitat and ecosystems, streambanks, and stream channels.
    3.1. Increase miles of stable streambanks and stream channels.
    3.2. Reduce the frequency of occurrence of bankfull flow.

4. **Flooding.** Decrease flooding.
    4.1. Remediation should reduce the effects and frequency of out-of-bank flooding through management of stormwater.
    4.2. Remediate stream-related flooding in known problem areas without increasing the problem in other areas.
    4.3. Increase regular storm drain maintenance and cleaning programs throughout the watershed.
    4.4. Incorporate sound floodplain management principles in flood planning.
    4.5. Minimize the effects of structural floodway and stream encroachments with regard to sediment load and natural streamflow.

5. **Water Quality.** Improve dry and wet weather stream quality.
    5.1. Re-evaluate designated uses and develop a phased achievement approach to revised designated uses by meeting associated water quality criteria in Darby and Cobbs Creeks.
    5.2. Develop a phased approach to meeting appropriate water quality standards in dry weather and wet weather.
    5.3. Prevent fish consumption advisories.

6. **Pollutant Loads.** Decrease pollutant loads to surface waters.
    6.1. Identify "hot spots" of runoff pollution and define pollution reduction measures to decrease loads of targeted water quality parameters.
    6.2. Identify and eliminate SSOs and illicit storm sewer connections in a manner consistent with the Clean Water Act and the Clean Streams Law.
    6.3. Eliminate septic tank failures.
    6.4. Implement the Nine Minimum Controls for CSOs.
    6.5. Minimize CSO volume and frequency in accordance with the National CSO Policy.
    6.6. Decrease inputs of floatables, debris, and litter from all sources.
    6.7. Increase I/I studies, sewer cleanings and inspections.

7. **Stream Corridors.** Protect and restore stream corridors, buffers, floodplains, and natural habitats including wetlands.
    7.1. Decrease loss of open space and habitat by responsibly managing new development.
    7.2. Increase open space and habitat by responsibly managing redevelopment of existing, vacant, and abandoned lands.
    7.3. Inventory and protect existing wetlands.
    7.4. Identify and pursue opportunities for wetland enhancement and wetland creation for stormwater treatment.
    7.5. Improve floodplain conditions through restoration or improvement of the connections between streams and their floodplains.
    7.6. Protect and restore riparian habitat and stream buffer zones with native species where feasible.
    7.7. Protect and restore upland habitats along riparian corridors and throughout the watershed where feasible.
    7.8. Increase the number of municipalities with an invasive species control program.

8. **Quality of Life.** Enhance community environmental quality of life.
    8.1. Increase community green and open space.
    8.2. Increase community access and recreational activities in city parks and streams (e.g., by increasing miles of greenways and trails along stream corridors).
    8.3. Increase the public sense of security along stream corridors (e.g., by increased police presence, lighting, signage, park maintenance).
    8.4. Improve and protect aesthetics along stream corridors(e.g., by litter/graffiti removal, enforcement against illegal practices such as dumping, controls on ATV use).
    8.5. Identify and protect historical and cultural resources along stream corridors.

9. **Stewardship.** Foster community stewardship.
    9.1. Increase public awareness of the value of streams to the community.
    9.2. Improve business and institutional awareness of and accountability for activities that affect water quality.
    9.3. Encourage and support establishment of watershed organizations, EACs, etc. to bear the watershed banner.
    9.4. Engage local officials and planners.
    9.5. Increase volunteer participation in implementing management options.
    9.6. Increase school-based education.

10. **Coordination.** Improve inter-municipal, inter-county, state-local, and stakeholder cooperation and coordination on a watershed basis.
    10.1. Increase watershed-wide adoption of the resolution and expand it to include the goals of the watershed management plan.
    10.2. Gain state and federal support through grant funding. Increase synchronization of and coordination of permits and regulation on a watershed basis.
    10.3. Formally adopt a watershed management plan gaining county commissioners' approval.
    10.4. Improve data and information exchange between municipalities and stakeholders.
    10.5. Improve coordination with downstream communities and governments along the Delaware River and Estuary.

3.3 Goals Prioritization

The goals and objectives represent the collective idea of the stakeholders on what the watershed management plan should achieve. Not all goals, however, are of equal importance. It is important to elicit from the stakeholders a collective opinion on the relative importance of each goal for the Cobbs Creek. Because the achievement of goals is an important yardstick for measuring the effectiveness of the management plan, some numerical representation of the importance of each goal is useful.

To develop a set of numerical weights that represent the importance of each goal relative to the other goals, a workshop was held on October 29, 2002, with members of the partnership participating. The goal of the workshop was to work towards a consensus on a numerical set of weights that best represent the collective opinion on the importance of each goal. Each participant filled in a worksheet that described, as a percent, the individual contribution of each goal to the overall goal of watershed management. These sheets provided a variety of opinions on how the goals should be weighted, and served as a guide to a discussion on the relative importance of each goal. Through the group discussion, a consensus set of goal weights was developed that best represents the importance of each goal as defined by the stakeholders. Table 3-1 shows the weights assigned to each goal. The weights represent a percentage of the overall importance of each goal relative to all goals.

Table 3-1: Stakeholder Priorities as Weights for Goals

Streamflow and Living Resources. Reduce the impact of urbanized flow on the living resources (increase baseflow and recharge, reduce impervious area and runoff peaks, improve stormwater ordinances).	12
Stream Habitat and Aquatic Life. Improve stream habitat and indices of aquatic integrity (improve physical habitat, benthic, fish, algae).	9
Stream Channels and Banks. Reduce streambank and stream channel deposition and scour to protect and restore the natural functions of aquatic habitat and ecosystems, streambanks, and stream channels (increase stabilized areas, reduce frequency of bankfull flow).	7
Flooding. Decrease flooding (improve stormwater management, trouble spots, inlet cleaning, floodplain management and structures).	11
Water Quality. Improve dry and wet weather stream quality (meet designated uses, prevent fish advisories).	9
Pollutant Loads. Decrease pollutant loads to surface waters (decrease runoff, SSO, septic tank, CSO, and debris loads).	10
Stream Corridors. Protect and restore stream corridors, buffers, floodplains, and natural habitats including wetlands.	11
Quality of Life. Enhance community environmental quality of life (protect open space, access and recreation, security, aesthetics, historical/cultural resources).	12
Stewardship. Foster community stewardship (increase awareness and responsibility, volunteer programs, education).	11
Coordination. Improve inter-municipal, inter-county, state-local, and stakeholder cooperation and coordination on a watershed basis.	8

In addition to the weights assigned to each goal, the workshop participants also provided some insight into the relative importance of each of the objectives within the goals. These were provided as an opinion on whether a particular objective had a high, medium, or low priority as part of the goal. No consensus building process was attempted for all of the objectives, since these play a lesser role in the overall evaluation. The project team assigned a value of 1 point for a low designation, 2 points for a medium designation, and 3 points for a high designation. The point totals on all the sheets were tallied, and average scores were computed to distribute the overall consensus weight for each goal over its sub-objectives.

The weights assigned to each goal were important in screening and evaluating the many possible alternative water management approaches to arrive at the recommended alternative.

3.4 Target C Evaluation Criteria Weighting

The stakeholders also were asked to help provide weights for the process of evaluating the six alternatives developed to meet the wet weather water quality and quantity objectives (Target C, see section 2). These weights represented the relative importance of each of the criteria used in the evaluation, in much the same way the goals were assigned weights. In this case, however, each member organization's weights were tested using the EVAMIX evaluation program, and no consensus was attempted on a single set of weights. The various weight sets provided a type of sensitivity analysis and helped to clarify the strengths and weaknesses of various combinations of BMPs in meeting the Target C objectives of a 20 percent reduction in stormwater flow to the streams.

4. Darby-Cobbs Study Results

This section summarizes the results of the numerous studies that have already been carried out within the watershed. Many of the studies covered the entire Darby-Cobbs-Tinicum watershed, others only the Cobbs Creek watershed. When available, results are included for the Darby, Cobbs, and Tinicum portions of the watershed, to facilitate future planning for the Darby Creek watershed by Delaware County. The primary focus of the section, however, is to provide more detailed information on the Cobbs Creek watershed as the basis for CCIWMP.

4.1 Watershed Description and Demographics

The Darby-Cobbs watershed is defined as the land area that drains to the mouth of Darby Creek at the Delaware Estuary, encompassing approximately 80 square miles in southeastern Pennsylvania. This area includes portions of Chester, Delaware, Montgomery, and Philadelphia Counties. The watershed may be subdivided into the Cobbs Creek, Darby Creek, and Tinicum subwatersheds. Figure 4-1 includes the watershed boundaries, hydrologic features, and political boundaries. Much of the information is based on the U.S. Census Bureau's TIGER (Topologically Integrated Geographic Encoding and Referencing) database.

Cobbs Creek drains approximately 14,500 acres or 27% of the total watershed area. The upper portions and headwaters of Cobbs Creek, including East and West Branch Indian Creek, include portions of Philadelphia, Montgomery, and Delaware Counties. The lower portion of Cobbs Creek watershed, including the lower mainstem and Naylors Run, drain parts of Philadelphia and Delaware Counties. Cobbs Creek discharges to Darby Creek.

The Darby Creek watershed drains approximately 29,000 acres or 55% of the total study area. The watershed is located primarily in Delaware County. The northwest corner of the watershed, including the headwaters of the mainstem, is located in Chester County. Darby Creek has a number of small tributaries, including Little Darby Creek, Ithan Creek, and Foxes Run.

The Darby-Cobbs watershed discharges to the Delaware River through the wetlands of the Tinicum Refuge. The Tinicum watershed includes portions of Philadelphia and Delaware Counties and totals 9800 acres or 18% of the total. Much of the area consists of low-lying wetlands, including the John Heinz National Wildlife Refuge. Named streams in the subwatershed include Hermesprota, Muckinipattis, and Stony Creeks.

In a relatively undisturbed watershed, watershed boundaries follow topographic high points or contours. The U.S. Geological Survey (USGS) has further subdivided the Darby-Cobbs watershed based on topography, as shown in Figure 4-2. These USGS subwatersheds are determined from the land area draining to a particular point of interest, such as a stream confluence or gauging site. These boundaries allow initial determinations of drainage areas and modeling elements. However, it is important in the urban environment to include the effects of man-made changes to natural drainage patterns.

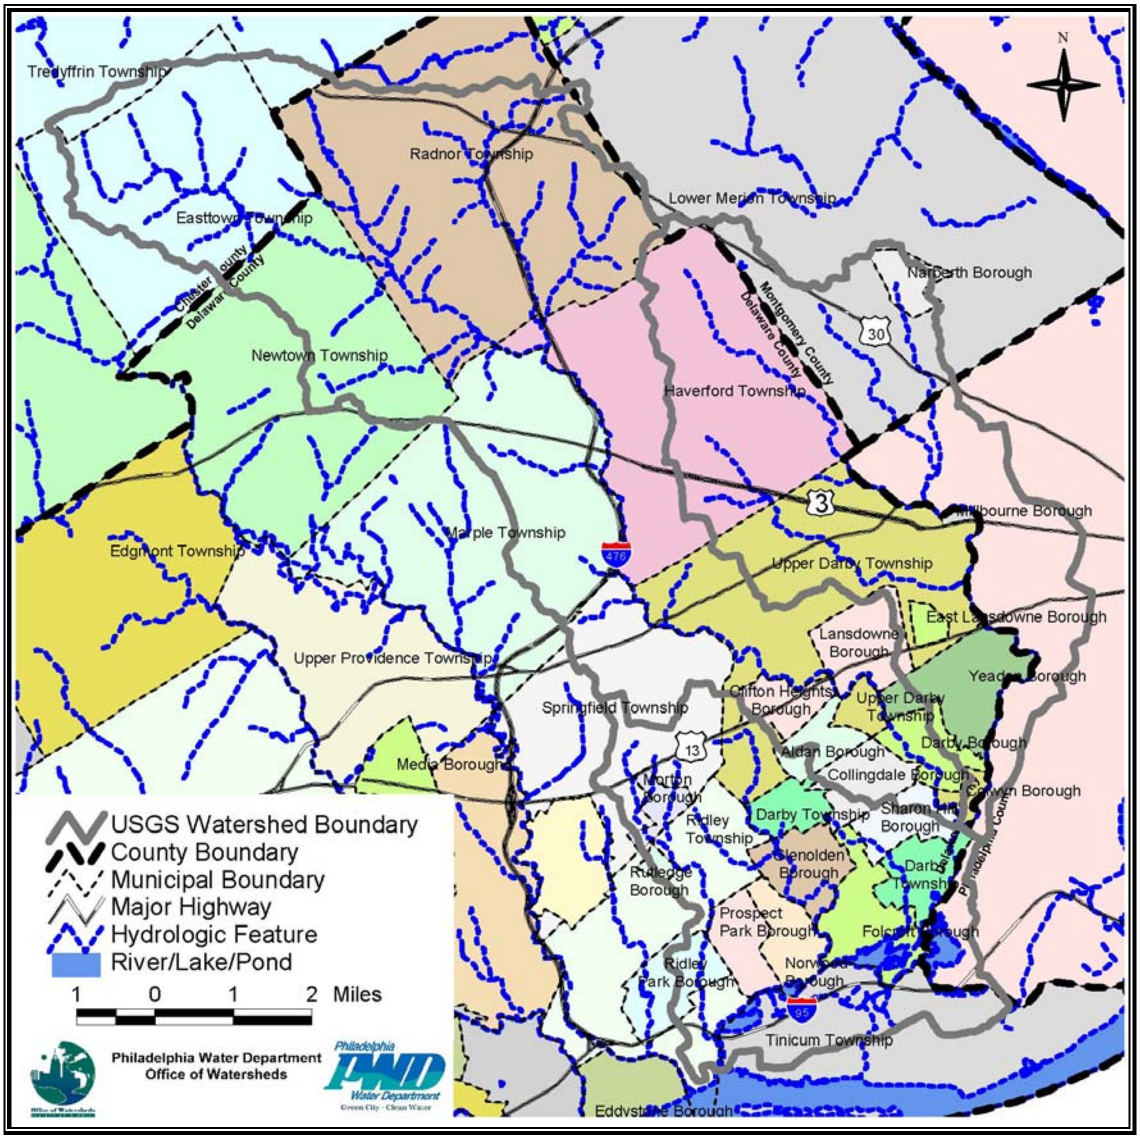

Figure 4-1 Darby-Cobbs Study Area

Geology and Soils

Geology and soils play a role in the hydrology, water quality, and ecology of a watershed. The Darby-Cobbs watershed falls within the Coastal Plain and Piedmont physiographic provinces. Geologic formations on the surface in the area include gneiss, schist, and serpentine formations in most of the watershed (Piedmont) and layers of sediment in the downstream reaches (Coastal Plain) as shown in Figure 4-3. Soils in the upper portions of the Darby Creek subwatershed include loams and silty loams, as shown in Figure 4-4. Soil in much of the rest of the watershed is classified as urban or made land and is not representative of the original undisturbed soil. Wetland soils are present in the Tinicum area.

Demographic Information

Population density and other demographic information in the watershed are available from the results of the 1990 census. Approximately 500,000 people live within the drainage area of the Darby and Cobbs Creeks. Figure 4-5 shows the population density in the watershed at the census block level. Spatial trends in population correspond closely to land use, with multi-family row homes displaying the greatest population density of 20 people per acre or more, single-family homes displaying a lower density, and other land use types displaying the lowest density. In addition to population data, the U.S. Census Bureau provides a range of socioeconomic data that are often useful in watershed planning and general planning studies. Median household income and mean home value (Figures 4-6 and 4-7) are two of the many sample datasets provided.

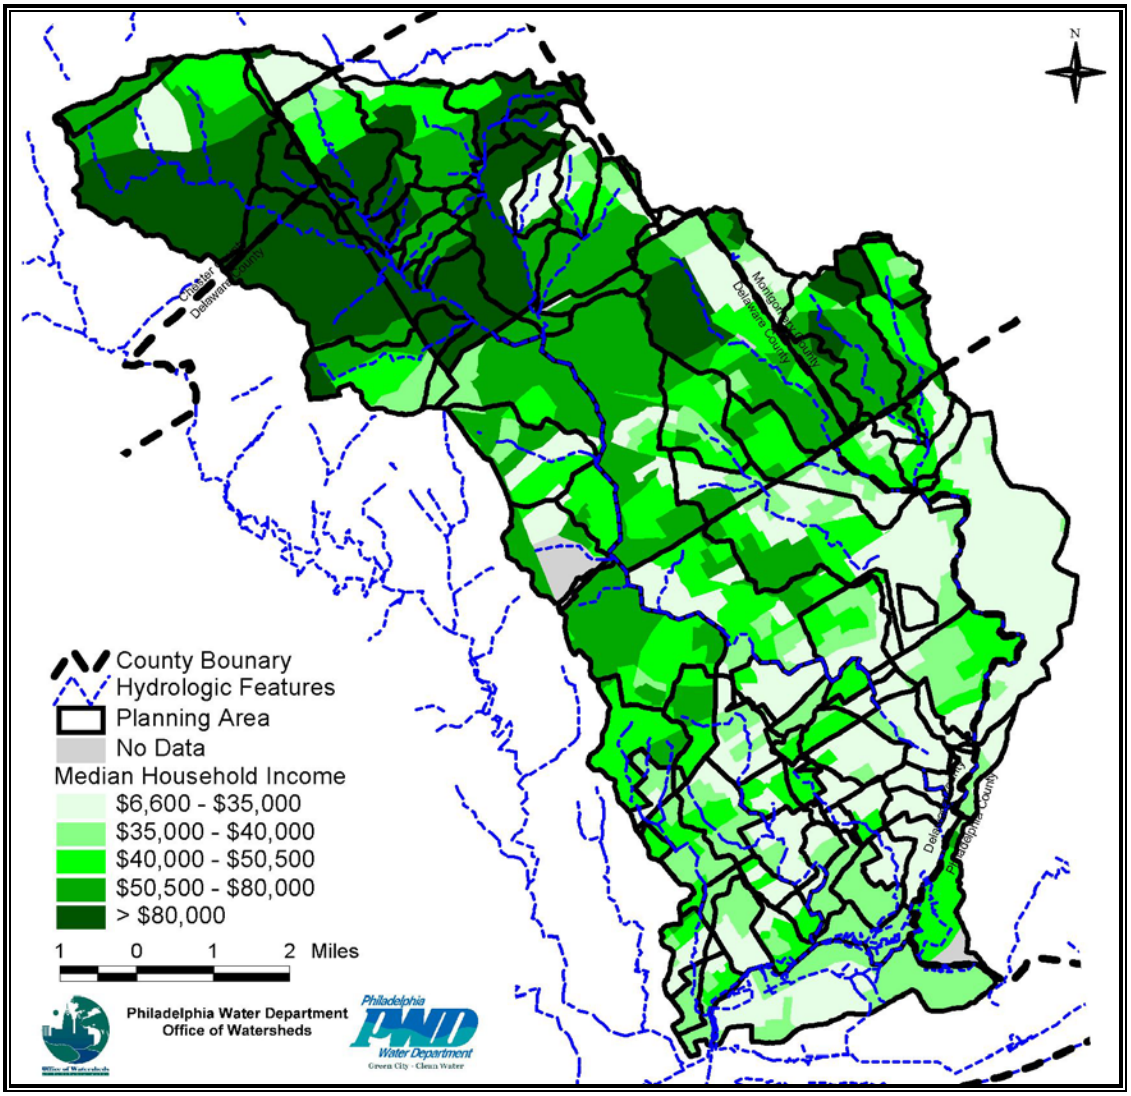

Figure 4-7 Mean Household Income

4.2 Watershed Status and Trends

This section was developed to serve as a basis for understanding the state of the Darby-Cobbs watershed, its relative environmental quality, and trends with respect to the management of factors that influence its quality. The report details the history and current conditions of the watershed and attempts to establish trends associated with a host of progress indicators. The results presented in this report were derived from past studies on the watershed and from recent data collection efforts conducted by the Philadelphia Water Department. 21 indicators were identified:

Land Use and Stream Health Relationship

Indicator 1: Land Use and Impervious Cover

Flow Conditions and Living Resources

Indicator 2: Streamflow
Indicator 3: Stream Channels and Aquatic Habitat
Indicator 4: Restoration Projects Lists of completed, in progress, and planned projects
Indicator 5: Fish
Indicator 6: Benthos

Water Quality

Indicator 7: Effects on Public Health (Bacteria)
Indicator 8: Effects on Public Health (Metals and Fish Consumption)
Indicator 9: Effects on Aquatic Life (Dissolved Oxygen)

Pollutants and Their Sources

Indicator 10: Point Sources
Indicator 11: Non-point Sources

Stream Corridor

Indicator 12: Riparian Corridor
Indicator 13: Wetlands and Woodlands
Indicator 14: Wildlife
Indicator 15: Flooding

Quality of Life

Indicator 16: Public Understanding and Community Stewardship
Indicator 17: School-Based Education
Indicator 18: Recreational Use and Aesthetics
Indicator 19: Local Government Stewardship
Indicator 20: Business and Institutional Stewardship
Indicator 21: Cultural and Historic Resources

Land Use and Stream Health Relationship

Indicator 1: Land Use and Impervious Cover

Urbanization of natural lands affects watershed hydrology, water quality, stream stability, and ecology. One of the primary indicators of watershed health is percent impervious cover in the watershed. Based on numerous research efforts, studies and observations, a general categorization of watersheds has been widely applied to watershed management based on percent impervious cover (Schueler 1995). Table 4-1 summarizes several impacts of traditional development on streams and watersheds, most of which are created by increased impervious cover.

Table 4-1 Impervious Cover as an Indicator of Stream Health (Schueler 1995)

Characteristic	Sensitive	Degrading	Non-Supporting
Percent Impervious Cover	0% to 10%	11% to 25%	26% to 100%
Channel Stability	Stable	Unstable	Highly Unstable
Water Quality	Good to Excellent	Fair to Good	Fair to Poor
Stream Biodiversity	Good to Excellent	Fair to Good	Poor
Pollutants of Concern	Sediment and temperature only	Also nutrients and metals	Also bacteria

This indicator measures:

- **GIS-estimated impervious cover of each subwatershed (% of total area)**
- **Model-estimated Directly Connected Impervious Area (DCIA) of each subwatershed (% of total area)**
- **Open space in each subwatershed (% of total area)**
- **Publicly-owned land in each subwatershed (% of total area)**

Where We Were:

By 1935, most of the early mills had left the lower Darby Creek watershed. Although its industrial base was in decline, large portions of the Darby Creek watershed area became occupied by dense housing developments, many of which were constructed before the emergence of zoning controls and other environmental and land management methods. As a result, the natural resources of the Darby Creek were negatively impacted by inadequate and polluted stormwater runoff and drainage systems, leaking and inadequate septic tanks, lack of open space and adequate recreation, illegal dumping, and an array of other urban ills.

Where We Are:

The upper reaches and headwaters of the Cobbs Creek watershed are characterized primarily by a mix of residential areas, while the lower portions are primarily high-density residential areas with commercial areas along highway corridors (Figure 4-8). Riparian lands within the City consist mainly of parkland left in a natural state. Land uses in the Darby Creek watershed consist of residential areas in the lower portions and a combination of low-density residential, commercial, parkland, and golf course uses in the upper reaches. The Tinicum watershed consists of residential and commercial development to the northwest and protected wetlands to the southeast. Based on these land uses, impervious cover is estimated for each portion of the watershed and listed in Table 4-2.

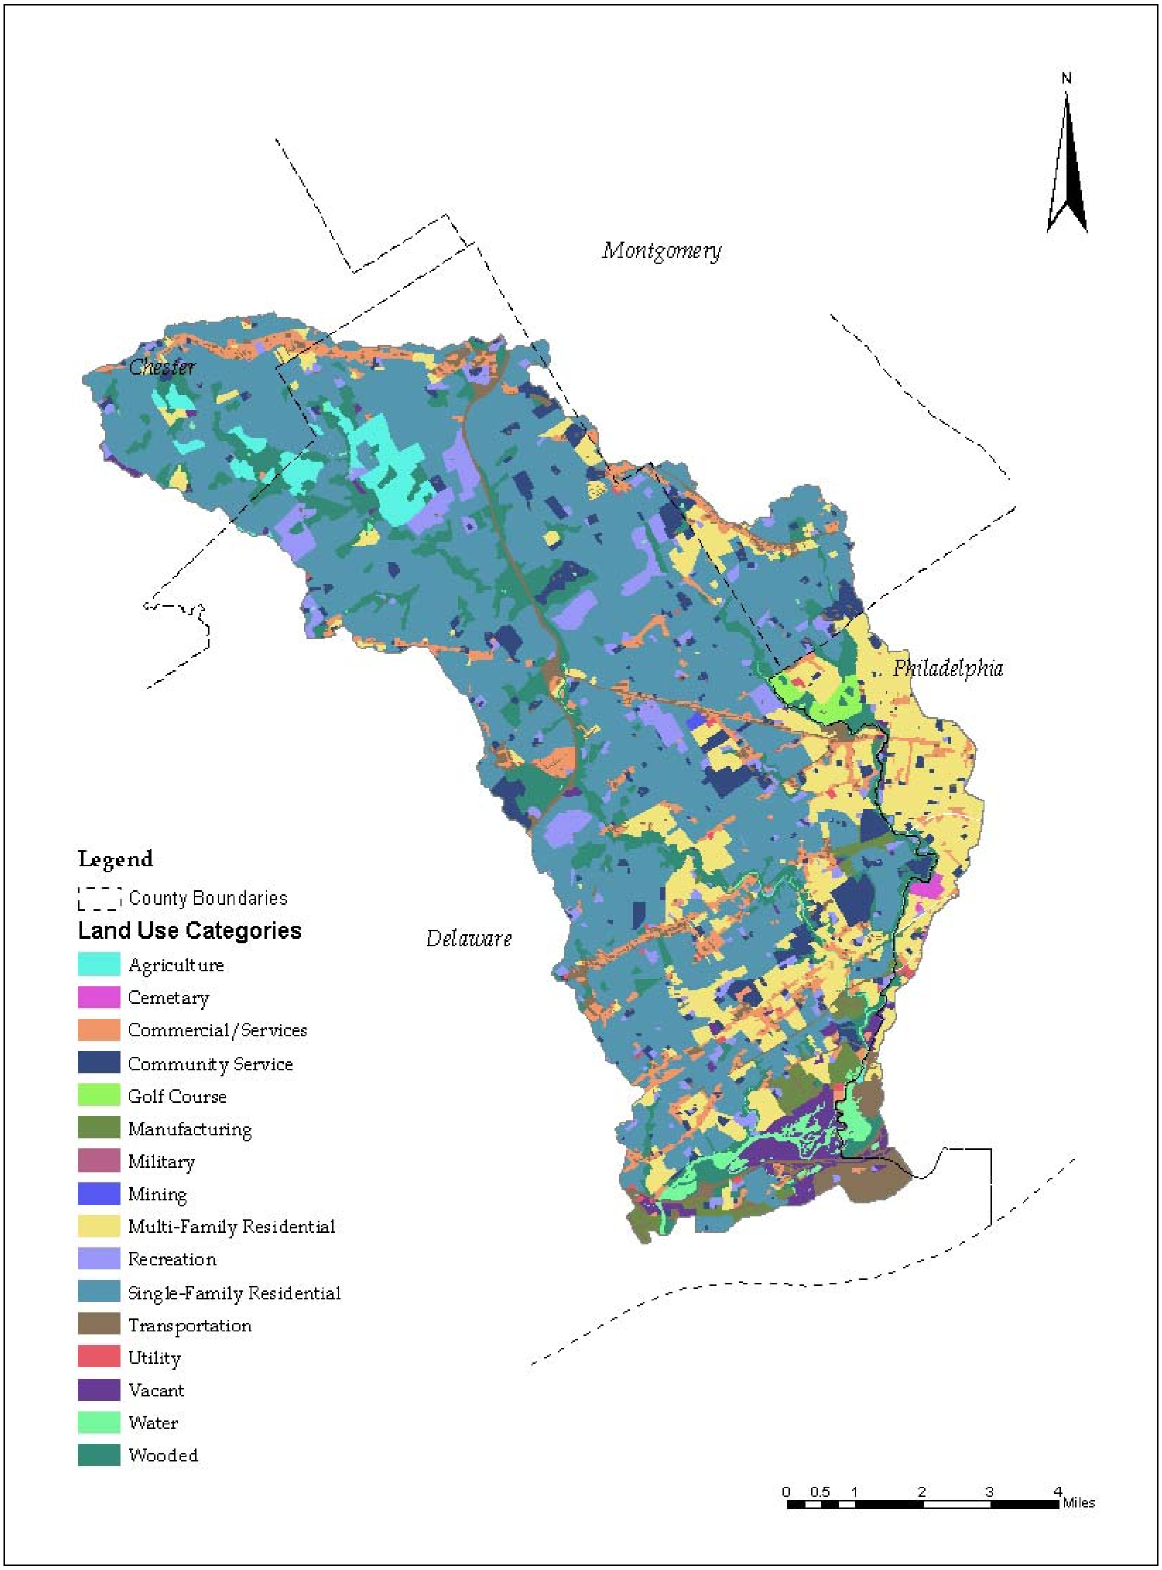

Figure 4-8 1995 DVRPC Land Use in the Darby-Cobbs Watershed

Table 4-2 Estimated Total Impervious Cover

Watershed	County	Area (ac)	% Impervious
Cobbs	Delaware	8,041	46.7%
Cobbs	Montgomery	2,644	40.6%
Cobbs	Philadelphia	3,562	60.2%
Darby	Chester	4,217	25.7%
Darby	Delaware	24,503	38.7%
Darby	Montgomery	70	44.2%
Darby	Philadelphia	558	66.7%
Tinicum	Delaware	5,811	49.4%

Tables 4-1 and 4-2 together suggest that the more developed areas of the watersheds are already degraded and that the developing portions can be expected to become degraded if action is not taken. The headwaters of Darby Creek in Chester County have the lowest estimated impervious cover at 25%. At this level, water quality and ecological health may still be fair to good, but erosion and sedimentation of the stream channel begin to become a problem. Philadelphia portions of the Cobbs and Darby Watersheds are the most impervious at over 60%. At this level, stream channels are highly unstable, and both water quality and ecological health tend to be poor. Remaining areas fall between these two extremes. It is estimated that about 50-75% of impervious area is directly connected (DCIA) to the drainage system.

The proportion of open space and publicly owned land are also informative indicators (Table 4-3). Analysis of the land use data reveals that over 90% of the Darby Creek watershed and the northern portion of the Cobbs Creek watershed is privately owned land. While the northern portion of the Darby Creek Watershed also has a high percentage of open space, it is made up primarily of privately owned land such as agricultural areas and golf courses. Other than the upper portion of the Darby Creek watershed, areas that have the most open space also tend to be those sections of the watershed with the most publicly-owned land. These include the Lower Cobbs, which has the most publicly-owned space due to Cobbs Creek Park, followed by Tinicum marsh which contains the John Heinz National Wildlife Refuge. Figure 4-9 indicates how the watershed is broken into subwatersheds.

Table 4-3 Estimated Open Space and Publicly Owned Land

Subwatershed	Total Area (acres)	Publicly Owned (% of total)	Open Space (% of total)
Upper Cobbs	6,473	7%	14%
Lower Cobbs	7,698	26%	25%
Upper Darby	16,910	6%	26%
Lower Darby	8,521	7%	21%
Tinicum	9,804	25%	27%

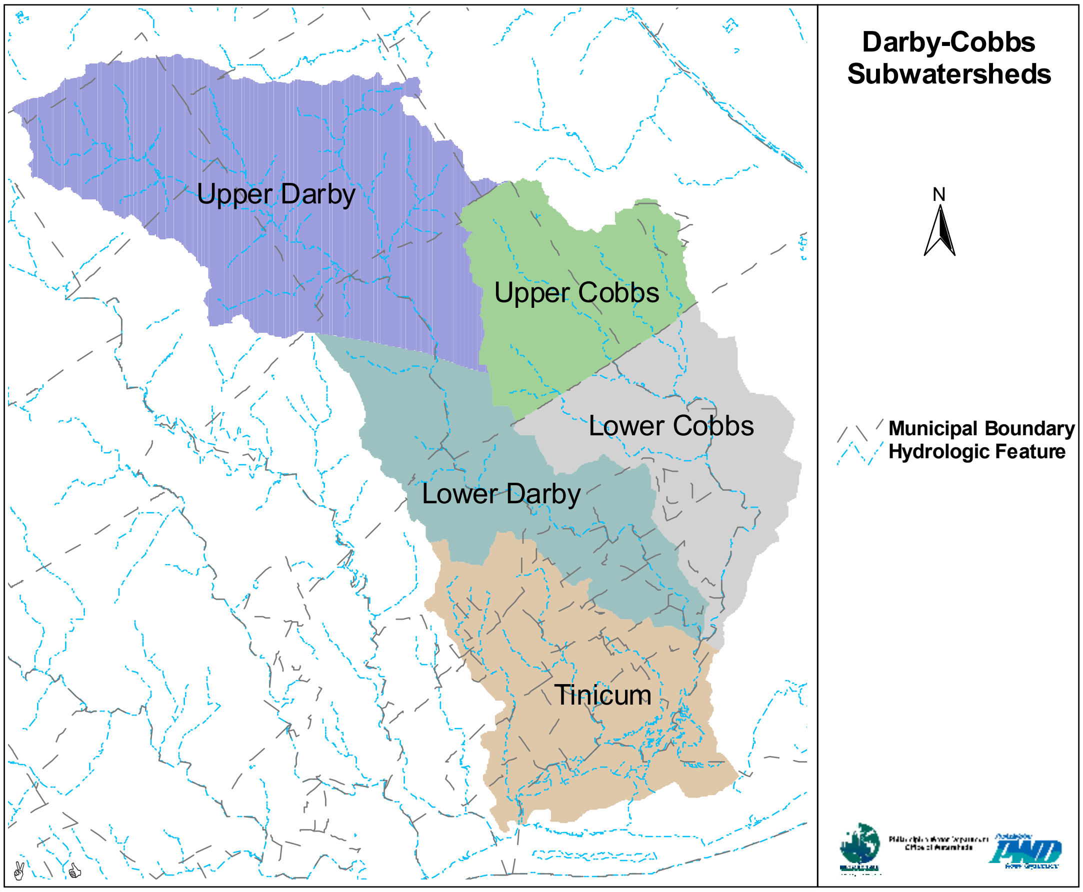

Figure 4-9 1995 Subwatersheds in the Darby-Cobbs Watershed

Flow Conditions and Living Resources

Indicator 2: Streamflow

As discussed in Indicator 1, urbanized land uses in a watershed affect stormwater runoff, streamflow, condition and shape of stream banks and channels, water quality, and aquatic habitat and ecosystems. Increases in impervious cover affect stream hydrology in a variety of ways:

- Increased magnitude and frequency of severe floods
- Increased frequency of erosive bankfull and sub-bankfull floods
- Reduced groundwater recharge leading to reduced baseflow
- Greater stream velocities during storm events

This indicator measures:

- **Average annual baseflow (% of total flow)**
- **Average annual baseflow (% of annual precipitation)**
- **Average annual stormwater runoff (% of annual precipitation)**

The Cobbs Creek watershed and the lower portions of the Darby Creek watershed are highly urbanized and contain a large proportion of impervious cover. Hydrologic impacts of urbanization can be observed through analysis of streamflow data taken from USGS gauges on Darby and Cobbs Creeks. In addition, data from French Creek in Chester County provide a picture of a nearby less-developed watershed.

Where We Were:
The analysis below represents a long-term period of record for each stream gauge. It is difficult to establish a trend over time, but an attempt will be made when the watershed is reassessed.

Where We Are:
Streamflow data were separated into their two main components: baseflow and stormwater runoff. In perennial streams, baseflow is the portion of streamflow caused by groundwater inflow and is present in dry and wet weather. Stormwater runoff is the portion of streamflow contributed by excess rainfall flowing over the land surface and through the drainage system. The results of this hydrograph decomposition exercise (Table 4-4) support the relationships between land use and hydrology discussed above. Based on the French Creek gauge and the two Darby Creek gauges, the hydrologic behavior of these two systems is similar. Pervious cover allows sufficient groundwater recharge to give streamflow relatively natural characteristics; a mean of approximately 20% of annual rainfall contributes to the stormwater component of streamflow, and baseflow represents approximately 65% of total annual streamflow. It is interesting to note that baseflow, as a percentage of precipitation, is higher in Darby Creek than in French Creek. Cobbs Creek exhibits behavior typical of a highly urbanized stream, with over 25% of rainfall contributing to stormwater runoff in a mean year and with mean baseflow comprising only 43% of mean annual streamflow.

Table 4-4 Summary of Hydrograph Separation Results over the Period of Record

	Period of Record (yrs)	Baseflow (% of Total Flow)	Baseflow (% of Precip)	Stormwater Runoff (% of Precip)
French Creek 01475127	33.0	64	31	17
Cobbs Creek 01475550	26.7	42	19	25
Darby Creek D/S 01475510	26.7	62	34	21
Darby Creek U/S 01475300	25.4	66	37	19

Indicator 3: Stream Channels and Aquatic Habitat

Healthy populations of fish and invertebrates require physical habitat features that allow them to feed, reproduce, and seek shelter during episodes of high flow. In the urban environment, where significant erosion and deposition occur, these features often are not available (Figure 4-10).

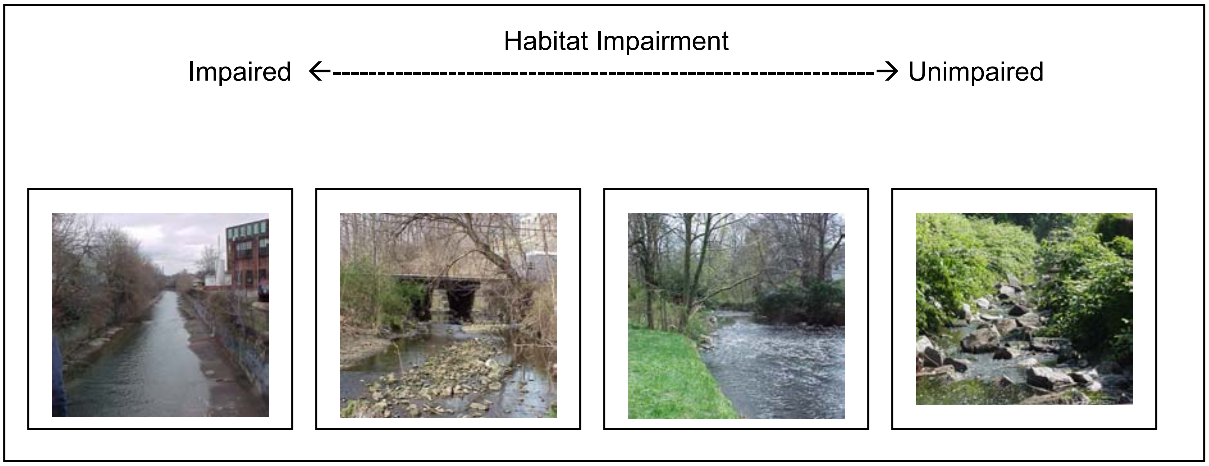

Figure 4-10 Habitat Impairment Comparisons

Fluvial geomorphology is the study of landforms associated with river channels and the processes that form them. The Rosgen classification system is commonly used to assess physical channel conditions. Of the channel types found in Cobbs, channels classified as “F” are highly impacted by urban flows, subject to erosion and deposition of sediment, and generally do not support diverse ecosystems. Channels classified as “B”, “C”, and “E” are generally stable under natural flow conditions and can support healthy stream habitats. Channels currently classified as one of the stable types may degrade into F channels over time when subjected to urban flows. Likewise, “F” channels can slowly start establishing new floodplains and can become “C” channels.

This indicator measures:

- **Habitat score relative to reference condition at various sites**
- **Channel type and expected trend**

Where We Were:
There is no historical data available for this indicator. Habitat and stream channels most likely degraded over a long period of time as the watershed developed. A trend will be established the next time this area is reassessed.

Where We Are:
In 1999, habitat at 7 sites throughout the Cobbs watershed was surveyed by PWD biologists (Figure 4-11). The sites were rated based on comparison to a reference reach, French Creek. The five sites in the headwaters received ratings of “Comparable to Reference” (1 site), “Supporting” (1 site), and “Partially Supporting” (3 sites), while the two downstream sites were determined to be “Partially Supporting” of aquatic communities.

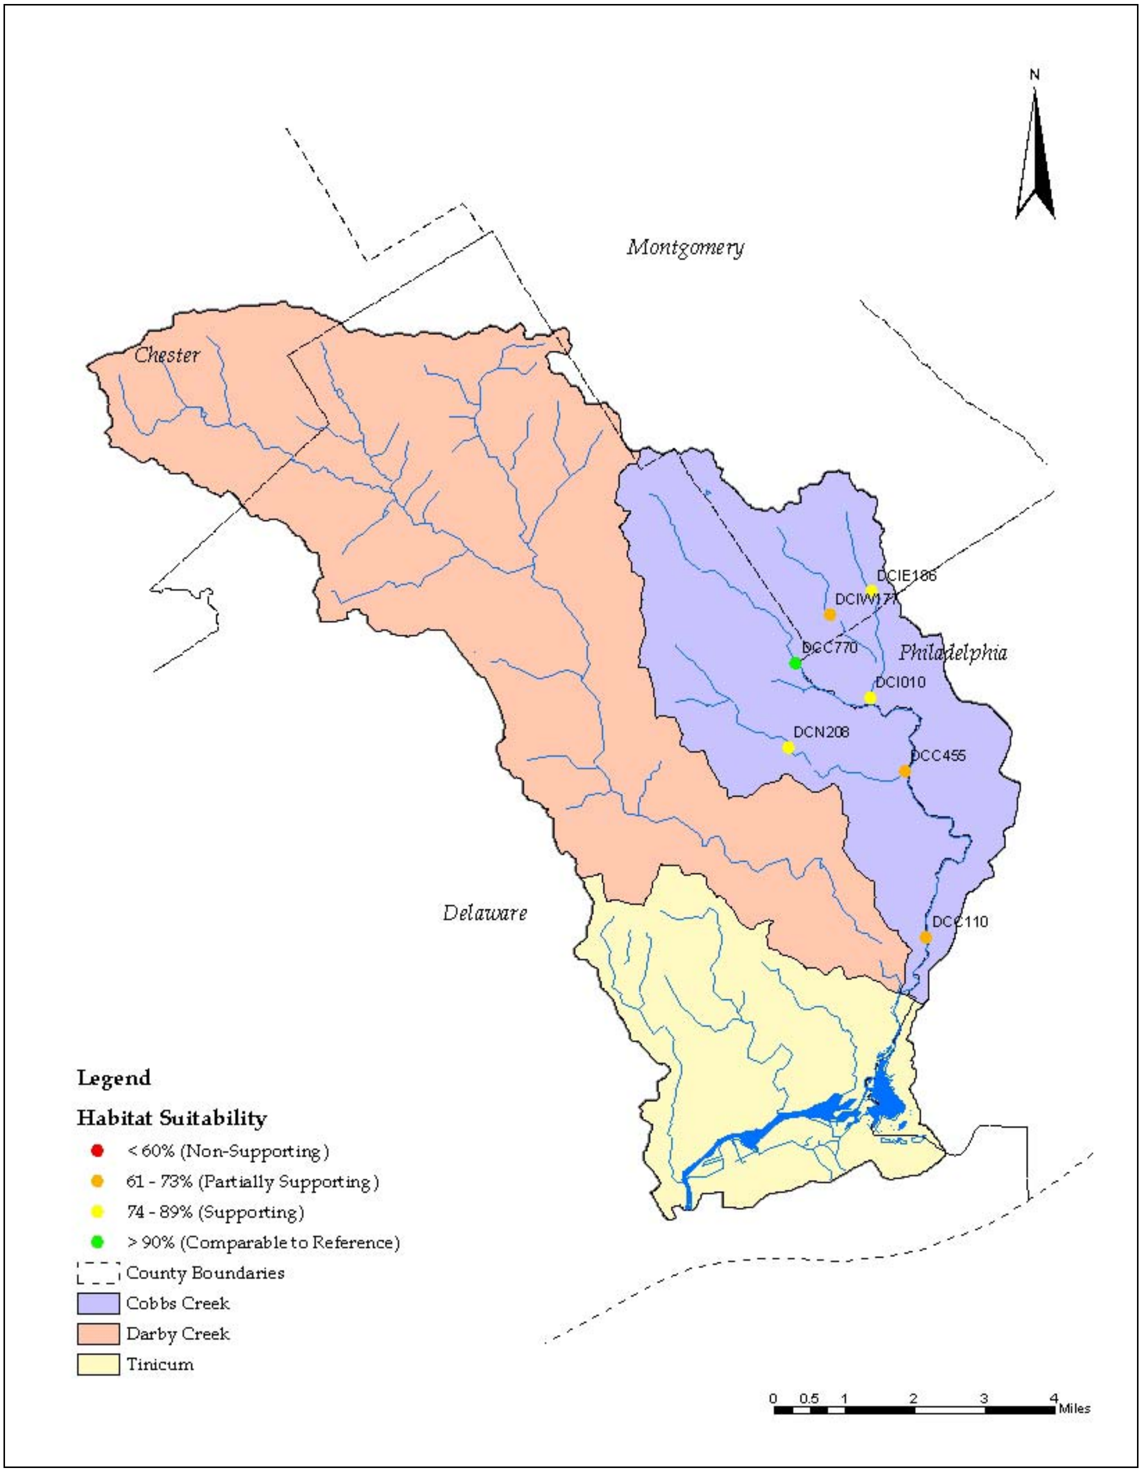

Figure 4-11 Cobbs Habitat Assessment (Philadelphia Water Department, 1999)

In 2002, Rosgen techniques were used to measure channel geometry and stability parameters to determine stream classification. Over 17 miles of stream were evaluated and selected reaches of Cobbs Creek, West Branch Indian Creek, and East Branch Indian Creek were classified.

Approximately 80% of the studied length was classified as a Rosgen type “F” channel (Figure 4-12). “B”, “C”, and “E” types are found in the headwaters, while the “F” types are found along most of the lower main stem. The Cobbs main stem is expected to continue widening through bank erosion, and upstream portions are expected to start downcutting and become more entrenched.

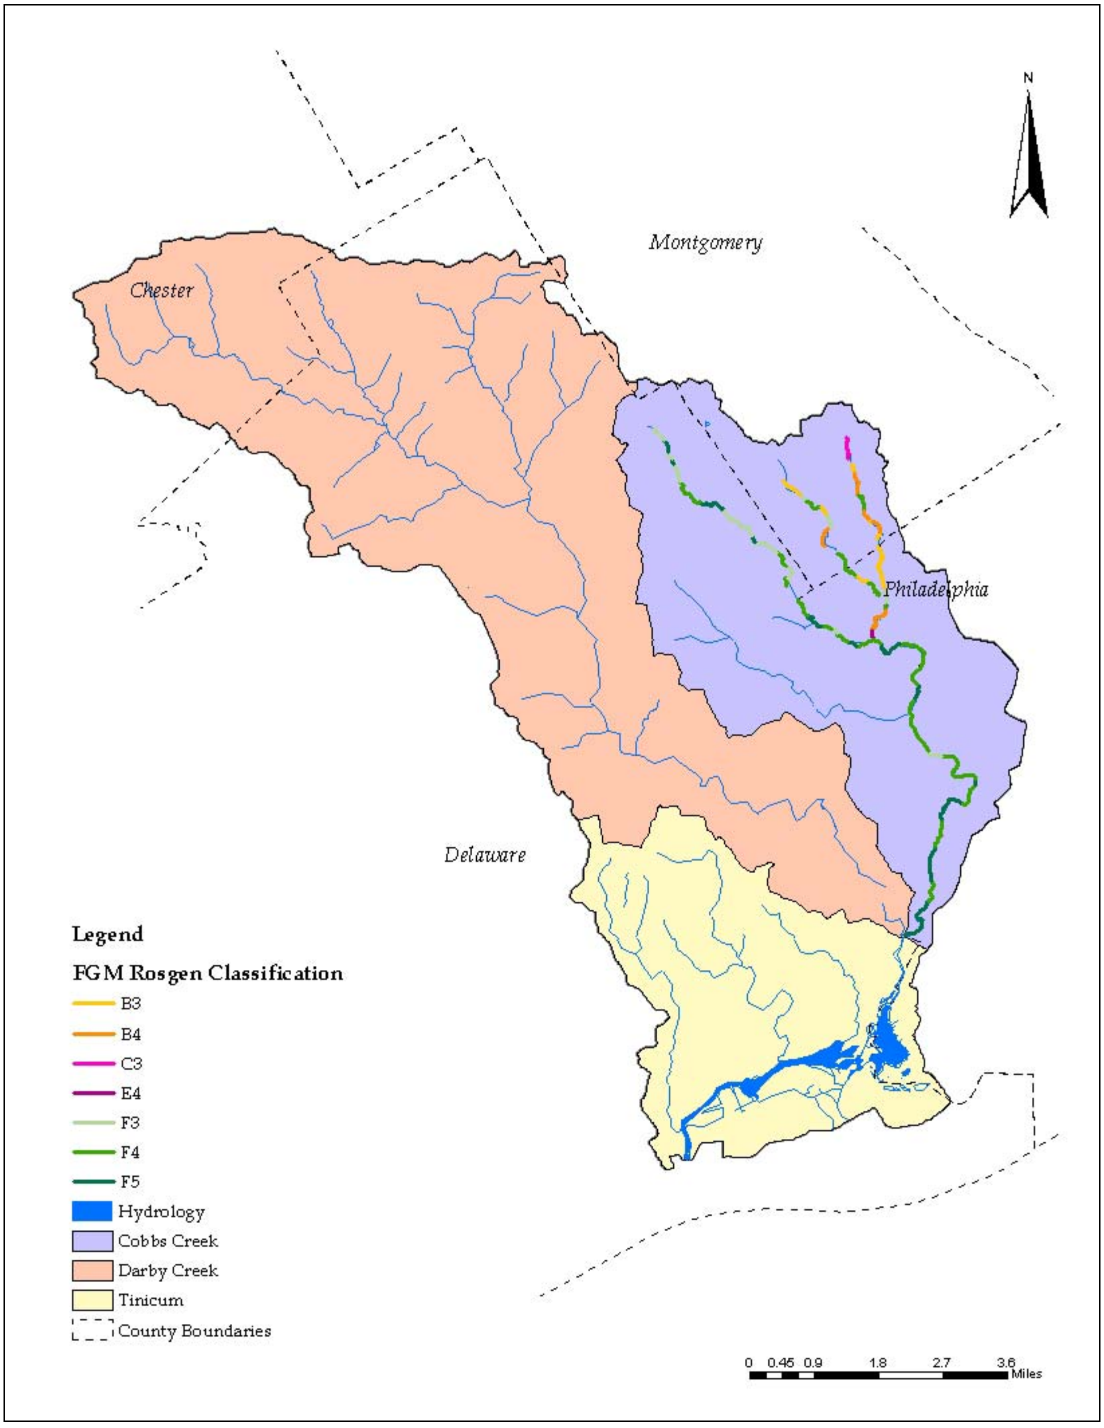

Figure 4-12 Fluvial Geomorphology Study - Rosgen Classification of Cobbs Reaches 2003

Indicator 4: Restoration and Demonstration Projects

Funding for watersheds and water–related projects has been increasing throughout the country in recent years. Grants are being issued to support various types of projects throughout the state of Pennsylvania. Begun in 1999, Pennsylvania's Growing Greener program has been an enormous source of environmental funding over the last few years. In fact, this program has become the largest single investment of state funds in Pennsylvania's history. There are also many other organizations and governmental agencies offering grant money and technical assistance for communities and other organizations to accomplish their environmental projects for improving our watersheds. Figure 4-13 depicts a stream reach that is planned for eventual restoration.

This indicator measures:

- **Lists of completed, in progress, and planned projects**

Figure 4-13 Bank Erosion in the Cobbs Creek Restoration Area

Where We Were:
The number of restoration projects in this watershed has increased with the introduction of the Growing Greener program and other funding programs.

Where We Are:
Many environmental projects have been funded in the Darby-Cobbs Watershed, from streambank restoration to environmental education programs. A list of grants issued over the last 6 years has been assembled. Table 4-5 represents a profile of the grants received and the projects being performed; this is in no way is a comprehensive list of all the projects in the watershed. 25 projects were identified with a total amount of received funding totaling over $1.5 million.

Table 4-5 Grants in the Darby-Cobbs Watershed

Funding Agency	Funding Program	Year	Lead Agency	Project	Amount Awarded
DCNR	Rivers Conservation Grants	1998	Darby Creek Valley Association and DelCo Anglers and Conservationists	Develop a river conservation plan for Darby Creek.	$69,000
DEP	Watershed Restoration Assistance Program (WRAP)	1998	Delco Anglers and Conservationists	Riparian enhancement of Darby, Ridley and Goose Creeks.	$1,000
DEP	Watershed Restoration Assistance Program (WRAP)	1998	Radnor Township	Restore 100 feet of Little Darby Creek streambank.	$24,470
DEP	Growing Greener	1999	Darby Borough	Restoration of streambanks and riparian buffers at a public park using various bioengineering techniques.	$25,000
DEP	Watershed Restoration Assistance Program (WRAP)	1999	Darby Borough Council	Bartram Memorial Park streambank and erosion control and riparian planting project	$25,000
DEP	Growing Greener	1999	Tinicum Township Delaware County	Replace existing Jansen Avenue tide gate with self-regulating tide gate	$261,203
DEP	Growing Greener	1999	Villanova University, Radnor	Villanova Stormwater Management Practice Demonstration Park -- Phase One Planning.	$10,120
DEP	Growing Greener	2000	Delco Anglers and Conservationists	Darby Creek Riparian Restoration Continuation	$1,047
DEP	Growing Greener	2000	Pennsylvania Environmental Council Inc.	Darby-Cobbs Watershed Partnership Education and Outreach Survey	$35,000
DEP	Growing Greener	2000	Marple Township	Lawrence Road/Darby Creek Bank Stabilization	$68,225
DEP	Growing Greener	2000	Friends' Central School	Cobbs Creek Watershed Monitoring and Restoration	$75,913
DEP	Growing Greener	2000	Pennsylvania Environmental Council, Inc.	Development of a series of informational products on environmental issues for municipal officials	$79,199

Flow Conditions and Living Resources

Indicator 4: Restoration and Demonstration Projects

Funding Agency	Funding Program	Year	Lead Agency	Project	Amount Awarded
DEP	Growing Greener	2000	City of Philadelphia Water Department	Sustainable Approach to Stream Habitat Restoration in an Impaired Urban Stream (Cobbs Cr.)	$150,000
DEP	Growing Greener	2000	Villanova University	Villanova stormwater bioretention traffic island	$59,112
League of Women Voters	Water Resources Education Network (WREN)	2001	Township of Lower Merion and Environmental Advisory Council	Produce a brochure entitled "Safeguarding our Streams" and produce a live television town meeting.	$5,000
DEP	Growing Greener	2001	Environmental Fund for Pennsylvania / Greenworks	The Value of Water	$24,174
DEP	Growing Greener	2001	Environmental Fund for Pennsylvania	Life on the Delaware River	$60,000
DEP	Act 167 Stormwater Management	2001	City of Philadelphia Water Department	Development of a Multi-Objective Model Framework for the Cobbs Creek Watershed	$62,100
DEP	Growing Greener	2001	Cobbs Creek Community Environmental Education Center	Cobbs Creek Watershed Stewards Initiative	$187,160
DEP	Growing Greener	2001	Villanova University-Institute for Environmental Engineering Research	Villanova stormwater porous concrete demonstration site	$85,500
EPA	104b3	2001	City of Philadelphia Water Department	Cobbs Creek Habitat Model	$250,000
EPA	Wetland Program Development Grants	2002	City of Philadelphia Water Department	Wetlands Program Inventory and Assessment	$175,000
DEP	Growing Greener	2002	Friends' Central School	Education and outreach on Cobbs and Darby Creeks	$31,380
DEP	CZM	2002	Delaware Riverkeeper Network	Bartram Park Streambank Restoration & Buffer Enhancement Project	$71,400
DEP	Growing Greener	2003	Villanova University	Project uses the Clean Water Fund to install storm water best management practices.	$39,300
Total Award for Darby-Cobbs (Years 1998 – 2003)					**$1,875,303**

Indicator 5: Fish

Fish are good indicators of stream health because their presence requires favorable environmental conditions within a certain range of stream flow, water temperature, water quality, and channel habitat. Abundance and diversity of fish are great indicators of water quality. Other indicators are the number of pollution tolerant fish and the proportion of fish with abnormalities. Dominance by a small number of pollution-tolerant species may indicate habitat and water quality degradation.

This indicator measures:

- **Abundance and pollution tolerance of species found at various sites**
- **Fish community integrity relative to reference condition at various sites**
- **Whether stream meets criteria for trout-stocking**

Where We Were:
There is no historical data available for this indicator. A trend will be established the next time this area is reassessed.

Where We Are:
During a 1999 Cobbs Creek assessment, fisheries data indicated that the fish community was numerically dense yet species poor. Figure 4-14 shows the percentage of pollution tolerant fish at each site. Both pollution tolerant and moderately pollution tolerant fish were found at each site. There was a range of diversity, with one site receiving a rating of good, two receiving a rating of moderate diversity, one a low diversity rating, and one a poor diversity rating (Figure 4-15). In all, 14 different species of fish were collected from in Cobbs Creek, West Indian Creek and Naylor's Run. (Figure 4-16).

Changes in trout stocking patterns have occurred over the last few years. The Cobbs Creek area has not been recently stocked with trout by the Philadelphia Fish and Boat Commission and does not meet quality criteria necessary to be stocked. During 2001-2003, Darby and Stony Creeks were stocked.

Figure 4-16 Fish Types and Abundance

Indicator 6: Benthos

The community of organisms on the bottom of water bodies is a good indicator of long-term water quality and the overall health of an aquatic system. Benthic organisms play roles in the aquatic ecosystem similar to the ones terrestrial small plant and animal species play in land-based communities. Benthic communities respond to changes in the aquatic environment and often provide an indication of concerns or evidence of successful restoration projects. Shown in Figure 4-17 is the life cycle of a mayfly, one example of a benthic macroinvertebrate.

This indicator measures:

- **State designation of attained and unattained reaches**
- **Benthic community integrity relative to reference condition at various sites**

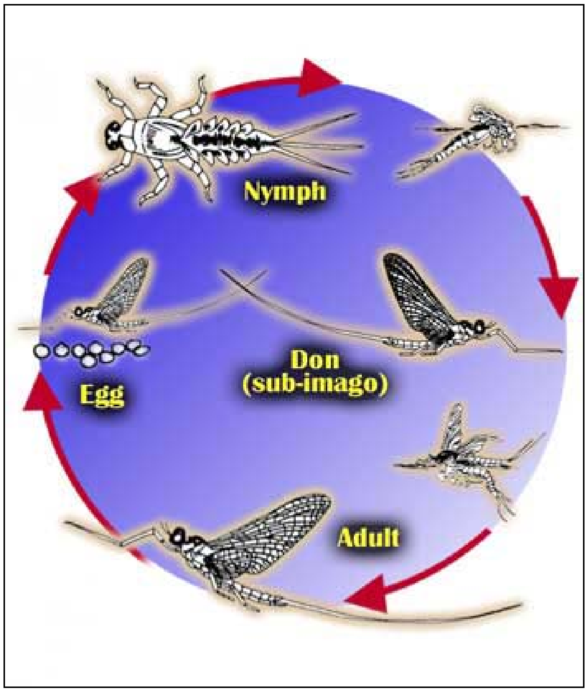

Figure 4-17 Life Cycle of a Mayfly

Where We Were:
There is no historical data available for this indicator. A trend will be established when this area is reassessed.

Where We Are:

PADEP classifies streams in the watershed as impaired, with the exception of upper Darby Creek. In Figure 4-18, the color green represents stream reaches that are not impaired and have attained designated water quality criteria; reaches in red are impaired and do not meet their designated criteria. Work by PWD biologists in the Cobbs portion (colored dots in Figure 4-18) confirm that benthic communities are moderately to severely impaired. According to the year 2004 proposed 303(d) list, sources of impairment are primarily habitat modification, municipal point sources, and urban runoff/storm sewers (PADEP, 2004). Impairment is caused by siltation, water/flow variability, habitat alterations, or other unknown causes in all cases. Much of the

Cobbs Creek impairment listing is based on assessment work in 2000, while Darby Creek was last assessed in 1996 or earlier.

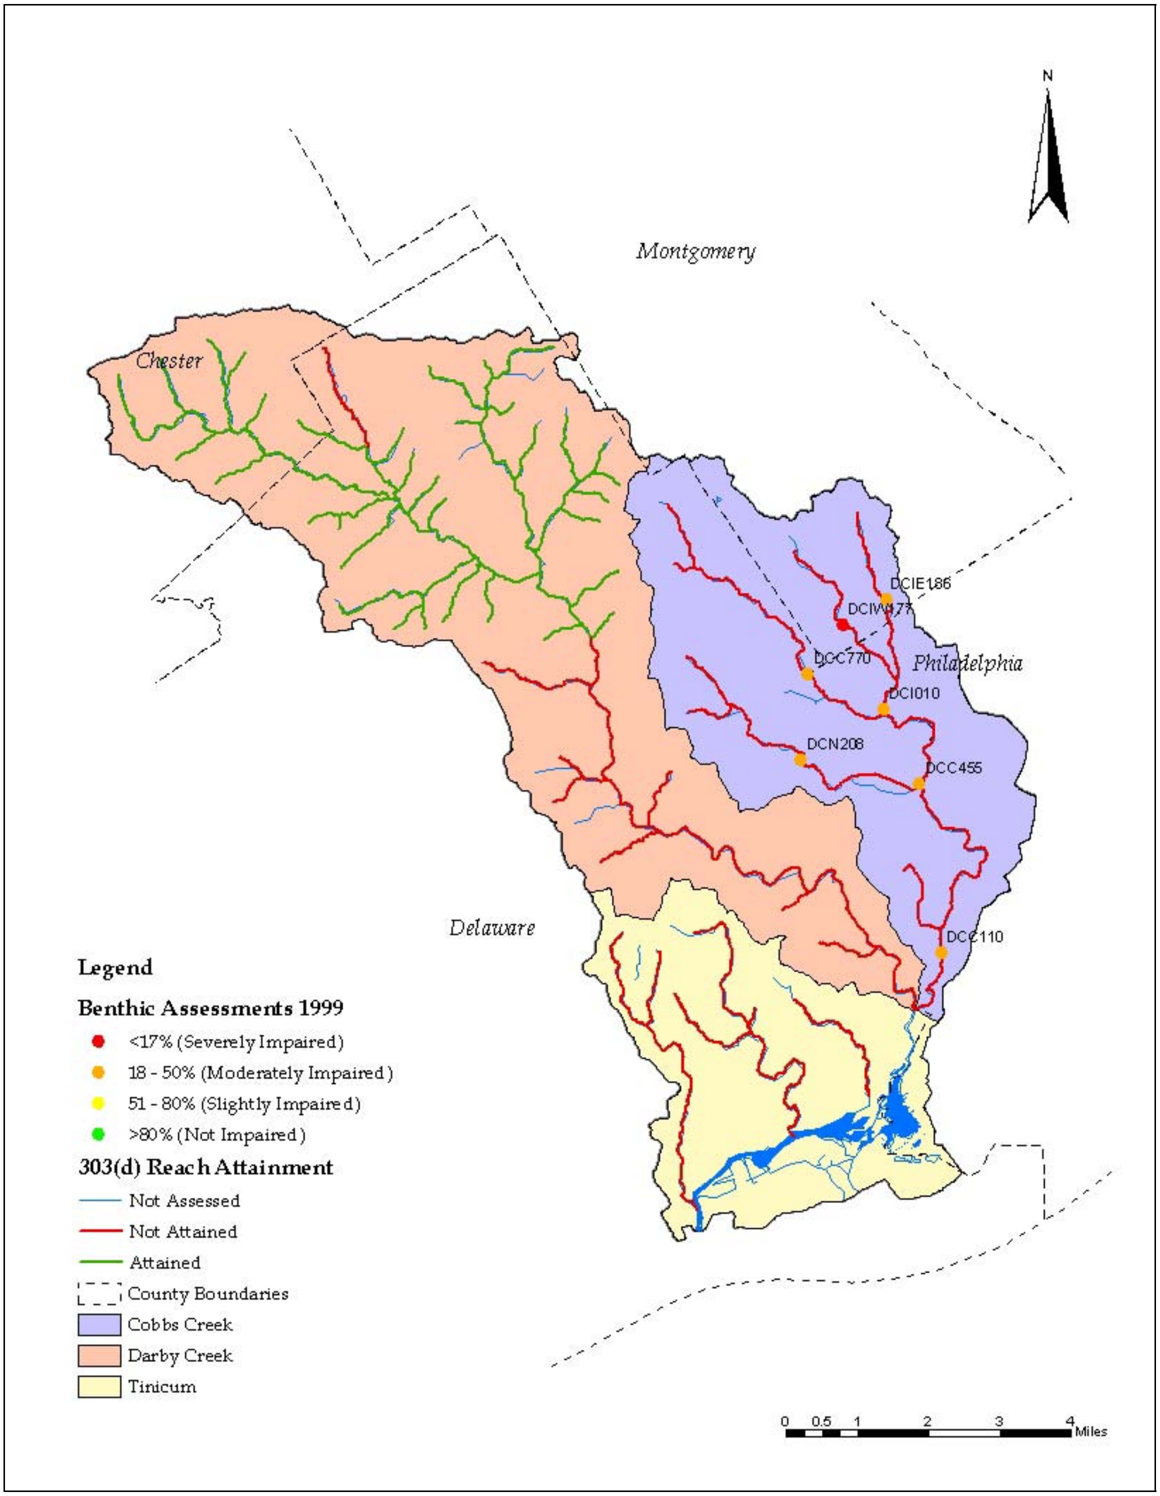

Figure 4-18 PWD Benthic Assessment Sites and State-Designated Impaired Reaches

Darby-Cobbs Watershed Status Report 2003

Flow Conditions and Living Resources

Indicator 6: Benthos

During a 1999 bioassessment of the Darby and Cobbs Watershed, pollution tolerance levels of macroinvertebrate communities showed all sites were dominated by moderately pollution-tolerant or pollution-tolerant macroinvertebrates, with a minimal number of pollution-intolerant macroinvertebrates. Due to increased flow over riffle systems, where most benthic organisms are found, reproductive and feeding strategies have been affected.

Water Quality

Indicator 7: Effects on Public Health (Bacteria)

Fecal contamination of natural waters may originate from both human and animal sources and may pose a threat to human health. Surface runoff transports waste material from pets, livestock, and wildlife to surface waters. Wet weather sewer overflows (both SSOs and CSOs) introduce domestic wastewater constituents to surface water. Illegal or accidental connection of sanitary sewers to storm sewers may also result in discharges of raw wastewater. Municipal wastewater treatment plants and septic systems release some bacteria to surface waters, but these inputs are generally small.

Fecal coliform bacteria are consistently very abundant in the intestines of warm blooded animals, including humans. Presence of fecal coliform bacteria is a fairly reliable indicator of fecal contamination of natural water, drinking water, and wastewater. Historically those bacteria have been used to indicate the possibility that other pathogens (e.g., bacteria, viruses, protozoa, etc.) may also be present. Measures taken to reduce the input of fecal coliform to natural waters are likely to reduce the input of other potential pathogens found in sewage and surface runoff.

Pennsylvania's water quality standard for fecal coliform bacteria in waters of the Commonwealth is as follows: during the swimming season (May 1 through September 30), the maximum fecal coliform concentration shall be a geometric mean of 200 CFU per 100 mL based on five consecutive samples each sample collected on different days; for the remainder of the year, the maximum fecal coliform level shall be a geometric mean of 2000 CFU per 100 mL based on five consecutive samples collected on different days.

This indicator measures:

- **Percent of fecal coliform samples meeting state standards at various sites**

Where We Were:
Approximately 100 surface water samples were tested for fecal coliform between 1970 and 1990 at a variety of sites. For samples taken in the headwaters of the system, approximately one-third to one-half met the current standard. At Cobbs Creek just above the confluence with Darby Creek, less than 10% of samples met the current standard.

Where We Are:
Samples were collected in 1999 and 2000 at several sites in the watershed (Figure 4-20). All these samples were taken in the summer months, when the strictest standard is in effect. In general, 0-20% of dry weather samples met the standard, and at most sites none of the wet weather samples met the standard. At Cobbs Creek site DCC-110, just above the confluence with Darby Creek, dry weather conditions seem to have improved over time; 25% of dry weather samples met the standard in 1999-2000 as compared to 4% in the 1970's. Overall, in the watershed, concentrations of fecal coliform bacteria seem to have remained about the same or increased slightly over time.

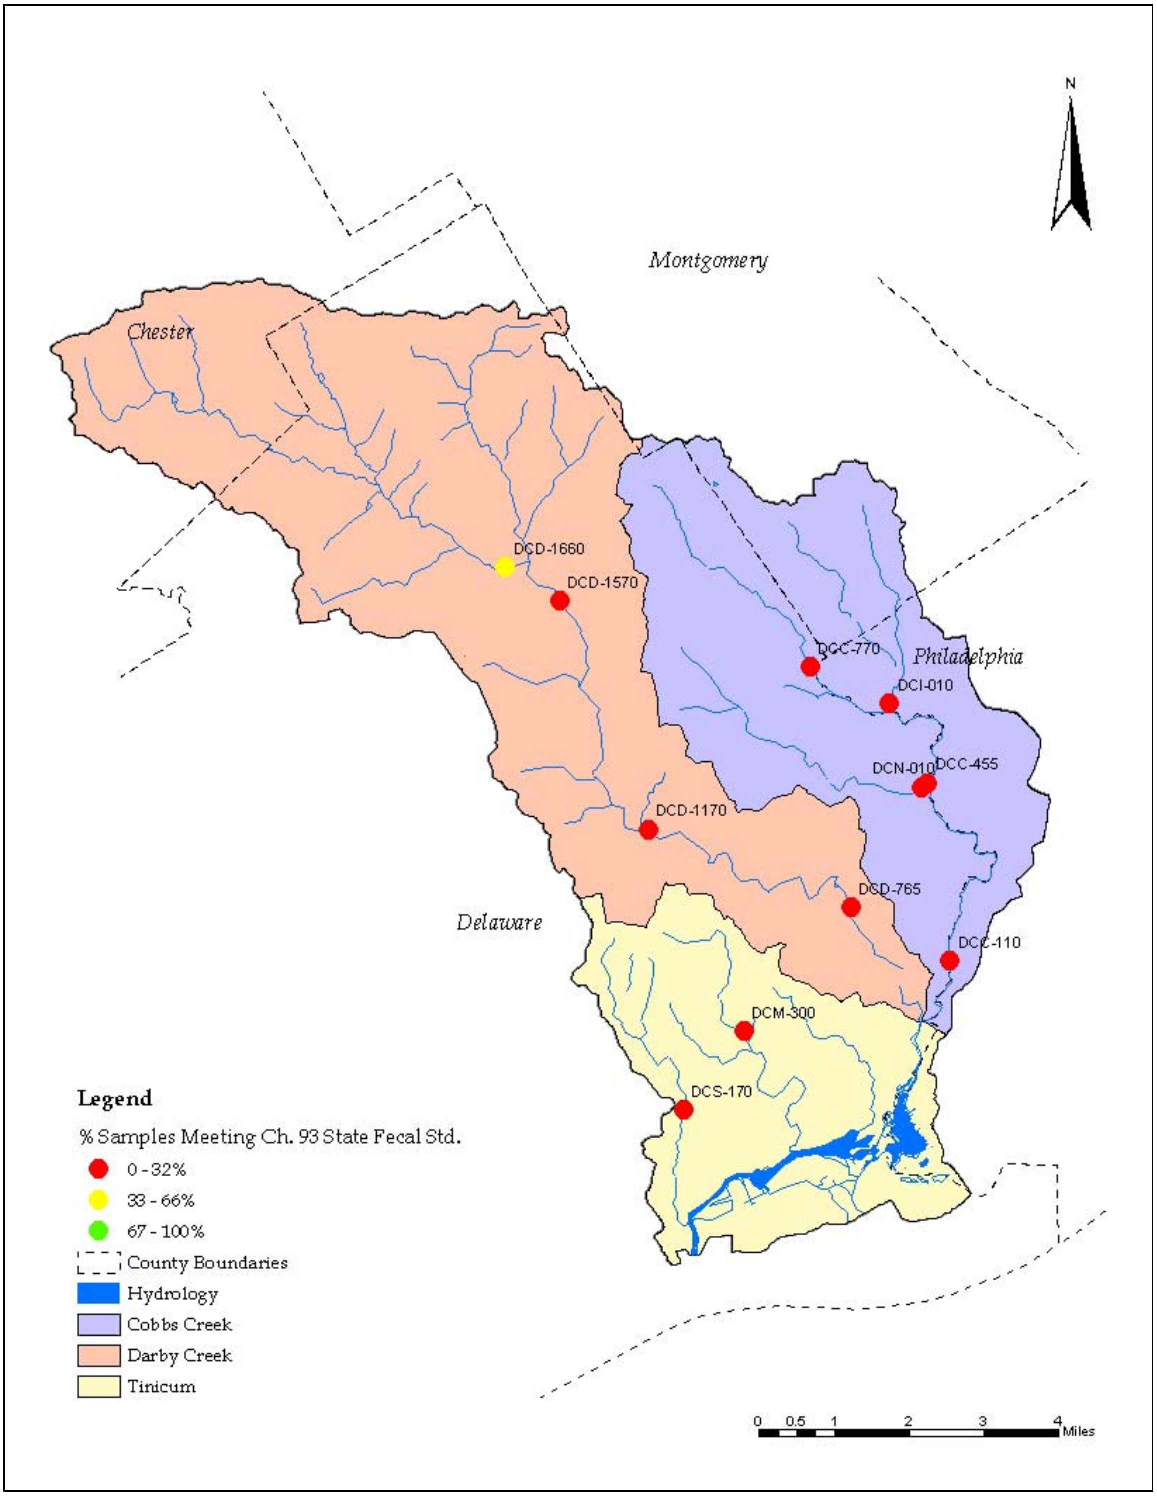

Figure 4-19 Water Quality Data for Fecal Coliform (1999)

Indicator 8: Effects on Public Health (Metals and Fish Consumption)

Toxic substances, including metals such as lead and organic substances such as PCBs, are sometimes introduced into the aquatic environment as a result of human activity. These substances exist in some sediments as a result of historical discharges, are introduced to the atmosphere through burning of fossil fuels, and are deposited on land surfaces through industrial and transportation activities. Precipitation and surface runoff introduce small concentrations of these substances to surface waters. Relatively small amounts of certain toxic substances can kill aquatic life through acute poisoning. Chronic exposure to toxins may be harmful at even smaller concentrations. Over time, fish may accumulate toxins from the water they live in and the food they eat. In some cases toxins may be present in harmful concentrations in their tissues.

Because toxic substances in the environment can affect aquatic life and humans who consume fish, PADEP has established maximum concentrations that are allowable in the water column. Standards based on aquatic life protection are generally much stricter than standards based on human health. In addition, Pennsylvania DEP samples fish tissue and issues fish advisories designed to warn the public as to what species may contain toxic chemicals. These contaminants can build up in the human body over time, possibly leading to health risks.

This indicator measures:

- **Percent of Cd, Cr, Cu, Pb, and Zn samples meeting state standards at various sites**
- **Areas with fish consumption advisories**

Where We Were:
Historical information on concentrations of toxins in fish tissue is not readily available. Information on concentrations of some metals was collected in the 1970's, and this can be compared to current water quality standards. Approximately 50 samples were collected at several sites between 1970 and 1980 for cadmium, lead, chromium, copper, and zinc together. Concentrations were generally low in the headwaters of the system but frequently exceeded standards in the downstream portions, especially during wet weather. Approximately 85-90% of dry weather samples and 75-80% of wet weather samples taken in the headwaters of the system met standards intended to protect aquatic life. At Cobbs Creek just above the confluence with Darby Creek, about 75% of dry weather and 60% of wet weather samples met standards.

Where We Are:
Comparing estimated historical loading rates data from the 1970's with data collected in 1999, the estimated loads for metals for the 1999 period are lower, with two exceptions. The loading rate for nitrate increased and the estimated upstream cadmium load is slightly higher.

Fish advisories are most often due to metals or organic chemicals. The April 2001 fish advisory for this watershed advises to limit consumption of white perch, striped bass, and carp to one meal a month, and to limit consumption of channel catfish to one meal every two months. American eel should not be eaten at all. This is all due to PCB pollution.

The number of permitted discharges in the watershed appears to have decreased over recent decades, but there are some indications of residual contamination due to past industrial activity. A search of US EPA's BASINS database identified 12 permitted industrial and municipal dischargers that have been active at some time in the last few decades. However, only 7 of these permits are currently active, indicating that five sources have become inactive since records were first kept. However, the lower portion of the Darby Creek watershed has recently been listed as a Superfund site, indicating the potential for introduction of toxic chemicals.

In 2000, between 50 and 100 samples were collected at each site for cadmium, lead, chromium, copper, and zinc together (Figure 4-20). The data indicate that standards intended to protect aquatic life are still sometimes exceeded. The data also shows that the situation has improved at all sites when compared to the 1970's. For most sites, 90-100% of samples meet the standards. At Cobbs Creek just above the confluence with Darby Creek, 93% of dry weather and 72% of wet weather samples meet the standard.

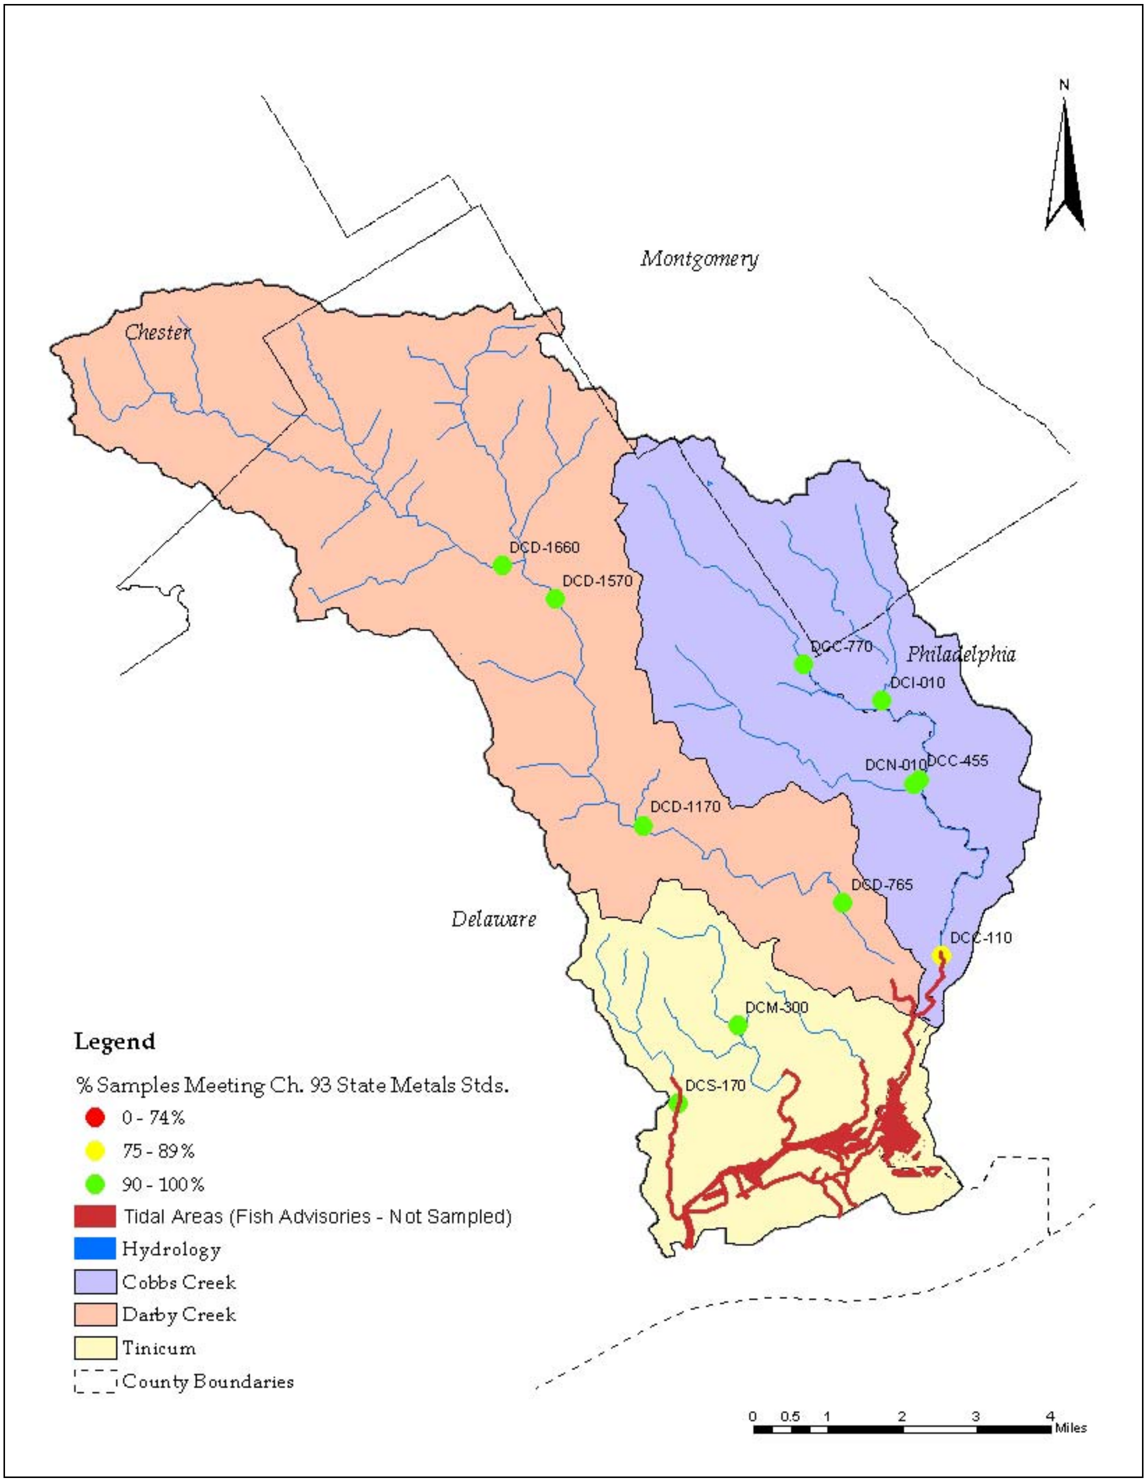

Figure 4-20 Water Quality Data for Metals (1999)

Indicator 9: Effects on Aquatic Life (Dissolved Oxygen)

Just as humans require oxygen gas for respiration, most aquatic organisms require dissolved oxygen (DO) in order to perform vital functions. Oxygen dissolves in water through air-water interaction at the surface of the flow and through photosynthesis of plants and algae. At the same time, DO is depleted through the respiration of microorganisms, animals, plants, and algae. In a healthy system, the balance between oxygen-depleting and oxygen-providing processes maintains DO at a level that allows aquatic organisms to survive and flourish. In a less healthy system, dissolved oxygen may be depleted below levels needed by aquatic organisms. The minimum dissolved oxygen concentration required by many common fish species found in rivers and streams is approximately 5 mg/L. PA DEP has set a water quality standard, or minimum allowable concentration, of 5 mg/L as a daily average and 4 mg/L as an instantaneous value for Cobbs Creek. Criteria in portions of Darby Creek are stricter to accommodate trout.

This indicator measures:

- **Percent of DO samples meeting state standards at various sites**

Where We Were:
Approximately 100 samples of DO were taken between 1970 and 1990. For all sites except one, DO was never less than 5 mg/L. On Cobbs Creek just above the confluence with Darby Creek, site DCC-110, low-DO conditions appear to have been common. Measurements were less than the standard approximately 20% of the time in dry weather and 10% in wet weather. These conditions may have been related to more frequent dry and wet weather sewer overflows. The low-DO conditions probably had an adverse impact on aquatic life.

In an aquatic biological investigation performed in 1995-1996, the overall water quality in Darby Creek was determined to be good. Iron, aluminum, total suspended solids, and fecal coliform were occasionally above the limit, but not at levels harmful to aquatic life. Some samples taken from Cobbs Creek showed low dissolved oxygen and elevated levels of ammonia, phosphorus, iron, lead and manganese. In the areas where fish quality was reported, the quality ranged from fair to good.

Where We Are:
Both discrete and continuous samples were collected between 1999 and 2003. Discrete samples produce a single DO value at the time the sample is taken. Continuous monitoring is preferred, as it records data from early morning, when DO is typically lowest due to respiration. Discrete samples suggest that dissolved oxygen is rarely below the instantaneous minimum allowable concentration standard under dry or wet conditions. Two sampling sites recorded concentrations below the standard of 4 mg/L. At DCD1660, in the headwaters of Darby Creek, 1 discrete sample out of 5 total indicated DO below 4 mg/L under wet weather conditions; continuous samples did not indicate any low DO values. At site DCC110, just above the confluence of Cobbs and Darby Creeks (Figure 4-21), 1 of 9 dry weather samples and 6 of 24 wet weather samples did not meet the 4 mg/L standard. This site is just below the Woodland Avenue dam and is most likely affected by poorly mixed water just above the dam.

Continuous DO data have been collected over approximately 10,000 hours between 1999 and 2003. Between 1999 and 2002, DO measurements were observed to be below the state criteria only at sites DCC110 and DCC115, just below and above the dam, respectively. At DCC-115, 19% of observations were less than 5 mg/L and 5% were less than 4 mg/L. At DCC110, 5% of samples were less than 5 mg/L and less than 1% were below 4 mg/L. The most recent data, collected in August-September 2003, show similar trends. DO reaches a minimum of 3-4 mg/L during wet weather at DCC110. The dry weather diurnal range, or difference between maximum and minimum DO concentration over the 24-hour cycle, varies from 1-2 mg/L at upstream sites to as high as 8-9 mg/L at DCC110. This difference suggests a high level of algal activity in the pool behind the dam. Figure 4-22 displays the trends mentioned above: an increase in diurnal amplitude as biological activity increases in dry weather, and a drop in DO as low-DO water is flushed over the dam in wet weather. A possible explanation is that upstream inputs of nutrients from sewage and stormwater sources lead to increased biological activity in the slow-flowing conditions found at sites DCC110 and DCC115.

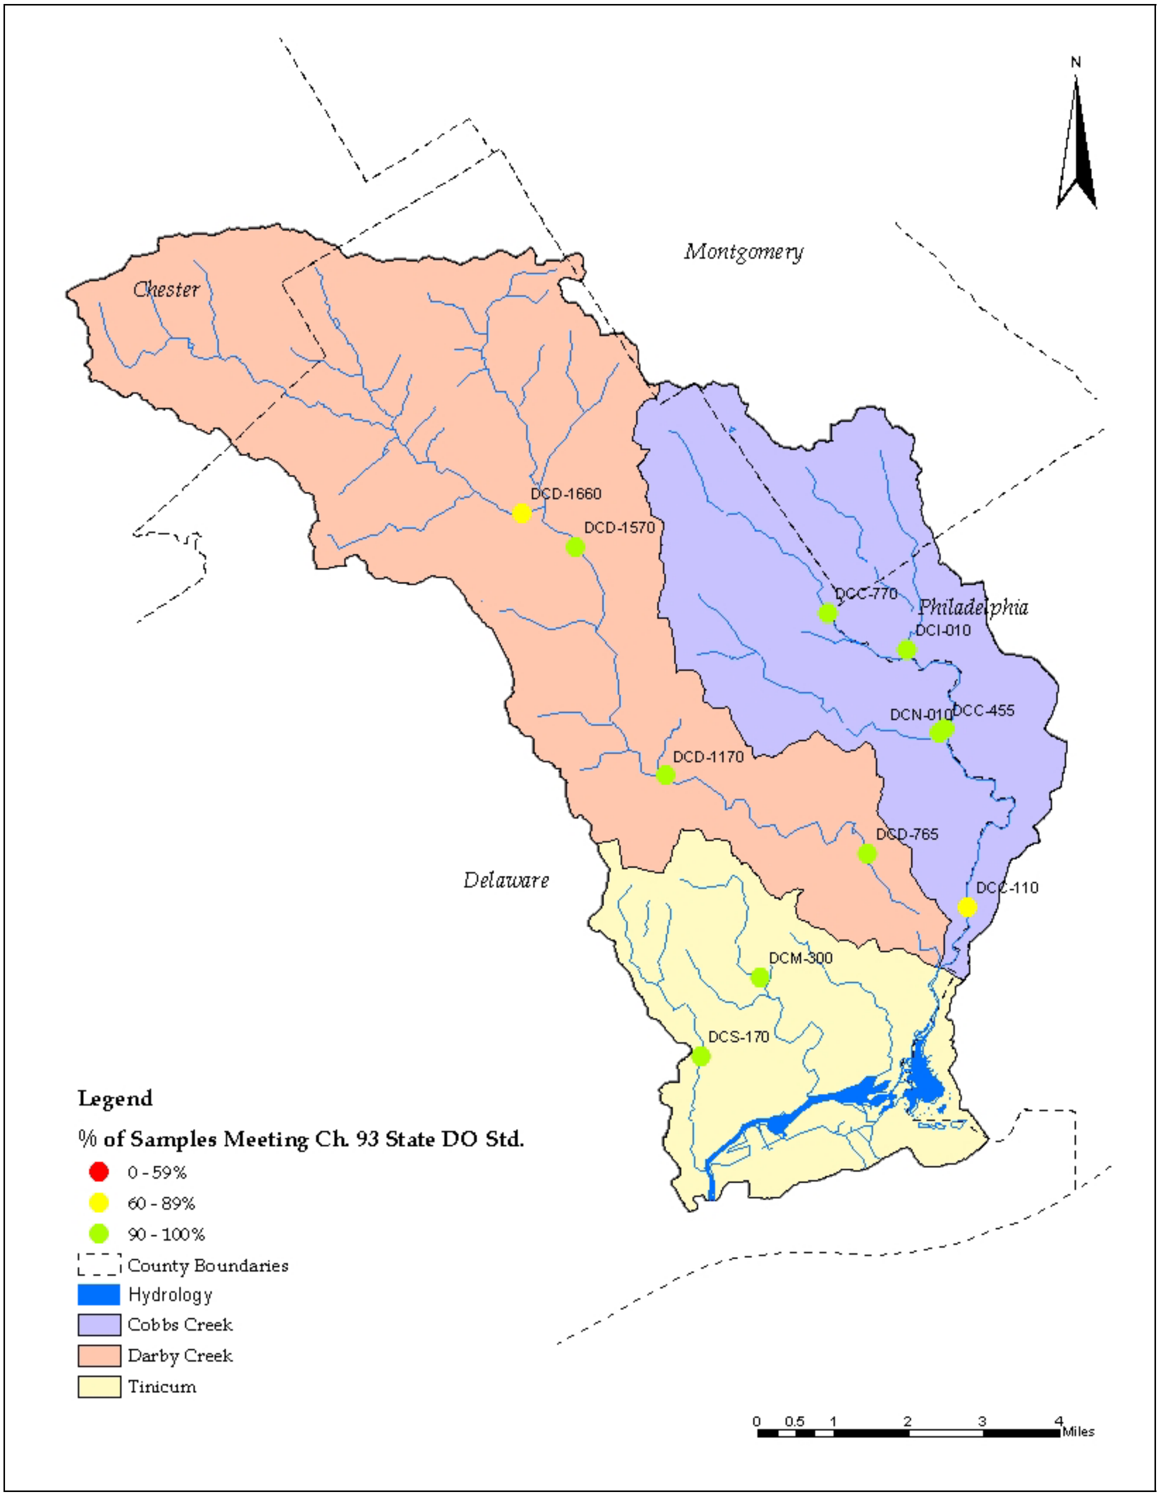

Figure 4-21 Water Quality Data for Dissolved Oxygen

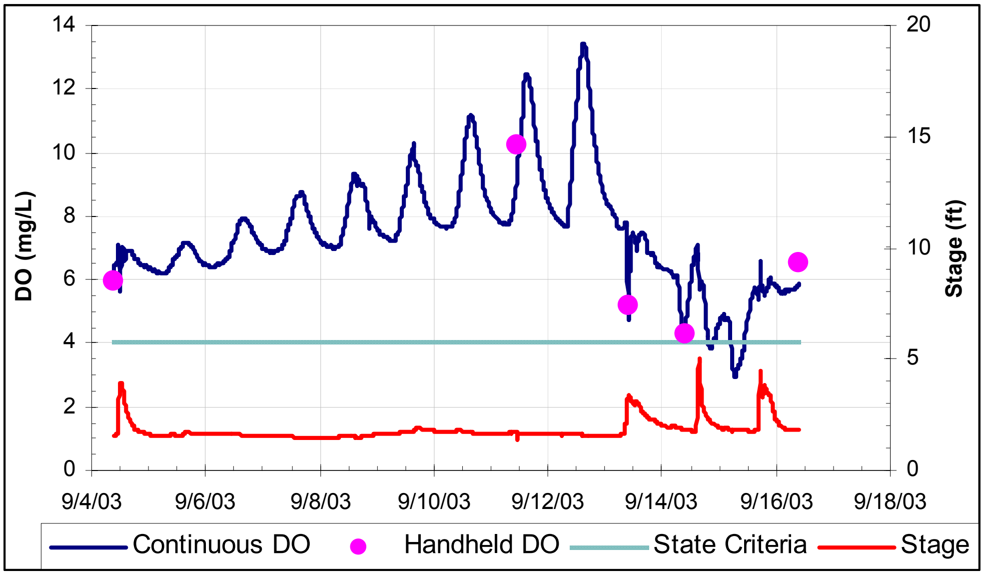

Figure 4-22 Stage and Dissolved Oxygen at DCC110 in September 2003

Pollutants and Their Sources

Indicator 10: Point Sources

A point source is any point where discharged water and pollutants can enter a water body, such as a pipe, channel, or ditch (Figures 4-23 through 4-25). Point source discharges that could include treated municipal wastewater, combined sewer overflows (CSO), separate sanitary overflows (SSOs), industrial process water, municipal separate storm sewer system (MS4) discharges, and/or cooling waters. Point sources are regulated under the Clean Water Act by the National Pollutant Discharge Elimination System (NPDES).

Figure 4-23 Stormwater Outfall

Figure 4-24 CSO Outfall

Figure 4-25 Municipal Wastewater Treatment Plant

A **municipal separate storm sewer system (MS4)** collects stormwater runoff from the land surface and discharges it directly to a receiving stream.

Combined sewer systems use one pipe to convey sanitary sewage and stormwater runoff to a combined sewage regulator chamber. The regulator captures all of the sanitary sewage in dry weather, and some of the combined sewage in wet weather, sending it to a wastewater treatment plant. The balance of wet weather flow is discharged to an area water body through a CSO outfall.

Sanitary Sewer Overflows (SSOs) occur when a municipal separate sanitary sewer system becomes overcharged in wet weather and overflows unintentionally to an area water body.

Municipal Wastewater Treatment Plants are facilities that process municipal sanitary waste and industrial and commercial discharges to the sewer system. These facilities treat the waste stream and discharge it to a local stream.

Industrial processes use water in manufacturing, power generation, or other activities to produce a product. By-products from the process can be discharged to area waterways with varying levels of treatment.

Pollutants and Their Sources

Indicator 10: Point Sources

This indicator measures:

- **Number of permitted industrial and municipal point sources**
- **Estimated annual percent capture of combined sewage**
- **Estimated pollutant contributions of industrial/municipal, CSO, and stormwater sources**

Where We Were:

Point source discharges from treatment plants and industrial facilities were a priority for increased control during the 1970s and 1980s as secondary wastewater treatment requirements and industrial pre-treatment regulations were imposed. Historical data indicate that there were 35 facilities in the watershed with National Pollutant Discharge Elimination System (NPDES) Permits.

Historical SSO and CSO discharges are not well documented, and there is only limited current data on SSOs. However, it can be inferred from water quality data that dry weather sewage discharges were much more common in the past (see Indicator 8). It is reasonable to conclude that the frequency and volume of CSO discharges in the Philadelphia portion of the Cobbs watershed have decreased over the past 20 years due to improved sewer maintenance and CSO control measures. These measures are discussed in detail later in this section.

Where We Are:

Active Industrial and Municipal Point Source Dischargers

There are believed to be 8 active industrial point source dischargers in the Darby-Cobbs Watershed. Current facilities with NPDES permits to discharge into the watershed are believed to be Sun Oil Company, SEPTA Victory Terminal, Meenan Oil Company, Mobil Oil Company, Boeing Defense and Space Group, Tinicum Township Sewerage Authority, and Township of Haverford Public Works Landfill. Several of the facilities that were once listed as active dischargers have since been eliminated. Kistler Fredrick, 2 Sunoco Service Stations, and Mobil Oil Corporation are no longer active dischargers. Wastewater treatment plants that once discharged in the watershed no longer do so, such as Township of Haverford public.

Estimated Annual Percent Capture of Combined Sewage

Portions of Philadelphia County, including 20% of the Cobbs Creek watershed, are serviced by combined sewers. The City of Philadelphia has 38 regulator structures within the watershed, as shown in Figure 4-26. Since the 1980s, PWD has made significant progress in reducing CSO discharges to Cobbs Creek. As required under EPA's CSO Control Policy, PWD has developed and implemented a CSO Long-Term Control Plan (LTCP) to improve and preserve the water environment in the Philadelphia area. Table 4-6 lists estimated capture percentages for regulator structures in the Cobbs Creek watershed, based on the modeling results listed in PWD's CSO Annual Reports.

Capture percentage is defined as the percentage of combined sewage (mixed sanitary sewage and stormwater) that is sent to a treatment plant during rainfall events over the course of a year. 85% capture is considered to be an ultimate goal for many communities as they implement CSO long term control plans. It is important to note that percent capture for a given year is strongly dependent on the frequency and magnitude of rainfall events during that year. The seven years of data listed in Table 4-6 are not sufficient to determine whether an increasing or decreasing trend has taken place. However, as the amount of data increases throughout implementation of the Long Term Control Plan, it will ultimately be possible to evaluate the effectiveness of control measures.

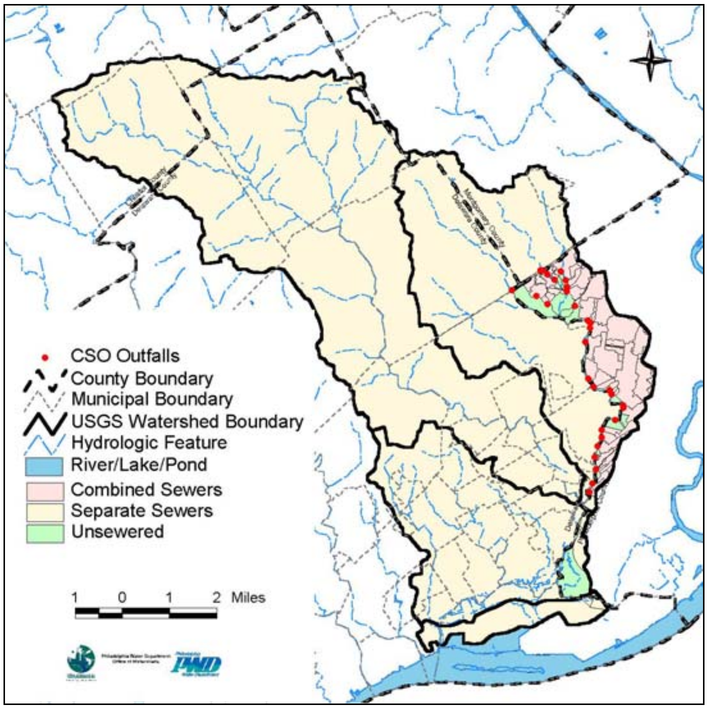

Figure 4-26 Types of Sewer Service and Locations of Regulator Structures

Table 4-6 Estimated Annual Combined Sewage Capture Percentages

Year	Precipitation (in)	Capture (%) – Lowest and Highest Structure	
		Cobbs Creek High Level	Cobbs Creek Low Level
2001	31.1	61 – 62	84 – 85
2000	43.2	51 – 52	74 – 75
1999	48.6	49 – 50	73 – 74
1998	30.7	65 - 67	87 - 88
1997	32.0	59 – 63	88 – 92

Model-Estimated Pollutant Contributions of Different Sources

Estimated annual pollutant contributions for the Darby and Cobbs watersheds are shown in Figure 4-27. For both systems, stormwater outfalls are the largest source of pollutants associated with urban and suburban runoff, including nutrients such as phosphorus and metals such as lead. For the Cobbs Creek watershed, CSO is a smaller but significant source of these constituents. CSO discharges are the dominant source of fecal coliform in the Cobbs watershed. Permitted industrial and municipal point source discharges make up less than 2% of annual streamflow in both systems. SSOs are thought to occur in both watersheds but have not been well documented to date.

Darby-Cobbs Watershed Status Report 2003

Pollutants and Their Sources

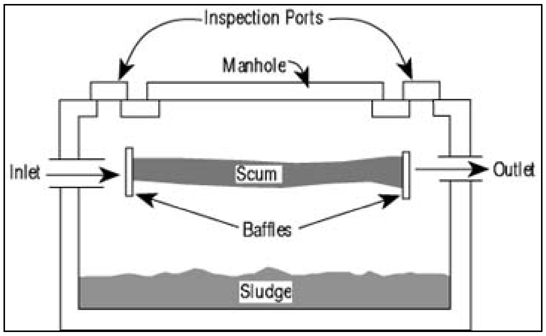
Indicator 10: Point Sources

Figure 4-27 Estimated Annual Proportional Contribution of Pollutant Source (Watershed Pollutant Loading Model)

Indicator 11: Nonpoint Sources

Nonpoint source pollution is any source of water contamination not associated with a distinct discharge point. This type of pollution is a leading cause of water quality degradation in the United States. Nonpoint sources include atmospheric deposition, stormwater runoff from pasture and crop land, and individual on-lot domestic sewage systems discharging through shallow groundwater. Stormwater from urban and suburban areas is considered a point source for regulatory purposes because it is collected in a pipe system and discharged at a single point.

Figure 4-28 Pasture Land



Source: Ohio State University Extension

Figure 4-29 Septic System

Agricultural activity is a major source of nonpoint source pollution in many areas. Animal manure and fertilizers applied to crops may lead to pollutant inputs to surface water and groundwater.

A properly sited and maintained **septic system** should not result in excessive inputs of nutrients to groundwater. However, failing septic systems are common and can result in nutrient inputs to shallow groundwater and ultimately to stream baseflow.

Background concentrations of some water quality constituents are present in groundwater and may be transferred to stream baseflow. Some constituents may be introduced through agricultural activity or failing septic systems, while others may be present as a result of local geology.

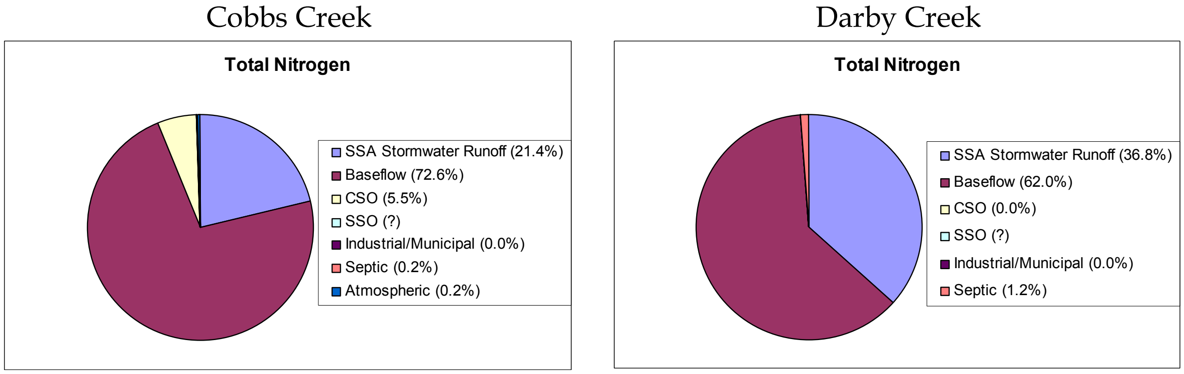
This indicator measures:

- **Model-estimated percent of total pollutant loads contributed by septic tanks**
- **Evidence that sanitary sewers are leaking during dry weather, or are in direct contact with the stream**

Where We Were:

Since most point sources were addressed in the 1970s and 1980s, regulatory agencies have been turning attention towards controlling nonpoint sources of pollution. Many of these sources began to be addressed only during the 1990s.

Where We Are:
Nonpoint sources in the Darby-Cobbs Creek watershed include atmospheric deposition, stormwater runoff from a very small amount of agricultural land, background concentrations in groundwater, and individual on-lot disposal systems (OLDS) discharging through shallow groundwater. The number of septic tanks within the watershed is hard to accurately quantify; 1990 census data indicated that about 2000 septic tanks were present in the watershed; this number is believed to be a high estimate of the actual number. Based on modeling estimates (Figure 4-30), septic tanks contribute up to 2% of total nitrogen and phosphorus loads. Atmospheric loads to wetlands and open water were estimated only for the Cobbs Creek system and were less than 1%. Background groundwater concentrations of total nitrogen were the largest source of that constituent in streamflow (60-70% of the estimated annual load). Dry weather contributions from leaking sanitary sewers could not be estimated based on current data, however, evidence that leaking is occurring is presented below.



Cobbs Creek

Darby Creek

Figure 4-30 Estimated Nutrient Inputs from Septic Tanks

Stream Corridor

Indicator 12: Riparian Corridor

The riparian areas buffering streams, rivers, lakes, and other water bodies are especially sensitive watershed zones. In their naturally vegetated and undisturbed state, floodplains and riparian areas provide stormwater management and flood control functions, both in terms of water quantity and water quality. An example of floodplain and riparian zone conservation and protection is Cobbs Creek Park (Figure 4-31). Philadelphia had the foresight years ago to establish greenways along Cobbs Creek and its tributaries, both for conservation and recreational purposes. With the exception of Heinz National Wildlife Refuge, Cobbs Creek Park and related facilities constitute the most significant conservation and recreation zone in the Watershed.

This indicator measures:

- **Miles of stream with a minimum buffer of 50 feet and 50 percent canopy cover**

Figure 4-31 Riparian Corridor in Cobbs Creek Park

Where We Were:
There is no historical data available for this indicator. A trend will be established the next time this area is reassessed.

Where We Are:
The areas adjacent to the creeks in Fairmount Park have been used as picnic and recreational areas, leading to alteration of natural vegetation. This invasive plant has a shallow root mass that does not affectively anchor the soil. Stream banks that are disturbed or dominated by invasive plants may be more vulnerable to erosion during storms. These disturbed areas are very susceptible to colonization by invasive plants, especially Japanese knotweed. The areas in Fairmount Park are superior in quality compared to most of the areas in the watershed. Many other areas in the watershed have completely lost their riparian buffers.

Stream Corridor

Indicator 12: Riparian Corridor

Buffers along stream corridors can be an important factor in enhancing stream habitat and preventing erosion. In 2002, the Heritage Conservancy was funded to develop a rapid assessment method to identify and map sections of stream lacking riparian forest buffers. The conservancy then assessed watersheds in southeastern Pennsylvania and mapped waterways lacking riparian forest buffers. Interpretation of 1" = 200' black-and-white high altitude aerial photographs and videotape from helicopter overflights were used to determine the presence or absence of a forested buffer for 975 miles of stream. For this analysis, a stream bank was classified as having a forested buffer if it was determined to have a 50 foot wide buffer of trees and 50 percent canopy cover. Each stream bank was analyzed independently. Table 4-7 shows that there are about 30 miles of stream within the watershed that are lacking forested riparian buffers on one or both banks.

Table 4-7 Lack of Riparian Forested Buffer

Riparian Buffer	Length (Stream Miles)
Buffer Lacking on One Bank	15.8
Buffer Lacking on Both Banks	13.7

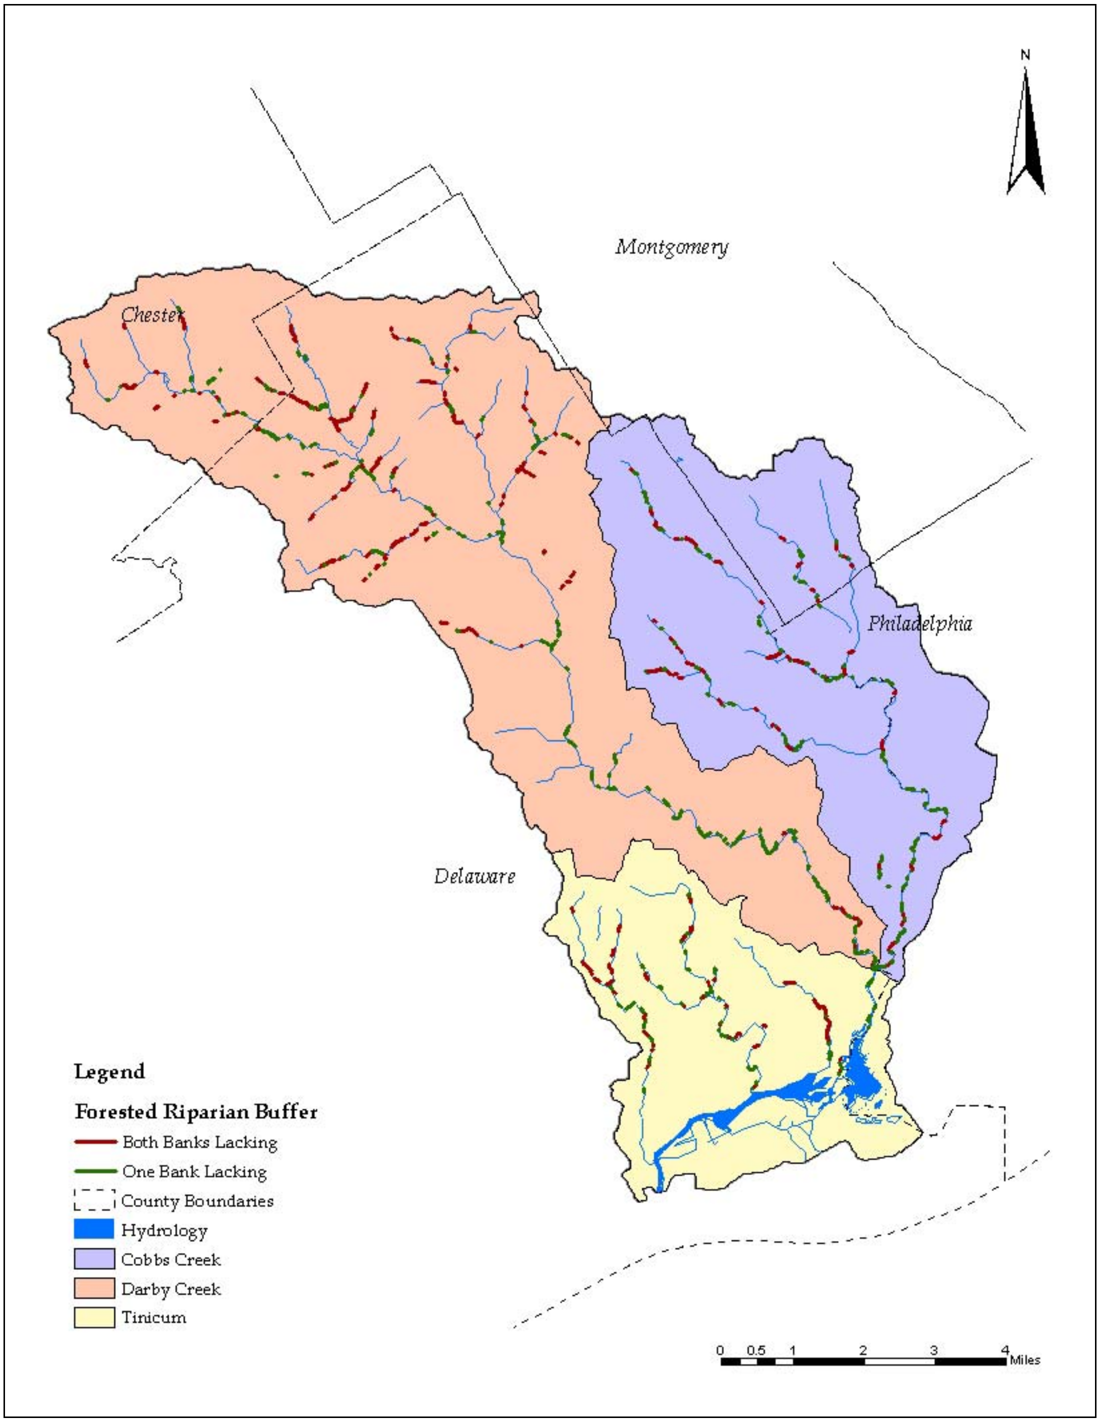


Figure 4-32 The Heritage Conservancy's Forested Riparian Buffer Analysis (2002)

Indicator 13: Wetlands and Riparian Woodlands

Wetlands and riparian woodlands are important natural filters for pollutants in stormwater. Wetlands and woodlands increase vegetation diversity, providing feeding and nesting habitat for birds and animals. They are important in preventing slope erosion and mitigating flood peaks by controlling runoff, and they allow for natural infiltration of rainfall and groundwater recharge.

The most significant functions that wetlands perform are:

- Wildlife Habitat
- Fish Habitat
- Water Quality Improvement (nutrient and toxicant reduction)
- Hydrologic (flood flow) modification
- Groundwater recharge

The location and size of a wetland may determine what functions it will perform. For example, the geographic location may determine its habitat functions, and the location of a wetland within a watershed may determine its hydrologic or water-quality functions. Many factors determine how well a wetland will perform these functions; such as climatic conditions, quantity and quality of water entering the wetland, and disturbances or alteration within the wetland or the surrounding ecosystem.
Wetlands of the Cobbs Creek watershed were evaluated for the first four of the functions noted above, and were further studied to understand their sensitivity to future disturbance and their potential for enhancement and improvement, where they may have experienced degradation.

This indicator measures:

- **Acres of wetland in the watershed**
- **Area of riparian buffer along waterways**
- **The quality of the wetlands**
- **The ability of the wetland and woodlands to improve water quality**

Figure 4-33 Example of a Wetland Area

Indicator 13: Wetlands and Riparian Woodlands

Where We Were:

There is little data available about the historical presence of wetlands and riparian woodlands in the watershed. The Fairmount Park Commission's Natural Lands and Restoration and Environmental Education Program (NLREEP) compiled some information regarding historic wetlands in their 1999 Natural Lands Restoration Master Plan. NLREEP reported that Philadelphia had an abundance of wetlands along the Delaware and Schuylkill Rivers in pre-colonial times. These included a variety of intertidal channels, marshes and mudflats, and gravel bars. Much of the south and southwestern parts of the city, including what is now FDR Park, were a mix of tidal channels and marshes. Nontidal wetlands were present inland from the tidal marshes and along streams (NLREEP,1999).

Urban and suburban development has resulted in the piping of historic streams, destruction of wetlands, and deforestation and modification of historic floodplains. Stormwater is piped directly to waterways rather than flowing overland through vegetation, wetlands, and woodlands. Also, because stormwater runoff frequently flows over impervious surfaces, and is then piped to the streams, the flow and volume of runoff is intensified. Stream channels of the Cobbs Creek watershed exhibit many effects of urbanization: degradation of the stream channel (including overwidening), erosion, loss of sinuosity, loss of the floodplain, stream connection, and loss/degradation of aquatic habitat. Because most stormwater is piped directly to the waterways of the Cobbs watershed, there is no longer a source of water to maintain many of the wetlands that once existed.

In a geomorphologic study of Cobbs Creek conducted in 2002, the creek was divided into 63 stream segments for analysis. Results suggest that increases in stormwater runoff intensity have widened the waterway channel, and reduced its depth. Stability of the streambed was evaluated, and 26 stream segments were observed to experience continuing streambed deterioration. In many reaches, the stream channel now occupies much of the land that once functioned as floodplain and wetland, reducing the presence of wetlands and riparian woodlands.

Finally, extensive development in the Cobbs Creek watershed has resulted in conversion of natural riparian lands to residential and active recreational land use. Primary land uses in the watershed, for the most part, preclude the existence of natural vegetated areas, due to the high density of development. For example, 25%of the residential land uses are row or multi-family homes, which typically have relatively little vegetated open area to control and improve stormwater runoff.

In summary, the number and combined areas of wetlands and riparian woodlands in the Cobbs Creek watershed have fallen over time as a result of development close to the stream edges and changes to the floodplain from concentrated stormwater flows.

Indicator 13: Wetlands and Riparian Woodlands

Where We Are:

Wetland information presented here for the Darby and Tinicum subwatersheds is based on limited information found in the National Wetlands Inventory; information presented for the Cobbs is based on a much more detailed study conducted by the Philadelphia Water Department. As shown in Figure 4-34 and Table 4-8, small, scattered wetlands are present throughout the riparian areas of Darby Creek and its tributaries. Cobbs Creek has far fewer riparian wetland areas. A large wetland system is present in the Tinicum subwatershed. Wetland communities of native vegetation are scarce in the Fairmount Park system.

Based on land use data, approximately 10% of the Darby-Cobbs watershed land area may be considered woodland. However, the greatest proportion of woodland occurs in the Darby subwatershed, although forested areas in the Cobbs watershed are more contiguous due to Cobbs Creek Park lands. There are large areas of woodland found in the park, though they are more extensive in the northern portion. In areas where trash dumping and encroachment of recreational activities occur, wooded areas have become fragmented, creating open habitat for exotic, aggressive tree species. Regrowth of understory and herbaceous layers is usually limited once these exotic species become established. Exotic control, replanting and trash removal are components of woodlands restoration.

The Cobbs Creek watershed is 14,200 acres in size, or about 22 square miles. The watershed in nearly totally developed - 92% of the watershed now supports homes, businesses, industries, and utilities. Of the land that is not developed (i.e., wooded, waterway, or vacant), only 5% still exists as riparian wetland and woodland, most of it serving as public open space (see Indicator 1: Land Use and Impervious Cover).

If runoff from the developed parts of the watershed (92%of the watershed) were settled and filtered using all of the vegetated riparian wetlands and woodlands in the watershed (5% of the watershed), almost 80% of the total solids in the stormwater could be removed before it discharged into the stream. However, most of the stormwater in Cobbs Creek watershed is piped directly to the stream channel, bypassing the wetlands and riparian woodlands that could improve the water quality through detention and trapping sediment. Also, the riparian woodlands along Cobbs Creek and its tributaries are now largely public open spaces (or in some cases, privately owned residential yards). Return of these lands to their original function of filtering and improving the quality of stormwater requires a public examination and decision-making process for resolving competing uses for riparian lands.

The total area of wetland in the Cobbs Creek watershed is relatively small considering the 22.4 linear miles of waterways. Field investigation of wetland presence and quality in the watershed indicates that only 46 wetlands, totaling 36.4 acres, remain along Cobbs Creek and its tributaries. The wetlands range in size from 0.01 acre to approximately 6 acres. Most wetlands are small; 26 of the wetlands surveyed were less than one-quarter acre in size.

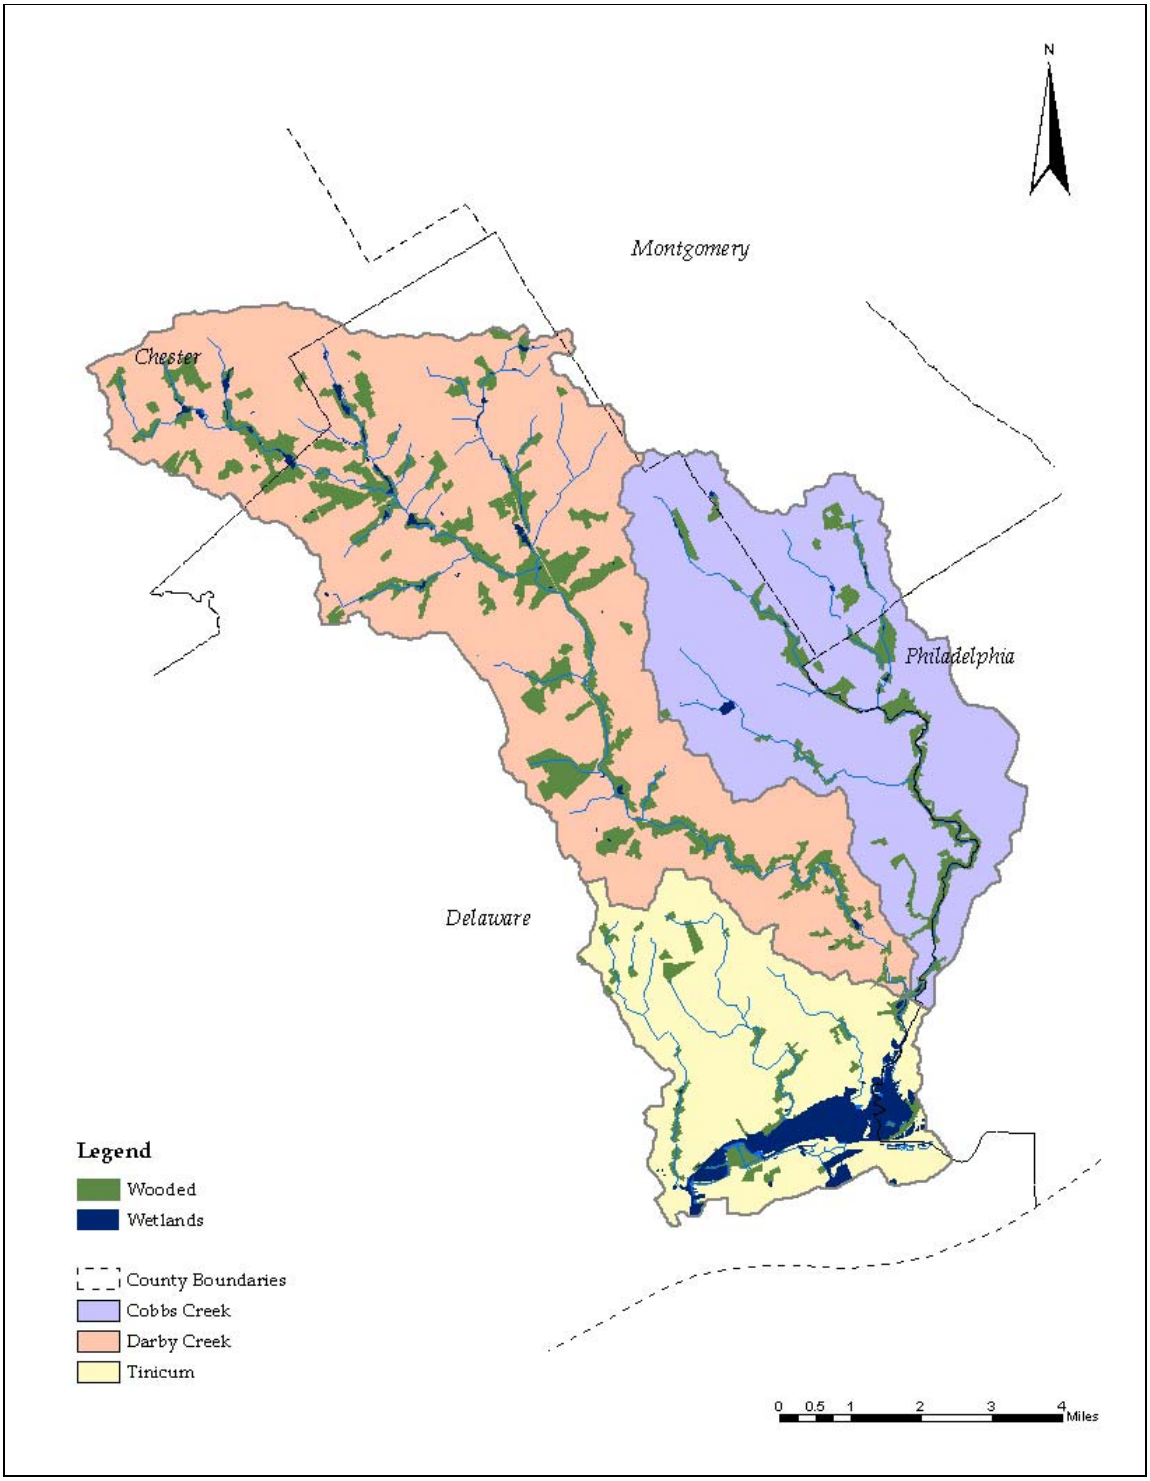

Figure 4-34 National Wetlands Inventory and PWD Surveyed Wetlands (2002 – 2003)

Table 4-8 Estimated Woodland and Wetland Area

Subwatershed	Total Area (acres)	Woodland (% of total)	Wetland (% of total)
Upper Cobbs	7500	4%	0.4%
Lower Cobbs	6700	13%	0.1%
Upper Darby	16,910	14%	1%
Lower Darby	8,521	14%	0.2%
Tinicum	9,804	6%	11%

The remaining Cobbs Creek wetlands were evaluated for their value as wildlife habitat, fish habitat, water quality improvement (nutrient and toxicant reduction), and hydrologic (flood flow) modification. Nearly all wetlands in the Cobbs Creek watershed exhibit impaired functions that indicate extensive disturbance and deterioration.

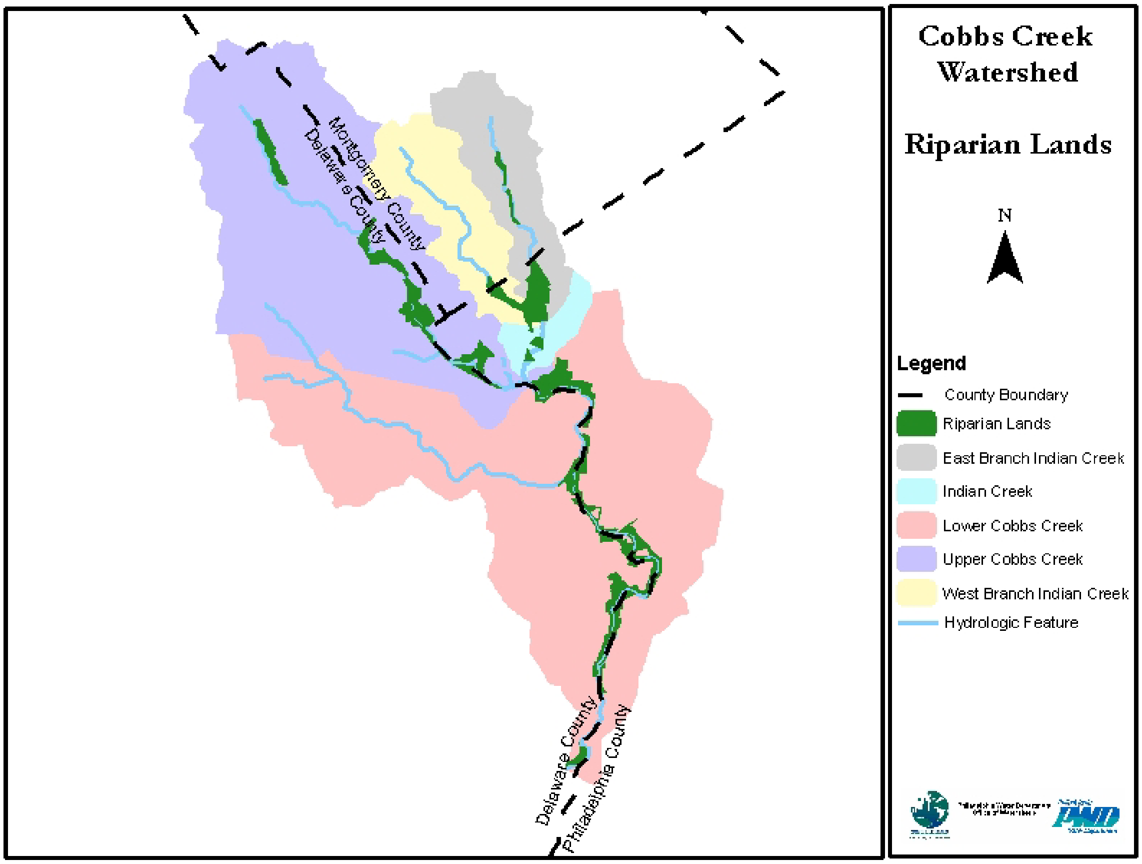

Figure 4-35 Open Lands in the Riparian Corridor

Results of the functional assessment indicate that the remaining wetlands in the Cobbs Creek watershed are degraded, and cannot serve as high quality habitats or perform many of their water quality improvement functions. If stormwater was redirected to the small areas of remaining wetlands, rather than being rerouted directly to the streams in the Cobbs Creek watershed, water quality improvement would be minimal given the current compromised conditions of the wetlands.

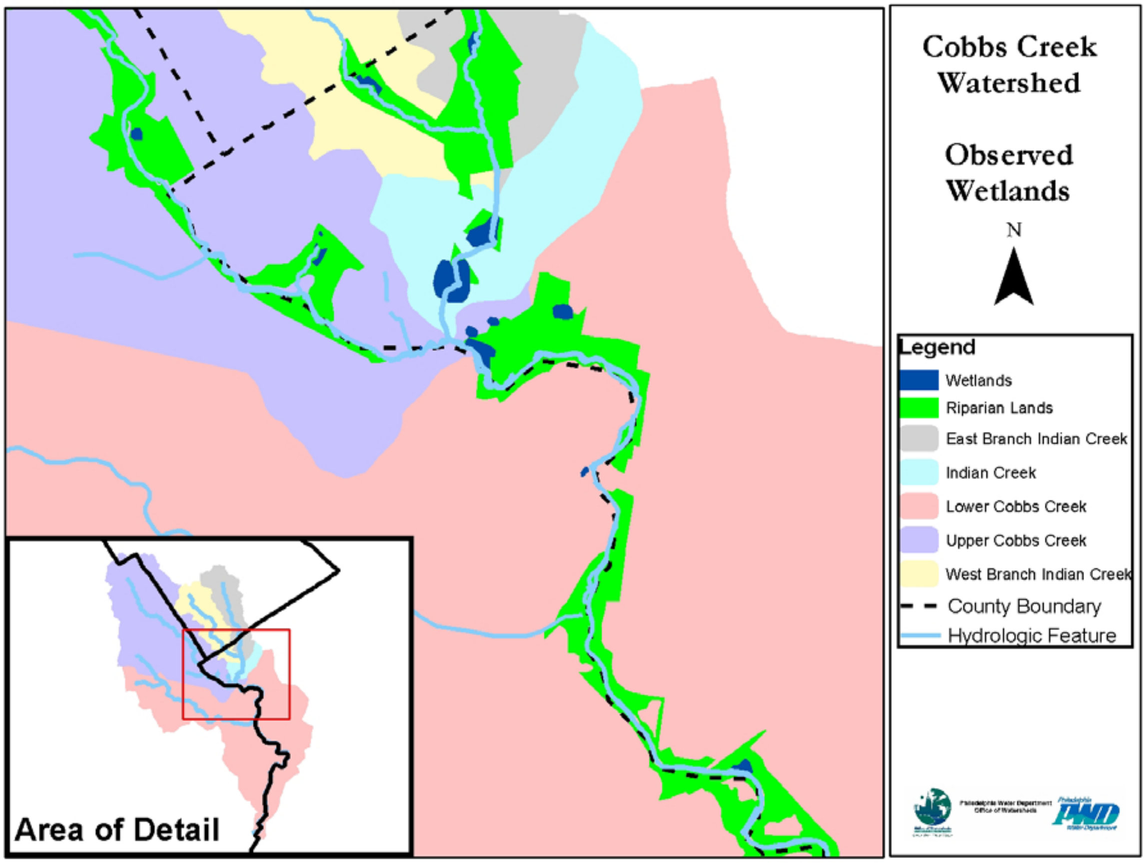

Figure 4-36 Wetlands Identified in the Cobbs Creek Watershed (2002 – 2003)

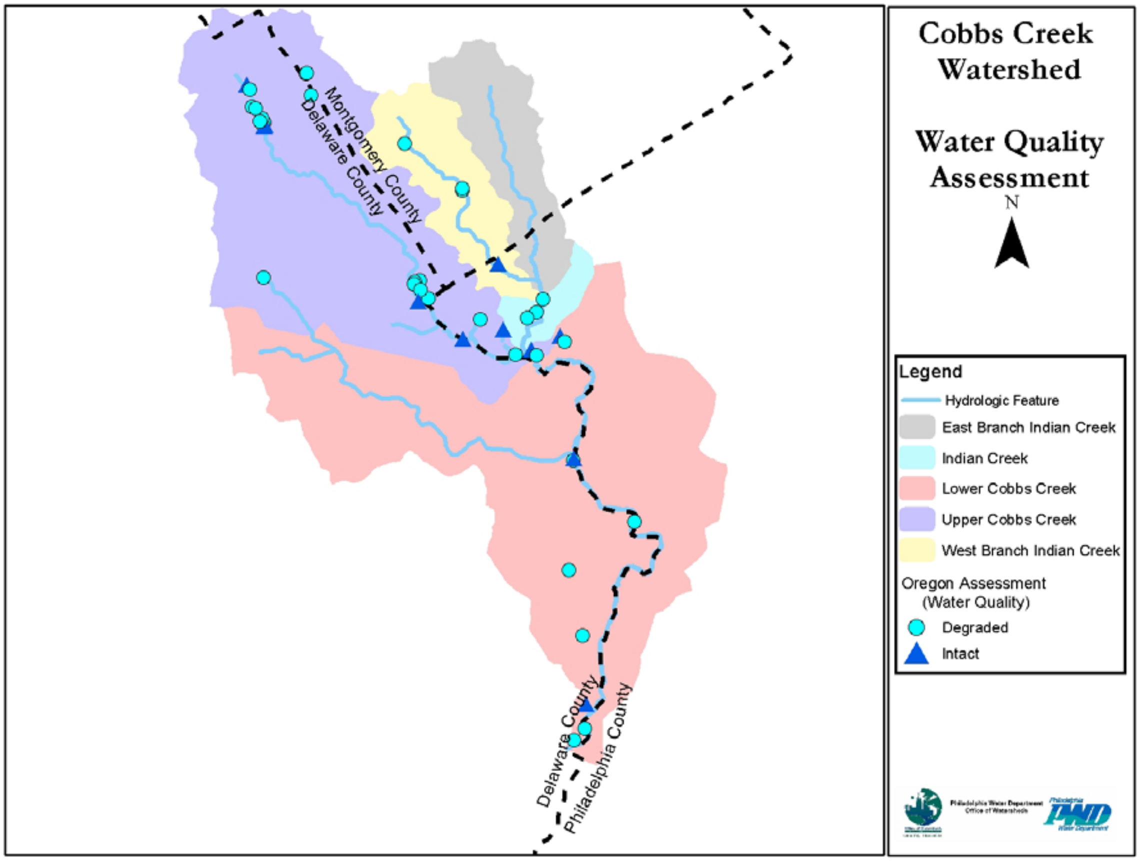

Figure 4-37 Results of Cobbs Creek Wetland Assessments (2002 – 2003)

Indicator 14: Wildlife

Wildlife includes birds, amphibians, and other animals that make their home in the watershed. Quality and diversity of wildlife habitats is also an indicator of watershed quality. Many species have specific habitat requirements. Their presence or absence indicates the health of the habitats. For example, healthy, naturally reproducing amphibian communities indicate the presence appropriate habitats. The red-bellied turtle (Figure 4-38) is one PA listed threatened species found in the watershed.

This indicator measures:

- **Species inventory, identification of any threatened and endangered species**

Figure 4-38 Juvenile Red Bellied Turtle

Where We Were:
There is no historical data available for this indicator.

Where We Are:
A wildlife assessment was completed for Cobbs Creek Park during the “Bio-blitz” in 2001 in which volunteers recorded observed species (Table 4-10). The species of reptiles and amphibians that were found in Cobbs Creek Park were red-backed, northern dusky and two-lined salamanders, snapping and painted turtles, eastern garter, northern water, and brown snakes, and green frogs and bullfrogs. An abundance of several bird species were observed, including Kingbirds, Robins, Catbirds and Chipping Sparrows. No birds or macroinvertebrates that were observed during the Bio-blitz were on the endangered species list. The assessment also determined that Cobbs Creek Park has a low density of deer.

Table 4-10 Species found during 2001 Bio-blitz in Darby-Cobbs Watershed

Birds (72 species)	
Great Blue Heron	Northern Mockingbird
Wood Duck	Brown Thrasher
Mallard Duck	Cedar Waxwing
Cooper's Hawk	European Starling
Red-tailed Hawk	Warbling Vireo
Solitary Sandpiper	Red-eyed Vireo
Spotted Sandpiper	Tennessee Warbler
Rock Dove	Nashville Warbler
Mourning Dove	Northern Parula
Ruby-throated Hummingbird	Yellow Warbler
Chimney Swift	Chestnut-sided Warbler
Red-bellied Woodpecker	Magnolia Warbler
Downy Woodpecker	Black-throated Blue Warbler
Hairy Woodpecker	Yellow-rumped Warbler
Northern Flicker	Black-throated Green Warbler
Eastern Wood-pewee	Blackburnian Warbler
Acadian Flycatcher	Prairie Warbler
Eastern Phoebe	Blackpoll Warbler
Great Crested Flycatcher	Black-and-white Warbler
Eastern Kingbird	American Redstart
Tree Swallow	Ovenbird
Northern Rough-winged Swallow	Northern Waterthrush
Barn Swallow	Mourning Warbler
Blue Jay	Common Yellowthroat
American Crow	Wilson's Warbler
Carolina Chickadee	Canada Warbler
Tufted Titmouse	Scarlet Tanager
White-breasted Nuthatch	Northern Cardinal
Carolina Wren	Indigo Bunting
House Wren	Eastern Towhee
Blue-gray Gnatcatcher	Song Sparrow
Veery	Red-winged Blackbird
Swainson's Thrush	Common Grackle
Wood Thrush	Baltimore Oriole
American Robin	American Goldfinch
Gray Catbird	House Sparrow
Aquatic Macroinvertebrates (12 taxa)	
Mayfly	Sow bugs
Caddisfly	Scuds
Damselfly	Leech
Blackfly	Aquatic Earthworm
Midge	Snails
Cranefly	Crayfish
Reptiles and Amphibians (4 species)	
Bullfrog	Two-lined Salamander
Northern Water Snake	Red-backed Salamander

Indicator 15: Flooding

This indicator measures:

- **Modeled peak flood stage at 3 bridge crossings along lower Cobbs Creek**

Impervious cover and improperly sized or maintained drainage systems in urban watersheds occasionally lead to flooding. Act 167, the Storm Water Management Act of 1978, requires each county in Pennsylvania to prepare and adopt a stormwater management plan for each designated watershed in the county. An official plan provides a mechanism for municipalities to plan for and manage increased runoff associated with possible future development and land use change.

Where We Were:
Frequent, serious flooding has not been a major concern in the Darby-Cobbs watershed. Floodplain mapping studies were conducted by FEMA to establish flood insurance rates for Delaware County in 1993 and for Philadelphia County in 1996. These studies include anecdotal evidence of major flooding during tropical storms. Additional anecdotal evidence is discussed in the Darby Creek River Conservation Plan, prepared by the Darby Creek Valley Association. A number of trouble spots are shown in Figure 4-39, including areas on Cobbs Creek, Naylors Run, Darby and Little Darby Creeks, and Ithan's Run. According to FEMA, flooding at several of these trouble spots may be caused by undersized culverts.

Where We Are:
FEMA studies include stream cross-sections at major road crossings. Figure 4-39 identifies several road crossings where bridge decks are in the 10-year floodplain. As an indicator, 3 cases were chosen where bridge decks along Cobbs Creek Parkway fall within the 10-year floodplain. A simulation was run for a large (3.3 in. total), intense (1.7 in/hr peak) storm on July 21-22, 1988. Table 4-11 indicates that the deck of each bridge was most likely impassable during this storm, which has a return period of about 12 years.

Table 4-11 Peak Flood Stage at 3 Bridges

Trouble Spot	Bridge	Deck Elevation (ft above city datum)	EsrimatedPeak Flood Stage (ft above city datum)
1	Woodland Ave./Main Street (just above 10-yr)	16.4	17.5
3	Cobbs Creek Parkway (below 10-yr)	25.6	27.9
4	Cobbs Creek Parkway (below 10-yr)	25.5	31.1

Figure 4-39 Reported / Estimated Flood-prone Areas

Quality of Life

Indicator 16: Public Understanding and Community Stewardship

Because a connection to the natural world and its waterways is less apparent in some communities of the Darby-Cobbs Watershed, the notion of environmental stewardship does not always top the list of daily priorities for many residents. Stewardship, therefore, must be built around the needs of the community as users of the watershed, as well as by making visible the critical ways the health of the watershed is integral to basic quality of life issues. Once this has been established, members of the community can be recruited to take action in protecting their watershed.
Within this context, citizens need to 1) become aware of the meaning of watershed and the watershed in which they live, 2) become informed about the actions they can take to improve watershed health and 3) move from understanding into action.

Stakeholders are those who care with their minds and hearts because they already understand their vital connection to the environmental health of their community. The watershed stakeholders include state and federal regulators, those whose jobs empower them to guard the quality of our rivers and streams. The stakeholders include all of the municipalities, separate entities on paper yet bound together by nature. The stakeholders include all those others – neighborhood groups, religious groups, schools, groups who define themselves as environmental advocates because their personal priorities demand they place their time there.

This indicator measures:

- **Number of responses to surveys**
- **Number of newspaper stories and letters to the editor about watershed-related issues**
- **Changes in membership in the Darby-Cobbs Watershed Partnership, DCVA, Cobbs Creek Community Environmental Education Center, and other current groups**
- **Number of Environmental Action Committees (EACs)**

Where We Were

A historical baseline has not been established for this indicator. Progress will be assessed next time this plan is updated.

Where We Are

A survey of watershed residents was conducted in 2000 in which there were about 342 respondents. Figure 4-40 shows the number of responses received in each municipality. Figure 4-41 shows the actual responses gauging citizen awareness and concern about watershed issues. Of note, a large proportion (47%) of residents live within 4 blocks of a stream, and many enjoy recreational activities along the stream corridor such as nature walks, picnics, and fishing. 57% of respondents indicated that they are concerned about pollution and would not eat fish from Darby or Cobbs Creeks.

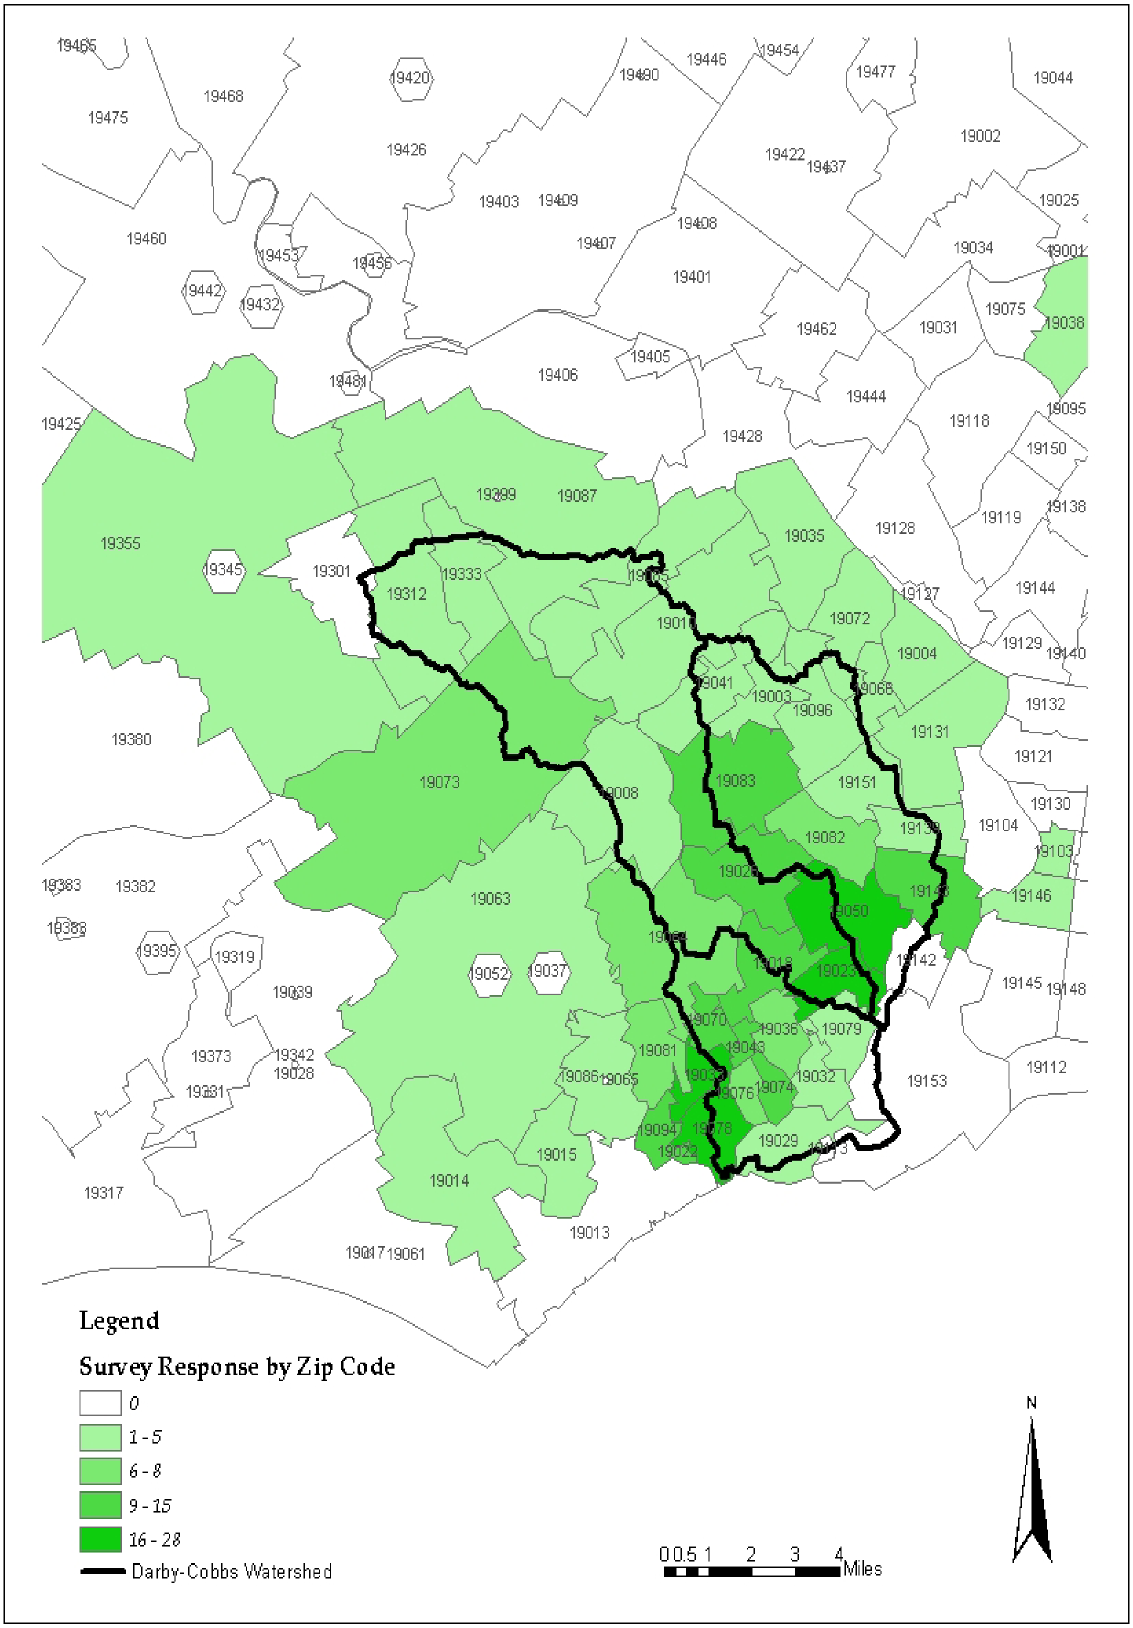

Figure 4-40 Residence Location of Respondents to Darby-Cobbs Watershed Survey

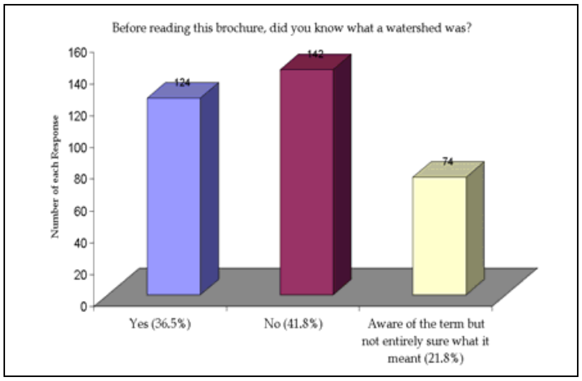
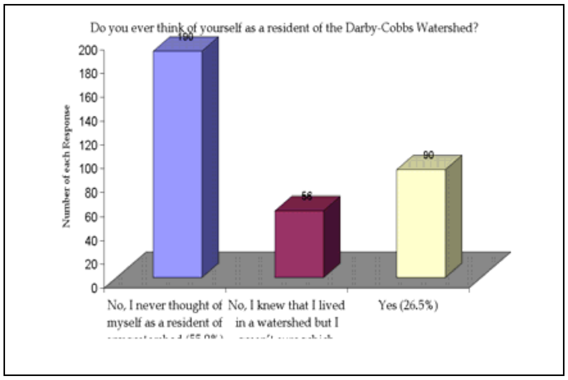
Quality of Life

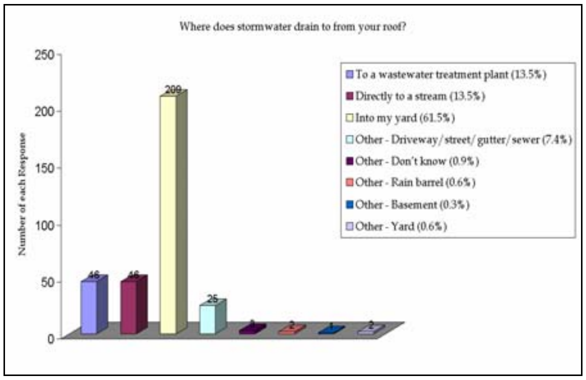
Indicator 16: Public Understanding and Community Stewardship

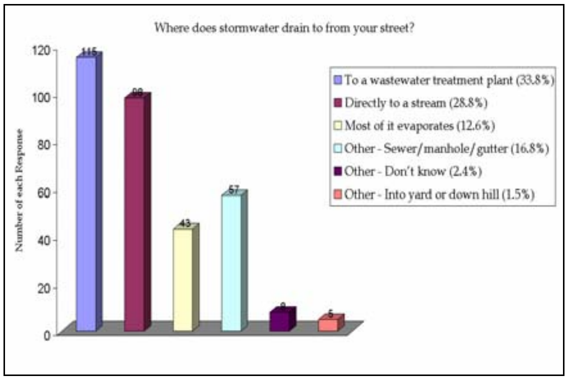
The media greatly influences community perception and may indicate, via public reaction, which events and issues are important to the community. A newspaper clipping survey of articles and letters to the editor in local weekly and daily papers that serve the watershed found nine articles specific to the watershed or the partnership since 2000.

Attendance at meetings held by watershed-related groups is another way to gauge interest among citizens. Eighteen stakeholders consistently attend meetings sponsored by the Partnership, Darby Creek Valley Association (DCVA), Cobbs Creek Community Environmental Education Center (CCCEEC) and other watershed-related forums. Four municipalities in the watershed have municipal appointed Environmental Action Committees (EACs) - Radnor, Marple, Lower Merion, Haverford. Active EACs indicate citizen advocacy for and support of actions needed on the municipal level.









Quality of Life

Indicator 16: Public Understanding and Community Stewardship

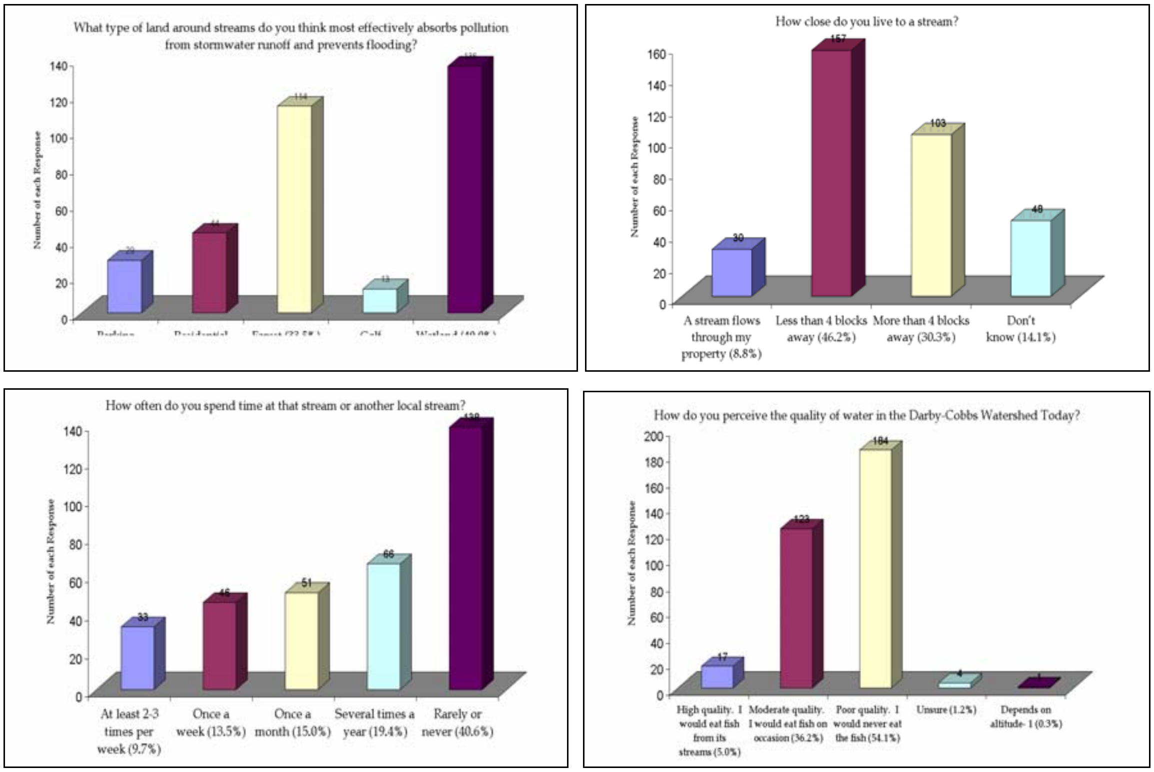


Figure 4-41 Darby - Cobbs Resident Survey Results

Indicator 17: School-Based Education

School aged children of today are the watershed stewards of the future. As such, school based education is an integral component of the long-term health of the watershed. School based education takes many forms, from lesson plans within the classroom, to hands-on activities outside of the classroom such as field trips to Cobbs and Darby creeks and nearby nature centers, as well as actual restoration projects. Teacher training programs, developed to assist teachers in bringing watershed concepts to their students, are critical to bringing watershed education to the students, as are partnership with groups like the Cobbs Creek Community Environmental Education Center and the John Heinz Wildlife Refuge at Tinicum. Being engaged in actual restoration projects, either through service learning, after school clubs, or as part of lesson plans, translates lessons into action. There are several ways to measure the success of school based education programs and each depends on the other.

Figure 4-42 Electrofishing in the Cobbs

This indicator measures:

- **Number of schools that have environmental or watershed management curricula**
- **Number of teachers trained through the Darby-Cobbs Teacher Training Program**
- **Number of schools participating in programs sponsored by the Cobbs Creek Community Environmental Education Center**

Where We Were
A historical baseline has not been established for this indicator. Progress will be assessed next time this plan is updated.

Where We Are
To date, 11 schools have interactive – incorporating lesson plans with hands on activities - environmental or watershed management curricula, including participation in the Earth Force Program. The schools are Turner Middle School (Phila.), Friends Central (Wynnewood), Nativity BVM (Media), St. Gabriel (Folsom), Pennwood JH, Beverly Hills MS (Phila), Sayre MS (Phila.), St. Cyprian (Phila.), Shaw MS (Phila.), Pepper MS (Phila.), Patterson ES. Forty-eight schools participate in programs sponsored by the Cobbs Creek Community Environmental Education Center.

With the creation of the Darby Cobbs Watershed Partnership, an opportunity arose to incorporate the concepts of an urban watershed environment into school-based curricula to better instruct students in pollution prevention concepts and stormwater runoff quantity issues within their neighborhoods. With the assistance of a Growing Greener grant, the Partnership developed a Darby-Cobbs Watershed Teacher Training program. Twenty teachers from various reaches of the watershed participated in five Saturday workshops, beginning in December of 2000 and ending in May 2001, built around the following modules: watershed management, stormwater management, water quality, ecological restoration, and a workshop session to develop service projects. Each session was taught through a combination of classroom and field experience.

Additionally, the new Academic Standards for Science and Technology and Environment and Ecology became a core requirement of the public school curriculum in January 2002 and testing on these topics commenced for the first time in spring 2003 as part of the PSSA. The standards establish the basic elements of what students should know and be able to accomplish at the end of grades four, seven, 10 and 12. Section 4.1 of these standards is dedicated to watersheds and wetlands. Goals for this topic area are for students to gain knowledge about water cycles, role of watersheds, physical factors, characteristics and functions of wetlands and impacts of watersheds and wetlands. A scope and sequence has been predetermined for each of the aforementioned grades.

Indicator 18: Recreational Use and Aesthetics

People seem to be innately drawn to water and areas of natural beauty. Not surprisingly then, park and recreational areas are often centered on scenic water features, such as lakes or rivers. Indeed, many acres of parkland are already developed along the Darby and Cobbs Creeks. However, many miles of Cobbs Creek are not accessible to the public. If the public has no way to get to a particular stream, it is less likely to be enjoyed. Parks, and the waterways that flow through them, serve many functions, some obvious and others unseen. For instance, parks and waterways are areas of active and passive recreation. Active recreation includes football, baseball, and canoeing, while passive recreation implies areas intended for quiet contemplation or conversation, an essential respite from the concrete and asphalt of the urban world. Natural amenities, when protected and preserved, elevate the quality of life for residents by providing a myriad of recreational, educational and other activities, in addition to enhancing the market value of homes and institutions.

This indicator measures:

- **Stream accessibility score for Cobbs Creek and tributaries**
- **Tons of trash removed from creek and buffer area**

Where We Were

A historical baseline has not been established for this indicator. Progress will be assessed next time this plan is updated.

Where We Are

An accessibility indicator was developed to determine the degree to which a community is able to reach their waterways (Table 4-12 and Figure 4-43). Accessibility was determined on a scale from 0 through 5, with zero representing a particular segment of stream that is inaccessible and 5 representing a completely accessible stream segment. The greater the availability of parking, trails, and public recreational land adjacent to the stream, the higher the accessibility rating. A segment of stream running through a private, industrial, or commercial site was given a rating of 0. A segment of stream running through a public park that has parking and trails leading to the stream was given an accessibility rating of 5. The number of stream miles and the percentage of the total stream miles with each particular accessibility rating were calculated. 1/3 of the waterways within the Cobbs watershed were given a rating of completely accessible. An additional 1/3 of the stream miles were rated as somewhat accessible.

Table 4-12 Accessibility by Stream Miles

Accessibility	Description	Length (Stream Miles)	% Of Stream Miles
0	Not Accessible	0.61	3%
1	Minimally Accessible	5.18	22%
2	Moderately Accessible	1.50	6%
3	Somewhat Accessible	8.06	34%
4	Highly Accessible	0.52	2%
5	Completely Accessible	7.81	33%

Maintenance records indicate that 26 tons of trash and debris have been removed from creeks and riparian buffer areas in Cobbs Creek and its parks between July and December 2003 by the Water Department's Waterways Restoration Team (WRT). The WRT is dedicated to removing large trash and debris – cars, appliances, shopping carts, from our streams in addition to restoring streambanks and streambeds that have been eroded as a result of pipe outfalls. The WRT partners on clean up and restoration efforts with the Fairmount Park Commission, CCCEEC and dedicated volunteers. A common vision is shared by all – to restore the grandeur and beauty of Cobbs Creek for the enjoyment of all residents.

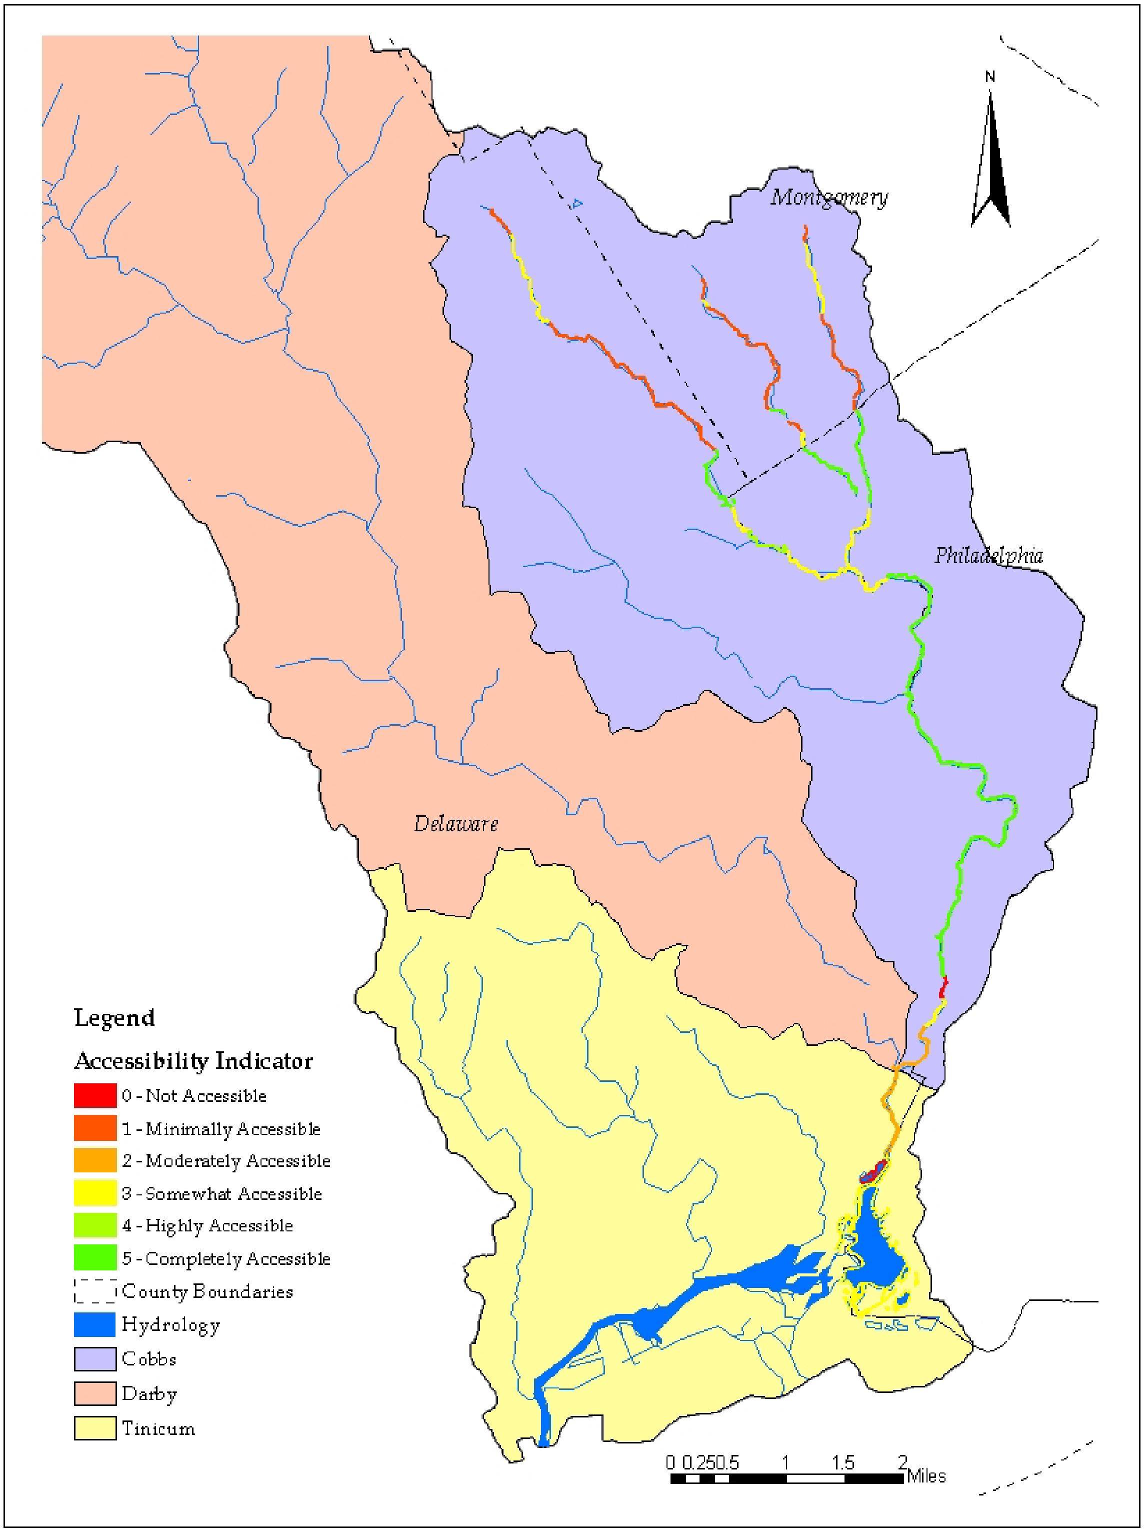

Figure 4-43 Stream Accessibility and Parks in Cobbs Creek Watershed (2003)

Indicator 19: Local Government Stewardship

Local government leadership is essential to ensuring that improvements made under watershed restoration planning are sustainable. Local governments must also support, encourage and complement the stewardship efforts of individuals, environmental groups, and businesses. A major goal is for local governments to work within their regulatory and statutory obligations while actively supporting the stewardship efforts within the watershed. It is also important that local governments implement voluntary actions to restore the watershed. Most importantly, to ensure the success of the watershed management plan, each local government within the watershed must embrace the goals and implementation strategies of the plan. A formal adoption of this plan would multiply its chance for success tremendously.

This indicator measures:

- **Municipalities participating in watershed-related surveys and having up-to-date sewage facilities plans**

Where We Were

A historical baseline has not been established for this indicator. Progress will be assessed next time this plan is updated.

Where We Are

Figure 4-44 shows the municipalities in the Darby-Cobbs watershed. For each municipality, responses have been tabulated (Table 4-13) for several surveys and requests. Sixteen of 44 jurisdictions (including municipalities, townships, boroughs and counties) have signed the Darby-Cobbs Resolution drafted by the Partnership. Five municipalities responded to a survey as part of the Darby Creek River Conservation Plan (RCP), while seven responded to a request letter. Approximately half of municipalities have responded to a survey under the Act 167 Storm Water Planning program. Legally, all municipalities have an Act 537 Plan, a plan that provides for the resolution of existing sewage disposal problems, future sewage disposal needs of new land development and future sewage disposal needs of the municipality. However, some plans are newer and more detailed than others.

Indicator 20: Business and Institutional Stewardship

Awareness is growing regarding the role of businesses and institutions in watershed degradation and restoration. Success of the watershed management plan will require stewardship on the part of stakeholders who represent the diversity of land uses in the watershed, including conservation groups, commercial, industrial, institutional and residential users. The goal of the Partnership is to have a proportional representation of these groups.

This indicator measures:

- **Number of businesses represented at Partnership meetings as a percentage of all citizens and organization present.**

Where We Were

A historical baseline has not been established for this indicator. Progress will be assessed next time this plan is updated.

Where We Are

Figure 4-45 shows the number of representatives of each type of group that have attended Partnership meetings. To date, 6 business representatives have attended, representing 2% of the total.

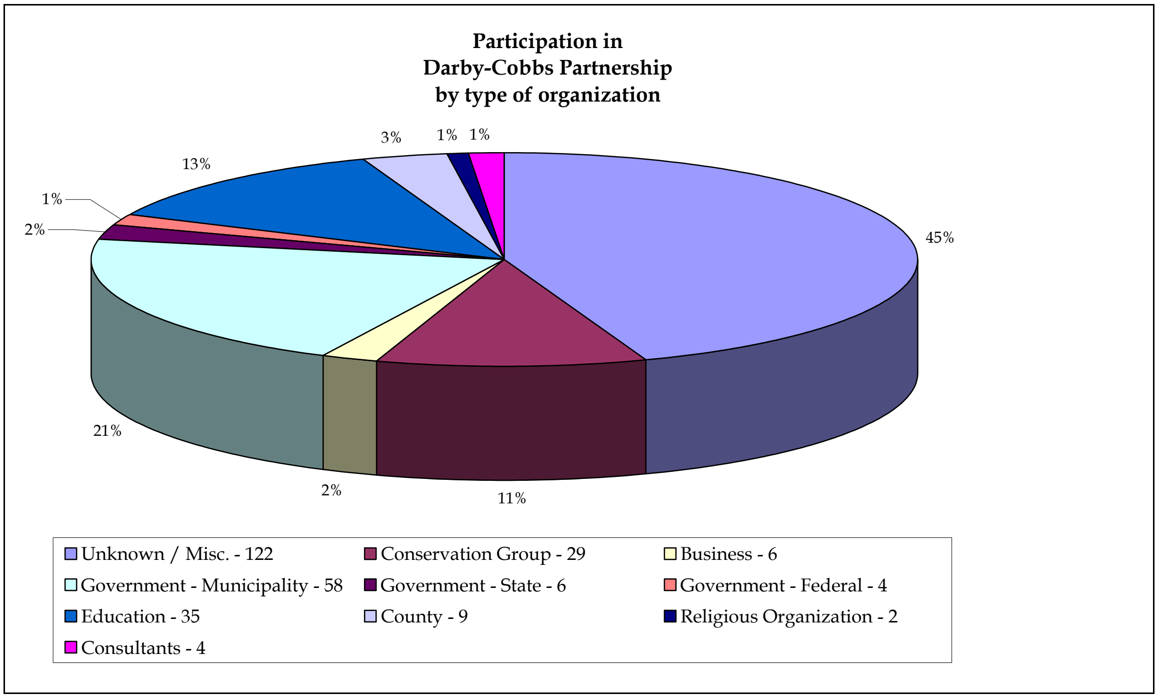

Figure 4-45 Distribution of Partnership Members' Affiliations (2003)

Indicator 21: Cultural and Historic Resources

Waterways have always been cradles of civilization, providing, among many things, a means of travel and rich floodplain soils in which to cultivate crops. Much later, waterways provided power for mills and fueled the beginnings of the industrial revolution. Consequently, historical and cultural resources are often concentrated in and along waterways. These resources enable us to better understand and appreciate different cultures and traditions, to recognize the struggles endured by our ancestors, and to comprehend the technologies of past generations. These cultural and historical resources can also be an invaluable tool to inform our understanding of our present conditions. Cultural and historic resources in the Darby-Cobbs watershed have been tabulated by DCVA in the Darby Creek River Conservation Plan.

This indicator measures:
- **National Register of Historic Places inventory**
- **Number of communities with historical management programs**
- **Number of nonprofit historical/cultural management organizations**

Where We Were
A historical baseline has not been established for this indicator. Progress will be assessed next time this plan is updated.

Where We Are
Figure 4-46 shows the locations of historic sites identified by the RCP planning process. A total of 171 sites were identified. Additionally, the RCP identifies 14 historical societies and commissions at the local level, four at the county level, and three located in Philadelphia. The RCP details many of the historically significant sites and structures.

Quality of Life

Indicator 21: Cultural and Historic Resources

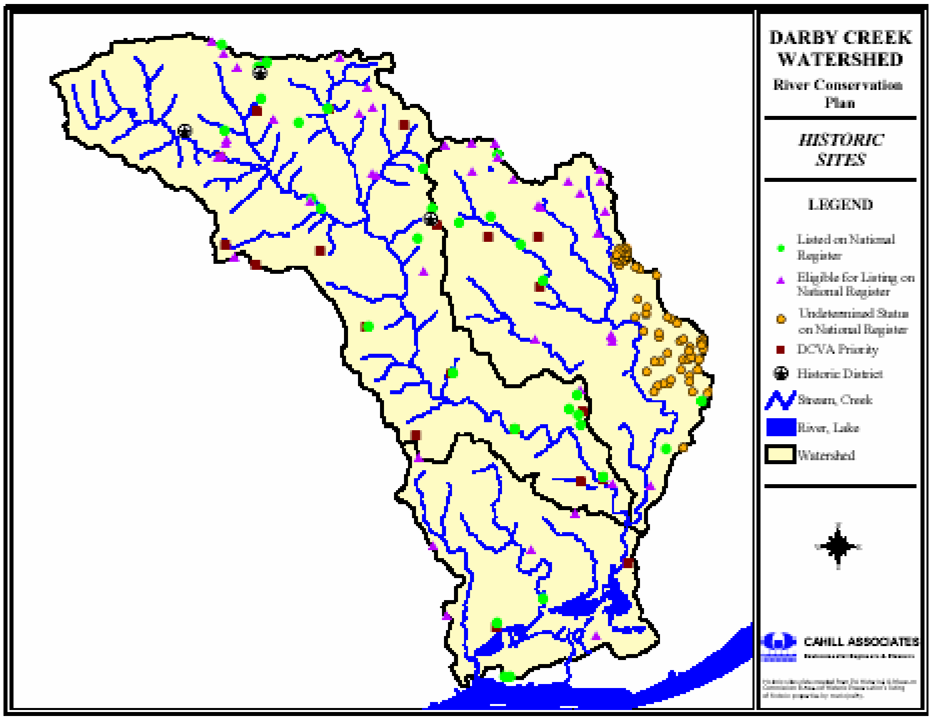

Figure 4-46 Historic Sites Identified in the RCP (2003)

Section 5: Development and Screening of Management Options

5.1 Menu of Options

This section summarizes a comprehensive list of stormwater and watershed management options that the Darby-Cobbs Watershed Partnership thinks may be applicable in the Cobbs watershed. This list serves as the starting point for the screening (Section 5) and evaluation (Section 6) steps that lead to the recommendations contained in the implementation guidance in Section 7. A large amount of detailed information on these options is available from existing sources. Rather than reproducing this information, this section provides references and links to these sources. The options are grouped under the three targets introduced in Section 2:

Target A: Dry Weather Water Quality and Aesthetics
- Regulatory Approaches
- Public Education and Volunteer Programs
- Municipal Measures
- Enhancing Stream Corridor Recreational and Cultural Resources
- Monitoring and Reporting

Target B: Healthy Living Resources
- Channel Stability and Aquatic Habitat Restoration
- Lowland Restoration and Enhancement
- Upland Restoration and Enhancement
- Monitoring and Reporting

Target C: Wet Weather Water Quality and Quantity
- Regulatory Approaches
- Public Education and Volunteer Programs
- Municipal Measures
- Stormwater Management
- Monitoring and Reporting

Target A

Target A is defined for Cobbs Creek as focusing on trash removal and litter prevention, and the elimination of sources of sewage during dry weather. Streams should be aesthetically appealing (look and smell good), accessible to the public, and be an amenity to the community.

Regulatory Approaches

AR1	On-Lot Disposal (Septic System) Management
AR2	Pet Waste, Litter, and Dumping Ordinances

These typical pollution reduction and aesthetic ordinances are already in effect in most locations, and can be effective at controlling diffuse sources of pollutants. They are particularly important in urban watersheds; however, they must be consistently enforced to be effective.

Public Education and Volunteer Programs

AP1 Public Education
AP2 School-Based Education
AP3 Public Participation and Volunteer Programs

Municipal Measures

AM1 Capacity Management Operation and Maintenance (CMOM)
AM2 Inspection and Cleaning of Combined Sewers
AM3 Sanitary Sewer Rehabilitation
AM4 Combined Sewer Rehabilitation
AM5 Illicit Discharge, Detection, and Elimination (IDD&E)
AM6 Stream Cleanup and Maintenance
AM7 Household Hazardous Waste Collection

AO1 Enhancing Stream Corridor Recreational and Cultural Resources

AMR Monitoring and Reporting

AO1 - Enhancing Stream Corridor Recreational and Cultural Resources
Preservation and enhancement of recreational and cultural resources may be integrated into comprehensive watershed management. These resources are part of the link between the human population and natural resources in a watershed. Strategies to provide access to water resources for recreational purposes encourage appreciation for and stewardship of these areas. Strategies to protect water-based historic structures should be implemented to insure that flooding and other impacts are avoided.

AMR - Monitoring and Reporting
Monitoring and reporting under Target A include monitoring of progress toward achievement of objectives (as measured by indicators) and monitoring of implementation of recommended management measures. For example, indicator 18 measures the tons of trash removed from streams and riparian areas (a measure of option implementation) and derives a stream accessibility score for reaches of the Creek (a measure of progress toward an objective).

Target B

Improving the ability of an urban stream to support viable habitat and fish populations focuses primarily on remediating the more obvious impacts of urbanization on the stream. These impacts include loss of riparian habitat, eroding and undercut banks, scoured streambed or excessive sediment deposits, channelized and armored stream sections, and invasive species. The primary tool to address these problems is stream restoration. Restoration focuses on improving channel stability, improving instream and riparian habitat, providing refuge that allows fish to avoid high velocity conditions during storms, and managing land within the stream corridor.

Channel Stability and Aquatic Habitat Restoration

BM1 Bed Stabilization and Habitat Restoration
BM2 Bank Stabilization and Habitat Restoration
BM3 Channel Realignment and Relocation
BM4 Plunge Pool Removal
BM5 Improvement of Fish Passage

Lowland Restoration and Enhancement

BM6 Wetland Creation
BM7 Invasive Species Management

Upland Restoration and Enhancement

BM8 Biofiltration
BM9 Reforestation

BMR Monitoring and Reporting

Many of the stresses faced by aquatic life in urban streams are the result of alternating extremes of high and low flow, and sediment scour and deposition. While stormwater BMPs that promote infiltration do help to reduce these extremes, a recent modeling analysis conducted by PWD indicates that impervious cover would have to be reduced by half or more to have a significant effect. This result indicates that stream restoration measures may be a more feasible means of improving the aquatic habitat in the short term. Modern design techniques may create areas of reduced velocity where aquatic life is protected during high flow. Techniques appropriate to our area are summarized in "Guidelines for Natural Stream Channel Design for Pennsylvania Waterways", by the Alliance for the Chesapeake Bay in March 2003. This publication is available online at http://www.acb-online.org/toolkits.cfm.

The Darby and Cobbs Creeks and their tributaries have numerous low dams that impede fish migration. As part of a stream channel and habitat restoration program, some of these dams may need to be modified or fitted with fish ladders to restore natural migratory patterns.

BMR - Monitoring and Reporting

Monitoring and reporting under Target B includes monitoring of progress toward achievement of objectives (as measured by indicators) and monitoring of implementation of recommended management measures. For example, Indicator 3 measures the channel condition and trend for each reach of the stream. This indicator is both a measure of implementation and a measure of progress toward the goal of reducing streambank and stream channel deposition and scour to protect and restore the natural functions of aquatic habitat and ecosystems, streambanks, and stream channels.

Target C

The third target is to restore water quality to meet fishable and swimmable criteria during wet weather. A comprehensive watershed management approach also must address flooding issues.

Regulatory Approaches

Zoning and Land Use Control

- *CR1* Requiring Better Site Design in New Development
    - Open Space Preservation Plan
    - Stream Buffer/Corridor Protection Ordinance
    - Wetlands Protection Ordinance
    - Steep Slope Ordinance
    - Cluster Development Ordinance
    - Transfer of Development Rights Ordinance
- *CR2* Requiring Better Site Design in Redevelopment (may include options in CR1)

CR3 Stormwater and Floodplain Management
CR4 Industrial Stormwater Pollution Prevention
CR5 Construction Stormwater Pollution Prevention
CR6 Post-construction Stormwater Runoff Management
CR7 Pollution Trading
CR8 Use Review and Attainability Analysis
CR9 Watershed-Based Permitting

The regulatory authority for controlling land use is vested in the municipalities through their ability to develop ordinances that regulate zoning and development practices. In areas that are undergoing development pressures, these ordinances are some of the most effective tools for watershed protection. In fully developed, urban watersheds such as the Cobbs Creek watershed, they are less effective, needed primarily to help improve conditions in areas that are re-developing.

A variety of approaches to environmentally responsible land use controls have been developed in recent years, and some are being implemented in the areas adjacent to Philadelphia that are undergoing rapid development. The Delaware Valley Regional Planning Commission (DVRPC) has collected information on these practices and local applications on their web site at http://www.dvrpc.org/planning/protectiontools.htm.

<u>*CR3* - Stormwater and Floodplain Management</u>

Ordinances that are important in both developing and developed areas deal directly with the way that stormwater is handled and floodplains are developed or re-developed. Municipal ordinances for stormwater and floodplain management should be consistent with the "Comprehensive Stormwater Management Policy" (Document 392-0300-002) released by PADEP in September 2002. This policy is intended "to more fully integrate post-construction stormwater planning requirements, emphasizing the use of ground water infiltration and volume and rate control best management practices (BMPs), into the existing NPDES permitting programs and the Stormwater Management Act ('Act 167') Planning Program." This policy and a draft model ordinance are available on the PADEP's web site at http://www.dep.state.pa.us/dep/deputate/watermgt/wc/subjects/stormwatermanagement.htm.

<u>*CR4* - Industrial Stormwater Pollution Prevention</u>

- Good Housekeeping
- Preventive Maintenance
- Visual Inspections
- Spill Prevention and Response
- Sediment and Erosion Control
- Employee Training
- Record Keeping and Reporting
- Fueling
- Maintaining Vehicles and Equipment
- Painting Vehicles and Equipment
- Washing Vehicles and Equipment
- Loading and Unloading Materials
- Liquid Storage in Above-Ground Tanks
- Industrial Waste Management and Outside Manufacturing
- Outside Storage of Raw Materials, By-Products, or Finished Products
- Salt Storage
- Flow Diversion
- Exposure Minimization Structures (dikes, drains, etc.)
- Erosion Prevention and Sediment Control
- Infiltration Practices

Detailed guidance on these industrial measures is available in EPA publication 832-R-92-006, "Storm Water Management for Industrial Activities: Developing Pollution Prevention Plans and Best Management Practices", released in September 1992. Municipalities may choose to adopt more stringent controls at the local level, or may work with state authorities to enforce the existing requirements. These measures are also appropriate for commercial and government operations involved in similar activities. The publication mentioned above is available online at http://www.epa.gov/clariton/clhtml/pubtitleOW.html.

CR5 - Construction Stormwater Pollution Prevention

- Sediment and Erosion Control Practices
- Good Housekeeping
- Waste Disposal
- Minimizing Offsite Vehicle Tracking of Sediments
- Sanitary/Septic Disposal
- Material Management
- Spill Response
- Control of Allowable Non-Stormwater Discharges
- Maintenance and Inspection
- Stormwater Management

Detailed guidance on these measures is available in EPA publication 832-R-92-005, "Storm Water Management for Construction Activities: Developing Pollution Prevention Plans and Best Management Practices", released in September 1992. Municipalities may choose to adopt more stringent controls at the local level, or may work with state authorities to enforce the existing requirements. These measures are also appropriate for commercial and government operations involved in similar activities. The publication mentioned above is available online at http://www.epa.gov/clariton/clhtml/pubtitleOW.html.

CR6 - Post-construction Stormwater Runoff Management

Post-construction Stormwater Runoff Management is part of the NPDES Phase 2 stormwater management plan.

CR7 - Pollution Trading

USEPA is exploring market-based measures as a way of reaching targeted overall pollutant load reductions in a watershed. EPA's "Final Water Quality Trading Policy" was released on January 13, 2003, and may be accessed at http://www.epa.gov/owow/watershed/trading/tradingpolicy.html. As this policy is adopted by the states and incorporated in regulations, it may increase incentives for cooperation and coordination between the municipalities and counties that share a watershed.

CR8 - Use Review and Attainability Analysis

USEPA provides procedures for reviewing the applicability and attainability of designated uses. This process may be appropriate for urban watersheds like the Cobbs. EPA document 833-R-01-002, "Coordinating CSO Long-Term Planning with Water Quality Standards Reviews", provides a framework for the process in areas served by combined sewers. This document is available on the EPA web site at http://cfpub.epa.gov/npdes/cso/guidedocs.cfm.

CR9 - Watershed-Based Permitting

A holistic watershed management approach provides a framework for addressing all stressors within a hydrologically defined drainage basin instead of viewing individual sources in isolation. Within a broader watershed management system, the watershed-based permitting approach is a tool that can assist with implementation activities. The utility of this tool relies heavily on a detailed, integrated and inclusive watershed planning process. Watershed planning includes monitoring and assessment activities that generate the data necessary for clear watershed goals to be established and permits to be designed to specifically address the goals. The policy statement and implementation guidance are available on the EPA's web site at http://cfpub.epa.gov/npdes/wqbasedpermitting/wspermitting.cfm

Public Education

CP1 Public Education and Volunteer Programs

Municipal Measures

CM1 Sanitary Sewer Overflow Detection
CM2 Sanitary Sewer Overflow Elimination: Structural Measures
CM3 Reduction of Stormwater Inflow and Infiltration to Sanitary Sewers
CM4 Combined Sewer Overflow (CSO) Control Program
  - Nine Minimum Controls
  - Long Term CSO Control Plan
  - Watershed-Based Planning

CM5 Catch Basin and Storm Inlet Maintenance
CM6 Street Sweeping
CM7 Responsible Landscaping Practices on Public Lands
CM8 Household Hazardous Waste Collection
CM9 Responsible Bridge and Roadway Maintenance

The first three measures above apply primarily to municipalities with separate sanitary sewer systems. The second, reduction of sanitary sewer overflow, is believed to be of critical importance in the Darby-Cobbs watershed. Inspection, cleaning, and when necessary, rehabilitation of aging sanitary sewers may be the single most important pollution reduction measures that should be implemented immediately in this watershed. Reduction of pollutant loads due to stormwater may be of secondary importance if significant loads are being introduced by sanitary sewage.

Structural Stormwater Management Facilities

Detailed information on structural BMPs for stormwater management is available in existing BMP manuals and is not reproduced here. Links to many of these manuals are available in Appendix A of the PADEP's Comprehensive Stormwater Management Policy (see link provided earlier in this document), and three are reproduced below:

Center for Watershed Protection Stormwater Manager's Resource Center

Stormwater Management

Source Control Measures

CS1	Reducing Effective Impervious Cover Through Better Site Design
CS2	Increasing Urban Tree Canopy
CS3	Porous Pavement and Subsurface Storage
CS4	Green Rooftops
CS5	Capturing Roof Runoff in Rain Barrels or Cisterns

The first measure, reducing effective impervious cover, refers to a variety of measures, including encouraging homeowners to reduce the size of paved areas on their properties. Porous pavement is an alternative to reduction of paved areas. Rooftops represent a large proportion of the impervious area in highly urbanized watersheds such as the Cobbs; constructing rooftop gardens over public and private buildings can be an effective structural measure to reduce urban runoff. This technology is catching on slowly in the United States, but there are some examples in our area.

Rain barrel programs are being sponsored by watershed partnerships in the greater Philadelphia area. Rain barrels are inexpensive but need to be implemented throughout a watershed to be effective as a runoff reduction measure. It is also important that their owners are properly trained and committed to operate and maintain them. Cisterns are similar to rain barrels in function; they also must be drained on a regular basis to provide effective stormwater control.

Tree planting and urban reforestation programs provide hydrologic benefits in addition to quality of life improvements. Leaf surfaces intercept some rainfall that might otherwise fall on impervious surfaces. The rainfall then either evaporates or is conveyed more slowly to the ground along plant stems and trunks.

Municipalities have the opportunity to provide incentives for private landowners to implement these innovative measures through ordinances, tax advantages, or a stormwater fee linked to impervious cover.

Onsite and Regional Stormwater Control Facilities

CS6	Maintaining/Retrofitting Existing Stormwater Structures
CS7	Modifying Catch Basins to Delay Stormwater Inflow
CS8	Retrofit of Existing Sewer Inlets With Dry Wells
CS9	Residential Dry Wells, Seepage Trenches, and Water Gardens
CS10	Infiltration Basins
CS11	Vegetated Swales and Open Channels
CS12	Bioretention Basins and Porous Media Filtration
CS13	Treatment Wetlands: Onsite and Regional
CS14	Dry Detention Basins
CS15	Wet Retention Basins
CS16	BMPs for Highway Runoff (may include various structural options in this list)

The options above are documented in the state manuals. Most of them may be implemented on the small scale of an individual property. Residential dry wells are an inexpensive way to infiltrate residential roof runoff and provide a benefit distributed over the watershed. Infiltration basins are similar but typically used on a larger scale requiring more land. Porous media filters and bioretention basins are most often used to detain, treat, and infiltrate parking lot runoff. Water gardens are similar to bioretention and can be implemented in backyards or public land such as school grounds. Proper design and maintenance, along with an effective public relations campaign, can alleviate typical concerns about mosquito control and basement flooding.

Retrofit of existing sewer inlets with dry wells is an innovative option that, while expensive, may be attractive in a completely urbanized area with very little land available for traditional BMPs. Using this technology, existing catch basins are retrofitted to provide some measure of storage and infiltration; with full implementation and favorable soil conditions, the resulting outflows may resemble the pre-development condition. The City of Portland, Oregon has implemented this approach and has provided some documentation in its Stormwater Management Manual (http://www.cleanrivers-pdx.org/tech_resources/2002_swmm.htm).

Dry detention and wet retention basins are traditional BMPs that typically provide detention and treatment functions but only limited infiltration. Their design is extensively documented in the state manuals. Constructed wetlands, either on-site or regional, provide similar detention and treatment functions; in addition, they may provide a cooling function and removal of some stormwater through evapotranspiration.

CMR - Monitoring and Reporting

Monitoring and reporting under Target C includes monitoring of progress toward achievement of objectives (as measured by indicators) and monitoring of implementation of recommended management measures. For example, indicator 7 measures the percent of water quality samples where the state fecal coliform standard is met. This indicator is a measure of progress toward the goal of improved water quality in wet weather.

5.2 Screening of Options

The extensive lists of management options described in the previous section were developed to meet each of the goals and objectives established for the Cobbs Creek watershed. Only those options deemed feasible and practical, however, were considered in the final list of management options. To identify these applicable options required a two-step evaluation.

Initial Screening. Some options could be eliminated as impractical for reasons of cost, space required, or other considerations. Options that were already being implemented, were mandated by one of the programs, or were agreed to be vital, were identified for definite implementation. The remaining options had to be screened for applicability to Cobbs Creek. This was done by developing a database and creating every possible combination of options, as described below.

Detailed Evaluation of Structural Options. Structural best management practices for stormwater and combined sewage were subjected to a more rigorous modeling analysis. Effects on runoff volume, overflow volume, peak stream velocity, and pollutant loads were evaluated at various levels of coverage. This is described in section 5.3

Table 5-1 lists the options chosen for each evaluation step.

Screening Methodology

Many of the options described above are appropriate to the Cobbs and did not require further evaluation or screening. Others, such as regulatory approaches for areas with new development were eliminated because the potential for new development in the watershed is limited, with the exception of the low-impact design (LID) techniques that can be adapted to redevelopment in urbanized areas. Eventually, the list was consolidated to 21 options that required more sophisticated analysis to test their appropriateness to the Cobbs Creek watershed (Table 5-2). It was decided that a semi-quantitative analysis based on cost-effectiveness would be appropriate, but the analysis should consider not just the cost-effectiveness of the individual option, but also the cost-effectiveness of the options in combination with each other. Thus, an initial screening approach for the 21 options was devised to examine the cost effectiveness of each option for controlling stormwater using an automated database approach.

Table 5-2 Options Chosen for Initial Screening

CR1	Requiring Better Site Design in New Development
CM8	Household Hazardous Waste Collection
CR7	Pollution Trading
CR8	Use Review and Attainability Analysis
CS1	Reducing Effective Impervious Cover through Better Site Design
CS2	Porous Pavement and Subsurface Storage
CS3	Green Rooftops
CS4	Capturing Roof Runoff in Rain Barrels or Cisterns
CM4-1	Increasing Size of Sewer Pipes (1 sub-option of CSO control program)
CM4-2	Structural CSO Storage Facilities (1 sub-option of CSO control program)
CS6	Maintaining/Retrofitting Existing Stormwater Structures
CS8	Retrofitting of Existing Sewer Inlets with Dry Wells
CS7	Modifying Catch Basins to Delay Stormwater Inflow
CS14	Dry Detention Basins
CS15	Wet Retention Basins
CS9	Residential Dry Wells and Seepage Trenches
CS10	Infiltration Basins
CS11	Vegetated Swales and Open Channels
CS12	Bioretention Basins and Porous Media Filtration
CS9	Water Gardens
CS13	Treatment Wetlands: Onsite and Regional

With 21 options under consideration, there are over 1 million ways in which the options can be combined, and it is not readily apparent whether certain combinations are better or worse than others when looking at their ability to meet the planning objectives in a cost-effective manner. Therefore, a computer program was written that worked through each possible combination. The program assigned qualitative cost and effectiveness scores to each option, determined the normalized cost and effectiveness of both individual options and all possible combinations, and tallied a final score as the ratio of effectiveness to cost. In this way, all the combinations were compared to each other in a consistent pattern.

To perform this screening, a cost algorithm was first developed to make an initial, qualitative assessment of the cost of each option. This assessment was taken as the cost of a realistic level of coverage (e.g., fitting 25% of all households with rain barrels may be a realistic goal but fitting 100% is not a realistic goal). A qualitative cost was developed for each option. The cost was given a score of 0 to 3 based on land acquisition, construction, and total salary as shown below.

Criteria for Assigning Initial Cost Classification

Cost	Description
High (3)	significant urban construction involved; or significant land acquisition required
Medium (2)	light construction involved; or field crew needed on a regular basis
Low (1)	non-structural; covered by existing staff salaries

The effectiveness of each option was scored on a similar scale based on the impact it has on short and long term goals as shown below.

Criteria for Assigning Initial Effectiveness Classification

Cost	Description
High (3)	may help meet one or more objectives in short term; instrumental in meeting objectives in long term
Medium (2)	leads to progress in short term, instrumental in meeting objectives in long term
Low (1)	does not lead to progress in short term; leads to limited progress in long term
None (0)	does not apply to a particular goal

Each option was then assigned a single cost-effectiveness score based on the difference or ratio of total effectiveness to total cost. Goal weighting factors were used to balance the relative magnitude of the effectiveness and cost scores. The weighting of these options was discussed in Section 3.

Once each option was assigned a cost effectiveness score they were placed in an alternative scenario with other options. The number of options in each alternative can vary from 1 option to all the options (21). The computer program created all possible combinations of 1 through 21 options, with each combination considered a unique "potential alternative". The following example illustrates the possible alternatives in a simplified case with three goals and three options.

	Effectiveness			Cost
	Goal 1	Goal 2	Goal 3	
Goal Priority	50%	30%	20%	
Option A	2	0	2	1
Option B	0	1	3	2
Option C	0	3	1	3

Possible Alternatives:
A, B, C
AB, AC, BC
ABC

The effectiveness score of an alternative was defined as the sum of option cost-effectiveness scores, weighted by objective priority:

$$E_{ABC} = E_{A1P1} + E_{A2P2} + E_{A3P3} + E_{B1P1} + E_{B2P2} + E_{B3P3} + E_{C1P1} + E_{C2P2} + E_{C3P3}$$

$$C_{ABC} = C_A + C_B + C_C$$

With: E = Effectiveness, C = Cost, and P = Priority. The subscripts denote options and goals; for example, E_{A1} is the effectiveness of option A with respect to goal 1.

Thus, E_{ABC} represents a simple way to measure the effectiveness of the combination of options a, b and c. C_{ABC} is the combined cost of options a, b and c.

The computerized analysis was not intended to provide a definitive answer on which options should or should not be included in the implementation plan. Rather, it was designed to provide insight into options that appear promising, and that appear to combine well with other options. Figure 5-1 shows the results of the cost effectiveness analysis for each option if installed on its own. The normalized scores (0 to 1) represent relative effectiveness at meeting goals (e.g., decreasing stormwater flows, increasing habitat), and cost to build. Cost-effective options are those with a high effectiveness score and a low cost score.

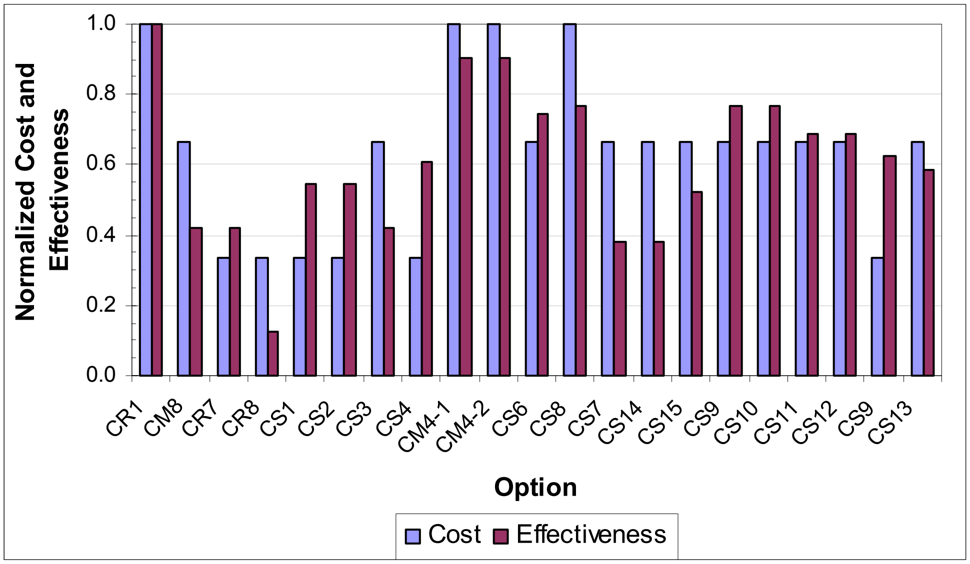

Figure 5-1 Cost–Effectiveness of Individual Options

Figure 5-2 attempts to assess the effectiveness of an option in combination with other options. The bars represent the results of the computerized analysis of all possible option combinations (over one million) by charting the earliest appearance of an option in combination with others. Thus, options 5 (reducing effective impervious cover through better site design) and 6 (porous pavement and subsurface storage) appear early, meaning they had a very high cost-effectiveness score ranking. Option 12 (retrofitting of existing sewer inlets with dry wells) had a low cost-effectiveness score, and made its first appearance only after more than 450 other combinations were rated as superior.

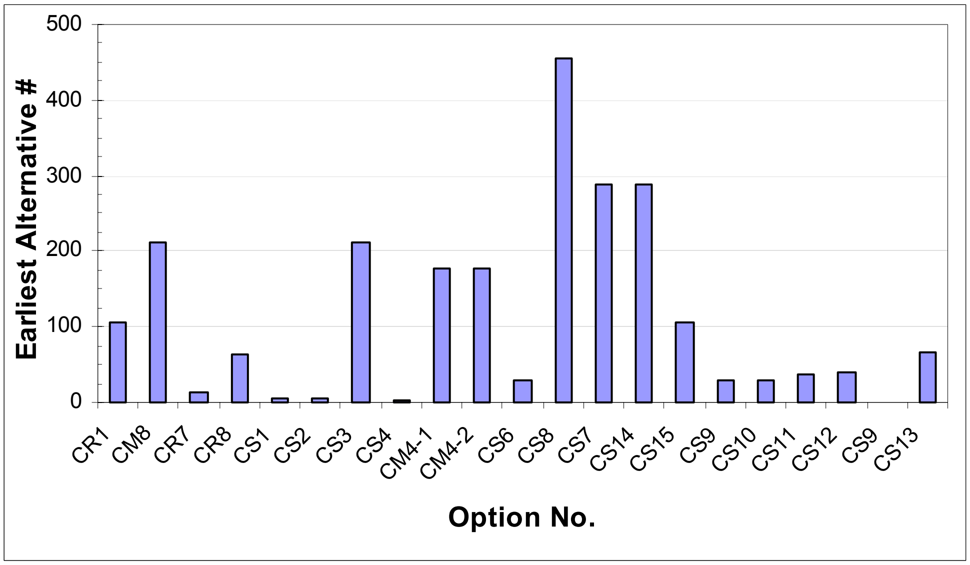

Figure 5-2 Effectiveness of Options in Combination

Table 5-3 summarizes the results of the option screening analysis. Each of the 21 options under consideration for inclusion in the implementation plan is shown in column 1.

Whether or not an option was included in the final set of alternatives was based on how well it did in the cost-effectiveness evaluation. Individually, each option has an effectiveness/cost ratio. How well the option did when combined with other options was judged by how early the option first appeared when results from the more than 1 million possible option combinations were sorted by the effectiveness/cost ratio of the combinations. The first appearance of an option was one way to judge, and its appearance within the 40 highest ranked option combinations was another. Table 5-3 shows the option results with color shading. Green options rated highly, and were likely to be included in the implementation plan. Yellow shaded options were ranked medium, and were possible options for inclusion. The pink highlighted options were the least cost effective options, and were the least likely to be included for implementation.

Table 5-3 Results of Initial Screening

🟩 High Score; 🟨 Medium Score; 🟥 Low Score

Opt. No.	Option Description	Normalized Cost Score	Normalized Effectiveness Score	Normalized E/C Ratio for Option Alone	First Alternative Appearance

5.3 Modeling Assessment of Structural BMPs

The automated option screening described above was done in a qualitative sense based on the options only, with no direct consideration of their ability to function under the specific circumstances of Cobbs Creek. Those BMPs that were deemed to be generally effective in meeting wet weather or Target C objectives were further assessed using the SWMM model. In this way, the BMPs could be assessed for their cost-effectiveness when implemented in Cobbs Creek. BMPs (or options) that appear to cost-effectively decrease stormwater flows or combined sewer overflows, or significantly reduce pollutant loading during wet weather were subjected to a series of model runs. BMPs were simulated at various levels of implementation within the watershed, and the results graphed. For the assumed level of implementation, the results in terms of pollutant reduction and amount of stormwater treated were then combined with planning level cost estimates, and the options were ranked according to their cost effectiveness. The modeling analysis is documented in more detail in the Comprehensive Characterization Report.

The results are shown in Tables 5-4 through 5-6. Note that the analysis was carried out separately for BMPs placed in CSO areas and in separate storm sewered areas to test the effects of location. There are clear differences in the efficiency of BMPs depending on where they are located. The analysis was also carried out for the cost effectiveness at removal of pollutants using TSS as surrogate for most pollutants, and for cost effectiveness at reducing or treating stormwater quantity reaching the creek. This is important because some BMPs appear to be more efficient at pollutant removal, while others are more efficient at reducing the volume of stormwater reaching the stream. Both are objectives of the watershed management plan.

Table 5-4 shows the estimated cost per gallon of stormwater treated, and the cost per pound of TSS removed for simulations of feasible levels of implementation for each of the types of BMPs under consideration. The results show that there is a wide range of costs, and that costs differ depending on whether a BMP is implemented in a CSO area, or in an area served by separate storm sewers. Table 5-5 shows the relative ability of each of the BMPs to either store stormwater, treat stormwater, or remove TSS, based on simulations of feasible implementation of each of the BMPs in the Cobbs Creek Watershed. Table 5-6 shows the list of options, ranked from most cost-effective to least cost-effective, grouped into highly effective (green), moderately effective (yellow), and least effective (pink) options.

Table 5-4 Cost Analysis Results Using SWMM Model

🟩 High Score; 🟨 Medium Score; 🟪 Low Score

	WATER QUALITY			WATER QUANTITY		
	TSS Removed			Volume Infiltrated/Evap/Captured		
BMP	Separate ($/lb)	Combined ($/lb)	Watershed ($/lb)	Separate ($/10^3 gal)	Combined ($/10^3 gal)	Watershed ($/10^3 gal)
Treatment Wetlands	0.98	0.43	0.71	2.89	0.38	0.98
Wet Retention Basins	2.94	2.18	2.66	15.02	2.42	5.91

The results of the SWMM model BMP simulations support a number of general conclusions about the implementation of BMPs in Cobbs Creek.

- The cost of runoff volume reduction is always higher in separate-sewered than in combined-sewered areas because temporary storage and release results in additional capture at CSO regulator structures. Larger cost differences between CSO and separate storm sewer areas occur where evapotranspiration and/or infiltration are minor components of the BMP (e.g., retrofitting sewer inlets with dry wells, residential dry wells and seepage trenches, bioretention and porous media filters).

- Generally speaking, if pollutant removal is significant for a given BMP, the cost difference between separate and CSO areas is smaller. Examples are porous pavement with subsurface storage, due to significant infiltration, and green rooftops, due to significant ET.

- Traditional BMPs like infiltration basins and wet retention basins can be effective where land is available to build them. These facilities typically have much larger capacities, are regional in nature, and exhibit economies of scale. They are not thought to be practical alternatives for the Cobbs watershed, but they are included for completeness.

- For the combined-sewered areas, real time control (RTC) is among the most competitive options in terms of both volume (5th) and load (4th) reduction. The RTC configuration being considered is highly specific to the Cobbs, and these results may not hold generally for other watersheds.

- In highly urbanized areas, large storage volumes can be achieved only through options such as porous pavement and gravel under parking facilities. Figure 5-3 shows the maximum amount of storage that could be built in the Cobbs watershed given a reasonable level of coverage for each BMP. Subsurface gravel under parking facilities represents over 60% of the storage that could feasibly be built. Bioretention and porous media filters represent the second largest volume at approximately 8%.

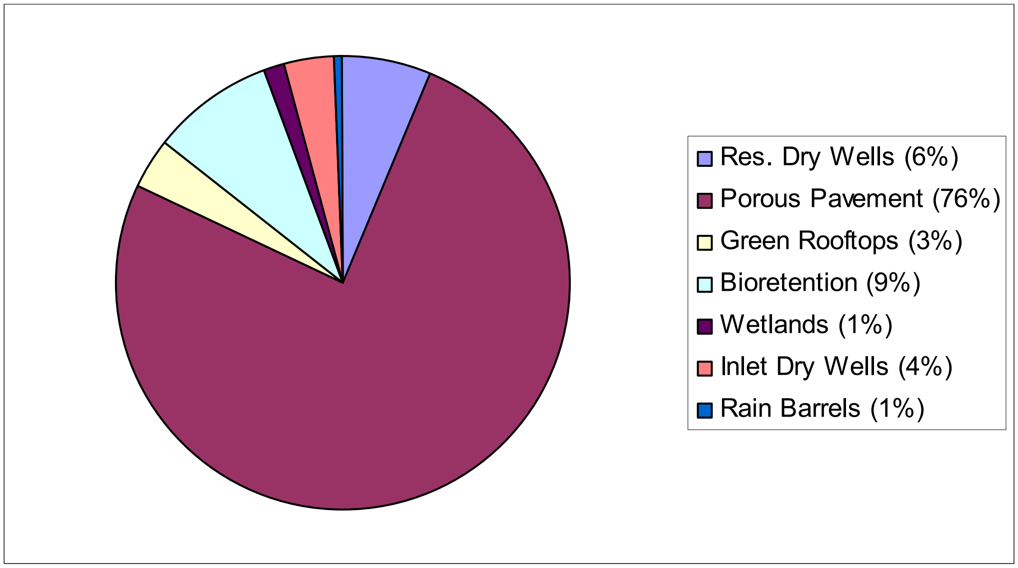

Figure 5-3 Total Storage Volume Feasible for Cobbs Watershed

- Given the urban conditions and soil in the Cobbs, only two of the modeled BMPs are capable of removing large quantities of stormwater (Figure 5-4). If porous pavement covered all parking lots, approximately 12% of stormwater could be removed through infiltration on an annual basis. If green rooftops covered all buildings, approximately 10% of stormwater could be removed through evapotranspiration.

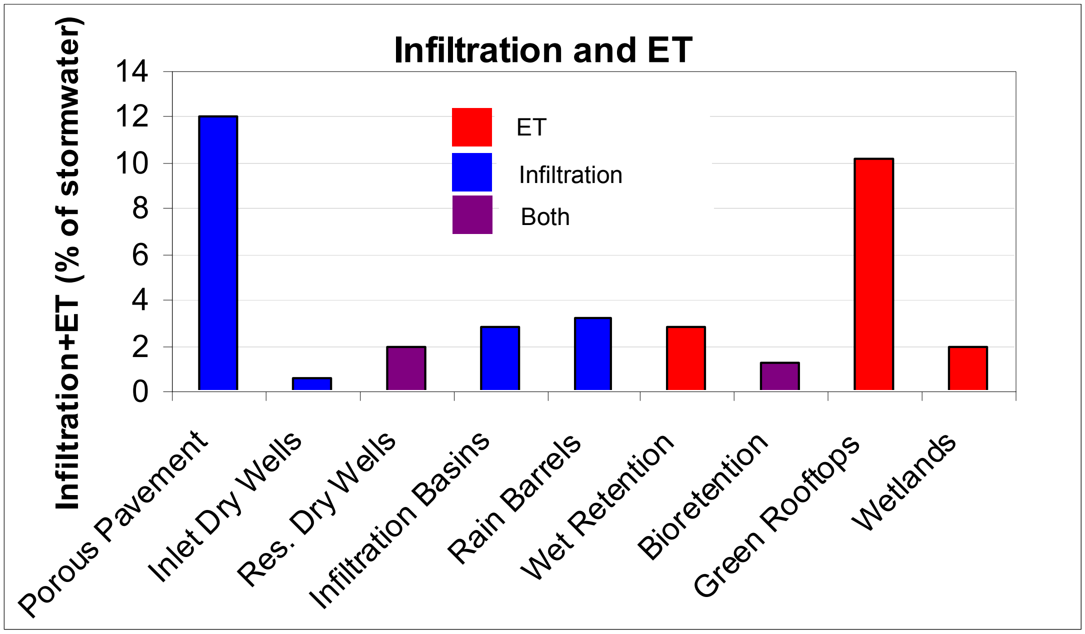

Figure 5-4 Potential Stormwater Volume Removal Given Full Coverage

The cost analysis of alternatives in areas of separate storm sewers shows:

- Wet Retention, wetlands, and infiltration basins are the most cost effective options for TSS removal on a dollar per pound basis. Wetlands and rain barrels are cost effective on a dollar per gallon stormwater treated basis.

- Dry wells in sewer inlets (>$1000/lb), green rooftops and porous pavement (~$100/lb) are particularly expensive for TSS reduction. Dry wells in sewer inlets and bioretention basins are expensive on a per gallon basis for stormwater treatment because of their relatively small area of infiltration.

The cost analysis of alternatives in areas of combined sewers shows:

- Wetlands, wet retention, rain barrels, infiltration basins, real time control, and residential dry wells are all relatively cost effective options on the basis of dollars per pound TSS removed and on the basis of dollars per gallon of stormwater treated.

- Green rooftops and porous pavement (both about $50/lb) are expensive choices either on the basis of TSS removal or on the basis of dollars per gallon stormwater treated.

It is also clear that the most expensive options in combined-sewered areas are more than an order of magnitude lower than the most expensive options in separate-sewered areas. Because hydraulic detention is the most important mechanism in combined-sewered areas, there is less difference in cost-effectiveness between the different types of BMPs.

In combined areas, the regulator structures represent an investment already made in pollution reduction. Thus money spent on stormwater best management practices results in greater load and volume reductions per dollar spent than in separate areas where no stormwater controls are in place. To meet an overall load reduction target in watersheds served by both combined and separate areas, it may be most efficient to focus management measures on the combined areas.

In Section 6, all the results presented above are used to assemble management alternatives that meet watershed goals in a cost-effective manner.

Section 6: Development and Evaluation of Management Alternatives

6.1 Development of Alternatives

BMPs, stream restoration measures, stormwater and CSO management technologies, and public education measures must be combined into coherent, integrated management plan alternatives that address the multiple objectives of the Darby-Cobbs Watershed Partnership. In highly urbanized watersheds, however, it is very difficult to develop appropriate water quality, quantity, and habitat objectives. For Cobbs Creek, PWD's approach is to define three separate sets of objectives or targets, and recommend BMPs and programs to achieve each of the targets. Targets are defined here as groups of objectives that each focus on a different problem related to the urban stream system. They can be thought of as different parts of the overall goal of fishable and swimmable waters through improved water quality, more natural flow patterns, and restored aquatic and riparian habitat.

The three targets of watershed restoration for Cobbs Creek are:

- TARGET A: Dry Weather Water Quality and Aesthetics
- TARGET B: Healthy Living Resources
- TARGET C: Wet Weather Water Quality and Quantity

By defining clear and achievable targets, and designing the alternatives and implementation plan to address the targets simultaneously, the plan will have a much higher likelihood of success. It will also result in realizing some of the objectives within a relatively short time frame, providing positive incentive to the communities and agencies involved in the program to continue and expand their efforts. This approach will also result in more immediate benefits to people living in the watershed than would an approach that attempts to meet all objectives completely in one implementation plan.

6.1.1 Target A: Options for Dry Weather Water Quality and Aesthetics

For Cobbs Creek, the focus of Target A is trash removal, litter prevention, and elimination of sources of sewage during dry weather. Because the options under consideration are aimed at the total elimination of trash and dry weather sources of sewage, no complex analysis was required to help define the program or assess its potential benefits. All options related to this target are included in the implementation plan.

Streams should be aesthetically appealing (e.g., look and smell good), accessible to the public, and be an amenity to the community. Access to and interaction with the stream during dry weather have the highest priority, because dry weather flows occur about 60-65% of the time during the course of a year, and are also the times when the public is most likely to be near or in contact with the streams. The water quality of the stream in dry weather, particularly with respect to bacteria, should be similar to background concentrations in groundwater. Many urban streams rarely meet water quality standards for bacteria, and urban streams often have significant BOD problems, even during baseflow or dry weather conditions.

The following outline shows the list of options recommended for inclusion in the implementation plan to achieve the objectives associated with Target A.

Regulatory Approaches

AR1 On-Lot Disposal (Septic System) Management
AR2 Pet Waste, Litter, and Dumping Ordinances

Public Education and Volunteer Programs

AP1 Public Education*AP2* School-Based Education
AP3 Public Participation and Volunteer Programs

Municipal Measures

AM1 Capacity Management Operation and Maintenance (CMOM)
AM2 Inspection and Cleaning of Combined Sewers
AM3 Sanitary Sewer Rehabilitation
AM4 Combined Sewer Rehabilitation
AM5 Illicit Discharge, Detection, and Elimination (IDD&E)
AM6 Stream Cleanup and Maintenance

AO1 Enhancing Stream Corridor Recreational and Cultural Resources

AMR Monitoring and Reporting

The outline shows that the options relevant to Target A focus on dry weather water quality and visual aesthetics of the stream, primarily removal of trash and elimination of illegal dumping. Also included are a range of regulatory and nonstructural options that address both water quality and quantity concerns. The measures in Table 6-1 may be grouped into three broad categories:

- Measures to Eliminate Sources of Trash and Litter
- Measures to Eliminate Sanitary Waste Inputs in Dry Weather
- Measures to Improve Public Access to Streams

Measures to Eliminate Sanitary Waste Inputs in Dry Weather

Measures to restore water quality during dry weather are fundamental to the plan. Elimination of dry weather sewer discharges due to blockages can be achieved by regularly cleaning and maintaining sewers. Leaking sewers are addressed by rehabilitating broken or leaking sewers, and identifying and correcting cross-connections (sanitary connections to stormwater lines).

In addition to sewage discharges, a program must be implemented to identify and eliminate any other pollutant sources (e.g., point sources or leaking septic tanks) that might be leading to instances of dry weather dissolved oxygen (DO) depression bacteria water quality standard exceedances.

Measures to Eliminate Sources of Trash and Litter

Another aspect of Target A objectives is to improve aesthetics by cleaning up trash and taking measures to reduce littering and illegal dumping. Many stakeholders in area watersheds have indicated that these measures are a primary concern. Options to achieve this include stream cleanup activities and the implementation of a wide range of nonstructural measures to educate the community about the importance of the stream, and about the direct consequences of their actions on the quality of the streams. Example implementation measures include school-based education, establishment of stakeholder and watershed groups, improved street sweeping and litter control, the establishment of municipal "clean stream teams" to clean up trash in the stream, and improved enforcement of existing littering and anti-dumping ordinances.

Measures to Improve Public Access to Streams

A significant portion of Cobbs Creek offers opportunities to improve access and use of the stream for passive recreation through the creation of trails, access points, and improved habitat within the riparian corridor. Areas where access can be improved will be indicated in the implementation plan.

6.1.2 TARGET B: Options for Healthy Living Resources

Improving the ability of an urban stream to support viable habitat and fish populations focuses primarily on the elimination of the more obvious impacts of urbanization on the stream. These include loss of riparian habitat, eroding and undercut banks, scoured streambed or excessive silt deposits, channelized and armored stream sections, trash buildup, and invasive species. The primary tool to accomplish this is stream restoration. Restoration focuses on improving channel stability, improving instream and riparian habitat, providing refuges for fish from high velocity conditions during storms, and managing land within the stream corridor.

Channel Stability and Aquatic Habitat Restoration

BM1	Bed Stabilization and Habitat Restoration
BM2	Bank Stabilization and Habitat Restoration
BM3	Channel Realignment and Relocation
BM4	Plunge Pool Removal
BM5	Improvement of Fish Passage

Lowland Restoration and Enhancement

BM6	Wetland Creation
BM7	Invasive Species Management

Upland Restoration and Enhancement

BM8 Biofiltration
BM9 Reforestation

BMR Monitoring and Reporting

Options for stream restoration were developed based on extensive studies carried out in the watershed by PWD in preparation for the Cobbs Creek Watershed Management Plan. Studies included a geomorphologic channel survey (stream assessment) of the entire creek, stormwater modeling, habitat and biological assessments, and modeling of stream velocities along a critical stretch of the creek. Assessment results indicate that the moderately impaired benthic community and pollution tolerant fish assemblages in Cobbs Creek reflect habitat deterioration and episodic water quality degradation throughout the entire watershed. Cobbs Creek watershed is a highly urbanized region where traditional methods of stream bank “reconstruction” and stormwater management have significantly channelized the stream and disconnected it from its historic floodplain, creating a system which is not in dynamic equilibrium (i.e., the amount of erosion and sedimentation is not equal to the amount of sediment transport out of the system). Furthermore, the stream has lost much of its link magnitude (e.g., small first order streams) and wetland systems due to development and increased impervious surfaces. Due to these changes, the stream’s hydrologic profile has been altered, decreasing the time to peak flow and increasing peak flow concentration. In doing so, storm events reaching or exceeding bankfull stage are no longer managed by the stream channel and floodplain.

Typical events scour stream banks, fill pools with sediment, and cover riffle structures with sediment at an accelerated rate. As a result, a highly ephemeral (short-lived) system with increased sediment deposition, decreased habitat heterogeneity (e.g. pool-riffle-run systems) and unstable stream banks has been created. These changes have had a deleterious effect on the benthic and ichthyfaunal communities inhabiting Cobbs Creek.

Results of water quality monitoring, habitat assessment, and biological monitoring, suggest the primary impact on the number, health, and diversity of fish species in Cobbs Creek is habitat modification. Restoration efforts, therefore, need to focus on habitat improvement and fishes’ ability to avoid high velocity flows during storms. Wetland and streambank restoration/creation projects and stream modeling will be combined with continued biological monitoring to ensure that appropriate procedures are being implemented to increase habitat heterogeneity within the aquatic ecosystem.

The options in Table 6-2 may be further broken into measures necessary used for stabilization of the stream channel, measures for habitat creation, measures to manage infrastructure in restoration areas, and measures to improve fish passage.

Measures for Channel Stabilization

- Bank stabilization, including boulder structures, bioengineering, root wads, plantings, and log and woody structures
- Bed stabilization, including rock/log vanes with grade control, rock/log cross vanes, and naturally occurring boulders and bedrock
- Realignment and relocation of the stream channel, to be used only on severely degraded stream sections

Measures for Habitat Restoration in the Stream and Stream Corridor

- Restoring stream banks, channels, and habitat features
- Restoring riparian (streamside) habitat, including wetlands
- Eliminating deep, poorly mixed pools to improve dissolved oxygen (DO) concentration
- Restoring pools and riffles, healthy banks, and creating safe areas of low flow velocity during storms
- Reforestation, with priority to floodplains, steep slopes, and wetlands
- Invasive species management, needed to increase biodiversity
- Wetland creation, often used in conjunction with stream realignment to improve floodplain areas subject to annual flooding
- Forest preservation

Measures to Manage Infrastructure in the Restoration Area

- Where possible, reducing impervious cover during corridor restoration
- Infrastructure retrofit or relocation of structures within the floodplain or encroaching on the channel
- Road and culvert maintenance

Measures to Improve Fish Passage

- Fish ladders, which allow fish to pass around obstructions
- Modification or removal of dams

A more detailed presentation of the above measures is included in the implementation guidance section (Section 7).

6.1.3 TARGET C: Options for Wet Weather Water Quality and Quantity

Improving water quality and flow conditions during and after storms is the most difficult target to meet in the urban environment. During wet weather, extreme increases in streamflow are common, accompanied by short term changes in water quality. Stormwater generally does not have DO problems, but sampling data indicate that concentrations of metals (such as copper, lead, and zinc) and bacteria do not meet water quality standards during wet weather. These pollutants are introduced by both stormwater and wet weather sewer overflows (CSOs and SSOs).

Target C options also must address flooding issues. Where water quality and quantity problems both exist, options must be identified that address both. Any BMP that increases infiltration or detains flow will help decrease the frequency of damaging floods; however, the size of such structures may need to be increased in areas where flooding is a major concern. Reductions in the frequency of erosive flows and velocities will also help protect the investment in stream restoration made as part of the implementation of Target B options.

Target C must be approached somewhat differently from the first two targets. Full achievement of this target means meeting all water quality standards during wet weather, as well as eliminating all flooding. Full achievement of these goals will be difficult, particularly with regard to wet weather water quality. It is certainly extremely expensive, and would require a long term effort. The only rational approach to full achievement of Target C goals is through stepped implementation with interim targets for reducing wet weather pollutant loads and stormwater flows. During implementation, monitoring must continue to continuously assess the effectiveness of the program. Based on the extensive modeling analysis carried out for Cobbs Creek to date, an initial goal of a 20% reduction in stormwater flows and stormwater/CSO related pollutant loads is challenging but achievable.

It is expected that changes to the approach, and even to the desired results, will occur as measures are implemented and results are monitored. With permits of 5-year duration for most discharge permits, discharge targets and reduction targets must be set and implementation designed in the first 5 years. Implementation for meeting Target C should occur over the next 5 years, with monitoring for effectiveness taking place for 5 years subsequent to implementation. During the last 5-year period, PWD will also work with the regulatory agencies to review water quality standards and determine whether any adjustments to them may be appropriate based on the results of monitoring.

On the Cobbs Creek, data indicate that restoring water quality to meet fishable and swimmable criteria during wet weather primarily means controlling sources of fecal coliform and restoring degraded stream habitat. Because urban streams are subject to extreme changes in flow and very heavy loading of fecal coliform from CSOs and stormwater, options focus on reducing stormwater and CSO overflows by:

- Reducing CSOs from reaching the stream
- Treating or infiltrating stormwater before it reaches the stream
- Implementing floodplain management, planning, and ordinances (e.g., restrict development in the 100-year floodplain)

Options related to Target C are divided into two groups. The first group, listed in the following outline, includes options recommended for full implementation regardless of what alternative is ultimately chosen. These options include a range of ordinances and regulatory measures, public education, measures related to existing municipal infrastructure, selected source controls, and possibilities for pollution trading and use review. The municipal measures focus on the elimination of sanitary sewer overflows and the causes of overflows such as blockages and excessive infiltration. Recommendations for implementing these options are included in Section 7.

CS2 Increasing Urban Tree Canopy
CS3 Porous Pavement and Subsurface Storage
CS4 Green Rooftops
CS5 Capturing Roof Runoff in Rain Barrels or Cisterns

Onsite and Regional Stormwater Control Facilities

CS6 Maintaining/Retrofitting Existing Stormwater Structures
CS8 Retrofit of Existing Sewer Inlets with Dry Wells
CS9 Residential Dry Wells, Seepage Trenches, and Water Gardens
CS12 Bioretention Basins and Porous Media Filtration
CS13 Treatment Wetlands: Onsite and Regional

CMR Monitoring and Reporting

The second group of Target C options includes structural measures designed to achieve specific, measurable discharge and pollutant load reductions. Table 6-1 lists the eight measures, a feasible implementation level for each, and the discharge and pollutant load reductions that are possible with each. Table 6-2 lists six alternatives, or combinations of these eight options that result in approximately a 20% reduction in wet weather flows and loads to the stream system.

Table 6-1 Available Options to Meet Flow and Load Reduction Targets

	Maximum Feasible Implementation	Volume Reduction		Pollutant Reduction
		CSO	Stormwater	
Municipal Measures				
CM4 Combined Sewer Overflow (CSO) Control Program				
• Real Time Control	15 Sites in PWD's SWDD	11%	0%	14%
Structural Stormwater Management Facilities				
Source Control Measures				
CS3 Porous Pavement and Subsurface Storage	50% of parking lots	3%	4%	8%
CS4 Green Rooftops	5% of rooftops	6%	7%	14%
CS5 Capturing Roof Runoff in Rain Barrels or Cisterns	25% of homes	4%	2%	6%
Onsite and Regional Stormwater Control Facilities				
CS8 Retrofit of Existing Sewer Inlets with Dry Wells	100% of inlets	5%	0%	6%
CS9 Residential Dry Wells, Seepage Trenches, Water Gardens	school grounds; 25% of homes	6%	1%	19%
CS12 Bioretention Basins and Porous Media Filtration	50% of parking lots	2%	0%	6%
CS13 Treatment Wetlands: Onsite and Regional	100% of identified potential	5%	1%	12%

Notes:
1. Volume reductions are % of total discharge (sum of CSO and stormwater)
2. “Maximum Feasible” considers technical feasibility and social acceptance, but not cost.

Each alternative is designed to fully meet the goal of 20% reduction in untreated stormwater reaching the stream, and a 20% reduction in pollutant loading through stormwater and/or CSOs. They differ in approach and cost, with each representing a slightly different “design approach”.

Table 6-2 Six Alternatives for Meeting 20% Flow and Load Reduction Target

	Unit	Alternative					
		1	2	3	4	5	6
Municipal Measures							
CM4 Combined Sewer Overflow (CSO) Control Program							
• CSO Storage Tanks	Yes/No	No	Yes	No	No	No	No
• Real Time Control	Yes/No	Yes	No	No	No	No	No

CS9 Residential Dry Wells, Seepage Trenches, Water Gardens	% of homes	25%	25%	15%	25%	0%	10%
CS12 Bioretention Basins and Porous Media Filtration	% of parking lots	5%	5%	0%	2%	50%	25%
CS13 Treatment Wetlands: Onsite and Regional	% of identified potential	100%	100%	100%	0%	0%	50%

Alternative 1: Real Time Control and Low-Cost Stormwater BMPs

This alternative combines real time control of CSOs within the combined sewered area of the watershed with BMPs that were identified as being cost-effective within the conditions found in Cobbs Creek. Stormwater BMPs are applied only to the areas served by separate storm sewers. The options applied to the separate sewered areas include the use of wetlands for all areas identified as suitable for wetland creation, installation of rain barrels on 25% of all homes, installation of residential dry wells for roof runoff on another 25% of homes, and sand filters or bioretention facilities installed on 5% of the parking lots within the watershed.

Alternative 2: Structural Storage and Low-Cost Stormwater BMPs

This alternative uses large scale retention of combined sewer flows through the use of large CSO tanks. In separate sewered areas, it is assumed that rain barrels are installed on 25% of the households, that 25% of the residences have dry wells to catch roof runoff, and that bioretention basins and/or sand filters are installed in 5% of parking lots.

Alternative 3: Low-Cost Stormwater BMPs throughout Watershed

This alternative uses only stormwater BMPs throughout the watershed; CSOs are addressed by infiltrating and detaining stormwater before it reaches the combined sewer. It includes wetlands at all feasible locations, rain barrels on 25% of all homes, and dry wells on 15% of all homes in the watershed.

Alternative 4: Stormwater BMPs with Focus on Private Property

This alternative uses only stormwater BMPs throughout the watershed. The concept is to examine the effectiveness of stormwater BMPs that are applied primarily to private properties through voluntary or incentive programs. It includes rain barrels on 25% of all homes, dry wells on 25% of all homes, sand filters or bioretention facilities installed on 2% of the parking lots within the watershed and green roofs installed on 2% of all homes in the watershed.

Alternative 5: Stormwater BMPs with Focus on Public Property and Parking

This alternative uses only stormwater BMPs throughout the watershed; however, the focus is primarily on BMPs applied to public lands and facilities. BMPs include bioretention and/or sand filters in 50% of the parking lots in the watershed, porous pavement with storage in 50% of the parking lots, and dry wells replacing 40% of the manholes along both combined and separate sewers throughout the watershed.

Alternative 6: A Mix of Stormwater BMPs

This alternative examines an implementation program that results in a mixture of BMPs that could be applied throughout the watershed. It includes wetland creation on 50% of the feasible locations, rain barrels installed on 20% of all homes, dry wells installed on 10% of the residences to collect roof runoff, sand filters/bioretention on 25% of the parking lots, porous pavement with underground stormwater storage on 25% of the parking lots, and green roofs on 2% of the homes.

6.2 Evaluation of Alternatives

The six alternatives described above are all designed to meet an interim target of 20% reduction in pollutant loading to Cobbs Creek during wet weather. Each represents a different approach to meeting this interim target. All achieve similar reduction in total load, but can have significantly different results when assessed in other ways. For example, costs for each approach are very different, and each approach differs in the degree that it might meet other planning objectives.

Ultimately, Target C options will be implemented within the watershed by a variety of stakeholders (counties, municipalities, watershed groups, State agencies, private businesses, etc.). In order to gain insight into the strengths and weaknesses of the various approaches, the six alternatives were evaluated using a multi-criteria evaluation program called EVAMIX.

6.2.1 Multi-Criteria Evaluation Using EVAMIX

EVAMIX is a matrix-based, multi-criteria evaluation program that makes use of both quantitative criteria (such as cost that are measured with numbers such as millions of dollars), and qualitative criteria (such as implementability, measured only as high, medium, or low) within the same evaluation, regardless of the units of measure. The use of EVAMIX requires the development of a two dimensional matrix consisting of the alternatives to be evaluated (columns) and a set of evaluation criteria (rows). For every combination of alternative and criteria, a score is assigned. Many of the quantitative criteria were scored using model simulation results, while a number of qualitative criteria were scored based on clearly defined definitions and professional judgment.

The other important input to EVAMIX is the selection of weighting factors for each of the criteria. Weights were provided by the Technical Advisory Group, and a separate EVAMIX simulation was run for each set of weights provided.

In summary, the following were used in carrying out the EVAMIX evaluation:

- The six Target C alternatives being evaluated
- A set of clearly defined criteria used to compare the alternatives
- Scores assigned to every alternative for each criterion
- Weighting factors assigned to each criterion. These weights represent the relative importance of each criterion as provided by the stakeholders.

6.2.2 Evaluation Criteria

Eighteen evaluation criteria were developed to assess the ability of the six Target C alternatives to meet planning objectives in a cost effective manner. Each criterion is described below.

Cost

Capital Cost

(quantitative, dollars)

Capital cost includes the cost of constructing best management practices. Cost estimates are based on unit costs (per gallon, per acre, etc.), are planning-level, and do not account for economies of scale or specific local conditions.

Operations and Maintenance (O&M)

(quantitative, 2003 dollars per year)

O&M cost is the annual cost to maintain the set of BMPs over an appropriate design life. A design life of 20 years is assumed if no specific information is available. When a dollar cost for O&M is not readily available in the literature or local experience, O&M is assumed to be a reasonable percentage of construction cost.

Stream Habitat and Aquatic Life

Peak Stream Velocity

(quantitative, % reduction)

This criterion is based on the maximum stream velocity generated in the SWMM model by the one-year synthetic rainfall record used for alternatives modeling. The percent reduction relative to existing conditions is recorded at the following model cross-sections: CC07986, CC13397, CC14215, CC23213, CC26523, CC33332, CC51627, EIC0639, and WIC0252. The number entered into EVAMIX is the average of the six cross-sections.

Groundwater Infiltration and ET

(quantitative, MG)

Infiltration and evapotranspiration that occur due to BMP addition are added throughout the watershed based on model results. Infiltration and evapotranspiration that occur over the land surface, outside of BMPs, are not included.

Stream Channels and Banks

Frequency of Bankfull Flow

(quantitative, years)

This criterion estimates the return interval of bankfull flow under existing conditions for each of the alternatives. Based on the known 50-year record of streamflow, 12 peak flow events with return intervals of 0.05 to 2 years were chosen. These storms were compiled into a synthetic rainfall record and run for each alternative. Frequency of bankfull flow was estimated through a regression of peak streamflow vs. the original return period under existing conditions.

Flooding

Peak Flood Stage (3 criteria for the 3 locations)

(quantitative, peak stage in feet above city datum)

Three cases were chosen where a bridge deck is located in the 10-year floodplain as defined by FEMA. A storm was identified that just inundates the bridge decks under existing conditions. Each alternative was modeled using the storm, and peak stage was recorded.

Reduction in Peak Streamflow

(quantitative, % reduction)

This criterion is based on the maximum streamflow generated in the SWMM model by the one-year synthetic rainfall record used for alternatives modeling. The percent reduction relative to existing conditions is recorded at the following model cross-sections: CC07986, CC13397, CC14215, CC23213, CC26523, CC33332, CC51627, EIC0639, and WIC0252. The number entered into EVAMIX is the average of the six values.

Water Quality and Pollutant Loads

Annual Average Fecal Coliform Load

(quantitative, col/year)

This criterion measures the estimated annual input of fecal coliform to the stream system from all sources. Fecal coliform is intended to act as a surrogate for a range of disease-causing microorganisms.

Annual Average TSS Load

(quantitative, lb/year)

This criterion measures the estimated annual input of total suspended solids to the stream system from all sources. TSS is intended to act as a surrogate for a range of pollutants, including metals such as copper, lead, and zinc.

Stream Corridors

Area of Wetlands Created

(quantitative, acres)

The creation of wetlands is considered a positive result. This criterion estimates created wetlands intended mainly for stormwater and CSO treatment.

Feasibility

Technical Implementability

(Qualitative; High/Medium/Low)

This qualitative criterion uses the following scoring approach.

High	The technologies in the alternative have been widely and successfully applied. Several local contractors will have experience with the technologies.

Medium	The technologies have been successfully applied in other cities or have been successfully demonstrated locally. At least one local contractor will have experience with the technologies. (“Medium” may also be appropriate for an alternative with a mix of technologies classified as “High” and “Low”).
Low	The technologies have been applied only in pilot or demonstration programs and only in a few places. It may be impossible to find a local contractor with experience.

Length of Time to Implement

(Qualitative; High/Medium/Low)

This qualitative criterion uses the following scoring approach.

High	The technologies in the alternative can be implemented in 2 years or less.
Medium	The technologies can be implemented in 2 to 5 years, or the alternative contains a mix of “High” and “Low” technologies.
Low	The technologies take more than 5 years to implement.

Feasibility Within the Legal Structure

(Qualitative; High/Low)

This qualitative criterion uses the following scoring approach.

High	Existing laws require or provide an incentive for implementation. For example, measures proposed may overlap with the “six minimum controls” required by NPDES Phase II regulations.
Low	Existing laws do not affect or provide disincentives for different aspects of the plan.

Social/Political Support

(Qualitative; High/Low)

This qualitative criterion uses the following scoring approach.

High	Overall, the measures proposed will be seen as positive by a majority of stakeholders (citizens, local governments, and non-profits).
Medium	The measure has both positive and negative aspects.
Low	Overall, the measures proposed will be seen as negative by a majority of stakeholders (citizens, local governments, and non-profits).

Degree of Construction Disturbance

(Qualitative; High/Medium/Low)

The proposed BMP that causes the most disturbance will control the assignment of this criterion. Low construction disturbance is positive.

High	Construction will require removal of large amounts of pavement (streets, parking lots) and/or construction will significantly affect parking, movement of people and vehicles, and the noise level. Examples include porous pavement and installation of dry wells in sewer inlets.
Medium	Some pavement removal is required. Effects on parking, traffic patterns, and noise are moderate.
Low	Pavement removal is not required or is minimal. Effects on parking, traffic patterns, and noise are minimal. Rain barrels are one example.

Maintenance Required

(Qualitative; High/Medium/Low)

Low maintenance is positive.

High	Existing public programs, staff, and funding will not cover maintenance, or maintenance will be a large burden on private land owners. Or, frequent maintenance is absolutely critical to BMP effectiveness, as with rain barrels.
Medium	Private land owners will be responsible for minor maintenance chores (e.g., minor landscape maintenance for a bioretention basin that would have been a parking island anyway). Public agencies can handle maintenance with existing staff and budget, and/or will dedicate staff time to outreach, workshops, etc.

Low	Maintenance can be performed through existing programs and existing funding. For example, maintenance of RTC will be integrated into current sewer maintenance.

6.2.3 Criteria Weights

A workshop was held with the Technical Advisory Group for Cobbs Creek to obtain stakeholder input on the relative importance of each of the criteria used in the evaluation. Since the implementation plan consists of recommendations to the various potential partners for implementing a variety of BMPs, it was not necessary to reach consensus on the weights or to select one alternative for implementation. In fact, results for every weight set provided by the participating stakeholders were used in the analysis.

Table 6-3 shows the various weight sets used in the evaluation, as well as an average of all the weights. The weights show the range of priorities tested, and indicate that the various weights provide a good measure of the sensitivity of the results to differing opinions on the importance of each criterion.

Table 6-3 Criteria Weights

Criteria		Average	Stakeholder or Stakeholder Group											
			1	2	3	4	6	7	8	9	10	11	12	13
1	Construction Cost	15.1	20	15	15	25	10	20	3	5	25	30	10	20

6.3 Evaluation Results

Table 6-5 shows the scores assigned to each alternative and the units the scores represent across all criteria. The first row of the table shows the alternatives in order of their ranks, from most desirable to least desirable. The second row indicates the average rank that the alternative achieved using all of the weight sets provided by the stakeholders. In general, the results were consistent.

- **Highly Ranked:** Alternative 5 was ranked as the best for 10 of the thirteen stakeholder weight sets, and was ranked 2nd on three of the weight sets. Alternative 1 ranked 1st on three of the weight sets, and 2nd on all the others. These two were clearly the highest ranked alternatives, as evidenced by their average rankings.

- **Moderately Ranked:** Alternative 3 was either ranked as the 3rd best or 4th best alternative for all weight sets. Alternative 6 was very sensitive to the selected weight set, and was ranked anywhere for 3rd best to 6th best.

- **Lowest Ranked:** Alternative 4 ranked anywhere from 4th best to 6th, and was one of the less highly ranked alternatives. Alternative 2 was clearly the worst alternative, scoring 5th best for two weight sets, and 6th best (last) on all the others.

Table 6-8 shows the alternatives in order of preference, highest to lowest. The table presents a summary of the strengths and weaknesses of each of the alternatives.

Table 6-5 Alternative Evaluation Summary

Target C: Wet Weather Alternatives	Avg. Rank	Strengths	Weaknesses	Comments
Alt. 5: Stormwater BMPs: Focus on Public Property/Parking - bioretention in 50% of parking lots - porous pavement in 50% of parking lots - dry wells in 40% of sewer inlets	1.23	Reductions in peak flow and peak velocities; significant recharge through porous pavement; favorable political/social climate	Relatively expensive; difficult to implement, with a long period of time to full implementation	Overall best ranked (first or second best using all weights). Indicates that main strength comes through high implementation of porous pavement
Alt.1 Real Time Control and Low-Cost Stormwater BMPs - RTC in combined areas - all feasible wetlands in separate-sewered areas - rain barrels on 25% of homes (sep. areas) - dry wells for 25% of homes (sep. areas) - bioretention in 5% of parking lots (sep. areas)	1.77	Lowest capital cost due to use of Real Time Control option; full implementation is relatively rapid; implementation relatively easy with low construction disturbance	Relatively little recharge; relatively low reduction in peak flow and peak velocity; relatively low fecal coliform/TSS removal; low implementation of wetland option	Overall, 2nd ranked alternative. Main strength comes from cost and ease of implementation. Use of private-based alternatives with limited treatment or storage means poorer ranking in water quality aspects.
Alt. 3: Low-Cost Stormwater BMPs throughout Watershed - all feasible wetlands - rain barrels on 25% of homes - dry wells for 15% of homes	3.23	Generally low cost (capital and O&M together); easy to implement; short time frame for implementation; minimal construction disturbance; full realization of wetland potential	Poor infiltration; poor peak flood and velocity reductions; weak political/social support	Mid-ranked alternative. Reliance on private sector solutions (dry wells, rain barrels) is low cost, but requires significant cooperation from citizens, thus harder to implement.
Alt. 6: A Mix of Stormwater BMPs - half of feasible wetlands - rain barrels on 20% of homes - dry wells for 10% of homes - bioretention in 25% of parking lots - porous pavement in 25% of parking lots - green roofs on 2% of buildings	4.15	Mid-range cost; good peak flow and velocity reduction; excellent reduction in TSS and fecal coliform	Relatively high O&M and capital costs; moderate to low feasibility; limited use of wetlands	BMP mixture, which would be done for practicality and to provide a variety of BMP approaches, results only in a moderately effective solution.

Alt. 4: Stormwater BMPs Focusing on Private Property - rain barrels on 25% of homes - dry wells for 25% of homes - green roofs on 2% of buildings	4.77	Full use of wetlands; limited construction disturbance	Poor reduction in peak flows, flooding, and peak velocity; poor infiltration; moderate to high cost; focus on private property implementation makes it harder to achieve full implementation	Relatively poorly ranked alternative across all weight sets
Alt 2: Structural Storage and Low-Cost Stormwater BMPs - tank storage for combined sewage - all feasible wetlands (separate-sewered areas) - rain barrels on 25% of homes (sep. areas) - dry wells for 25% of homes (sep. areas) - bioretention in 5% of parking lots (sep. areas)	5.85	Technically feasible; easy to implement within regulatory structure	Extremely high cost; fairly limited effect on peak stream flow and peak velocity; relatively poor reduction in fecal coliform and TSS	Ranked as poorest of the alternatives. Main drawbacks are high cost and limited water quality benefit.

6.4 General Conclusions

The alternatives analysis presented above is not meant to yield an exact scenario for implementation. Rather, the computerized option screening results, the extensive modeling of BMPs, and the evaluation of the alternatives for Target C were all designed to help with developing a cost-effective approach to management of the Cobbs Creek watershed. Each analysis yielded additional insight into approaches that are most applicable to the specific conditions found in the watershed. The general conclusions resulting from the various computer analyses are presented here. These conclusions form the basis for the recommended implementation plan provided in section 7.

The primary conclusion is that *no single approach can achieve all the goals and objectives. The use of Targets with associated management approaches and schedules is considered the most practical and efficient way to achieve the planning objectives.*

Target A and Target B have specific measures that must be implemented, and full achievement of the targets is envisioned. For Target C, no single option or BMP is sufficient, and none are clearly superior to all others. This indicates that flexibility, “seeing what works where, and adjusting”, is probably the best approach to implementation. A mixed approach (not having a plan to implement certain BMPs as a primary approach), however, appears to lead to only moderately successful alternatives.

Some general conclusions are:

- Alternatives that rely on the use of public property provide more ability to control implementation than those that rely on private property.
- Private property BMPs (rain barrels, residential dry wells) can be effective and low cost, if reasonable levels of implementation and regular maintenance can be achieved.
- Porous pavement and parking lot options are extremely effective at meeting Target C objectives for infiltration.
- Real time control is an attractive option for the CSO areas of Cobbs Creek because it is effective and low cost.
- Structural controls such as large retention tanks for CSO control are a poor choice in terms of cost-effectiveness and effectiveness at restoring lost resources.
- Placing BMPs in CSO areas tends to maximize their effectiveness when compared to the same BMP in a separate sewered area. This is shown by the lower cost-per-gallon of stormwater treated in CSO areas.
- Use of wetlands for stormwater treatment is both effective and relatively inexpensive.
- Regional basins (infiltration, wet retention) can be cost-effective but are probably not feasible on a large scale in the Cobbs Creek watershed due to space constraints.
- There are larger differences in cost-effectiveness when considering implementation in CSO areas vs. implementation in separate-sewered areas when ET and/or infiltration are minor components of the BMP (e.g., dry wells in sewer inlets, residential dry wells, sand filters). These low ET/infiltration BMPs are more effective when placed in CSO areas rather than in separate sewered areas.
- Because there is generally a greater load and volume reduction per dollar spent in CSO areas, pollution trading options may be an interesting implementation approach to consider.

Section 7: Implementation Guidelines

This section presents the plan for implementation of those water management options that were identified by the Darby-Cobbs Watershed Partnership as best meeting the planning goals and objectives under the site specific conditions of Cobbs Creek. Following extensive screening and evaluation, only those options that are cost-effective and feasible under the specific conditions found in the Cobbs Creek watershed are included in the implementation plan. The section starts with summary tables of the recommended options, organized by the level of government or agency responsible for carrying out the recommendation under current regulations. More detailed information on each recommended option is then presented for each of the three targets.

Summary Tables

The summary section first presents the options in tables. A separate table was made presenting recommended actions for PADEP, Montgomery County, Philadelphia, watershed municipalities, and other stakeholders. Tables indicate which options are the responsibility of that agency or level of government for each of the three targets. In the following sections, more detailed information about recommended options is presented, organized in groups under each of three water management targets. Each option is first presented in a summary table format (what, who, where, and when), followed by text and figures that further describe the option and the implementation approach being recommended.

PADEP Actions

Action	Where	When
Industrial Stormwater Pollution Prevention	Industrial sites	Short-term
Construction Stormwater Pollution Prevention	Construction sites	Short-term
Pollution Trading	To be determined	Long-term
Use Review and Attainability Analysis	To be determined	Short-term
Stewardship/Advocacy of Watershed Management Plan	Watershed-wide	Short-term
Watershed-Based Permitting	Watershed-wide	Medium-term
Monitoring and Reporting	Watershed-wide	Ongoing

Philadelphia Actions

Action	Where	When
Pet Waste, Litter, and Dumping Ordinances	Watershed-wide	Short-term
Public Education	Watershed-wide	Short-term
School-Based Education	All schools	Short-term
Public Participation and Volunteer Programs	Watershed-wide	Short-term
Inspection and Cleaning of Combined Sewers	Watershed-wide	Short-term
Combined Sewer Rehabilitation	Combined-Sewered Areas	Medium-term
Stream Cleanup and Maintenance	Cobbs Creek within or along City boundary	Short-term
Enhancing Stream Corridor Recreational and Cultural Resources	Along the stream corridor	Medium-term
Bed Stabilization and Habitat Restoration	Cobbs Creek 40%, West Indian Creek 44%	Short-term
Bank Stabilization and Habitat Restoration	Middle section of Cobbs Creek	Short-term
Channel Realignment and Relocation	Cobbs Creek, East and West Indian Creek	Short-term
Plunge Pool Removal	CSO and stormwater outfalls	Short-term
Improvement of Fish Passage	Woodland Avenue dam	Short-term
Wetland Creation	Riparian corridor	Short-term
Invasive Species Management	Riparian corridor	Short-term
Reforestation	Riparian corridor	Short-term
Requiring Better Site Design in Redevelopment	Watershed-wide	Short-term
Stormwater and Floodplain Management	Watershed-wide	Short-term
Post-Construction Stormwater Runoff Management	Municipalities required to do Phase II permit	Short-term
Sanitary Sewer Overflow Detection	Separate-Sewered Areas	Short-term
Sanitary Sewer Overflow Elimination: Structural Measures	Separate-Sewered Areas	Medium-term
CSO Control Program	Philadelphia combined sewer system	Short-term
Catch Basin and Storm Inlet Maintenance	All inlets	Short-term
Street Sweeping (Philadelphia Streets Department)	Streets and Parking Lots	Short-term
Responsible Landscaping on Public lands	Green space	Short-term
Responsible Bridge and Roadway Maintenance	Roadways and bridges	Short-term
Reducing Effective Impervious Cover through Better Site Design	Watershed-wide	Long-term
Increasing Urban Tree Canopy	Watershed-wide	Medium-term
Porous Pavement and Subsurface Storage	Parking lots watershed-wide	Long-term
Green Rooftops	Appropriate public buildings chosen by PWD	Medium-term
Capturing Roof Runoff in Rain Barrels or Cisterns	Homes where dry wells are not feasible	Medium-term
Maintaining/Retrofitting Existing Stormwater Structures	Watershed-wide	Short-term
Retrofitting Existing Sewer Inlets with Dry Wells	Inlets in combined-sewered areas	Long-term
Residential Dry Wells, Seepage Trenches, and Water Gardens	Homes and schools watershed-wide	Long-term
Bioretention Basins and Porous Media Filtration	Watershed-wide	Long-term
Treatment Wetlands: Onsite and Regional	Riparian corridor	Medium-term
Monitoring and Reporting	Watershed-wide	Ongoing

Delaware and Montgomery County Municipality Actions

Action	Where	When
On-Lot Disposal (Septic System) Management	All areas with septic systems	Short-term
Pet Waste, Litter, and Dumping Ordinances	Watershed-wide	Short-term
Public Education	All Cobbs Creek municipalities	Short-term
School-Based Education	All schools	Short-term
Public Participation and Volunteer Programs	All Cobbs Creek municipalities	Short-term
Capacity Management Operation and Maintenance	Separate-Sewered Areas	Short-term
Inspection and Cleaning of Sanitary Sewers	Separate and Combined Sewered Areas	Short-term
Sanitary Sewer Rehabilitation	Separate-Sewered Areas	Medium-term
Illicit Discharge, Detection, and Elimination (IDD&E)	All areas with a storm or combined sewer.	Short-term
Stream Cleanup and Maintenance	Cobbs Creek within or along City boundary	Short-term
Enhancing Stream Corridor Recreational and Cultural Resources	Along the stream corridor	Medium-term
Bed Stabilization and Habitat Restoration	Cobbs Creek 40%, West Indian Creek 44%	Short-term
Bank Stabilization and Habitat Restoration	Middle section of Cobbs Creek	Short-term
Channel Realignment and Relocation	Cobbs Creek, East and West Indian Creek	Short-term
Plunge Pool Removal	CSO and stormwater outfalls	Short-term
Improvement of Fish Passage	Woodland Avenue dam	Short-term
Wetland Creation	Riparian corridor	Short-term
Invasive Species Management	Riparian corridor	Short-term
Reforestation	Riparian corridor	Short-term
Requiring Better Site Design in Redevelopment	Watershed-wide	Short-term
Stormwater and Floodplain Management	Watershed-wide	Short-term
Post-Construction Stormwater Runoff Management	Municipalities required to do Phase II permit	Short-term
Sanitary Sewer Overflow Detection	All areas with separate sewers	Ongoing program
Reduction of Stormwater Inflow and Infiltration to Sanitary Sewers	Separate-Sewered Areas	Medium-term
Catch Basin and Storm Inlet Maintenance	All inlets	Ongoing program
Street Sweeping	Streets and Parking Lots	Short-term
Responsible Landscaping on Public lands	Green space	Short-term
Responsible Bridge and Roadway Maintenance	Roadways and bridges	Short-term
Reducing Effective Impervious Cover through Better Site Design	Watershed-wide	Long-term
Increasing Urban Tree Canopy	Watershed-wide	Medium-term
Porous Pavement and Subsurface Storage	Parking lots watershed-wide	Long-term
Capturing Roof Runoff in Rain Barrels or Cisterns	Homes where dry wells are not feasible	Medium-term
Maintaining/Retrofitting Existing Stormwater Structures	Watershed-wide	Short-term
Residential Dry Wells, Seepage Trenches, and Water Gardens	Homes and schools watershed-wide	Long-term
Bioretention Basins and Porous Media Filtration	Watershed-wide	Long-term

7.1.1 Regulatory Approaches

On-Lot Disposal (Septic System) Management (AR1)
Related goals: 5, 6
Related Indicators: 7, 11, 19, 20

What	Who	Where	When
Septic tank management program required as part of the municipality's Official Act 537 Sewage Facilities Plan	Municipalities through state certified Sewage Enforcement Officers (SEO) • All Act 537 plans are outdated and should be updated with exception of Lower Merion Township	All areas with septic systems; See Table 7-1	Within next 5 years;

Septic tank management programs are presently required of all Pennsylvania municipalities as part of their Official Act 537 Sewage Facilities Plans. Keeping these plans up to date, including provisions related to operation and maintenance of on-lot sewage disposal systems (OLDS) is an important means of controlling the release of pathogens and nutrients within the watershed.

The Pennsylvania Sewage Facilities Act (Act 537) requires that all Commonwealth municipalities develop and implement comprehensive official plans that provide for resolution of existing sewage disposal problems, provide for future sewage disposal needs of new land development, and provide for future municipal sewage disposal needs (See Section 1). When a municipality adopts a plan, the plan is submitted for review and approval by the Pennsylvania Department of Environmental Protection (PADEP). By regulation, the planning process is not final until an Act 537 Plan has been approved by PADEP. Municipalities are required to revise (unless they are exempt from revising) the "Official Plan" if a new land development project is proposed or if unanticipated conditions or circumstances arise, making the base plan inadequate. There are two basic types of plan changes. "Plan revisions" resulting from new land development are completed using "planning modules" that are specific to individual projects. An "update revision" is used by municipalities to make broad changes to their Official Plan.

Act 537 planning has been a municipal requirement since July 1, 1967. Legally, all municipalities have an Act 537 Plan; however, some plans are newer and more detailed than others. A list of municipalities within the Cobbs Creek Watershed indicating the age and status of their Act 537 Plans is presented in Table 7-1 below. Note that all municipalities have outdated plans, with the possible exception of Lower Merion Township and the City of Philadelphia. Municipalities are shown in Figure 7-1.

Table 7-1 Act 537 Plans in Cobbs Creek Watershed

Municipality	County	Plan Approval Date	Status
Colwyn Borough	Delaware	1/1/1972	> 20 years; update in progress
Darby Borough	Delaware	1/1/1972	> 20 years; update in progress
East Lansdowne Borough	Delaware	1/1/1972	> 20 years; update in progress
Haverford Township	Delaware	1/1/1972	> 20 years; update in progress
Lansdowne Borough	Delaware	1/1/1972	> 20 years; update in progress
Lower Merion Township	Montgomery	6/16/1998	Plan between 5 and 10 years old
Millbourne Borough	Delaware	1/1/1972	> 20 years; update in progress
Narberth Borough	Montgomery	1/1/1973	> 20 years
Philadelphia	Philadelphia	11/10/1993	Plan between 5 and 10 years old
Radnor Township	Delaware	1/1/1974	> 20 years; update in progress
Upper Darby Township	Delaware	3/1/1975	> 20 years; update in progress
Yeadon Borough	Delaware	1/1/1972	> 20 years; update in progress

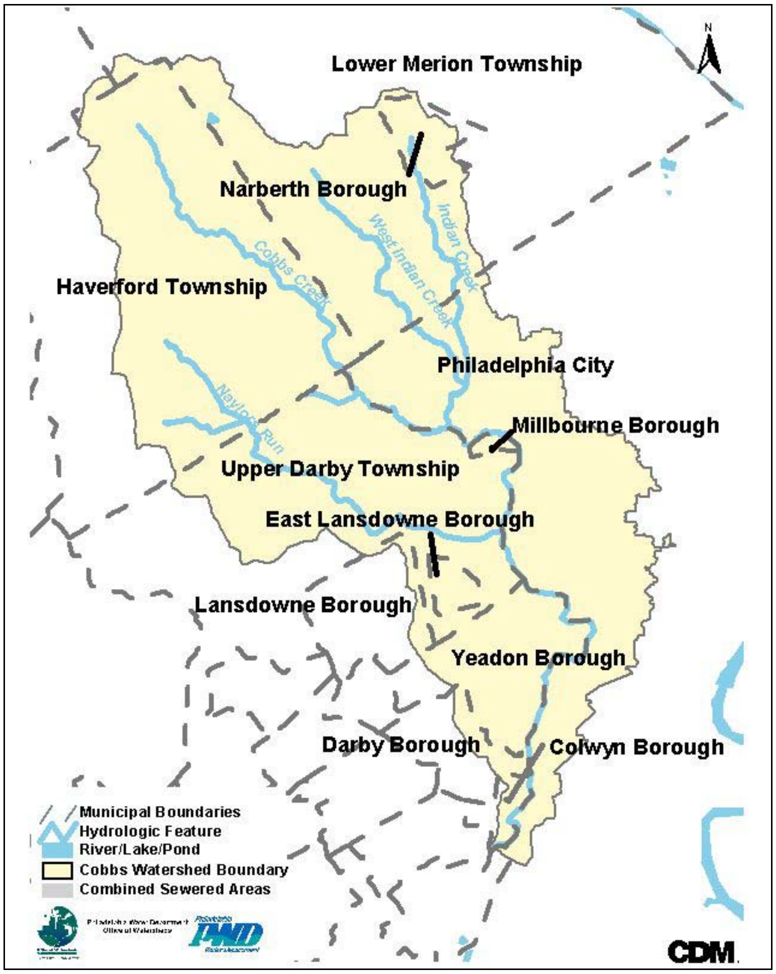

Figure 7-1 Cobbs Watershed Municipalities

Relevant Provisions of Act 537

- All municipalities must develop and implement an official sewage plan that addresses their present and future sewage disposal needs. Local agencies are required to employ both primary and alternate Sewage Enforcement Officers (SEO) responsible for overseeing the daily operation of that agency's OLDS permitting program.

- Local agencies, through their SEO, approve or deny permits for construction of on-lot sewage disposal systems prior to system installation. The SEO is responsible for conducting soil profile testing, percolation testing, OLDS design review, and approving or denying OLDS permit applications.

- Local agencies, through their SEO, must manage the permitting program for individual on-lot disposal systems and community on-lot systems with design flows of 10,000 gallons-per-day or less.

- Municipalities are required to assure the proper operation and maintenance of sewage facilities within their borders.

Municipalities should maintain information on the location, type and operational status of existing sewage facilities, as well as results of sanitary surveys. This information, however, is often incomplete. Septic tank data were included in the U.S. census through 1990, but were believed to be inaccurate and were not included in the 2000 census. County health departments may have information, and assessments have been attempted through voluntary questionnaires submitted by municipalities. These tasks have proven to be difficult but can be completed through perseverance.

Implementation of a Comprehensive Septic Tank Management Program

Each municipality shown in the above table should update its Act 537 plan in the coming 5-year period.

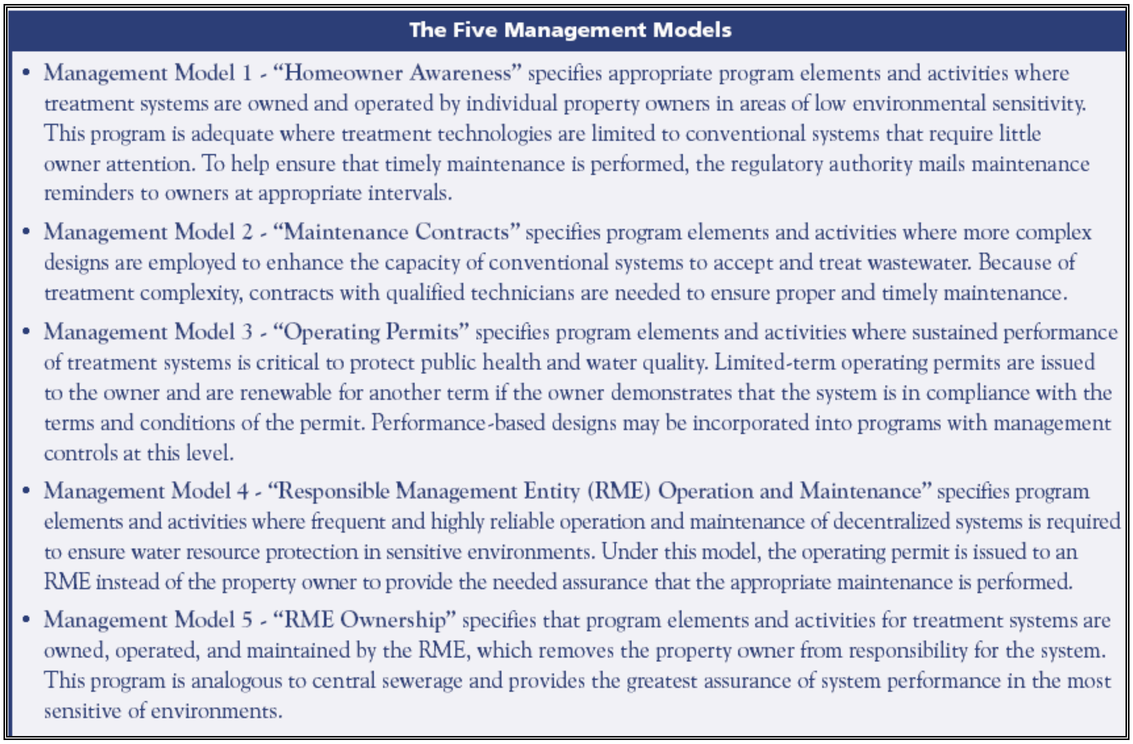
Table 7-2 below presents 1990 census sanitary survey results along with the area within the Cobbs Creek Watershed for Delaware County Municipalities. Implementation of septic system management programs should be actively pursued in municipalities that have a large estimated number of septic systems and a high percentage of their total area within the watershed: Haverford Township, Upper Darby Township, and Yeadon Borough.

Table 7-2 Septic System Data from 1990 Census

Municipality	Area (Acres)	Area in Watershed (Acres)	Percent of Area in Watershed (Acres)	Housing Units with Public Sewer	Housing Units with Septic Systems	Total Housing Units Occupied
Colwyn borough	164	96	58.60%	970	0	924
Darby borough	522	140	26.80%	4027	8	3709
East Lansdowne borough	132	132	100.00%	999	0	961
Haverford township	6406	3873	60.50%	17942	250	17727
Lansdowne borough	753	111	14.70%	5092	11	4917
Lower Merion township	15265	2375	15.60%			
Millbourne borough	44	44	100.00%	405	4	379
Narberth borough	316	268	84.90%			
Philadelphia city	91287	3562	3.90%			
Radnor township	8811	32	0.40%	9568	1013	9838
Upper Darby township	4824	2700	56.00%	33925	137	32746
Yeadon borough	1032	910	88.20%	1973	40	4794

The implementation of comprehensive septic tank management programs in those three municipalities ideally will be consistently designed to provide degrees of protection based on an assessment of the environmental sensitivity of the area.

The EPA has recently issued Voluntary National Guidelines for Management of Onsite and Clustered Wastewater Treatment Systems (EPA 832-B-03-001), covering all aspects of a comprehensive program, from design, inspection, and enforcement to public education and long-term planning. This document presents several different management models to choose from; division of responsibility and ownership between private land owners and public agencies varies between the different models. Municipalities should select that approach which best suits their conditions.



The Five Management Models

- Management Model 1 - "Homeowner Awareness" specifies appropriate program elements and activities where treatment systems are owned and operated by individual property owners in areas of low environmental sensitivity. This program is adequate where treatment technologies are limited to conventional systems that require little owner attention. To help ensure that timely maintenance is performed, the regulatory authority mails maintenance reminders to owners at appropriate intervals.
- Management Model 2 - "Maintenance Contracts" specifies program elements and activities where more complex designs are employed to enhance the capacity of conventional systems to accept and treat wastewater. Because of treatment complexity, contracts with qualified technicians are needed to ensure proper and timely maintenance.
- Management Model 3 - "Operating Permits" specifies program elements and activities where sustained performance of treatment systems is critical to protect public health and water quality. Limited-term operating permits are issued to the owner and are renewable for another term if the owner demonstrates that the system is in compliance with the terms and conditions of the permit. Performance-based designs may be incorporated into programs with management controls at this level.
- Management Model 4 - "Responsible Management Entity (RME) Operation and Maintenance" specifies program elements and activities where frequent and highly reliable operation and maintenance of decentralized systems is required to ensure water resource protection in sensitive environments. Under this model, the operating permit is issued to an RME instead of the property owner to provide the needed assurance that the appropriate maintenance is performed.
- Management Model 5 - "RME Ownership" specifies that program elements and activities for treatment systems are owned, operated, and maintained by the RME, which removes the property owner from responsibility for the system. This program is analogous to central sewerage and provides the greatest assurance of system performance in the most sensitive of environments.

Pet Waste, Litter, and Dumping Ordinances (AR2) Related goals: 5, 6, 8, 9 Related Indicators: 7, 8, 9, 10, 11, 16, 17, 18, 19, 20			
What	Who	Where	When
Adopt and enforce ordinance to require the removal of pet waste by the animal's owner within the municipality; Adopt and enforce ordinance to prohibit littering and dumping within the municipality.	See Table 7-3 (may not identify all municipalities with ordinance)	Entire Watershed	within 5 years; update as needed

Some municipalities in the Cobbs Creek watershed have adopted an ordinance to address removal of pet waste by the animal's owner and an ordinance that prohibits littering and dumping. These ordinances tend to be similar in scope but vary in penalties. Table 7-3 shows the municipalities in the watershed that are known to have adopted pet waste and littering ordinances.

Table 7-3 Pet Waste and Littering Ordinances in the Cobbs Creek Watershed

Municipality	**Pet Waste Ordinance**	**Littering and Dumping Ordinance**
Colwyn Borough

Upper Darby Township		
Yeadon Borough		

*** Note: Ordinances for East Lansdowne Borough were not reviewed for this analysis.*

Source: www.ordinance.com, Delaware Valley Regional Planning Commission

Municipalities currently without ordinances are strongly encouraged to adopt them within the next two years. As an example of possible ordinance language, the following excerpts from Haverford Township's pet waste ordinance and Lansdowne Borough's Littering and Dumping Ordinance appear below.

Pet Waste Ordinance	Littering and Dumping Ordinance
Haverford Township All excrement from animal(s) on the owner's property will be the responsibility of the owner of the offending animal to abate, and the owner shall clean the area of excrement on a daily basis. It shall be the duty of the owner of any animal to pick up and remove in its entirety any excrement from said animal from all public and private property. Excrement must not be deposited in a street or at a curbside, but must be removed from the area completely.	Lansdowne Borough The practice of throwing or dumping any discarded matter of any kind in or on any private or public property, vacant or occupied within the Borough of Lansdowne is prohibited. The practice of storing or depositing abandoned or junked vehicles, machinery, etc., in or on any public or private property, vacant or occupied is prohibited. The use or ownership of any unsafe or dangerous building or structure upon any public or private property, vacant or occupied, is prohibited. Driving or permitting the use of a motor vehicle that deposits its contents or other debris on any road within the Borough of Lansdowne is prohibited.

While pet waste and littering ordinances are enacted primarily for aesthetic purposes, reduction of pathogens and debris in stormwater, and thus in Cobbs Creek, can be reduced through their enforcement. Municipalities can assist residents in abiding by ordinances by placing trash cans in areas with higher pedestrian traffic. Plastic bags should be provided with trash cans in areas heavily used by dog owners. Homeowners' associations should also be asked to notify residents of these ordinances and to provide trash cans and plastic bags in those neighborhoods as well.

7.1.2 Public Education and Volunteer Programs

Public Education (AP1) Related Goals: 7, 8, 9, 10 Related Indicators: 16, 17, 18, 19, 20, 21			
What	Who	Where	When
Public Education Plan Educational Program Implementation	Municipalities on the Phase II List (see Table 7-4)	All municipalities in the Cobbs Creek Watershed	Short-term: first 5 years coinciding with the stormwater permit (See Table 7-5)

Public education about watershed management is an integral part of the watershed implementation plan. It is designed to educate citizens on the importance of the watershed to the community, and on ways that individual behavior can impact water quality and the riparian and aquatic environment associated with Cobbs Creek. In accordance with the Cobbs Creek Plan's stated purpose of integrating various existing programs, and to avoid duplication of effort, the recommended implementation plan follows the Stormwater Management Program Protocol ("Protocol") to meet the six Minimum Control Measures required of municipal permittees under Phase II NPDES Stormwater Regulations (found at 40 CFR §§ 122.26 – 123.35). In this way, implementation of these public education measures by municipalities will satisfy federal NPDES permit requirements for municipal separate storm sewer systems ("MS4s"), described in detail at 40 CFR §122.34.

Table 7-4 lists the municipalities that should work together with the City of Philadelphia on Public Education about watershed management issues. Assuming that a single, watershed-wide public education campaign focusing on all three targets (A, B, and C) can be implemented, PWD should, at a minimum, work with Haverford Township, Upper Darby Township, and Lower Merion Township to cover most of the watershed.

Table 7-4 Cobbs Creek Municipalities on Phase I or II Stormwater List

Municipality	County	% of Muni. Area Drained by Watershed	% of Watershed within Muni.
Colwyn Borough	Delaware	55%	1%
Darby Borough	Delaware	17%	1%

Haverford Twshp.	Delaware	59%	26%
Lansdowne Borough	Delaware	9%	<1%
Millbourne Borough	Delaware	100%	<1%
Radnor Twshp.	Delaware	1%	<1%
Upper Darby Twshp.	Delaware	50%	18%
Yeadon Borough	Delaware	85%	6%
Lower Merion Twshp.	Montgomery	18%	19%
Narberth Borough	Montgomery	92%	2%
City of Philadelphia	Philadelphia	4%	26%

Public Education Plan

PWD and the primary watershed municipalities should jointly develop a public education plan. The public education plan must target homeowners, business owners, and developers, focusing on connections between their actions, stormwater runoff, and water quality. By the end of Year 1, cooperating municipalities should have a comprehensive plan in place that will help tap into the target audiences' existing communication channels to inform them about improving stormwater quality. During the following permit years, municipalities should monitor the effectiveness of the plan, and update it to ensure information about the target audiences is accurate.

PADEP has made available a template for a public education plan, available on the PADEP website, www.dep.state.pa.us, directLINK "stormwater". The plan should include an approach to collecting information on the three target audience categories. Municipalities should create a comprehensive inventory of the newsletters, newspapers, web sites, meetings, magazines, organizations, associations, etc. used by the target audiences. Cooperation of the municipalities under the Cobbs Creek Watershed Plan in gathering this information should help eliminate redundancy of effort. During the remaining years of the stormwater permit, municipalities are responsible for ensuring that information in the public education plan is accurate and current.

In addition to the PADEP mandated information, other information relevant to watershed management should be included on topics such as:

- Improper Disposal to Storm Drains
- Automobile Maintenance
- Car Washing
- Animal Waste Collection
- Restorative Redevelopment: Public Education Aspects

Public Education Implementation

Once the public education plan is developed, it must be implemented. This means distributing educational materials provided by PADEP that contain messages related to watershed (and stormwater) management. Municipalities can find educational materials needed to implement the educational program on the PADEP website, www.dep.state.pa.us, directLINK "stormwater."

To fulfill NPDES stormwater permit requirements, municipalities should implement two phases of educational outreach. During the first stage, the focus is on raising the awareness of target audiences. In the second stage, municipalities should aim to educate the target audiences about the problems and potential solutions. PADEP presents requirements in the stormwater permit for the "what" and "when" of this minimum measure component, but it does not specify the "how." Municipalities should use their Public Education Plan to determine the most effective means of getting educational materials into the hands of target audiences. Any additional educational activities should show compliance with this Minimum Control Measure. This includes educational activities by watershed groups, and certainly should make use of the existing Cobbs Creek Partnership activities.

In Year 1, municipalities are required to start raising target audience awareness. Raising awareness can be accomplished by use of PADEP materials. PADEP has made available copies of the pamphlet entitled, "When It Rains, It Drains" (available on the PADEP website, www.dep.state.pa.us, directLINK "stormwater)." This document addresses the issue of pollution related to stormwater runoff and activities that citizens can use to improve stormwater quality. It also provides an overview of a typical stormwater management program. Using the information on distribution channels in the Public Education Plan, municipalities should disseminate these pamphlets to all the target audience categories in the community.

In Year 2, municipalities should begin to educate all the target audiences. This includes distributing fact sheets to developers about their responsibilities under the state and federal stormwater regulations. To meet this requirement, municipalities should distribute the Fact Sheets prepared by PADEP, and run a stormwater ad in local newspapers.

In addition to targeting developers, municipalities may distribute posters to schools, community organizations and institutions, and businesses. Topics such as responsible vehicle maintenance, household hazardous waste disposal, and pet waste management are important to stormwater management. PADEP has developed a series of posters that convey messages about these topics.

Another useful measure is storm drain stenciling. While not required by the Protocol, any stenciling done by outside organizations may contribute to meeting permit requirements for this Minimum Control Measure.

Public education directors should check any links to PADEP's stormwater website and update the links if necessary.

In Years 3-5, the implementation continues. This consists mainly of continuing with distribution of posters and fact sheets, and running additional ads in local newspapers.

The schedule for developing and implementing the plan to meet Phase II stormwater requirements is shown in Table 7-5 below.

Table 7-5 Schedule for Implementation of the Public Education Program

PERMIT YEAR		
	Education Plan	**Educational Program**
Year 1	Determine Target Audience Develop Public Education Plan Raise Target Audience Awareness	• Disseminate materials to all target audiences using appropriate distribution channels • Newspaper advertisement • Other components of Plan
Years 2-5	Implement the plan Revise Plan as needed	• Disseminate materials to all target audiences using appropriate distribution channels • Newspaper advertisement • Other components of Plan

Source: PADEP MS4 Stormwater Management Program Protocol, 2003

School-Based Education (AP2) Related Goals: 8, 9 Related Indicators: 17, 18, 21			
What	Who	Where	When
Implement PA Environmental Education Curriculum; engage schoolchildren and watershed protection through resources such as Cobbs Creek Community Environmental Education Center and the John Heinz Wildlife Refuge at Tinicum.	School districts, supported by municipal governments and non-profits	All schools	Short-term (within 5 years)

Besides requirements found in the MS4 Stormwater Management Program Protocol, another important aspect of public education is to reach children through school curricula.

School-based watershed education takes many forms, from lesson plans within the classroom, to hands-on activities outside of the classroom such as field trips to Cobbs and Darby creeks and nearby nature centers, as well conducting actual restoration projects. Teacher training programs, developed to assist teachers in bringing watershed concepts to their students, are critical, as are partnerships with groups like the Cobbs Creek Community Environmental Education Center Inc, and the John Heinz Wildlife Refuge at Tinicum. Being engaged in actual restoration projects, whether through service learning, after school clubs, or as part of lesson plans translates lessons into action.

Sources for lesson plans include the following:

- Incorporate the Pennsylvania Environmental Education Curriculum developed by PADEP into middle school curricula. This curriculum introduces concepts in watersheds, wetlands, stormwater, drinking water, and water and air pollution.
- Use local examples of watershed protection and restoration to enhance the program. The Cobbs Creek Community Environmental Education Center works with schools to provide watershed-based educational opportunities, including the Environmental Scholars Program, Tree Survey Project, Urban Watershed Program, Environmental Clubs, Learning Grove / Trail Development Project, Park Management Program, and Teacher Training Program.

Public Participation and Volunteer Programs (AP3) Related Goals: 4, 6, 7, 8, 9, 10 Related Indicators: 15, 10, 11, 12, 13, 14, 16, 17, 18, 21			
What	Who	Where	When
Public Participation Volunteer Monitoring and Storm Drain Stenciling	Municipalities	All municipalities in the Cobbs Creek Watershed	First 5 years coinciding with the stormwater permit.

Public participation is another facet of implementation that must follow the Stormwater Management Program Protocol (“Protocol”) to meet the six Minimum Control Measures required of municipal permittees under the Phase II NPDES Stormwater Regulations (found at 40 CFR §§ 122.26 – 123.35). The public must participate in issues related to municipal actions to address stormwater impacts on water quality. This includes new planning initiatives, changes to ordinances and other local regulations. This requirement overlaps the public participation aspects of the watershed management plan, and suggests that a unified and coordinated approach between municipalities would be efficient. All municipalities in the watershed (listed in Table 7-4) are required to have a public participation program.

Prior to adoption of any ordinance required under the PADEP Stormwater Protocol, municipalities must provide adequate public notice and opportunities for public review and input, and hold hearings to obtain public feedback. This can be done in conjunction with normal public sessions of the municipal governing body. The notice must be published in a local newspaper of general circulation. Involving citizen groups, watershed organizations and businesses as much as possible will obtain broad support for stormwater management efforts. The current Steering Committee for the Cobbs Creek Watershed Plan is an obvious example of such inclusion, and can help municipalities to meet this requirement.

Although the actual public participation requirements can be met by following guidelines for Act 167 planning, it is recommended that municipalities do more than the minimum. Some options for additional public participation are listed below.

- Develop a Public Involvement and Participation Plan: by the end of Year 1, a municipality may want to have a comprehensive plan in place that will guide your efforts to recruit volunteers and obtain participation at public meetings. This could be part of the Public Education Plan discussed above.

- Produce strategies for recruiting participation from six categories of stakeholders: municipal employees, homeowners, businesses, schools, watershed associations and other volunteer groups and developers.

- Develop a comprehensive stakeholder mailing list.

- Conduct Public Meetings: PADEP suggests using a general stormwater public meeting to kick-off public education and participation efforts. This has already been done for the Cobbs Partnership and Steering Committee, and municipalities are encouraged to make use of this. Invite representatives from all six stakeholder categories. It is important that all stakeholder interests have the opportunity to participate. Meeting agendas should include, but not be limited to, the overview presentation on the watershed management and stormwater program and time for questions from the audience.

An important aspect of public participation is the establishment of volunteer programs. There are many types of volunteer programs that can help manage stormwater and improve a community's water quality. The goal of the volunteer program is to obtain and sustain volunteer support that will aid watershed management efforts. To reach this goal, it is important to develop a program that reflects stakeholders' concerns and interests. Examples of volunteer programs are:

Volunteer Monitoring Program

Municipalities should determine which type of assessment the program will undertake and develop a study design using the manual entitled *Designing Your Monitoring Program: A Technical Handbook for Community-Based Monitoring in Pennsylvania* as the basis for planning and implementing your monitoring program (PADEP, 2001).

Storm Drain Stenciling Program

Municipalities should establish procedures for storm drain stenciling and organize volunteers to carry out the program. PADEP has provided resource materials in a References and Resources CD-ROM on developing and implementing a storm drain stenciling program.

Stream Cleanup and Restoration Activities

Citizen participation in stream cleanups is a good way to get the community involved in keeping the streams free of trash and debris. Stream cleanups can be coordinated with PWD's Waterways Restoration Unit. Other participatory activities can include support of riparian plantings during stream restoration activities.

7.1.3 Municipal Measures

Capacity Management Operation and Maintenance (CMOM) (AM1)
Related Goals: 1, 5, 6
Related Indicators: 7, 9, 11

What	Who	Where	When
Program to manage and maintain sewer systems; plans in place to track SSOs and overflow response plan.	Separate Sewered Municipalities	Separate Sanitary Sewer Areas	Medium term: 5+ years

CMOM programs are recommended for all areas with separate sanitary sewer systems and are an important component of Target A because they help prevent dry weather discharges. Recommendations in this section cover both the dry and wet weather aspects of the program; recommendations that are specific to SSO abatement are included here for completeness and are referred to under Target C. The recommendations in this section are adapted from the "Consensus Recommendation of the SSO Federal Advisory Subcommittee" published in October 1999.

(1) General Standards

- Properly manage, operate and maintain, at all times, all parts of collection system. Perform maintenance and inspections using techniques similar to those recommended for combined sewers in option AM2.
- Provide adequate capacity to convey base flows and peak flows for all parts of the collection system.
- Take all feasible steps to stop, and mitigate the impact of, sanitary sewer overflows in portions of the collection system.
- Provide notification to parties with a reasonable potential for exposure to pollutants associated with the overflow event.
- Develop a written summary of the CMOM program and make it, and the audit under section (5), available to any member of the public upon request.

(2) Management Program

Develop a capacity, management, operation and maintenance (CMOM) program to comply with the above general standards. If any element of this section is not appropriate or applicable for the CMOM program in question, it does not need to address the element, but a written summary must explain why that element is not applicable.

The management program should consist of the following six components.

1. Goals
The program must identify in detail the major goals of the CMOM program consistent with the general standards identified above.

2. Organization
A) Identify administrative and maintenance positions responsible for implementing measures in the CMOM program, including lines of authority by organization chart or similar document; and (B) establish the chain of communication for reporting SSOs from receipt of a complaint or other information to the person responsible for reporting to the NPDES authority.

3. Legal Authority
Include legal authority, through sewer use ordinances, service agreements or other legally binding documents, to:
(A) Control infiltration and connections from inflow sources;
(B) Require that sewers and connections be properly designed and constructed;
(C) Ensure proper installation, testing, and inspection of new and rehabilitated sewers (such as new or rehabilitated collector sewers and new or rehabilitated service laterals);
(D) Address flows from satellite municipal collection systems; and
(E) Implement the general and specific prohibitions of the national pretreatment program that you are subject to under 40 CFR 403.5.

4. Measures and Activities
The CMOM program must address the elements listed below that are appropriate and applicable to the sewer system and identify the person or position in the organization responsible for each element.
(A) Maintenance of facilities
(B) Maintenance of a map of the collection system
(C) Management of information and use of timely, relevant information to establish and prioritize appropriate CMOM activities, and to identify and illustrate trends in overflows.
(D) Routine preventive operation and maintenance activities
(E) Assessment of the current capacity of the collection system and treatment facilities
(F) Identification and prioritization of structural deficiencies and identification and implementation of short-term and long term rehabilitation actions to address each deficiency
(G) Appropriate training on a regular basis.
(H) Equipment and replacement parts inventories including identification of critical replacement parts.

5. Design and Performance Provisions
(A) Requirements and standards for the installation of new sewers, pumps and other appurtenances; and rehabilitation and repair projects.

(B) Procedures and specifications for inspecting and testing the installation of new sewers, pumps, and other appurtenances and for rehabilitation and repair projects.

6. Monitoring, Measurement and Program Modifications
Monitor the implementation and, where appropriate, measure the effectiveness of each element of the CMOM program. Program elements must be updated as appropriate based on monitoring or performance evaluations. The summary of the CMOM program should be modified as appropriate to keep it updated and accurate.

(3) Overflow Response Plan:

An overflow response plan should be developed and implemented that identifies measures to protect public health and the environment including, but not limited to, mechanisms to:

(i) ensure that all overflows are made aware of (to the greatest extent possible);

(ii) ensure that overflows are appropriately responded to, including ensuring that reports of overflows are immediately dispatched to appropriate personnel for investigation and appropriate response;

(iii) ensure appropriate reporting pursuant to 40 CFR 122.42(e).

(iv) ensure appropriate notification to the public, health agencies, and other impacted entities (e.g. water suppliers) pursuant to 40 CFR 122.42(h). The CMOM plan should identify the public health and other officials who will receive immediate notification.

(v) ensure that appropriate personnel are aware of and follow the plan and are appropriately trained; and

(vi) provide emergency operations.

(4) System Evaluation and Capacity assurance plan:

A plan should be prepared and implemented for system evaluation and capacity assurance if peak flow conditions are contributing to an SSO discharge unless either (1) already taken steps to correct the hydraulic deficiency or (2) the discharge meets the criteria of 122.42(g)(2). At a minimum the plan must include:

(i) **Evaluation**: Steps to evaluate those portions of the collection system which are experiencing or contributing to an SSO discharge caused by hydraulic deficiency or to noncompliance at a treatment plant. The evaluation should provide estimates of peak flows (including flows from SSOs that escape from the system) associated with conditions similar to those causing overflow events, provide estimates of the capacity of key system components, identify hydraulic deficiencies, including components of the system with limiting capacity and identify the major sources that contribute to the peak flows associated with overflow events.

(ii) **Capacity Enhancement Measures**: Establish short and long term actions to address each hydraulic deficiency including prioritization, alternative analysis, and a schedule.

(iii) **Plan updates**: The plan should be updated to describe any significant change in proposed actions and/or implementation schedule. The plan should also be updated to reflect available information on the performance of measures that have been implemented.

(5) CMOM Program Audits

As part of the NPDES permit application, an audit should be conducted, appropriate to the size of the system and the number of overflows, and a report submitted of such audit, evaluating the CMOM program and its compliance with this subsection, including its deficiencies and steps to respond to them.

(6) Communications

The permittee should communicate on a regular basis with various interested parties on the implementation and performance of its CMOM program. The communication system should allow interested parties to provide input to the permittee as the CMOM program is developed and implemented.

Inspection and Cleaning of Combined Sewers (AM2)
Related Goals: 6, 7, 10
Related Indicators: 11, 19

What	Who	Where	When
inspection activities routine maintenance, monitoring activities	PWD	Combined Sewered Areas (see Figure 7-2)	First 5 years coinciding with the stormwater permit.

Maintenance of sewers includes activities required to keep the system functioning as it was originally designed and constructed. Any reinvestment in the system, including routine maintenance, capital improvements for repair or rehabilitation, inspection activities, and monitoring activities are generally classified as maintenance.

An inspection program is vital to proper maintenance of a wastewater collection system. Without inspections, a maintenance program is difficult to design, since problems cannot be solved if they are not identified. Sewer inspections identify problems such as blocked, broken, or cracked pipes; tree roots growing into the sewer; sections of pipe that settle or shift so that pipe joints no longer match; and sediment and other material building up and causing pipes to break or collapse. The elements of an inspection program include flow monitoring, manhole inspections, smoke/dye testing, closed circuit television inspection, and private sector inspections. Private sector building inspection activities include inspection of area drains, downspouts, cleanouts, sump discharges and other private sector inflow sources into the system.

In addition to inspection, routine maintenance must also include sewer cleaning, root removal/treatment, cleaning of mainline stoppages, cleaning of house service stoppages, and inspections and servicing of pump stations.

PWD is responsible for implementation of this option in the combined sewer areas of the Cobbs Creek watershed, but municipalities with separate sewers should have similar permanent and active sewer maintenance programs in place under CMOM (see AM1). Figure 7-2 shows the areas where sanitary sewers and combined sewers exist. All municipalities in the watershed are responsible for sewer maintenance.

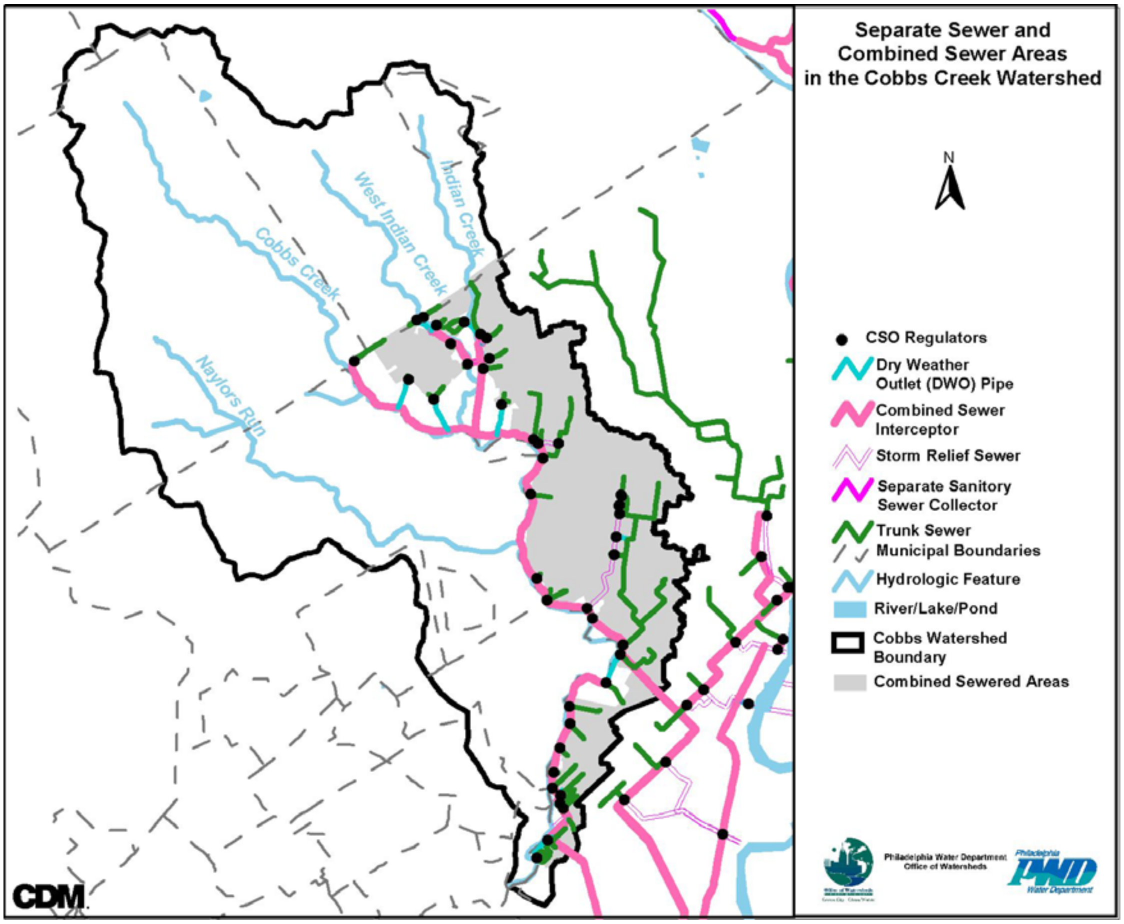

Figure 7-2 Separate Sewer and Combined Sewer Areas in Cobbs Creek

PWD has combined sewer maintenance responsibilities in the Cobbs Creek watershed. CSO regulations (the Nine Minimum Controls discussed in Section 1) have required that PWD carry out improved sewer maintenance. Some of the activities PWD is carrying out include the review and improvement of on-going operation and maintenance programs, and comprehensive inspection and monitoring programs to characterize and report overflows and other conditions in the combined sewer system.

Sanitary Sewer Rehabilitation (AM3) Related Goals:5, 6 Related Indicators:7, 11			
What	Who	Where	When
Perform major repairs or replacement on sections of sewer determined to be in poor condition.	All municipalities with separate sanitary sewer systems	All municipalities with separate sanitary sewer systems	Medium Term

The CMOM and sewer inspection programs discussed in previous sections may identify sections of sewer that are in poor condition and in need of major repair or replacement. This section is adapted from fact sheets provided on the EPA web site: http://www.epa.gov/owm/mtb/rehabl.pdf.

Under the traditional method of sewer relief, a replacement or additional parallel sewer line is constructed by digging along the entire length of the existing pipeline. While these traditional methods of sewer rehabilitation require unearthing and replacing the deficient pipe (the dig-and-replace method), trenchless methods of rehabilitation use the existing pipe as a host for a new pipe or liner. Trenchless sewer rehabilitation techniques offer a method of correcting pipe deficiencies that requires less restoration and causes less disturbance and environmental degradation than the traditional dig and-replace method.

Trenchless Sewer Rehabilitation Methods:

- Pipe Bursting, or In-Line Expansion
- Sliplining
- Cured-In-Place Pipe
- Modified Cross Section Liner

These alternative techniques must be fully understood before they are applied. These four sewer rehabilitation methods are described further in the following sections.

Pipe Bursting or In-Line Expansion

Pipe bursting, or in-line expansion, is a method by which the existing pipe is forced outward and opened by a bursting tool. The Pipebursting™ method, patented by the British Gas Company in 1980, was successfully applied by the gas pipelines industry before its applicability was identified by other underground utility agencies. Over the last two decades, other methods of in-line expansion have been patented as well. During in-line expansion, the existing pipe is used as a guide for inserting the expansion head (part of the bursting tool). The expansion head, typically pulled by a cable rod and winch, increases the area available for the new pipe by pushing the existing pipe radially outward until it cracks. The bursting device pulls the new pipeline behind itself.

Sliplining

Sliplining is a well-established method of trenchless rehabilitation. During the sliplining process, a new liner of smaller diameter is placed inside the existing pipe. The annular space, or area between the existing pipe and the new pipe, is typically grouted to prevent leaks and to provide structural integrity.

Cured-In-Place Pipe

During the cured-in-place pipe (CIPP) renewal process, a flexible fabric liner, coated with a thermosetting resin, is inserted into the existing pipeline and cured to form a new liner. The liner is typically inserted into the existing pipe through an existing manhole. The fabric tube holds the resin in place until the tube is inserted in the pipe and ready to be cured. Commonly manufactured resins include unsaturated polyester, vinyl ester.

Modified Cross Section Lining

The modified cross section lining methods include deformed and reformed methods, sewagelining™, and rolldown. These methods either modify the pipe's cross sectional profile or reduce its cross sectional area so that the liner can be extruded through the existing pipe. The liner is subsequently expanded to conform to the existing pipe's size. Another method of obtaining a close fit between the new lining and existing pipe is to temporarily compress the new liner before it is drawn through the existing pipeline. The sewagelining™ and rolldown processes use chemical and mechanical means, respectively, to reduce the cross-sectional area of the new liner.

External Sewer Rehabilitation Methods (adapted from EPA/600/R-01/034)

External rehabilitation methods are performed from the above ground surface by excavating adjacent to the pipe, or the external region of the pipe is treated from inside the pipe through the wall. Some of the methods used include:

External Point Repairs
Chemical Grouting (Acrylamide Base Gel, Acrylic Base Gel)
Cement Grouting (Cement, Microfine Cement, Compaction)

Internal Sewer Rehabilitation Methods
The basic internal sewer rehabilitation methods include:

Chemical Grouting

Internal grouting is the most commonly used method for sealing leaking joints in structurally sound sewer pipes. Chemical grouts do not stop leaks by filling cracks; they are forced through cracks and joints, and gel with surrounding soil, forming a waterproof collar around leaking pipes. This method is accomplished by sealing off an area with a "packer," air testing the segment, and pressure injecting a chemical grout for all segments which fail the air test. The three major types of chemical grout are: Acrylic, Acrylate, and Urethane.

Continuous Pipe

Insertion of a continuous pipe through the existing pipe (Polyethylene and Polypropylene)

Segmental

Short segments of new pipe are assembled to form a continuous line, and forced into the host pipe. Generally, this method is used on larger sized pipe and forced into the host pipe. (Polyethylene, Polyvinyl Chloride, Reinforced Plastic Mortar, Fiberglass Reinforced Plastic, Ductile Iron, Steel)

Fold and Form Pipe

This is similar to sliplining, except that the liner pipe is deformed in some manner to aid insertion into the existing pipe. Depending on the specific manufacturer, the liner pipe may be made of PVC or HDPE. One method of deforming the liner is to fold it into a "U" shape before insertion into the existing pipe. The pipe is then returned to its original circular shape using heated air or water, or using a rounded shaping device or mandrel. Ideally, there will be no void between the existing pipe and the liner pipe after expansion of the liner pipe with the shaping device. For the "U" shape liner, the resulting pipe liner is seamless and jointless.

Spiral Wound Pipe

This involves winding strips of PVC in a helical pattern to form a continuous liner on the inside of the existing pipe. The liner is then strengthened and supported with grout that is injected into the annular void between the existing pipe and the liner. A modified spiral method is also available that winds the liner pipe into a smaller diameter than the existing pipe, and then by slippage of the seams, the liner expands outward.

Combined Sewer Rehabilitation (AM4) Related Goals: 5, 6, 9, 10 Related Indicators: 7, 8, 9, 10, 11, 19, 20			
What	Who	Where	When
Perform major repairs or replacement on sections of sewer determined to be in poor condition.	PWD	Combined-Sewered Areas	Medium Term

Rehabilitation of combined sewers is conceptually similar to rehabilitation of separate sanitary sewers. Refer to option AM3 for information on specific techniques.

Illicit Discharge, Detection, and Elimination (IDD&E) (AM5)
Related Goals: 5, 6, 8, 9, 10
Related Indicators: 7, 8, 9, 10, 11, 16, 19, 20

What	Who	Where	When
IDD&E Program in conformance with Phase II Stormwater Permits and the LTCP for PWD.	All Municipalities required to do Phase II permit (see Table 7-4) PWD in CSO Areas	All areas with a storm sewer or combined sewer. See Figure 7-2	Five year program associated with stormwater permit. (See Table 7-7)

In accordance with the Cobbs Creek Plan's stated purpose of integrating various existing programs, and to avoid duplication of effort, the recommended implementation plan follows the Stormwater Management Program Protocol ("Protocol") to meets the six minimum control measures required of municipal permittees under the Phase II NPDES Stormwater Regulations (found at 40 CFR §§ 122.26 – 123.35). One of the six minimum controls is an IDD&E program. The IDD&E program can be summarized as consisting of the following steps:

- Develop map of municipal separate storm sewer system outfalls and receiving water bodies
- Prohibit illicit discharges via PADEP-approved ordinance
- Implement an IDD&E Program that includes 1) field screening program and procedures and 2) elimination of illicit discharges
- Conduct public awareness and reporting program (see under Public Education above)

A similar approach to controlling dry weather flows is being followed by PWD under the Long Term Control Plan (LTCP) for CSOs.

Each step is explained in more detail below.

Develop an Outfall Map

The federal regulations define an outfall as "a point source as defined by 40 CFR 122.2 at the point where a municipal separate storm sewer discharges to waters of the United States". A "point source" is defined as "any discernable, confined and discrete conveyance, including but not limited to any pipe, ditch, channel, tunnel, conduit, well, discrete fissure, container, rolling stock, concentrated animal feeding operation, vessel, or other floating craft from which pollutants are or may be discharged."

Many of the outfalls along Cobbs Creek have already been located under the studies performed for the Cobbs Creek Watershed Management Plan. Municipalities should work with PWD to develop a consistent set of outfall maps that meet the specific requirements of the Phase II program.

Illicit Discharge Ordinance

A Model Ordinance is available from PADEP and should be used as is. PADEP discourages changes to the model ordinance, because it has been prepared to meet the MS4 permit requirements. However, some municipalities already have good stormwater ordinances. Municipalities who do not wish to enact the model ordinance in its entirety must get approval from PADEP to ensure that the MS4 permit requirements are met.

The model ordinance must be enacted in the first year of the permit term, except where a municipality commits to a multi-municipal, watershed-based program following this Protocol, in which case the schedule is delayed one year. Subsequent to completion of the Act 167 Plan (or Plan Update), the ordinance must be modified to reflect Plan requirements. Regardless of the timing of the Act 167 Plan (or Plan Update) an ordinance must be enacted within the first two years of the permit term for all municipalities in Cobbs Creek.

IDD&E Program

Following PADEP protocol, the IDD&E Program must consist of the following three elements, which must be implemented according to the schedule shown below.

- Conduct Field Screening
- Identify Source of Illicit Discharges
- Develop and Implement a Strategy to Remove or Correct Illicit Discharges.

Field Screening

Field screening is necessary to identify source(s) of actual illicit discharges. Field screening must start in Year 2 of the permit. PADEP provides a checklist that must be used when conducting field screening. Every outfall in priority areas must be screened two times a year. This activity can be accomplished concurrently with other existing field activities, such as regularly scheduled fire hydrant inspections, road repairs, landscaping activities, other field work conducted during county preparation of the Act 167 stormwater plan, etc.

Using a PADEP supplied Checklist, the staff designated to conduct field screening collect visual data. The screening should be conducted at least 72 hours since the last precipitation event, and at least 48 hours should pass between the first screening at a particular outfall and the second screening at that outfall. If someone conducting the field screening discovers a dry-weather flow, they (or another designated individual with the proper training) must collect a sample of that flow for analysis. Such a discovery triggers the requirements under the other two program elements:

- Identify Source of Illicit Discharges
- Remove or Correct Illicit Discharges

Identify the Source of Illicit Discharges

The following IDD&E Program elements only apply if a dry-weather flow is identified during field screening activities in Years 2, 3, 4, and/or 5. For each illicit discharge that is identified during field screening, the following program elements must be carried out.

- Collect and analyze samples of the dry-weather flow.

If field inspectors identify a dry-weather flow at an outfall during field screening, they should take two grab samples of the flow and analyze the samples for the characteristics and pollutants listed in the Table 7-6 below.

Table 7-6 Dry-Weather Flow Sampling Analysis Requirements

Characteristic/Pollutant	Method
Color	Visual observation
Odor	Visual observation
Turbidity	Visual observation
Sheen/scum	Visual observation
PH	In-field analysis
Total chlorine	In-field analysis
Total copper	In-field analysis
Total phenol	In-field analysis
Detergents/surfactants	In-field analysis
Flow	In-field measurement
Bacteria	Laboratory analysis

- Identify the source of the discharge.

The data obtained from visual, in-field, and laboratory analysis will provide the information necessary to determine the source of the dry-weather flow or floatables. Based on the pollutants contained in the sample, it should be possible to determine if the source is from illegal dumping in a storm drain, a cross-connection, or a leak in a pipe. Potential sources of the dry-weather flow can be located by tracing the flow upstream using storm drain maps and by inspecting upgradient manholes and storm drains. If need be, a more focused test to pinpoint the source can be tried, such as dye testing, smoke testing, and television camera inspection.

Remove or Correct the Illicit Discharge

Once the source has been identified, municipalities need to determine if it is a case of improper dumping or if a property owner has an improper physical connection to the storm sewer system. This will help to select the most appropriate method for correcting or removing the discharge. If it is a case of improper dumping, the only recourse may be to conduct intensified education of residents living in and traveling through that area. If it is a case of an improper physical connection, the appropriate action can be taken to correct the discharge. A plan of action to eliminate elicit connections might include plugging discharge points or disconnecting and reconnecting lines.

If a violation is found, the property owner should be notified of the violation and given a timeframe for removal of the source. After that time has passed, the outfall can be screened to identify the dry weather discharge. The property should be visited a final time to confirm that the property owner removed or corrected the source. The results of all discussions, tests, and screenings should be documented for follow-up purposes. Progress evaluation of the municipal IDD&E program will depend on the ability to tabulate the number of illicit connections corrected and the status of those in the process of being corrected.

All municipalities within Cobbs Creek that have a sanitary sewer system are required to carry out this program. Table 7-4 lists the municipalities, and Figure 7-1 shows the location of the sewered areas.

The PADEP protocol has laid out a very specific time table for completion of this program by the municipalities. The timing is shown in Table 7-7 below.

Table 7-7 Implementation Schedule for IDE&E Program

PERMIT YEAR	*IMPLEMENTATION SCHEDULE PERMIT REQUIREMENTS AND MEASURABLE GOALS*			
	Mapping	**Ordinance**	**Program**	**Education**
Year 2	· Establish priority areas for 25% of system	Implement and enforce	· Screen Priority Areas · Take corrective actions to remove illicit discharges (as needed)	· Distribute educational material (see Public Education and Outreach Minimum Measure)
Years 3-5	· Establish priority areas for 25% of system	Implement and enforce	· Screen Priority Areas · Take corrective actions to remove illicit discharges (as needed)	· Distribute educational material (see Public Education and Outreach Minimum Measure)

Stream Cleanup and Maintenance (AM6) Related Goals: 2, 4, 6, 8, 9 Related Indicators: 3, 4, 5, 6, 10, 11, 15, 16, 17, 19, 20			
What	Who	Where	When
Remove litter and heavy debris. Maintain habitat improvements (fish ladders, FGM, elimination of plunge pools).	PWD Waterways Restoration Unit; Fairmount Park volunteers and other volunteer groups	Portions of Cobbs Creek and tributaries within or along the City boundary; areas outside the City maintained by volunteers only	Begin within 5 years; monthly maintenance schedule to be determined

Keeping streams free of trash is a continuous activity. NLREEP volunteers alone have removed over 2,000 bags of trash from the stream corridor since 1998. Public education should help in reducing trash and debris reaching the streams, however, PWD and municipalities need to put into place a permanent maintenance schedule. PWD has implemented a permanent Waterways Restoration Unit. This team periodically removes trash and large debris from Cobbs Creek on a rotating schedule. For reaches of stream within the City or along the City boundary, the team will focus on removal of litter and heavy debris, and maintenance of in-stream aquatic habitat improvement projects including fish ladders, fluvial geomorphologic restoration projects, and elimination of outfall plunge pools. For reaches of stream outside the City, municipalities should organize periodic stream cleanups using volunteer groups.

Municipalities that have the greatest length of stream within their boundaries include Haverford Township, Upper Darby Township, and Lower Merion Township.

Enhancing Stream Corridor Recreational and Cultural Resources (AO1) Related Goals: 7, 8, 9 Related Indicators: 16, 17, 18, 19, 20, 21			
What	Who	Where	When
Establish and improve trails and greenways using measures recommended in the Darby RCP and the Fairmount Park Trails Master Plan. Protect historic sites listed in the Darby RCP.	Outside Philadelphia: partnership of Department of Conservation and Natural Resources (DCNR), county planning departments, and municipalities. Inside Philadelphia: Fairmount Park Commission.	See Figures 7-3 and 7-4.	Medium term: 5-15 years

Part of Target A addresses the accessibility of Cobbs Creek. Once dry weather water quality and aesthetics have been improved, the recreational value of the Creek will be enhanced, and better accessibility becomes important. A stream accessibility analysis (Section 4, Indicator 18) indicated that much of the headwaters of the Cobbs are inaccessible. The recommended actions focus primarily on improving access to public lands where recreational potential is greatest.

Outside the City of Philadelphia, implementation of the Upper Cobbs Creek Area Greenway is recommended in the Darby Creek Watershed River Conservation Plan. Most of the proposed greenway extension lies in Haverford Township (Figure 7-3). The main recommendations from the RCP are:

- Link existing Fairmount Park green areas northward to Haverford College
- Link the Cobbs greenway to the Darby Creek main-stem through the Merion Golf Club and Haverford State Hospital Site.

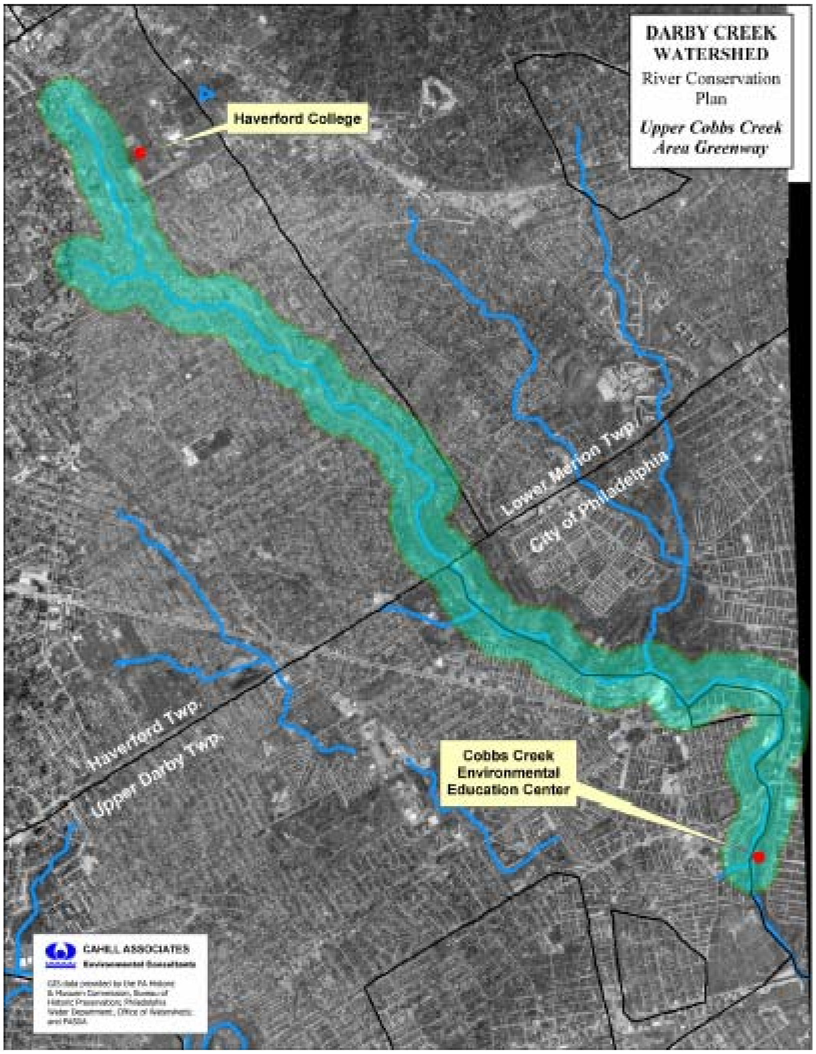

Figure 7-3 Upper Cobbs Creek Area Greenway (Source: Darby RCP)

Fairmount Park's Natural Lands Restoration and Trails Master Plan contains specific recommendations for creating and enhancing trails in the Cobbs section of the Park. These are shown in Table 7-8 and in Figure 7-4.

Table 7-8 Fairmount Park Trails Master Plan Recommendations for Cobbs Creek

- Provide maximum support and development of positive volunteer educational and restoration efforts already in place.
- Eliminate redundant and problematic trails that are contributing to the ecological decline of the natural areas.
- Increase perceived safety by providing better trail sight lines and perimeter lighting.
- Create well-defined trail heads that have good transit and regional connections.
- Provide access points/gateways to adjacent neighborhoods.
- Provide interpretive and educational opportunities for the diverse ecological and cultural settings of the park.
- Provide for adequate parking and controlled access to the trails to eliminate/reduce likelihood of trails as entrance points for motorized vehicles (particularly ATV's and abandoned autos).
- Provide maintenance strategies and restoration solutions for eroded and degraded trails that will continue to be used.

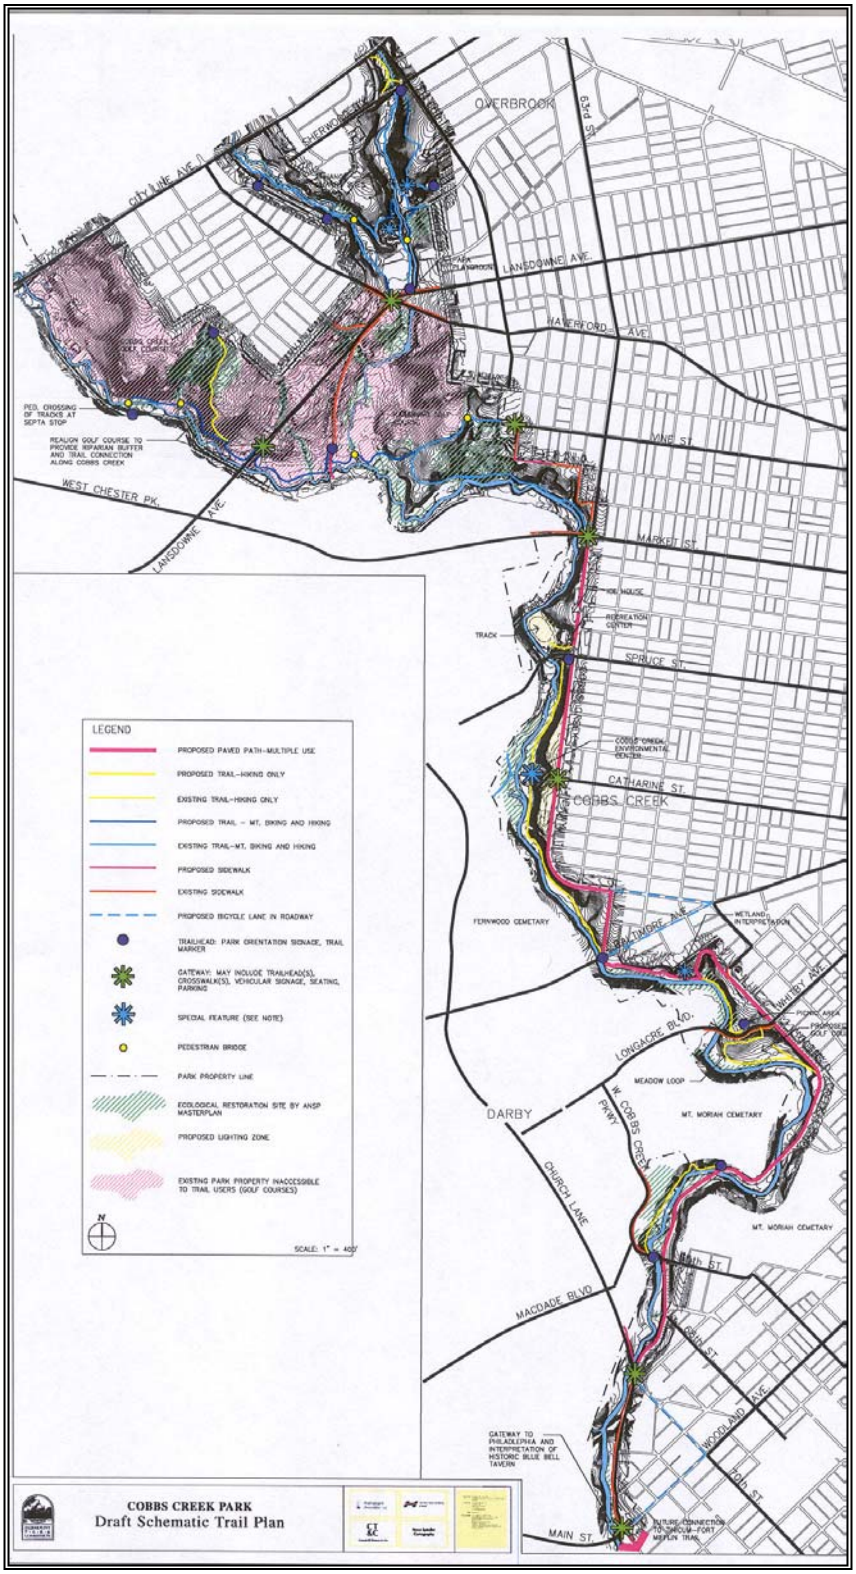

Figure 7-4 Cobbs Creek Schematic Trail Plan (from www.nlreep.org)

7.2 Target B: Healthy Living Resources

Stream and Riparian Corridor Improvement

The Cobbs Creek Watershed Management Plan proposes a comprehensive stream and riparian corridor restoration strategy. Given the historic degradation of the water quality and ecology of Cobbs Creek and its tributaries from urbanization, an interdependent set of corridor improvement actions are recommended. The actions - ranging from conservation of existing open spaces, to stream stabilization actions, to creation of new wetlands and biofiltration areas – together constitute a fully integrated riparian corridor improvement strategy that provides new habitat and water quality improvement. In the Philadelphia portion of the riparian corridor, this approach is intended to complement and expand the Fairmount Park Commission's Natural Lands Restoration and Environmental Education Program (NLREEP).

These riparian corridor improvement actions, when implemented simultaneously, will result in improvements that span the waterway and riparian corridor, from the developed properties along one bank to the developed properties along the opposing bank. Thus, riparian corridor actions improve the ecology of the Cobbs Creek landscape and optimize the ways in which the limited remaining open space can help improve water quality. The long-term benefits of an integrated riparian strategy significantly outweigh the short-term construction disturbances that are needed to implement the Cobbs Creek riparian corridor improvements.

The riparian corridor is defined here as the land area that borders a stream and which directly affects and is affected by the water quality. The riparian corridor typically includes floodplains, shorelines, wetlands, and riparian forest. For the purposes of the Cobbs Creek riparian corridor improvement strategy, the riparian area also includes the stream channel. Thus, the full undeveloped land and waterway area between the existing land development that surrounds the corridor will be considered for ecological improvement and for biofiltration functions that will improve water quality. Listed below are the options recommended for implementation across the corridor, from the lowest point in the landscape (the stream channel) to the highest (upland forest).

BMR Monitoring and Reporting

Timeline. The most effective approach to riparian corridor improvement is to perform all the proposed streambed, streambank, wetland, and riparian upland improvements simultaneously along a reach, or stream section. When one section is completed, work shifts downstream, section by section, for the length of the Cobbs Creek corridor. Implementing one set of corridor actions, for example, bed stabilization, without complementary actions, such as bank stabilization, will result in only limited success, because the aquatic and streamside land environments must function interactively to provide optimal stability. For this reason, the riparian corridor improvement strategy is both a short-term and long-term plan. Restoration activities in sections of the Creek that are in greatest need of improvement should be implemented early (targeting stream sections that are causing or contributing to water quality or ecological impairment first). For the Cobbs Creek corridor, it is anticipated that significant improvements in water quality and ecology can be realized by addressing high priority locations early in the planning cycle, with lower priority sections receiving riparian corridor improvement later in the cycle (Figure 7-5 and Table 7-9). It is important to note that the next step in implementing the riparian corridor improvement strategy is to develop a corridor improvement facilities plan, under which integrated designs are prepared for the full range of corridor improvements (e.g., bed and bank stabilization, and wetland creation and enhancement). Also included in this facilities plan are recommended solutions to problems created by channel obstructions such as bridge abutments.

Aside from land management strategies, restoration efforts are generally recommended for implementation beginning in headwater reaches and continuing downstream to avoid undermining any previous efforts. However, restoration projects for the East and West Indian Creeks may occur simultaneously with ongoing efforts upstream of the confluence of East Indian Creek and Cobbs Creek.

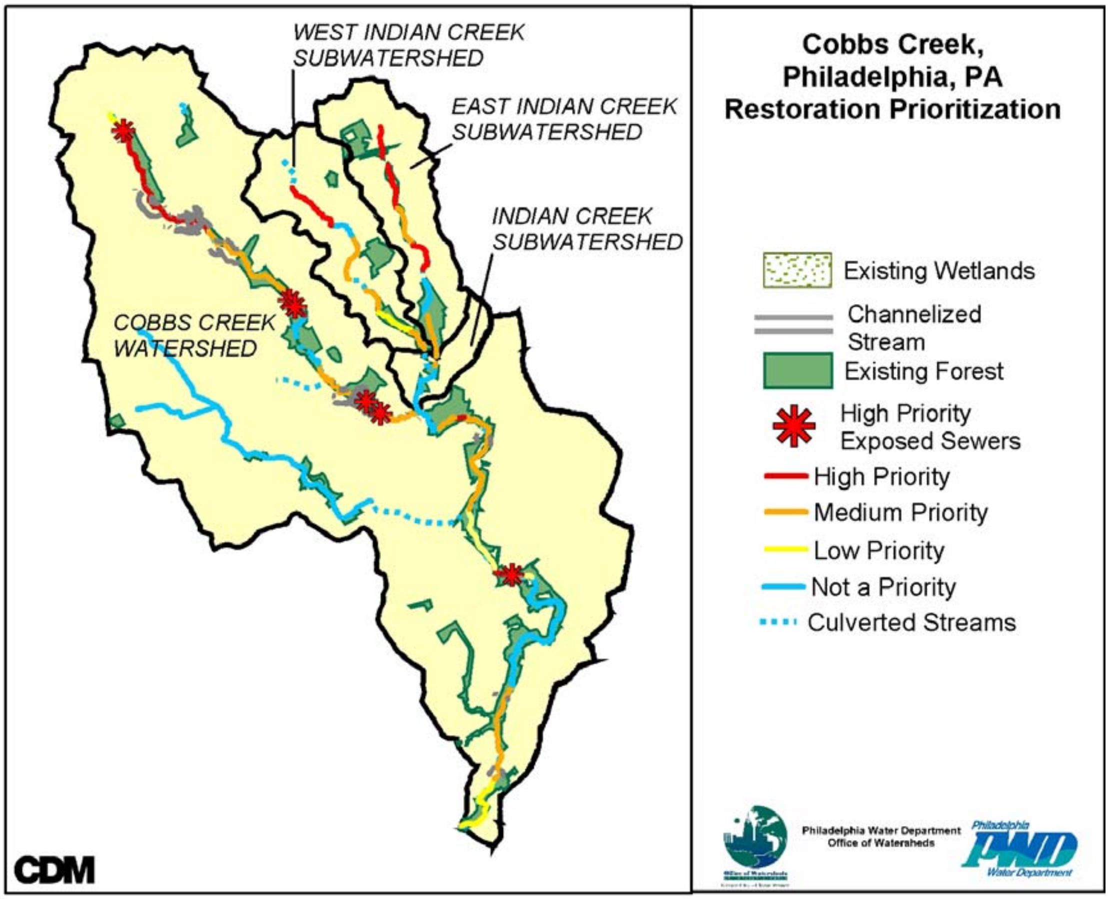

Figure 7-5 Cobbs Creek Watershed Restoration Prioritizations

Table 7-9 Total Miles of Stream by Stream Restoration Priorities

Subwatershed	Priority	Length (miles)
Cobbs	Not a Priority	5.53
Cobbs	Low Priority	3.87
Cobbs	Medium Priority	10.53
Cobbs	High Priority	4.82
East Indian Creek	Not a Priority	1.94
East Indian Creek	Low Priority	0
East Indian Creek	Medium Priority	1.96
East Indian Creek	High Priority	2.37
West Indian Creek	Not a Priority	0.55
West Indian Creek	Low Priority	0.96
West Indian Creek	Medium Priority	2.48
West Indian Creek	High Priority	1.25

7.2.1 Channel Stability and Aquatic Habitat Restoration

The Cobbs Creek watershed is strongly influenced by existing land use and anthropogenic channel changes. Cobbs, East Indian, and West Indian Creeks are all adjusting to increased flows and velocities that have resulted from extremely large amounts of impervious surface and the presence of structures associated with utilities. Changes to channel platform, pattern, and geometry will continue to occur. Cumulative impacts seen today and those that are expected to occur throughout the watershed are bed and bank erosion, channel over-widening, channel down-cutting, the lack or overabundance of sediment, less or no connection to the floodplain, and increased dominance by invasive species. Reach ranking results show that the Cobbs Creek subwatershed is the least stable, followed by West Indian and then East Indian Creeks. Headwater reaches in each subwatershed are more degraded than reaches nearer to the confluences with Cobbs Creek and Darby Creek. Final reach ranks also suggest that land use adversely impacts habitat to a greater degree than it impacts channel stability, while infrastructure is the opposite.

Overall, based on existing conditions, the Cobbs Creek subwatershed contains the greatest amount of degraded channel and has the highest restoration priority. Reaches assigned the highest restoration priority within this subwatershed are those that are severely degraded and/or continue to degrade. In all cases, the highest priority reaches contain infrastructure. Utilities present within these reaches that are of most concern consist of exposed sewer pipes and dams. Reaches both upstream and downstream of these utilities sometimes were included in the prioritization because they are being impacted by these structures or because expected future restoration/retrofit designs may require additional channel length. Multiple consecutive reaches that yielded high final ranking scores, generally those that were greater than the average stability score for the subwatershed, were also assigned a high restoration priority. The least amount of restoration is recommended for the downstream portion of Cobbs Creek.

Results of the reach ranking for the East Indian Creek subwatershed reveal that the downstream portion of the creek is more stable than the upstream portion. Degradation and corresponding higher geometry scores within the upstream portion of the creek can be attributed to a far greater number of disturbances to the channel by landowners. Disturbances such as landscaping, fountains, footbridges, etc. occur less frequently as the East Indian Creek flows downstream. Additionally, as the East Indian Creek flows downstream, land use transitions to less concentrated single family residential development and/or commercial businesses. This change in land use correlates with the width of riparian buffer present and is reflected in the reach habitat scores for the downstream portion of the East Indian Creek. The downstream portion of the East Indian Creek contains the lowest priority reaches, or the most stable reaches, in the entire Cobbs Creek watershed.

Results of the West Indian Creek ranking revealed similar results to those of East Indian Creek. Land use trends for both subwatersheds are alike in that the headwaters are primarily single family residential areas where a large amount of channel disturbances have occurred. Reach ranking reveals that the middle section of the creek are the least stable and show the least amount of natural habitat. West Indian Creek headwater reaches, although some reach ranks suggest this portion of the channel is more stable, are considered the least stable due to anthropogenic changes. Approximately 30% of the total linear feet of channel within this subwatershed have been altered. It follows that the most stable portions of West Indian Creek are the three downstream most reaches, where the riparian corridor is widest and the fewest channel disturbances are present.

Bed Stabilization and Habitat Restoration (BM1) Related Goals: 3 Related Indicators: 3, 4			
What	Who	Where	When
Design structures that provide grade control while diverting flow away from the channel banks. Bed stabilization measures include rock/log vanes with grade control, rock/log cross vanes, and using naturally occurring boulders and bedrock. Incorporate habitat improvements along with the stabilization measures.	Municipalities bordering streams recommended for restoration.	Cobbs Creek (40%) and West Indian Creek (44%) were identified as the areas with the highest percentage of actively degrading creek beds. (See Figure 7-5)	Begin within 5 years; complete restoration program within 10-15 years; monthly maintenance schedule to be determined

Bed conditions in stream channels subjected to urbanized flow often do not support a healthy aquatic ecosystem. High-velocity urbanized flows result in downcutting and widening of the bed over time, and deposition of fine sediments disrupts macroinvertebrate communities that are critical links in the aquatic food chain. Loss of pool and riffle sequences deprives fish of the variety of habitats they need to feed, spawn, and seek shelter from high flows. These channel changes tend to begin downstream and migrate their way upstream over a period of time.

Bed stabilization is recommended for those reaches that are currently degrading through incising or downcutting. Bed stabilization measures include rock/log vanes with grade control, rock/log cross vanes, and using naturally occurring boulders and bedrock. These measures reduce erosion by diverting high flows away from banks and by controlling the grade (slope) of the bed. They also stop downcutting from migrating upstream and restore habitat features that lead to healthy macroinvertebrate and fish communities. Detailed design plans are recommended for those stretches shown in Figure 7-6.

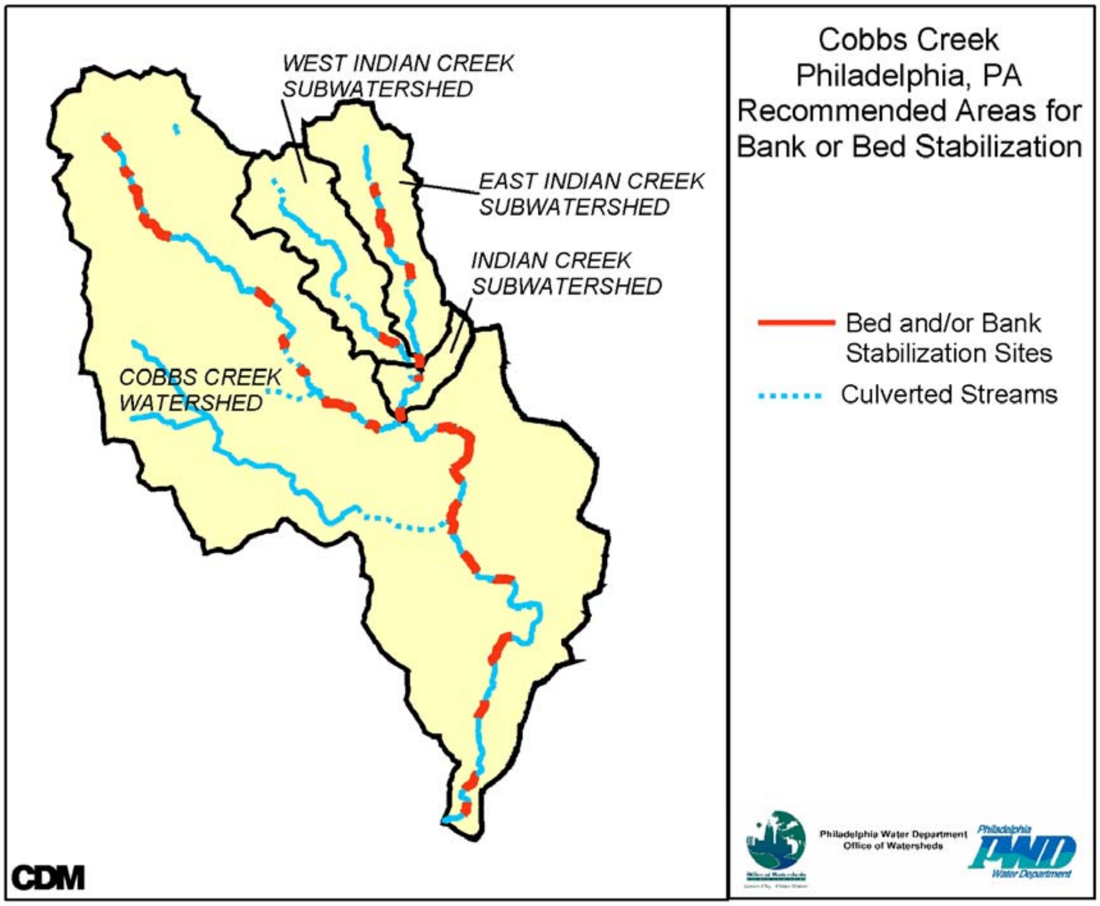

Figure 7-6 Recommended Areas for Bank and/or Bed Stabilization

Bank Stabilization and Habitat Restoration (BM2) Related Goals: 3, 4, 7, 8 Related Indicators: 3, 4, 12, 13, 15, 16, 19			
What	Who	Where	When
Bank stabilization design that may consist of boulder bank and boulder toe stabilization, bioengineering, root wads, plantings, and log and woody structures.	PWD; Fairmount Park NLREEP Municipalities bordering streams recommended for restoration. Municipalities bordering streams recommended for restoration.	Mid-sections of Cobbs Creek are the least stable, highest priority, bank stabilization areas. Channel banks rated as moderate or high should be evaluated further for site specific bank stabilization measures. These methods are best suited to small, local areas of bank erosion in East and West Indian Creek headwaters where discharges are the lowest. (See Figure 7-5)	begin 0-5 years; monthly maintenance schedule to be determined

The fine sediment that is deposited in the beds of many urban streams is often the result of bank erosion upstream. In addition to downcutting the stream bed, high-velocity urban flows result in steep, sometimes vertical banks that disconnect the stream from its historical floodplain. Using natural stabilization measures on banks also provide fish habitat and areas of reduced velocity during storms. A properly restored bank prevents further erosion, reconnects the stream to its floodplain (wetlands and riparian forest as appropriate), and provides fish habitat. It also may remove a hazardous and unsightly condition caused by a collapsing bank.

Bank stabilization measures can vary from small plantings to the installation of boulder walls, based on the severity of the erosion and whether it is localized or continues for some distance along a bank. Boulder structures are used in smaller channels that are eroding and over-widening to the point where property is, or is expected, to be lost. More natural bank stabilization methods such as bioengineering, root wads, plantings, logs, and woody structures are appropriate in areas where the bankfull width is limited and significant additional channel changes are not expected (future increases in the rate of erosion, sediment supply, tree fall, channel widening, and channel migration are not expected). These measures enhance aquatic habitat in addition to providing stabilization. Since 1998, NLREEP has repaired approximately 1020 feet of unstable banks and beds in Cobbs Creek Park, primarily along tributaries to the main stem. Figure 7-5 identifies the 5.9 miles of highest priority where additional stabilization will be recommended within 5 years. The most appropriate measures for each reach will be determined in the detailed design stage.

Channel Realignment and Relocation (BM3)
Related Goals: 3, 7
Related Indicators: 3, 4, 12, 13

What	Who	Where	When
Realignment and relocation for portions of creek channel. Daylighting recommended for two channel sections.	PWD Municipalities bordering streams recommended for restoration.	Five portions of Cobbs Creek, four portions of East Indian Creek and two portions of West Indian Creek that are potential stream realignment and relocation areas. Daylighting: downstream most portion of West Indian Creek and a section upstream of City Line Avenue. (See Figure 7-7)	begin 0-5 years; monthly maintenance schedule to be determined

In the most severely degraded reaches of Cobbs Creek, stabilization of the existing bed and banks may not be possible, or migration of the stream channel may threaten valuable infrastructure. In these areas, realignment and relocation of the stream channel may be necessary. This measure increases stability by creating a new channel along a path that is natural for the stream to follow. The design of bed and bank structures is not constrained by existing conditions. In some cases, the existing channel makes an ideal site for a riparian wetland. Channel realignment and relocation is commonly implemented for portions of a channel rather than for an entire length of channel due to construction and maintenance costs, and the amount of disturbance that occurs to existing natural habitat. Stream channel realignment and relocation is best suited to consecutive severely degraded reaches. Potential realignment and relocation sites totaling 8.0 miles of stream are shown on Figure 7-7.

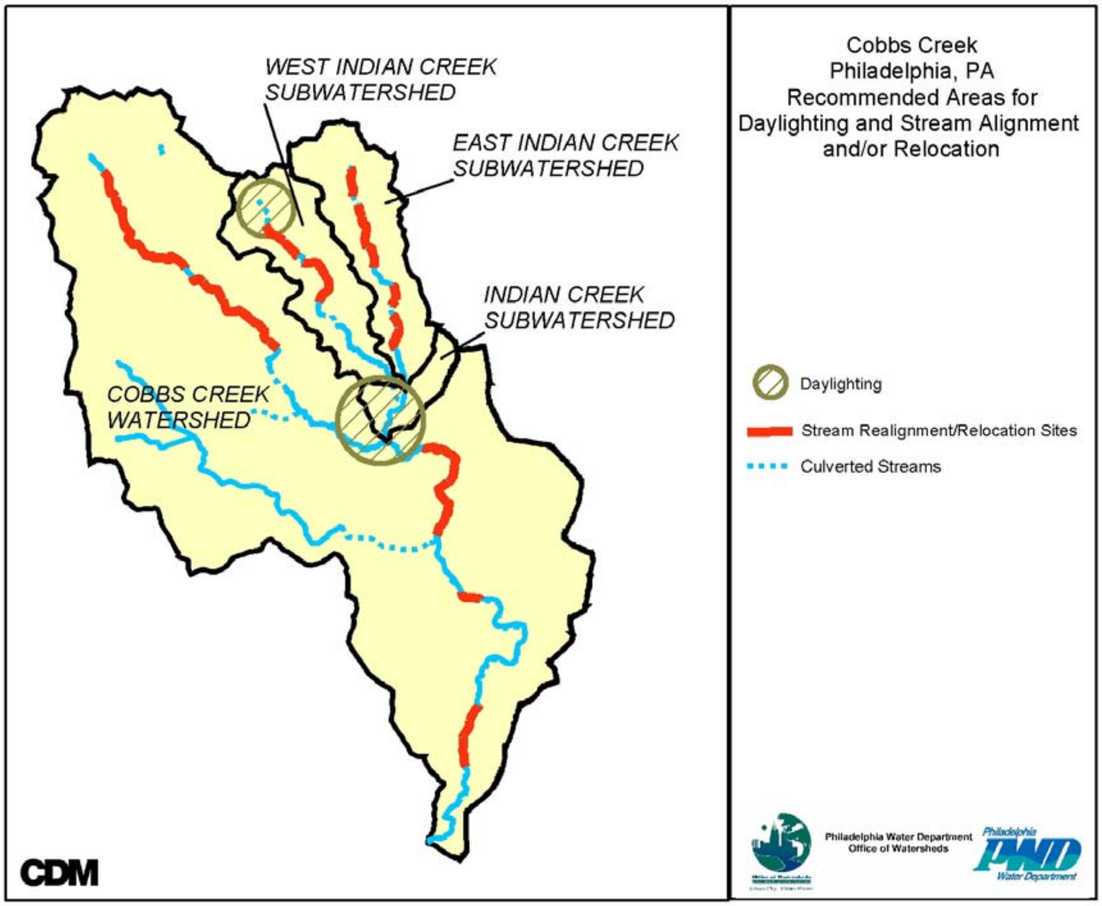

Figure 7-7 Recommended Areas for Stream Realignment and/or Relocation

Plunge Pool Removal (BM4) Related Goals: 3, 4, 9 Related Indicators: 3, 15, 19, 20			
What	Who	Where	When
Remove plunge pools below stormwater and CSO outfalls.	PWD Municipalities bordering streams recommended for restoration.	Outfalls shown in Figure 7-8	begin 0-5 years; monthly maintenance schedule to be determined

When stormwater and combined sewer outfalls discharge directly to the stream channel, they may create deep, poorly mixed pools. Both types of outfalls discharge along the length of the Cobbs and its tributaries (Figure 7-8). Because these pools are typically near the bank and not in the main flow, they can become poorly mixed during low flow. These pools often have increased odors and reduce the aesthetic quality of the stream. DO Biological activity in the sediment and water column can reduce dissolved oxygen to low levels, and this low-DO water can be flushed out and affect downstream areas during wet weather. The depression of DO is a function of both pollutant loads from the outfalls and in stream baseflow, and the physical condition of the channel. When DO is in an acceptable range in the well-mixed portion of the channel but not in nearby plunge pools, elimination of the plunge pools can be expected to eliminate the water quality condition that might affect the aquatic ecosystem.

When possible, outfalls can discharge further up the bank into a wetland or biofiltration area; these areas provide detention, evaporation, cooling, and treatment of pollutant loads in addition to protecting the integrity of the stream channel. Opportunities for creation of these areas will be discussed later in this section. Where the only place for an outfall to discharge is directly into the stream channel, the area may be protected using appropriate bed and bank stabilization features as discussed in previous sections.

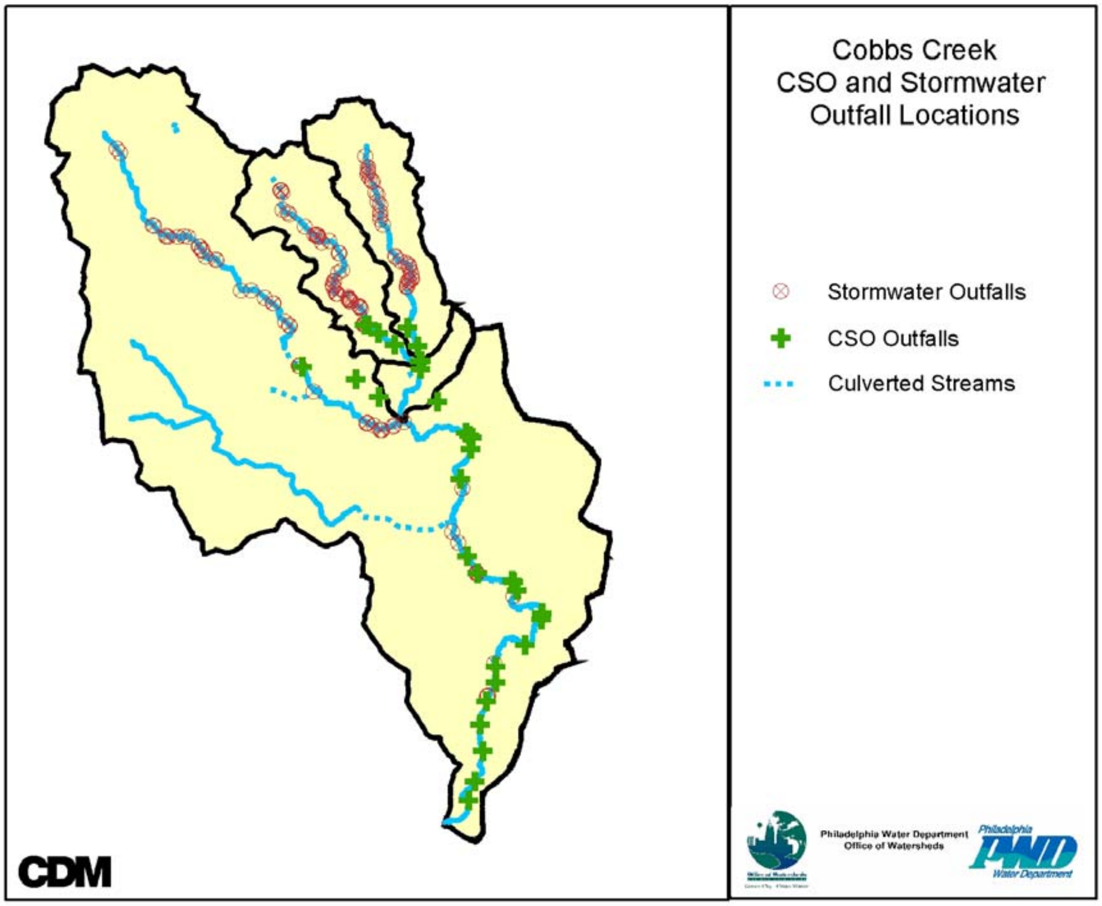

Figure 7-8 Stormwater and CSO Outfalls

Improvement of Fish Passage (BM5) Related Goals: 2, 8, 9, 10 Related Indicators: 3, 5, 6, 16, 19, 20, 21			
What	Who	Where	When
Undertake a detailed study to recommend dam removal, modification, or installation of a fish ladder.	PWD; Fairmount Park NLREEP	Woodland Avenue dam (See Figure 7-9).	Short-term (within 5 years)

For the Cobbs Creek, the State designated aquatic life uses for the non-tidal portion of the creek are Warm Water Fishes (WWF) and Migratory Fishes (MF). The designated recreational water uses also include boating, when surface water flow or impoundment conditions allow; fishing, for recreation and or consumption; water contact sports; and esthetics, for a clean setting to recreational pursuits.

Target A options are designed to ensure that water quality in Cobbs Creek is supportive of fish, and the channel improvements discussed in Target B create suitable aquatic habitat features. In addition to fish that live exclusively in fresh water, creation and enhancement of fish habitat along the Cobbs channel will create an environment suitable for migratory and semi-migratory fish. These anadromous species, such as American shad, spend portions of their life cycles in salt water and portions in fresh water. Currently, a dam at Woodland Avenue excludes migratory fish from most of Cobbs Creek. Historically, migratory fish ranged upstream to just below the current site of Cobbs Creek golf course, where a natural rock ledge (today a low dam) restricts further migration (Figure 7-9). NLREEP has identified ecological benefits to removing the Woodland Ave. dam (Natural Lands Restoration Master Plan); however, the dam is a historic structure and its removal or modification reqires further study. The effects of this dam on the stream channel and upstream sediment will be considered as part of detailed fluvial geomorphological restoration design for the stream corridor.

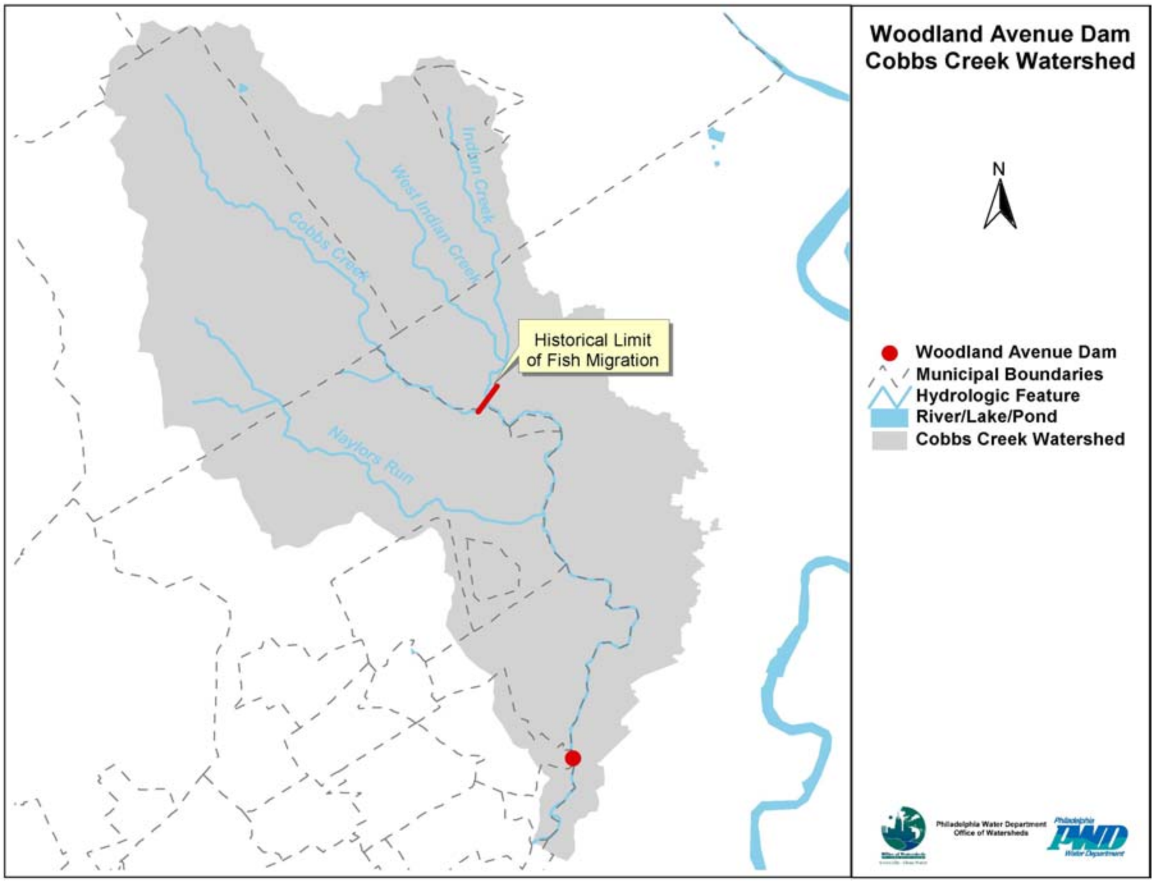

Figure 7-9 Woodland Avenue Dam

7.2.2 Lowland Restoration and Enhancement

One major riparian corridor improvement action, from both an ecological and water quality improvement perspective, is creation and enhancement of wetlands along Cobbs Creek. NLREEP has completed several wetland creation and enhancement projects in Cobbs Creek Park since 1998, including a constructed stormwater treatment wetland at the confluence of Cobbs Creek and Naylors Run. The Cobbs and Indian Creek subwatersheds were field surveyed in 2002/2003 to assess additional wetland creation and improvement opportunities. Existing wetlands were evaluated for their ability to perform important wetland functions (e.g., flood flow alteration, water quality improvement, and habitat). Existing wetlands were then assessed to determine if they were degraded and might be enhanced. Finally, locations where new wetlands could be created were identified. New wetland creation opportunities were classified into two groups:

- Wetlands immediately adjacent to the waterway and which would receive flood flows frequently during the year (< one year storm), and,
- Pocket wetlands that can be created using check dams that are higher in the landscape and that would receive stormwater flows from adjacent subwatershed areas, but would receive flood flows only from major storm

events.

Wetlands Enhancement. Along the Cobbs and Indian Creek subwatersheds, 45 existing wetland areas were identified during the field investigation, and each was evaluated for wetland enhancement potential. Almost one-third of the wetlands exhibited high enhancement potential (Table 7-10), because they had a direct hydrologic relationship with the stream yet showed degraded conditions at present. Half of the wetland areas showed moderate enhancement potential, because their hydrologic relationship with the waterway had been partially compromised or they exhibited somewhat degraded conditions. The potential enhancement sites are designated on Figure 7-10; the site numbers correspond to those in the Comprehensive Watershed Characterization Report (soon to be available on the Partnership website).

Table 7-10 Wetland Enhancement Potential

Wetland Enhancement Potential	
Enhancement Rating	*Wetland Areas*
High	13
Moderate	27
Low	5

In general, priority will be given to wetland creation and enhancement over reforestation of uplands because of the greater water quality benefits provided by wetlands.

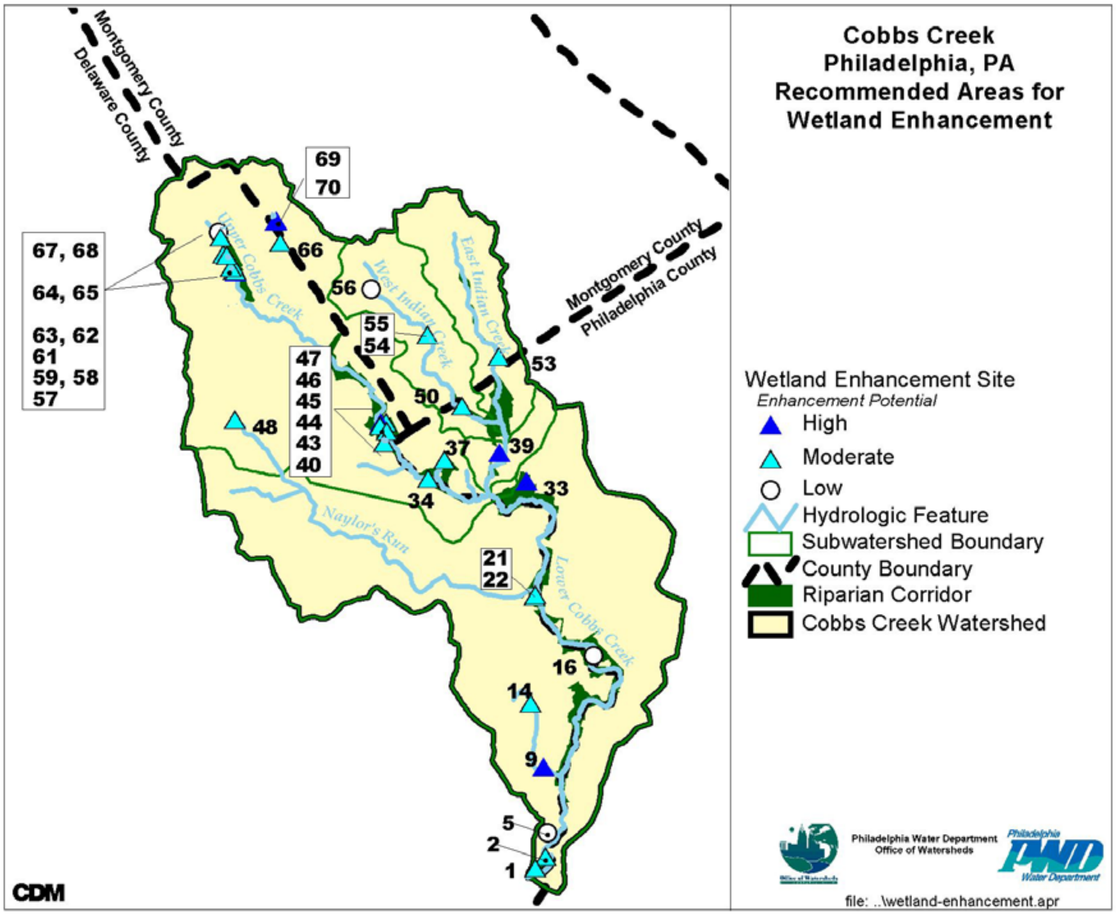

Figure 7-10 Potential Sites for Wetland Enhancement

Wetland Creation. Wetland creation opportunities have been evaluated for the many areas of Cobbs and Indian Creek where stream relocation and realignment are proposed. Because stream relocation and realignment typically involve extensive grading and replanting, new runoff patterns and hydrology can be created that are more similar to original riparian conditions, whereby the riparian corridor received storm runoff sheet flow from the adjacent landscape. In addition, wetland habitats can be created that allow more diverse habitat along Cobbs Creek. Wetlands are rich habitats that rely on saturated soils and vegetation adapted to these conditions. They could be recreated concurrently with channel realignment, bank restoration, and planting of more diverse native vegetation, including hydrophytic species adapted to saturated soil conditions.

Wetlands must have an adequate input of water, either by flooding or runoff, to maintain the soil and vegetation characteristics that are unique to wetlands. Field investigation of wetlands revealed, however, that several factors preclude the creation of extensive areas of new wetland. These include:

- extensive urban and suburban encroachment into the riparian corridor
- competing active recreational uses along the waterway

- steep slopes adjacent to the waterway limiting potential for floodplain hydrology

The wetland field investigation identified only 10 areas (comprising about 10-20 acres) *adjacent to the stream or in the floodplain* as wetland creation locations that would likely experience long-term success. These wetland creation locations are identified in Figure 7-11; the site numbers correspond to those in the Comprehensive Watershed Characterization Report.

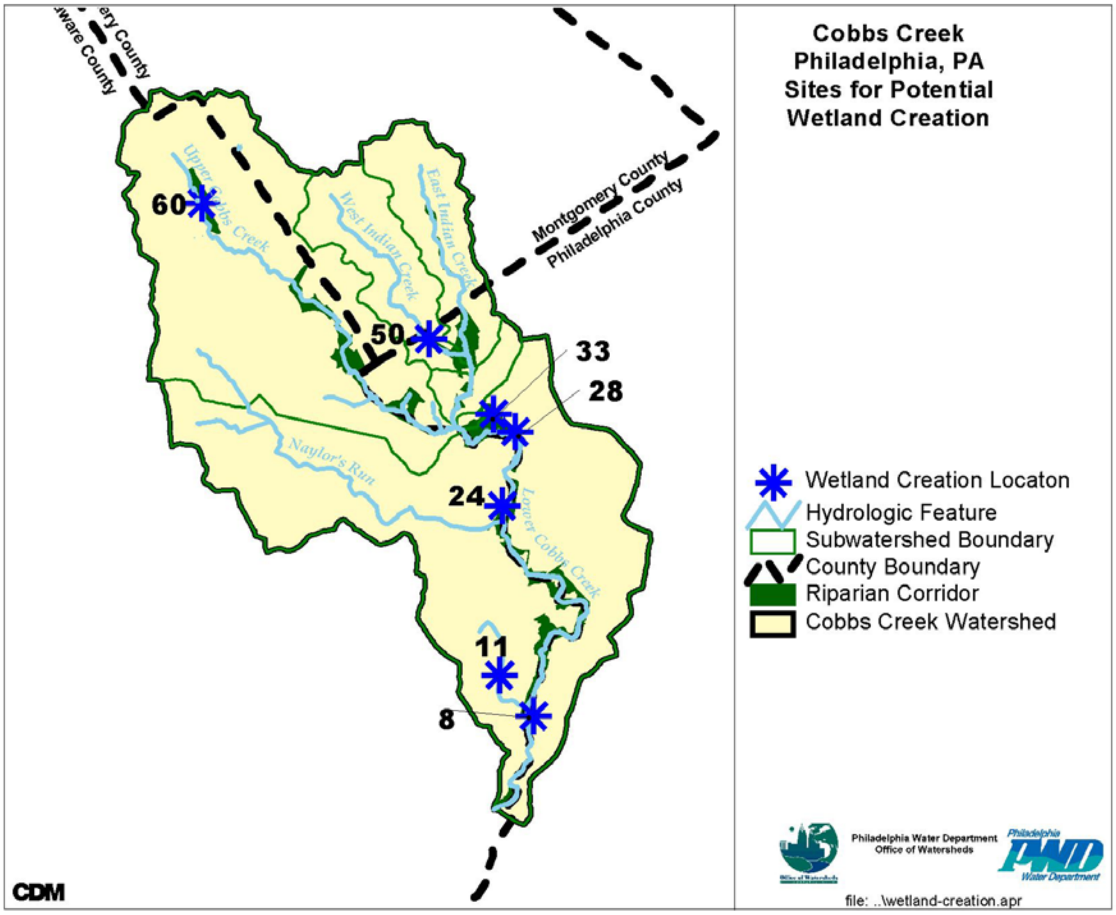

Figure 7-11 Potential Sites for Wetland Creation

However, as noted above, two types of wetland creation are recommended: floodplain wetlands and pocket wetlands. There are numerous opportunities for creation of pocket wetlands throughout the watershed; as stormwater runoff from the adjacent subwatershed is redirected over the riparian landscape, check dams and piping may be used to spread the runoff over the vegetated riparian land surface. Locations for creating pocket wetlands will need to be evaluated in the future as the riparian corridor restoration design is developed during the facilities planning stage. This is because opportunities for creation of pocket wetlands arise from bank restoration, revegetation, and biofiltration actions that will be implemented as part of the integrated riparian corridor improvement strategy for the Cobbs Creek watershed.

Both floodplain wetlands and pocket wetlands offer significant opportunity for water quality and ecological improvement along the Cobbs Creek riparian corridor, and will play a central role as the design of the riparian corridor improvements is developed.

Assuring long term success for wetland creation projects will involve future monitoring to measure integration of the wetland into the riparian landscape and to correct defective conditions, where possible. However, proper design of the wetland to assure adequate input of water (via flooding or runoff), protection from erosion, and maintenance of the diverse planted vegetation is essential to long-term success. Wetland creation projects typically involve monitoring and maintaining the created wetland's hydrology, vegetation (including invasive species), and erosion characteristics for a period of 3 years following creation.

It is estimated that wetlands can remove up to 80% of the total suspended sediments and pollutant loads they receive (Winer, 2000). It is estimated that approximately 50 to 100 acres of wetland creation may be possible in the Cobbs Creek watershed given an intensive creation effort as part of the riparian corridor improvement strategy. If implemented, the area of wetlands created could potentially provide significant improvement of CSO discharges and stormwater runoff from about 5,000 to 10,000 developed acres of the 14,000 acre Cobbs and Indian Creek watersheds (available in the Comprehensive Watershed Characterization report).

Wetland Creation (BM6)
Related Goals: 1, 2, 4, 5, 7, 9, 10
Related Indicators: 1, 2, 3, 4, 7, 8, 9, 15, 19

What	Who	Where	When
Wetland creation and enhancement for flood flow alteration, groundwater recharge, increased habitat, increased plant and animal diversity, and improved water quality.	PWD; Fairmount park NLREEP Municipalities bordering streams recommended for restoration.	Locations available for floodplain wetland creation are limited; areas for pocket wetland creation are extensive, especially where they are adjacent to lands proposed for stream realignment and back restoration. (See Figure 7-11)	Prototype design and evaluation phase in years 1-5; watershed-wide implementation over two 10 year phases, with initial high priority phase.

Further investigation of all potential wetland enhancement and creation opportunities should include the following: identification of landowners, rainfall data collection and evaluation, runoff calculations, soils investigation, water budget, native species investigation, and groundwater/soil saturation monitoring.

The existing historic dam near 67th Street and Race Street, known long ago as Old Mill Pond, has been identified as an area where a floodplain wetland could be created (Figure 7-12). A Philadelphia atlas from 1910 shows that this area has been inundated historically. The existing dam is on top of a natural rock ledge that has prevented fish from migrating further up the Cobbs. Enlargement of the historic dam at this location would recreate extensive floodplain wetlands in a largely undeveloped area, that would provide significant wetland acreage and water quality improvement for stormwater flows from the separate sanitary areas.

Any increase in the height of the dam would result in a gain of intermittently flooded area. This increased area would provide better “wetland treatment” of Cobbs Creek waters, especially during times of stormwater discharge. In the past, consideration has been given to lowering or removing the dam, but such actions would reduce both wetted area and treatment effectiveness. Raising the high water level by ten feet would provide a gain in approximate wetland area of close to 25 acres. The additional storage volume provided at high flow would be approximately 50 million gallons, representing a potential “treatment facility” equivalent value of $100 million to $200 million when compared to the cost of building treatment structures.

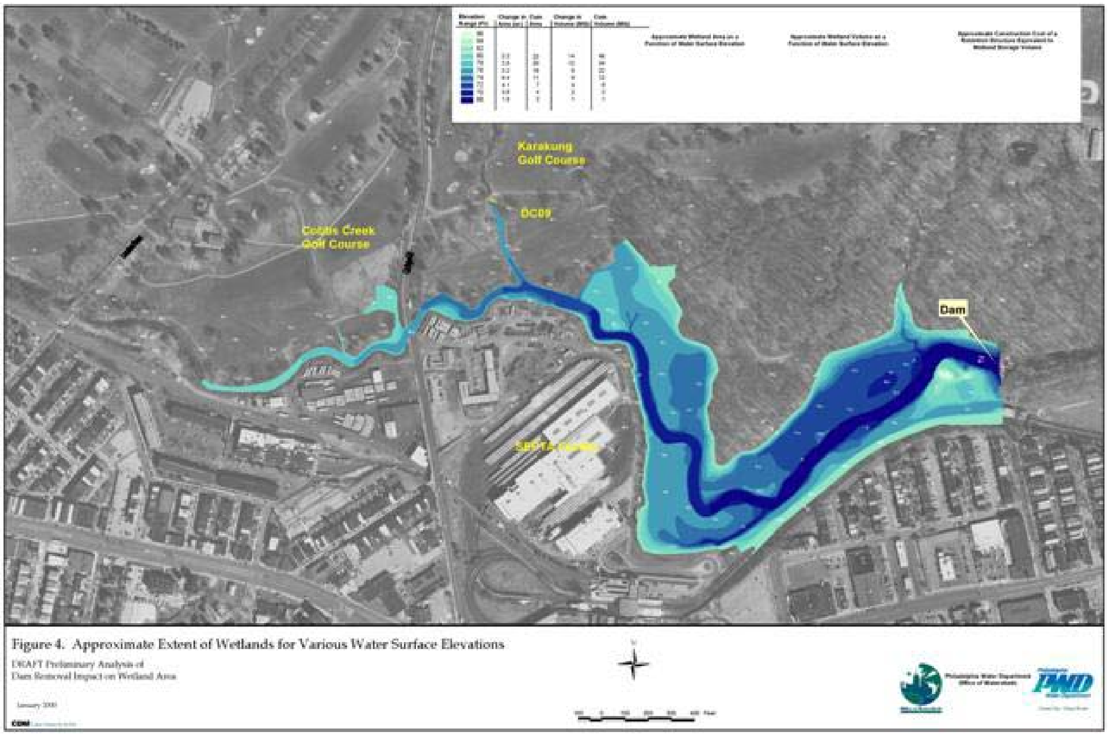

Figure 7-12 Proposed Dam Modification

Invasive Species Management (BM7)
Related Goals: 7
Related Indicators: 12, 13, 14, 19

What	Who	Where	When
Implement an Invasive Species Management Plan (already in effect in Fairmount Park)	PWD; Fairmount Park NLREEP	lowland and upland habitat restoration sites	Within 5 years

A plan to control invasive plant species is necessary when restoring or enhancing wetlands and riparian forests. Invasive species provide little value to native animals that depend on native species for habitat and food. Japanese knotweed (*Polygonum cuspidatum*) is the one prevalent invasive species that was observed during the field reconnaissance. In many areas, knotweed, due to its aggressive nature, has already out-competed native vegetation. Maintaining a healthy riparian plant community along Cobbs Creek, and East and West Indian Creeks will retain biodiversity and support a healthy stream ecosystem.

NLREEP has implemented an invasive species control program in the Fairmount Park portion of the stream corridor. It is recommended that invasive species control be expanded to the remaining natural areas of the corridor. Implementation of an invasive species management plan would assist natural succession within the riparian buffer and decrease further impacts of invasive species.

Planting plans for all restoration efforts should complement the invasive species management plan by recommending appropriate native planting to supplement areas where invasives have been eliminated. Although invasive species management priority areas are considered those that contain 80% or greater invasive species, the most practical approach is to recommend invasive species management be implemented for all riparian restoration sites. Recommended areas where restoration will occur are shown in Figure 7-10 above. An invasive species management plan will require, at a minimum, a three-year commitment to ensure success.

7.2.3 Upland Restoration and Enhancement

Biofiltration (BM8) Related Goals: 1, 4, 6, 9, 10 Related Indicators: 1, 2, 3, 4, 15, 19, 20			
What	Who	Where	When
Biofiltration involves creating sheet flow over the vegetated landscape to slow the rate of runoff, facilitate groundwater recharge, and remove sediment, nutrients, and toxicants from the runoff.	PWD; Fairmount Park NLREEP	Throughout Cobbs, East and West Indian Creek riparian corridors; focus on vegetated landscape	2 10-year implementation phases (high and medium priority)

The goal of the Cobbs Creek riparian corridor improvement strategy is to identify all opportunities along the riparian corridor for natural landscape designs that achieve water quality improvement. For higher landscape positions at the outer edges of the riparian corridor there are extensive opportunities to implement biofiltration to improve runoff. Biofiltration involves creating sheet flow over the vegetated landscape to slow the rate of runoff, facilitate groundwater recharge, and remove sediment, nutrients, and toxicants from the runoff. Typical biofiltration approaches include installation of stormwater swales and check dams along natural drainageways that spread runoff, creation of bioretention plantings and hydrology, and hydrologic features that allow sheet flow to spread over grassed and shrub/scrub fields to achieve water quality improvement. The advantage of biofiltration is that it is compatible with recreational use of the riparian corridor, because flows are very shallow and are usually only present during rainfall events.

Analysis of the existing stormwater management in the Cobbs Creek watershed shows that most stormwater outfalls discharge directly to the waterway. However, if the stormwater was redirected over the vegetated landscape higher in the stream valley, it would follow the natural slope and land contour as it traveled down to the stream. There are over 640 acres of undeveloped land along the Cobbs Creek riparian corridor, mostly in the Upper and Lower Cobbs Creek subwatersheds, but almost none of that land carries runoff sheet flow because the stormwater piping system conveys all flows, from storms large and small, directly to the stream. In order to achieve water quality improvement goals it is important to optimize the ability of this vegetated riparian land to receive overland runoff, rather than piping the runoff directly into the stream.

Under the Natural Lands Restoration Master Plan, NLREEP has constructed a number of stormwater infiltration and biofiltration projects in the Fairmount Park portion of the Cobbs corridor. One example is an excavated basin to capture runoff from a portion of Cobbs Creek golf course.

Biofiltration has an effectiveness range of about 25-60% in removing suspended solids from runoff, and the concept of directing runoff to sheet flow over the vegetated riparian landscape matches fully with the way that such lands function naturally in an undeveloped watershed. Thus, the goal of biofiltration is to restore sheet flow of runoff over the landscape, by using piping and hydraulic controls to spread runoff from smaller storms over the vegetated surface. It is essential that the design for biofiltration provide for high velocity flows from major storms to be bypassed, to avoid erosion.

Reforestation (BM9) Related Goals: 1, 3, 7, 8, 9 Related Indicators: 1, 2, 4, 12, 13, 16, 18, 19			
What	Who	Where	When
Reforestation adjacent to the channel to provide wetland habitat and other associated benefits.	PWD; Fairmount Park NLREEP Municipalities bordering streams recommended for restoration.	Priority reforestation sites: lands adjacent to the creek that are not developed and are currently unforested. Potential reforestation sites are existing ball fields, golf courses, hospital grounds, seminaries, and cemeteries located adjacent to the channel. These should also be evaluated. (See Figure 7-13)	begin 0-5 years; monthly maintenance schedule to be determined

The riparian corridor restoration and enhancement plan being proposed in this section covers the width of the stream corridor from developed edge to developed edge, including both lowland and upland forest. Reforestation that occurs adjacent to the channel will provide wetland habitat and other associated benefits. Although priority reforestation areas consist of floodplains, steep slopes, and wetlands, smaller areas such as public rights-of-way, parks, schools, and neighborhoods also provide reforestation opportunities. Benefits of reforestation are numerous: cooler temperatures, rainfall interception, reduced runoff, reduced sediment load, reduced discharge velocities, increased groundwater recharge, increased species diversity and habitat, and improved air quality and aesthetics. In the Fairmount Park portion of the corridor, NLREEP has planted over 26,000 trees, shrubs, and herbaceous species since 1998.

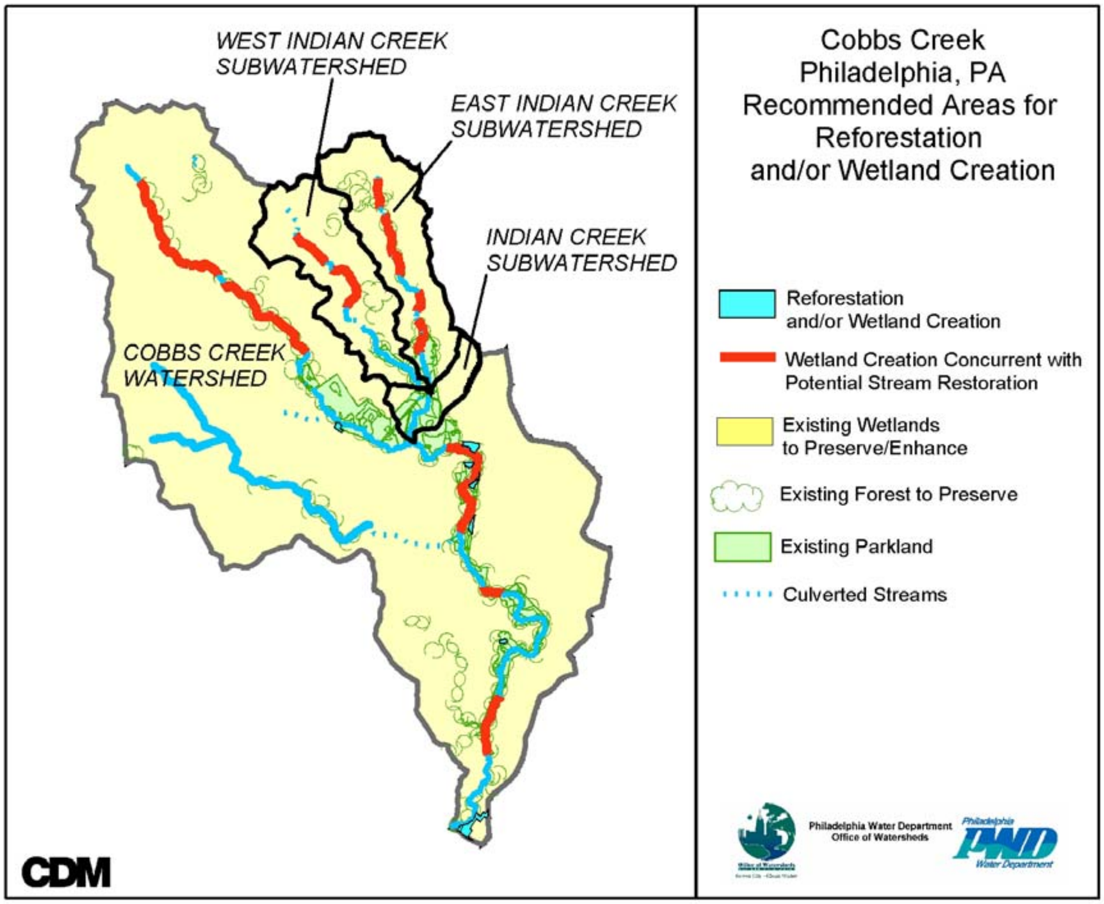

Figure 7-13 Recommended Areas for Reforestation

7.3 Target C: Wet Weather Water Quality and Quantity

Target C must be approached somewhat differently from the first two targets. Full achievement of this target means meeting all water quality standards during wet weather, as well as eliminating all flooding. Full achievement of these goals will be difficult, particularly with regard to wet weather water quality. It would certainly be extremely expensive, and would require a long term effort. The only rational approach to full achievement of Target C goals is through stepped implementation with interim targets for reducing wet weather pollutant loads and stormwater flows. During implementation, monitoring must continue to continuously assess the effectiveness of the program. Based on the extensive modeling analysis carried out for Cobbs Creek to date, an initial goal of a 20-30% reduction in stormwater flows and stormwater/CSO related pollutant loads is challenging but achievable.

In addition to the reduction in discharge volume, an important measure of progress is the percent capture of combined sewage in combined-sewered areas. It is estimated that implementing real time control will increase percent capture to approximately 80% in the middle portion of the Cobbs, and additional BMPs will increase it still further. In addition to capture by regulator structure, the quality of some CSO and stormwater flows will be improved in treatment wetlands before they reach the creek. A more precise assessment of percent capture will be performed during the initial stages of this plan.

It is expected that changes to the approach required to meet Target C, and even to the desired results, will occur as measures are implemented and results are monitored. With permits of 5-year duration for most discharge permits, discharge targets and reduction targets must be set and implementation designed in the first 5 years. Implementation for meeting Target C should occur over the next 5 years, with monitoring for effectiveness taking place for 5 years subsequent to implementation. During the last 5-year period, PWD should also work with the regulatory agencies to review water quality standards and determine whether any adjustments to them may be appropriate based on the results of monitoring.

7.3.1 Regulatory Approaches

Encouraging or Promoting Better Site Design in Redevelopment (CR2) Related Goals: 1, 7, 9, 10 Related Indicators: 1, 12, 13, 16, 19, 20			
What	Who	Where	When
Adopt or improve ordinances to encourage developers to use low impact methods for new (“greenfield”) development and redevelopment of urban areas.	See Table 7-14 (may not identify all municipalities with ordinances)	Entire Watershed	within 5 years; update as needed

Environmentally friendly site design, also called low impact development (LID) and conservation site design, encompasses a range of site design elements for developers, and design requirements from municipalities. Some examples of LID design concepts include maintaining stream buffers, designing for open space, reduced street and sidewalk footprints where appropriate, and parking lot designs that reduce runoff and encourage infiltration. Stormwater source controls, infiltration BMPs, and treatment BMPs can be integrated with LID designs. Recommendations for incorporating these features in the Cobbs watershed are found throughout Target C.

LID is intended to reduce the impact of development on natural resources and water resources. Municipal design requirements are intended to preserve or increase open space, protect sensitive natural resources, and limit impervious cover. The environmental *goals* of land development and stormwater ordinances are closely related, although the ordinances themselves and mechanisms for enforcing them may be separate. This section discusses land use-related regulatory approaches to better site design, while the next section discusses regulatory approaches to stormwater management.

It appears that most of the municipalities in the Cobbs Creek watershed encourage several standard low impact development practices through their existing land use ordinances. However, these guidelines tend to focus on clustering housing by allowing higher-density multi-family residential developments with common open spaces. Separate language focusing specifically on the protection of natural resources is recommended. While most municipalities in the watershed have already adopted a steep slope ordinance, Lower Merion Township is currently the only municipality within the watershed with a cluster development ordinance and wetlands protection ordinance in place. Table 7-14 identifies the municipalities located in the watershed that have adopted low impact development ordinances.

Source: www.ordinance.com, Delaware Valley Regional Planning Commission

The Delaware Valley Regional Planning Commission (DVRPC) has recently completed the task of reviewing the municipal zoning ordinances of the Delaware Valley's 353 municipalities. Based upon this analysis, DVRPC has created a list of "outstanding sample natural resource and open space protection ordinances." These model ordinances as well as additional information on DVRPC's program are available at:

- DVRPC Natural Resource Protection Information - http://www.dvrpc.org/planning/protectiontools.htm
- Model Ordinances - http://www.dvrpc.org/planning/Protection%20Tools/ordinances.htm

Guidelines for LID in an Urban Setting

Table 7-15 identifies various zoning ordinances that could be adopted by the municipalities in the Cobbs Creek watershed. While some municipalities already incorporate elements of these zoning measures within their existing code, it is recommended that ordinances specific to low impact development be adopted to better facilitate future growth and redevelopment within these municipalities. Model ordinances for each of these examples are available on the DVRPC website at the address listed above.

Table 7-15 Selected Components of Low Impact Development Ordinances

Municipal Zoning Ordinance	Description
Net-Out of Resources / Site Capacity Calculations	Protect wetlands, floodplains, and riparian buffers by removing them from the area considered for new development and redevelopment. In calculating the developable area, environmentally sensitive areas should be excluded. Some local governments allow increased densities in the remaining developable land area to provide an incentive for protecting sensitive environments. Existing trees should be protected if possible; if not, the land owner may contribute to a mitigation fund for each tree cut down.
Wetlands Management Ordinance	Protects environmentally sensitive wetlands areas. This ordinance usually requires wetlands delineation within the municipality and prohibits any type of development in a delineated wetland area.
Cluster Development Ordinance	Allows developers to build at higher densities on one portion of a site in exchange for preserving another portion as open space. Land preservation percentages and densities vary, but the preferred percentage is for at least 50% of the tract to remain as open space. Achieving a landowner's financial objectives may be a function both of partial development and donation of a conservation easement (and its inherent deductibility under the federal tax code).
Planned Residential Development (PRD)	Facilitates residential development in areas designated by the municipality. Provisions are made for higher housing densities, thereby creating larger contiguous common open spaces, and providing for pedestrian access between residential areas.
Steep Slope Ordinance	Regulates development on areas designated as steep slopes. The minimum gradient classified as steep varies by municipality, but according to DVRPC 8% is typical.
Transfer of Development Rights (TDR)	Designates areas of a municipality as "sending" and "receiving" areas. Allows community to preserve open space and natural features while still permitting growth. Development is moved from large tracts of rural land (sending area) to areas designated for higher densities (receiving area).

While the measures above were originally intended for new development, they may be adapted for larger redevelopment projects in urban areas. Older areas often have large areas of vacant and abandoned properties that may be demolished all at once, creating significant open space. Cluster development, for example, could be applied on these larger sites.

In addition to the specific ordinances above, municipalities should require, or provide strong incentives for, innovative site design when urbanized areas are redeveloped.

Effective conservation design techniques to consider include the following:

- Review municipal codes and require smaller footprints for impervious surfaces, such as road and sidewalk widths. Review any stipulation of a minimum size lot that development and stormwater ordinances apply to. In the City of Philadelphia, the ordinance requiring all downspouts to be connected directly to the sewer system is not appropriate in all cases; wherever feasible, infiltration (e.g., using dry wells) should be encouraged over disposal of stormwater to combined or separate storm sewers.

- Depending on the zoning classification, specify a maximum effective impervious cover allowed after construction. Many publications recommend that impervious cover connected directly to the drainage system be limited (see "Reducing Effective Impervious Cover through Conservation Site Design" for specific recommendations). Developers are then free to choose a combination of methods to meet the requirement: an absolute reduction in impervious cover, directing runoff onto depressed landscaped areas, tree credits, and structural BMPs. Consider incentives in the stormwater control calculations to reduce directly connected impervious surfaces.

- For areas experiencing redevelopment, structural stormwater controls may be tied to the impervious area calculations discussed above. Developers have an incentive to reduce impervious area because it may be more cost effective than installing structural stormwater BMPs. Specific recommendations for stormwater ordinances are discussed under option CR3.

- Promote discussions early in the development review process at the sketch plan/conceptual plan level (before developers have spent large sums of money on design and engineering). A number of municipalities around the U.S. have concluded that sketch/conceptual plans are more important in the planning process than preliminary plans because early intervention and change allows greater opportunity to include innovative low impact development designs. Some municipalities have opted to eliminate the final plan and accept the preliminary plan as the final plan as an incentive to developers to participate.

- After the final plan is submitted, require a pre-construction meeting and a site visit to discuss construction issues and pollution prevention.

- Consider incentives in addition to regulations. For example, award density or stormwater control bonuses for reducing impervious cover. Streamline project reviews and waive permit fees when conservation design objectives are met. Tie stormwater fees and/or property taxes to impervious cover and stormwater management practices.

Stormwater and Floodplain Management (CR3) Related Goals: 1, 4, 6, 7, 9, 10 Related Indicators: 1, 2, 12, 13, 15, 19, 20			
What	Who	Where	When
Participate in finalization of the watershed-wide Act 167 plan and model ordinance being developed by Delaware County. Adopt and enforce the model ordinance. Source: www.ordinance.com, Delaware Valley Regional Planning Commission

The majority of municipalities in the watershed have adopted ordinances limiting development in the floodplain or designating a floodplain conservation district. The protection offered varies by municipality, but an effective ordinance should place controls on land development within the 100-year floodplain as well as limit development within riparian corridors.

EPA provides a model for a floodplain preservation ordinance at the following website link:

- EPA Model Ordinances

http://www.epa.gov/owow/nps/ordinance/osm1.htm

Led by Delaware County, the four counties in the Cobbs Creek watershed (and the Darby-Cobbs watershed as a whole) are cooperating to develop an official Act 167 Stormwater Management Plan and model ordinance. The model ordinance will specify measures that must be undertaken to promote infiltration, improve water quality, reduce streambank erosion rates, and protect against flooding. These requirements will apply to both new (also called "greenfield") development and redevelopment (including brownfields or former industrial sites), and to both separate-sewered and combined-sewered areas. As of February 2004, the plan and model ordinance were still under development; all counties and municipalities will be invited to provide input before the plan is finalized.

Adoption and implementation of the model ordinance is a critical step that will allow municipalities to begin implementing many of the wet weather management measures mentioned later under Target C. For example, the ordinance will require a specific storage volume to be created on a developed site and will indicate that it must be a BMP capable of water quality treatment. The developer will then consult a stormwater manual designated by the municipality to determine an appropriate BMP and appropriate design criteria.

While many of the state manuals provide excellent guidance for new development, PWD plans to develop a manual with specific guidance for redevelopment projects given local conditions. Some preliminary ideas for this BMP manual are listed below:

<u>Commercial/Industrial Land Uses</u>

1. Use better site design techniques, landscaped areas, and tree credits to decrease impervious cover directly connected to the drainage system.
2. Directly-Connected Parking Lots

- Convert to porous pavement (or other drainage mechanism) and subsurface storage if feasible. If converted, the entire parking lot is no longer considered effective impervious area.
- If porous pavement and storage are not feasible, install a depressed bioretention (and/or porous media filtration) system. If the parking lot area is drained to a bioretention system it is no longer considered effective impervious area.

3. Directly-Connected Rooftops

- If parking lot storage is installed, route rooftop drainage to the storage. The rooftop area will no longer be considered an effective impervious cover if it is drained to the storage.
- If parking lot storage is not feasible, route rooftop drainage to dry wells. If dry wells are not feasible, route rooftop drainage to rain barrels or tanks. In either case, the rooftop is no longer considered an effective impervious area.

3. Other approaches may be proposed and considered on a case-by-case basis.

Residential Land Uses

1. Use better site design techniques, landscaped areas, and tree credits to decrease effective impervious cover.
2. Route roof runoff to dry wells if feasible. If dry wells are not feasible, route rooftop drainage to rain barrels or tanks. In either case, the rooftop is no longer considered an effective impervious area.
3. Other approaches may be proposed and considered on a case-by-case basis.

Industrial Stormwater Pollution Prevention (CR4)
Related Goals: 1, 5, 6, 9, 10
Related Indicators: 1, 2, 3, 4, 7, 8, 9, 10, 19, 20

What	Who	Where	When
Enforcement of NPDES requirements for Industrial Stormwater Management Dissemination of information on spill prevention and pollution prevention plans.	The PADEP is the Designated Authority responsible for issuing, administering, and enforcing NPDES permits Municipalities are responsible for information dissemination.	All sites contributing storm water discharges associated with industrial activity within the watershed	Within 5 years

Industrial stormwater pollution prevention measures can contribute significantly to achieving the watershed plan's wet weather implementation targets. These measures include monitoring and enforcing existing industrial stormwater permit requirements under Phase I of the NPDES program, as well as, Official Industrial Pollution Prevention Plans and Spill Response Actions required by the state. Full implementation of these measures should be monitored and enforced throughout the watershed.

NPDES Industrial Stormwater Permits

All sites contributing storm water discharges associated with industrial activity, defined in federal regulations (40 CFR §§ 122.26(b)(14)(i)-(xi)), are required to be covered under Phase I of the NPDES stormwater program. This includes discharges from any conveyance that is used for collecting and conveying storm water and that is directly related to manufacturing, processing or raw materials storage areas at an industrial plant. This includes, but is not limited to, storm water discharges from industrial plant yards; immediate access roads and rail lines used or traveled by carriers of raw materials, manufactured products, waste material, or by-products used or created by the facility; material handling sites; refuse sites; sites used for the application or disposal of process waste waters; sites used for the storage and maintenance of material handling equipment; sites used for residual treatment, storage, or disposal; shipping and receiving areas; manufacturing buildings; storage areas (including tank farms) for raw materials, and intermediate and final products; and areas where industrial activity has taken place in the past and significant materials remain and are exposed to storm water. The term material handling activities includes storage, loading and unloading, transportation, or conveyance of any raw material, intermediate product, final product, by-product or waste product.

The PADEP is the Designated NPDES Authority responsible for issuing, administering, and enforcing NPDES stormwater permits under the EPA's regulatory provisions set forth in 40 CFR.

Storm water discharges from most industrial facilities are covered under General Permits when they discharge into municipal separate sanitary sewers. General NPDES permits have a fixed term not to exceed 5 years. An operator of a storm water discharge associated with industrial activity which discharges through a large or medium municipal separate storm sewer system shall submit, to the operator of the municipal separate storm sewer system receiving the discharge the following information: the name of the facility; a contact person and phone number; the location of the discharge; a description, including Standard Industrial Classification, which best reflects the principal products or services provided by each facility; and any existing NPDES permit number.

In addition, the operator of a storm water discharge associated with industrial activity covered under a general, group, or individual permit, shall provide the following minimum information (40 CFR § 122.26 (c)(i)):

- A site map showing topography, drainage features, buildings, and areas where materials or activities may contribute pollutants to storm water.
- An estimate of the area of impervious surfaces (including paved areas and building roofs) and the total area drained by each outfall (within a mile radius of the facility) and a narrative description of materials handled or stored as well as measures taken to control pollutants in the runoff.
- A certification that all outfalls that should contain storm water discharges associated with industrial activity have been tested or evaluated for the presence of non-storm water discharges which are not covered by a NPDES permit; tests for such non-storm water discharges may include smoke tests, fluorometric dye tests, analysis of accurate schematics, as well as other appropriate tests. The certification shall include a description of the method used, the date of any testing, and the on-site drainage points that were directly observed during a test;
- Existing information regarding significant leaks or spills of toxic or hazardous pollutants at the facility that have taken place within the three years prior to the submittal of this application;
- Quantitative data based on samples collected during storm events from all outfalls containing a storm water discharge associated with industrial activity for a number of water quality parameters.

Industrial Pretreatment Requirements

Industrial pretreatment requirements are another area where enforcement can result in lower pollutant concentrations in storm water. Under PA Code Title 25 § 94.15, the operator of the sewerage facilities in cases where pollutants contributed by industrial users result in interference or pass through, and the violation is likely to recur, must develop and implement specific local limits for industrial users and other users, as appropriate, that together with appropriate sewerage facility or operational changes, are necessary to ensure renewed or continued compliance with the plant's NPDES permit or sludge use or disposal practices.

Additional Measures

Information on existing pollution prevention plans and spill response requirements should be provided to relevant industries in the watershed as part of the Phase II public education measures.

Industrial Pollution Prevention Plans are one means to prevent spills and accidental releases. Under PA Code Title 25 § 91.34 (Activities Utilizing Pollutants):

- Persons engaged in an activity which includes the impoundment, production, processing, transportation, storage, use, application or disposal of pollutants shall take necessary measures to prevent the substances from directly or indirectly reaching waters of this Commonwealth, through accident, carelessness, maliciousness, hazards of weather or from another cause.
- PADEP may require a person to submit a report or plan setting forth the nature of the activity and the nature of the preventative measures taken. The Department will encourage consideration of the following pollution prevention measures, in descending order of preference, for environmental management of wastes: reuse, recycling, treatment and disposal.

Spill response is another area that can improve wet weather water quality in Cobbs Creek. Spill response requirements are promulgated under PA Code Title 25 and issued under section 5 of The Clean Streams Law (35 P. S. § 691.5).

Under PA Code Title 25 § 91.33 (Incidents Causing or Threatening Pollution):

- If, because of an accident or other activity or incident, a toxic substance or another substance which would endanger downstream users is discharged, it is the responsibility of the person at the time in charge of the substance to immediately notify PADEP by telephone of the location and nature of the danger and, if reasonably possible to do so, to notify known downstream users of the waters.
- In addition to the notices, the person shall immediately take steps necessary to prevent injury to property and downstream users, and within 15 days from the incident, remove from the ground the residual substances to prevent further pollution.

Construction Stormwater Pollution Prevention (CR5) Related Goals: 1, 5, 6, 9, 10 Related Indicators: 1, 2, 3, 4, 7, 8, 9, 10, 19, 20			
What	Who	Where	When
Construction Site Stormwater Program in conformance with Phase II Stormwater Permits • Enact an Ordinance • Review and approve Erosion and Sediment Control Plans • Distribute Educational Materials	All Municipalities required to do Phase II permit (see Table 7-4)	N/A	Five year program associated with stormwater permit (See Table 7-15)

In accordance with the Cobbs Creek Plan's stated purpose of integrating various existing programs, and to avoid duplication of effort, the recommended implementation plan follows the Stormwater Management Program Protocol ("Protocol") to meet the six minimum control measures required of municipal permittees under the Phase II NPDES Stormwater Regulations (found at 40 CFR §§ 122.26 – 123.35). One of the six minimum controls is a Construction Site Stormwater (CSS) Program.

In Pennsylvania, two programs currently exist that address stormwater runoff from construction activities: 1) the Erosion and Sediment Control Program under 25 Pa. Code Chapter 102, and 2) the NPDES Stormwater Construction Permit Program.

The Erosion and Sediment Control Plan submitted by the developer must contain BMPs appropriate to the site and the surrounding area that might be impacted by the construction activities, as well as for post-construction runoff. Construction activity-related BMPs are available to developers and others through the Erosion and Sediment Pollution Control Program Manual, (PADEP ID: 363-2134-008) on PADEP's website, www.dep.state.pa.us, directLINK "stormwater," and available at the County Conservation District (CCD).

The CSS program can be summarized as consisting of the following steps:

- Enact, implement and enforce a stormwater control ordinance using PADEP model language (a model PADEP is available),
- Coordinate the review and approval of Erosion and Sediment Control Plans with the County Conservation District(s) (CCD) or PADEP for any earth disturbance of one acre or more causing runoff or any earth disturbance five acres or more. Make approval of the Erosion and Sediment Control Plan a prerequisite for the formal approval of land development and redevelopment plans or the issuance of building permits, and

- Distribute educational materials to land developers with the applications for building permits and other land development/redevelopment.

Municipalities must have an agreement with their local CCD that addresses these reviews and permitting requirements. This agreement ensures the close coordination between the municipality and the CCD on these important issues affecting water quality. Note that a NPDES Stormwater Construction Permit is required for earth disturbance activities where the construction disturbs five acres or more, or there is a discharge from a site to the MS4 where earth disturbance is one acre or more.

In most cases, the County Conservation District implements these two programs, and PADEP is responsible for implementing and enforcing these programs in cases where the County does not have this responsibility. By requiring review and approval of Erosion and Sediment Control Plans by the CCD or PADEP (and proof of NPDES Stormwater Construction Permits where required), and by coordinating building permit and other land development permits or approvals with the CCD (or PADEP in some cases), municipalities will meet MS4 permit requirements for this component of the Construction Stormwater Runoff Management Minimum Control Measure. Utilizing this existing statewide program, the municipality avoids the need to do a duplicative, independent review of every Erosion and Sediment Control plan.

All municipalities in the watershed are required to fulfill this aspect of the stormwater regulations. Table 7-15 shows the schedule for implementation.

Table 7-15 Implementation Schedule for Construction Stormwater Pollution Prevention

PERMIT YEAR	*IMPLEMENTATION SCHEDULE*	
	Construction Site Stormwater Program	**Developer Education**
Year 1	• Ordinance: enact an ordinance requiring: • the review and approval of Erosion and Sediment Control Plans by the local County Conservation District or PADEP • for any earth disturbance one acre or more with runoff to the MS4, or five acres or more regardless of the planned runoff, and • as a prerequisite for the formal approval of land development plans or the issuance of building permits • Process: Establish an agreement with the local CCD for the review and approval of Erosion and Sediment Control Plans for all earth disturbance activities equal to or greater than one acre with runoff to the MS4 (or five acres or more regardless of the planned runoff) • Standard: Require that the Erosion and Sediment Control Plans be developed in accordance with the requirements of Chapters 102 (erosion and sedimentation) of the PADEP regulations	Meet permit requirements and measurable goals for Year 1 under Public Education and Outreach minimum control measure.
Years 2-5	Implement the ordinance and agreement for review of Erosion and Sediment Control Plans	Meet permit requirements and measurable goals for Year 2 under Public Education and Outreach minimum control measure.

Post-Construction Stormwater Runoff Management (CR6)
Related Goals: 1, 5, 6, 9, 10
Related Indicators: 1, 2, 3, 4, 7, 8, 9, 10, 19, 20

What	Who	Where	When
Post-Construction Stormwater Runoff Management in conformance with Phase II Stormwater Permits • Enact Ordinance • Coordinate Review and Approval of Plans • Ensure BMP Maintenance	All Municipalities required to do Phase II permit (see Table 7-4)	N/A	Five year program associated with stormwater permit. (See Table 7-16)

In accordance with the Cobbs Creek Plan's stated purpose of integrating various existing programs, and to avoid duplication of effort, the recommended implementation plan follows the Stormwater Management Program Protocol ("Protocol") to meets the six minimum control measures required of municipal permittees under the Phase II NPDES Stormwater Regulations (found at 40 CFR §§ 122.26 – 123.35). One of the six minimum controls is a Post-Construction Stormwater Runoff Management Program. The program can be summarized as consisting of the following steps:

- Enact, implement and enforce a stormwater control ordinance using PADEP model language,
- Coordinate the review and approval of post-construction BMPs simultaneously with the review and approval for construction Erosion and Sediment Control Plans as described in the Construction Minimum Control Measure, and
- Ensure long-term operation and maintenance of the BMPs

PADEP links management of post-construction run-off with the Construction Minimum Control Measure component discussed above. Approvals for construction activities will be dependent on how post-construction issues are addressed. For example, if an applicant's plan for a land development or redevelopment project adequately addresses stormwater issues during construction but does not do so for post-construction impacts, then it must not be approved until the post-construction issues are addressed.

Ordinance

Municipalities must enact, implement and enforce a stormwater control ordinance using PADEP model language. The ordinance must address the proper standard for BMPs and operations and maintenance requirements for the BMPs. The ordinance will apply a statewide post-construction requirement until the water quality-based

Act 167 Plan is adopted by the County and implemented by the municipality, at which time the municipality will need to amend it to include those requirements.

The ordinance should require that all development and redevelopment activities with earth disturbance one acre or more with runoff to the MS4 (or five acres or more regardless of the planned runoff), be conducted in accordance with the ordinance. No formal approval of land development plans or issuance of building permits should occur without municipal approval of post-construction stormwater controls. A Model Ordinance is available from PADEP.

Implement Program

The municipalities must commit municipal resources or establish an agreement with the local CCD or other service provider (e.g., municipality's consulting engineer) for coordination of post-construction BMP approvals. There must be a process to review the post-construction controls in conjunction with the review process for construction approval.

Ensure that the post-construction controls will meet state water quality requirements.

The requirements for post-construction controls depend upon the status of the Act 167 Stormwater Management planning in the watershed. Where a water-quality-based Act 167 plan has been completed (or updated), those local watershed requirements apply. Otherwise, statewide requirements must be implemented.

It is the municipalities' responsibility to ensure that the BMPs meet the water quality requirements. However, PADEP will be reviewing post-construction plans for Individual permits, and some County Conservation Districts have the expertise to conduct the reviews under an agreement with the municipality similar to that for the Construction Minimum Control Measure.

Operation and Maintenance of Post-Construction BMPs

It is the municipalities' responsibility to ensure that the post-construction BMPs required and approved pursuant to the program are constructed, operated and maintained. Many BMPs may be "non-structural"; they will require no operation or maintenance. Examples are use of open space and vegetated buffers in development design, minimization of soil disturbance and compaction during construction, and minimization of directly-connected impervious areas. Other BMPs - "structural BMPs" - will require proper operation and maintenance. Examples include wet ponds, grassed swales, infiltration basins and bioretention areas.

Municipalities will need to have a monitoring program that ensures that the post-construction BMPs are constructed, operated and maintained, within the first permit term of 5-years.

The program must have two elements:

- Implementation: ensure installation of the BMPs as designed. Coordinate the monitoring with the CCD, especially where a permit has been issued.

- Operation and Maintenance: some of the structural BMPs will require maintenance over time to be effective. Municipalities must have a system to monitor these BMPs. If any BMPs are not operated or maintained and are ineffective, municipalities must develop a plan to address them. The PADEP Model Ordinance provides legal tools to accomplish this.

All municipalities within the Cobbs Creek Watershed must carry out this program (see Table 7-4). The schedule for full implementation is provided, in accordance with the new Phase II rules, in Table 7-16.

Table 7-16 Post-Construction Stormwater Runoff Management: Implementation Schedule

PERMIT YEAR	*IMPLMENTATION SCHEDULE*	
	Stormwater Management Program	Long Term Operation and Maintenance
Year 1	• Ordinance: Enact an ordinance requiring: • No formal approval of land development plans or issuance of building permits without municipal approval of post-construction stormwater controls • Development and redevelopment activities with earth disturbance of one acre or more with runoff to the MS4, or five acres or more regardless of the planned runoff, be conducted in accordance with the ordinance • Process: Rely on PADEP review of permits where applicable; where no PADEP review of post-construction controls is conducted, use municipal resources, or establish an agreement with the local CCD or other service provider (e.g., municipal engineer), for coordination of post-construction BMP approvals • Standard: Require post-construction structural and non-structural BMPs be designed, constructed and maintained to meet (1) the requirements of the approved Act 167 plan and the municipal ordinance, or until such Act 167 Plan is in place, (2) the PADEP statewide water quality requirements.	• Ensure that stormwater BMPs are built, operated and maintained as designed
Years 2-5	• Implement the ordinance and post-construction BMP approval process	• Ensure that stormwater BMPs are built, operated and maintained as designed

Pollution Trading (CR7) Related Goals: 1, 2, 5, 6, 7, 9, 10 Related Indicators: 1, 7, 8, 9, 10, 11, 12, 13, 14, 16, 19, 20			
What	Who	Where	When
Investigate Opportunities for Pollution Trading; potentially use as part of the framework for distributing BMPs throughout the watershed	All Municipalities	Cobbs Creek Watershed	Long Term, following establishment of TMDLs.

Pollution trading presents an intriguing option to mitigating the impacts of stormwater on Cobbs Creek. Trading could focus on sources of stormwater, TSS, Fecal Coliform, and Cryptosporidium, and could occur between municipalities within the watershed. In Cobbs Creek, only trading between non-point sources is feasible in the absence of point sources, which presents a greater challenge than point source trading. Trading could only occur between municipalities and or private entities responsible for controlling stormwater.

Trading under TMDLs is not yet well established, however, some general guidelines exist. Usually under trading arrangements, the total pollutant reduction must be the same or greater than what would be achieved if no trade occurred. A “buyer” and “seller” would agree to a trade in which the buyer compensates the seller to reduce pollutant loads. Buyers would purchase pollutant reductions at a lower cost than what they would spend to achieve the reductions themselves. Sellers would provide pollutant reductions and receive compensation. Stormwater sources could negotiate trades bilaterally or may trade within the context of an organized program. Sources could negotiate prices or exchange rates for loading reductions themselves, or they may face those established by a market.

To form a tradable allowance market, a few conditions must exist.

- Mitigation measures must show a variety of unit costs, some high, some low. In the case of Cobbs Creek, there are potential cost differences between types of BMPs, and potential cost differences based on the placement of the BMP (either in a CSO area or in a separate storm sewered area).
- All participants are price conscious and seek the lowest cost alternative. This is generally true; however, issues of jurisdiction may impede trading. For example, a municipality may not wish to install a BMP in another municipality.
- An authority exists for the management of stormwater that has determined the ecological limits of Cobbs Creek and can facilitate trading credits. At this time, no such authority exists, however elements of this watershed plan do address this issue through Target C objectives.
- The authority can compute appropriate allowance prices (based on the private and public cost of stormwater management) and can operate as a clearinghouse

for purchase and sale of allowances among participants.

- Runoff is apportioned to each parcel based on “natural” runoff rates, and additional runoff must be controlled, either by use of BMPs, or by buying allowances to cover their storm-water management responsibility. This aspect would be an integral part of any TMDL, which would establish total loads and apportion reductions.

In general, trading will not occur except in the context of a TMDL. Under the TMDL, total loads would be established and apportioned based on ecological impact and assessment of current loads. For Cobbs Creek, TMDLs have not been established, and trading remains a potential, future activity. (Thurston, Goddard, Szlag, Lemberg, 03; USEPA, 1996)

Use Review and Attainability Analysis (CR8)

What	Who	Where	When
Coordinate water quality standards review and revision with PWD's CSO LTCP	EPA and PADEP in partnership with PWD and other permitted dischargers	Cobbs Creek and tributaries	within 5 years (1 NPDES CSO permit cycle)

The CSO Policy calls for the development of a long-term control plan (LTCP) which includes measures that provide for compliance with the Clean Water Act, including attainment of water quality standards. The CSO Policy provides that "development of the long term plan should be coordinated with the review and appropriate revision of water quality standards (WQS) and implementation procedures on CSO-impacted receiving waters to ensure that the long-term controls will be sufficient to meet water quality standards" (59 FR 18694).

As part of a renewed focus on this commitment, EPA has issued a guidance document, Coordinating CSO Long-Term Planning with Water Quality Standards Reviews (EPA-833-R-01-002). This document lays a strong foundation for integrating water quality standards reviews, implementation of high-priority CSO controls, and development of well-designed and operated LTCPs that support attainment of water quality standards without causing substantial and widespread economic and social impacts. In addition to CSO impacts, many of the processes, procedures and ideas presented can be used to address wet weather issues such as stormwater and other point and nonpoint sources on a watershed basis. An iterative, phased implementation of CSO controls fits well with the watershed approach. Because Cobbs Creek is impacted by a variety of sources, and because some existing water quality criteria may be difficult to meet (e.g., bacteria levels during wet weather), it is an appropriate candidate for designated use review and possible revision.

Depending on the impacts, possible water quality standards revisions could include:

1. Re-evaluating recreational uses and applying criteria for bacteria at the point of contact rather than at the end-of-pipe,
2. Segmenting the water body to preserve recreation in areas where it actually occurs, and
3. Revising the use by creating subclasses to recognize intermittent exceedances of bacteriological criteria.

EPA identifies 11 steps to integrate use review into an LTCP. Steps 1 through 5 address the completion and initiation of an LTCP, steps which have been completed on the Cobbs. Steps 6 through 9 specifically address incorporating use review in the LTCP as discussed in more detail below. Steps 10 and 11 consist of LTCP implementation and compliance monitoring.

Step 6 - Review and accept draft LTCP and evaluate the attainability of water quality standards; implement and, through water quality monitoring, evaluate effectiveness of priority controls (e.g., for sensitive areas) and controls common to all alternatives.

The use review processes begins when watershed communities and the team coordinating LTCP implementation approach the state to discuss possible changes. EPA regulations at 40 CFR 131.10(j) require a Use Attainability Analysis (UAA) whenever a state proposes to reduce the level of protection for a water body. A UAA is a structured scientific assessment of the physical, chemical, biological, and economic factors affecting the attainment of the use. If the State Water Director agrees that a UAA is appropriate, UAA guidance is available from EPA.

If sufficient data are available, the State Water Director evaluates the attainability of the applicable water quality standards. The data collected and analyses conducted by the CSO community may be sufficient to justify a water quality standards revision, or may show that a water quality standards revision is not justified. If the regulating authority agrees that the data and analyses support a water quality standard revision (recognizing the revision may produce more or less stringent standards), this represents a commitment from the regulating authority to proceed with proposing water quality standards revisions. If the data and analyses show that currently applicable water quality standards can be attained, and that revisions to the water quality standards are not justified, the regulatory authority notifies the community and the coordination team.

If sufficient data are not available to evaluate the attainability of the use, the state water director, in consultation with the coordination team, identifies the parameters for which additional information is needed. If the community wishes to pursue a water quality standards review, these additional data should be collected while implementation of the LTCP is initiated.

Step 7 - Propose revisions and revise WQS, if needed.

Once the community has implemented priority CSO controls, the state may determine that a water body has the potential to support improved aquatic life. Under this circumstance, the state would upgrade the aquatic life use for the water body. In other cases, the state may determine that the recreational uses are not fully attained all the time, and may refine the recreational uses to reflect the maximum level of control from a well-designed and operated control program that does not cause substantial and widespread economic and social impact.

EPA's water quality standards regulations at 40 CFR 131.21(b) require that any analyses, including the UAA, used in support of the water quality standard revision be made available for public review and comment at the time the revisions are proposed. Subsequent to public review and comment and appropriate revision, the state submits the revision, supporting analyses and public comments to EPA for review.

Before the revisions in the water quality standards may be used for CWA programs, including TMDLs and NPDES permits, EPA must approve the state-adopted water quality standards revision (see 65 FR 24641, April 27, 2000). Where there has been close coordination and cooperation, the approval process is more likely to proceed expeditiously. EPA is expected to approve a state's new or revised standard within 60 days, or disapprove within 90 days.

Step 8 - Revise LTCP, as appropriate.

If the water quality standards decisions differ from those that the CSO community anticipated, or if the previously implemented controls have not performed as predicted, the community would have to revise the draft LTCP.

Step 9 - Review and approve LTCP, and modify permit.

The NPDES authority coordinates the review of the revisions and, if appropriate, approves the final LTCP, which provides that CSO discharges do not contribute to exceeding of water quality standards or noncompliance with other CWA requirements. The NPDES authority issues a permit or administrative order, or proceeds with revisions to an enforceable order requiring implementation of the approved LTCP.

Watershed-Based National Pollutant Discharge Elimination System (NPDES) Permitting Implementation (CR9) Related Goals: 1, 5, 6, 8, 9, 10 Related Indicators: 2, 7, 8, 9, 10, 11, 16,19, 20

Watershed-Based NPDES Permitting

Watershed-based NPDES permitting is an approach to developing NPDES permits for multiple point sources located within a defined geographic area (watershed boundaries) to meet water quality standards. This approach, aimed at achieving new efficiencies and environmental results, provides a process for considering all stressors within a hydrologically defined drainage basin or other geographic area, rather than addressing individual pollutant sources on a discharge-by-discharge basis. This plan provides the first steps in this process. In the long term, a watershed-based permit in the Cobbs system can provide the regulatory framework for implementation of this integrated watershed management plan.

Watershed-Based NPDES Permitting Related to Other Watershed Management Activities

A truly comprehensive watershed management approach should bring together key programs under the Clean Water Act, such as the NPDES Program, the TMDL Program, the Section 319 Nonpoint Source Program, and Section 404 Wetlands Permitting, as well as the Source Water Assessment Program under the Safe Drinking Water Act. Watershed-based NPDES permitting can be another tool to facilitate comprehensive programmatic integration at a watershed level and ensure that permitting activities tie into existing watershed management efforts.

Developing and Implementing a Watershed-Based NPDES Permitting Approach

EPA's suggested process for developing and implementing a watershed-based NPDES permitting approach consists of the following six steps. This integrated watershed management plan fulfills most requirements of the first three steps.

Step One - Select a Watershed and Determine the Boundaries
Step Two - Identify Stakeholders and Facilitate Their Participation

Step Three - Collect and Analyze Data for Permit Development
Step Four - Develop Watershed-Based Permit Conditions and Documentation
Step Five - Issue Watershed-Based NPDES Permit
Step Six - Measure and Report Progress

Step One - Select a Watershed and Determine the Boundaries

Watershed boundaries will influence the scale and scope of every aspect of the process, particularly stakeholder involvement and data collection. The physical characteristics of the area and the jurisdictional limits affect the process for defining the boundaries of a watershed. The larger the watershed boundaries, the larger the scope of complexities such as multi jurisdictional issues, data collection and management, stakeholder involvement, and funding. Those initiating the process for watershed-based NPDES permitting should keep these factors in mind when defining watershed boundaries. The watershed should be of a manageable size to allow for integration and coordination of water quality program activities with the permitting process. This step is complete for the Cobbs system.

Step Two - Identify Stakeholders and Facilitate Their Participation

Successful watershed management efforts require identifying and involving the key players, or stakeholders, that should participate in the process from the outset because they influence and are affected by watershed decisions. Early and continuous stakeholder involvement can garner stakeholder participation and support on potentially contentious decisions. Stakeholder involvement is particularly important in watershed-based permitting, where sustained voluntary participation of nonpoint sources might be the key to meeting water quality goals, regardless of the watershed-based permit limits reflected in NPDES permits for point sources.

The stakeholder group could serve as the collective decision making body for some aspects of the watershed-based NPDES permitting effort (e.g., goal setting) or as a group that simply provides advice and guidance to the permitting authority. Given the various backgrounds, interests, and areas of expertise among the group, it is important that everyone has a general understanding of the NPDES program and the watershed-based NPDES permitting concept.

The Darby-Cobbs Watershed Partnership provides the foundation of this stakeholder group. In the long term, a more formal group with clearly defined responsibilities may need to be formed. This possibility is discussed in the institutional arrangements section of this plan.

Step Three - Collect and Analyze Data for Permit Development

A watershed-based permit addresses multiple sources within the watershed. This data collection and analysis process will be similar to that used in developing TMDLs for impaired water bodies. Data collection and analysis for watershed-based permitting, however, is further complicated by the fact that the analysis might address not only multiple sources but also multiple pollutants. This section lists questions stakeholders should consider when conducting initial data collection and analysis, and lists potential sources for those data. The water quality data and pollutant loading model results produced as part of this plan form the foundation for step 3.

Step Four - Develop Watershed-Based Permit Conditions and Documentation

In addition to individual monitoring and reporting requirements, watershed-based NPDES permits may contain watershed-wide requirements that could be applied to multiple dischargers in the watershed. For example, permittees might form a monitoring consortium to collect ambient water quality data that supplements end-of-pipe monitoring data required by NPDES permits. Through a monitoring consortium, permittees could generate data that could be used in Clean Water Act section 305(b) water quality reports and other watershed assessments. Depending on the structure of the watershed-based permit(s), watershed-wide requirements might be coordinated across several individual permits or contained in a single permit that applies to multiple sources. EPA has developed guidance on monitoring consortiums that might be helpful to permitting authorities in developing watershed-wide monitoring and reporting requirements (USEPA 1997). Although no mechanism currently exists in Pennsylvania to implement watershed-based permitting, the CCIWMP presents sufficient information to develop permit conditions because there are no point sources other then stormwater discharges in the watershed.

Step Five - Issue Watershed-Based NPDES Permit

The most important factors affecting the process for issuing a watershed-based permit will be the administrative requirements and the type or structure of the permit. Permitting authorities, permittees, and other stakeholders need to be familiar with the specific administrative requirements for permit issuance in their jurisdiction (in accordance with 40 CFR Part 124). Administrative requirements address public notice and comment; public hearings; EPA and state or tribal permit review; actions required for final permit issuance (e.g., approval of the state environmental board); and requirements for modification or for permit appeal after final permit issuance. These requirements vary by jurisdiction.

Watershed-based NPDES permitting approaches will vary from watershed to watershed. As a result, the types of permits developed through a watershed-based permitting process will vary. There is no single model or example of what an NPDES permit developed through watershed-based permitting should look like. Possible watershed-based permitting mechanisms are variations of general and individual point source NPDES permitting approaches.

Step Six - Measure and Report Progress

The ultimate goal of watershed-based permitting is to ensure that receiving water quality is protected through the implementation of an integrated, holistic approach. Progress toward attaining this overall goal can be measured at both the watershed and permit levels. The monitoring and reporting recommendations made in this plan form the foundation for step 6.

Potential Benefits and Challenges of Watershed-Based NPDES Permitting

A number of benefits can be expected from watershed-based permitting. Although the specific benefits will be unique to each project, they will likely include a mix of environmental and administrative benefits such as; integration of water-related programs, targeted and maximized use of resources to achieve greatest environmental results, local cooperative efforts, watershed-wide monitoring plans, and trading and other market-based strategies.

Like the benefits of watershed-based permitting, the challenges of implementing this approach will be unique to each watershed and each permit. Some challenges would be; expanded stakeholder involvement, integrating nonpoint sources, need for more flexible program infrastructure, conflicting jurisdictional requirements, and making an initial investment.

7.3.2 Public Education and Volunteer Programs

Public Education and Volunteer Programs (CP1) Related Goals: Related Indicators:			
What	Who	Where	When
See Public Education and Volunteer Programs under Target A options.	All Municipalities	All Municipalities	Short-term: first 5 years coinciding with the stormwater permit (See Table 7-5)

7.3.3 Municipal Measures

Sanitary Sewer Overflow Detection (CM1) Related Goals: 6, 9, 10 Related Indicators: 10, 11, 19, 20			
What	Who	Where	When
SSO Detection Program	Municipalities with separate sewer systems in Cobbs Creek (see Table 7-4)	See Figure 7-2 (map of separate sewers and responsible authorities)	Permanent ongoing program should be part of each agencies program

Discharges from sanitary sewers to Cobbs Creek during wet weather have been identified as a serious concern. Some of the techniques used for inspection of sewer lines can also be used for identifying potential locations of SSOs. Some of the most effective techniques for identifying the location of SSOs are listed below. (Source: Protocols for Identifying Sanitary Sewer Overflows, American Society of Civil Engineers EPA Cooperative Agreement #CX 826097-01-0, June 2000)

Sewer System Mapping

GIS maps of the sewer system should be developed in all municipalities. These maps serve as the basis for hydraulic modeling, and are key to many of the techniques described below.

Customer and/or Public Complaint

When a basement backup occurs or an SSO occurs in an area exposed to view, it is almost certain that someone will call the sewerage agency and report the incident. The agency should have a plan in place to investigate the reported SSO, find its cause, and take remedial measures to avoid recurrence of the SSO.

Visual Inspections after Overflows

Visual inspections can be used to confirm the occurrence of SSOs at suspected locations. The agency should develop a list of such locations and update it periodically. Immediately following a major storm, an inspection team should be sent to investigate these locations. A visual inspection program can be enhanced by encouraging participation of the public through providing opportunities for the public to become part of the solution.

Scheduled Maintenance Inspection

Municipal sewerage agencies should be performing routine maintenance inspections of their system. While the maintenance crew is performing the inspection, it can also look for signs of SSO. SSOs are most likely to occur pumping stations, manholes, stream crossings, and cleanouts.

GIS-Based Analysis of Past SSOs

GIS analysis can answer questions related to location, condition, trends, patterns, and modeling. Listed below are some typical questions that GIS can answer:

- What exists at a given location?
- Where is the location of an object or outcome with a number of specific characteristics?
- What has changed over a given period?
- What is the spatial distribution of areas with a certain attribute?

Sanitary Sewer Management Systems

A Sanitary Sewer Management System (SSMS) can be used to store, organize and analyze large quantities of data associated with sewer system operation, maintenance, inspection, modeling and rehabilitation. The SSMS may include the following modules:

- Inventory Module
- Flow Module
- Modeling Module
- Inspection Module
- Maintenance Module
- Rehabilitation (CIP) Module
- Mapping Module

Analysis of the data in the SSMS can reveal many problem areas, trends, and patterns. For example, the database can be searched to develop a list of lines with flat slopes or areas where frequent maintenance is needed. Another application of the SSMS is analysis of historical data.

Flow Monitoring

Flow monitoring at strategic locations may be used to identify potential locations of SSOs. Flow monitors can be installed in open channels and pumping stations to obtain the data necessary for proper system evaluation. In conjunction with flow monitoring, rain gauges should also be installed. Many open channel temporary flow meters have both velocity and depth measuring sensors. Municipalities are encouraged to make use of the existing rain gauge network in the Cobbs Creek watershed.

Flow data can be used to determine the average daily flow, the infiltration rate, and the inflow rate. The rain gauge data can be used to determine the recurrence interval or severity of the storm event (for example, 5-year) that caused the inflow. The flow data will also indicate whether a surcharge occurred during the flow monitoring period.

Monitoring of Receiving Stream for Sewage Indicators

This technique may be used for identifying the locations of dry weather SSOs. Samples from a nearby stream are taken at regular intervals along the stream and tested for fecal coliforms. Significant presence of these bacteria could be an indication of sewage leaking from the sewer line into the stream.

Closed Circuit Television (CCTV) Inspection

CCTV inspection has been widely used for inspection of sewer line interiors. The final product of a CCTV inspection is videotape and a field log prepared and narrated by an operator. The videotape provides a visual and audio record of problem areas in the sewer line. Evaluation of the CCTV records help identify structural problems; locate leaking joints and non-structural cracks, blockages, and dropped joints; and identify areas of root intrusion.

Sewer Scanner and Evaluation Technology Surveys (SSET)

The SSET is a new pipeline inspection technology developed in Japan. The equipment consists of a scanner, a CCTV, and a three-axis mechanical gyroscope. The mechanics of placing the SSET in the sewer line are similar to those of CCTV inspection. The images produced by SSET are of higher quality than CCTV images. Interpretation of the results is done in the office by an engineer rather than in the field by a technician. This increases the speed of field operations and reduces the cost.

Surcharge Level Alarms/Remote Monitoring

These devices can be placed at strategic locations in the manholes and pumping stations. Once the flow reaches a certain elevation, the alarm goes off and sends a signal to a control center via a telephone line or SCADA system. The sewerage agency should have a plan in place to respond immediately to such alarms. In addition to taking appropriate action, the responding agency should also record the event in a database.

Dye Tracing

Dyed water testing consists of dye tracing or flooding, and is done to locate possible sources of inflow such as area drains or catch basins suspected of being connected to the sewer line, or sources of rainfall-induced infiltration/inflow which indirectly contribute to the flow in the sewer line through the soil and pipe cracks. Dye testing is normally used to complement smoke testing of suspect areas. The downstream manhole is monitored to see if the dye water injected into an outside source such as a downspout has found its way into the sewer system. Color CCTV may also be used for locating problem areas after the dye enters the pipeline through the surrounding soil. Figure 5-4 is a sample form for recording the results of dye water inspection.

Smoke Testing

The purpose of smoke testing is to locate rainfall-dependent I/I sources which could lead to SSOs during a storm events. Public notification is an important and critical element of any smoke testing program. Specific I/I sources detected by smoke testing includes roof, yard, and area drain connections; catch basins; and broken service lines. The testing procedure consists of pumping non-toxic smoke through a manhole into the sewer pipe for distances up to 600 ft. The smoke will surface through open breaks in the pipe connections. All such sources are photographed and documented.

Aerial Monitoring

Aerial monitoring by helicopter may be used to gain a general understanding of conditions along a sewer line which may lead to an SSO. For example, washout may expose a section of pipe, which would then be at risk of damage and subsequent SSO. Examples of features which may be observed during such monitoring include manholes with broken or missing covers and sewer lines exposed by erosion.

Monitoring of Grease Buildup

A significant cause of SSOs during dry weather is sewer stoppages resulting from grease buildup. Such stoppages occur most frequently in downtown areas where restaurants are major sources of flow in the sewer system. A list of locations of grease buildup should be developed and these locations should be regularly inspected. Grease buildup can be prevented by enforcing grease ordinances, by effective pretreatment programs, and by promoting public education. The grease accumulations can be removed using the many available cleaning techniques, such as bucket machines with brushes, power rodders, and high velocity jet cleaners. Bioaugmentation, which involves the addition of bacteria cultures to sewers to speed up the breakdown of grease deposits, can also be effective.

Pump Station Inspection

Pump station failures can lead to significant SSO problems. Such failures can be avoided by regular inspections. The frequency of inspections may vary from once a day to once a month, depending on the size and criticality of the station, and reliance on monitoring by means such as the SCADA system.

Manhole Inspection

Manhole interiors are inspected for physical soundness for evidence surcharging such as high water marks on manhole walls. The observed defects should be compiled into a database that will be used to estimate the I/I attributable to each manhole and to establish manhole maintenance and rehabilitation program.

Line Lamping

Line lamping is done in conjunction with manhole inspection by inspecting the interior of the sewer lines connected to the manhole using an artificial light and a mirror. Lamping helps identify pipe defects and provides a basis for selecting sewers for television inspection.

Building Inspection

Building inspections are conducted to investigate extraneous flow from connections to sump pumps, foundation drains, downspouts, or leaking laterals. Building inspections should include investigation of the causes of basement backups.

Ground Penetrating Radar

Ground penetrating radar uses the transmission and reflection properties of an electromagnetic wave passing through the soil to determine soil properties and the depth and extent of subsurface objects. The speed and amplitude of the electromagnetic wave are dependent on the moisture content of the soil. This principle can be used to detect leaking joints in the line and voids around the pipe, which may be caused by soils being washed out. In such locations, the signal will be delayed because the speed of the wave will be reduced, and the amplitude of the wave will be attenuated.

Soil Moisture and Temperature Monitoring

When the ground is relatively dry, a larger portion of the rainfall will penetrate the soil, which will result in a decrease of groundwater to sanitary sewers. However, as the soil moisture increases, the amount of infiltration to sewers increases. For this reason, the impact of subsequent storm will be more severe: while the system did not overflow during the first storm, it will do so during the second storm, although the second storm of smaller intensity than the first. By monitoring the soil moisture and temperature, it may be possible to develop a measure for assessing the occurrence of SSOs.

Inspections of Stream Crossings and Parallel Lines

Pipes running alongside or crossing streams are often vulnerable to SSOs. If the sewer is buried under the streambed, the scouring action of the stream bed will eventually expose it, causing the pipe to lose its soil support. The pipe segments may move under the water pressure and joints may open, or the pipe may become exposed as a result of bank erosion. Any such openings admit significant amounts of flow, which may exceed the capacity of the sewer pipe. Stream crossings that include inverted siphons often become clogged with accumulations of silt and debris, which may cause an overflow upstream. The foundations of aerial stream crossing piers are also subject to scouring and may lead to foundation failure of the sewer line.

Sewer pipes that cross or parallel streams should be inspected to ensure that they are not broken or cracked. The manholes on each side of the stream should be checked for excess flow, which would indicate a leaking sewer under the stream. Since these sewers are usually in remote areas, they are vulnerable to vandalism and can overflow undetected for long periods.

All municipalities in the Cobbs Creek watershed should have a routine and effective SSO detection program. Once SSOs are found and the cause determined, proper measures to eliminate the SSO should be taken.

Figure 7-2 shows the areas where separate sanitary sewers exist. All municipalities with separate sanitary sewers are responsible for developing an effective SSO detection program.

Sanitary Sewer Overflow (SSO) Elimination: Structural Measures (CM2)
Related Goals: 6, 9, 10
Related Indicators: 10, 11, 19, 20

What	Who	Where	When
Implement a CMOM program (option AM1). Update and implement official Act 537 Sewage Facilities Plans.	Municipalities with separate sewer systems in Cobbs Creek (see Table 7-4)	See Figure 7-2 (map of separate sewers and responsible authorities)	Short-term (within 5 years of SSO detection)

Discharges to waters of the United States from municipal sanitary sewer collection systems are prohibited, unless authorized by an NPDES permit. Permits authorizing discharges from such systems must contain technology-based effluent limitations, based upon secondary treatment and applicable water quality standards. NPDES permits for municipal wastewater treatment plants should require record-keeping and reporting of overflows that result in a discharge. Permits should also contain requirements for operation and maintenance of the sanitary sewer collection system.

The EPA and PADEP are continuing to address SSO problems with compliance assistance and enforcement in accordance with the Compliance and Enforcement Strategy Addressing Combined Sewer Overflows and Sanitary Sewer Overflows, issued April 27, 2000. In addition to the national policy, Act 537, enacted by the Pennsylvania Legislature in 1966, requires that every municipality in the state develops and maintains an up-to-date sewage facilities plan. The main purpose of a municipality's sewage facilities plan is to ensure that the sewage collection and treatment systems have adequate capacity to convey present and future to sewage flows to a wastewater treatment facility. Official plans contain comprehensive information, including:

- The location of treatment plants, main intercepting lines, pumping stations and force mains, including their size, capacity, point of discharge and drainage basin served (preferably in a GIS format).
- Descriptions of problems with existing sewerage facilities and operation and maintenance requirements
- Planning objectives and needs
- Physical description of planning area
- Evaluation of existing wastewater treatment and conveyance systems
- Evaluation of wastewater conveyance and treatment needs

EPA has developed a comprehensive management framework called Capacity, Management, Operations, and Maintenance (CMOM) to assist municipalities in developing more comprehensive sanitary sewer system management programs. A

CMOM program, as described in option AM1, helps to prevent SSOs. Once a recurring SSO is detected using the methods recommended under option CM1, measures must be taken to eliminate the discharge.

Reduction of Stormwater Inflow and Infiltration (RDII) to Sanitary Sewers (CM3) Related Goals: 6, 9, 10 Related Indicators: 10, 11, 19, 20			
What	Who	Where	When
RDII Reduction Program	Municipalities with separate sewer systems in Cobbs Creek (see Table 7-4)	See Figure 7-2 (map of separate sewers and responsible authorities)	Short-term

Where significant RDII is detected, measures can be taken to seal the sanitary sewer system to reduce inflow of stormwater and groundwater. These measures are discussed in detail under option AM3, sanitary sewer rehabilitation.

Combined Sewer Overflow (CSO) Control Program (CM4) Related Goals: 5, 6, 9, 10 Related Indicators: 7, 8, 9, 10, 11, 19, 20			
What	Who	Where	When
Nine Minimum Controls Long Term Control Plan (LTCP) Capital Projects Watershed Plan Development	Philadelphia Water Department (PWD)	Philadelphia combined sewer system (Figure 7-14)	NMCs complete and ongoing RTC short-term (within 5 years)

The fundamental goal of the Philadelphia Water Department's (PWD) combined sewer overflow (CSO) program is to improve and preserve the water environment in the Philadelphia area and to fulfill PWD's obligations under the Clean Water Act and the Pennsylvania Clean Streams Law by implementing technically viable, cost-effective improvements and operational changes.

The PWD's strategy to attain these goals has three primary phases: aggressive implementation of a comprehensive program for Nine Minimum Controls; planning, design and construction of 17 capital projects that further enhance system performance and reduce CSO volume and frequency; and comprehensive watershed-based planning and analyses that will identify additional, priority actions to further improve water quality in Philadelphia area water bodies.

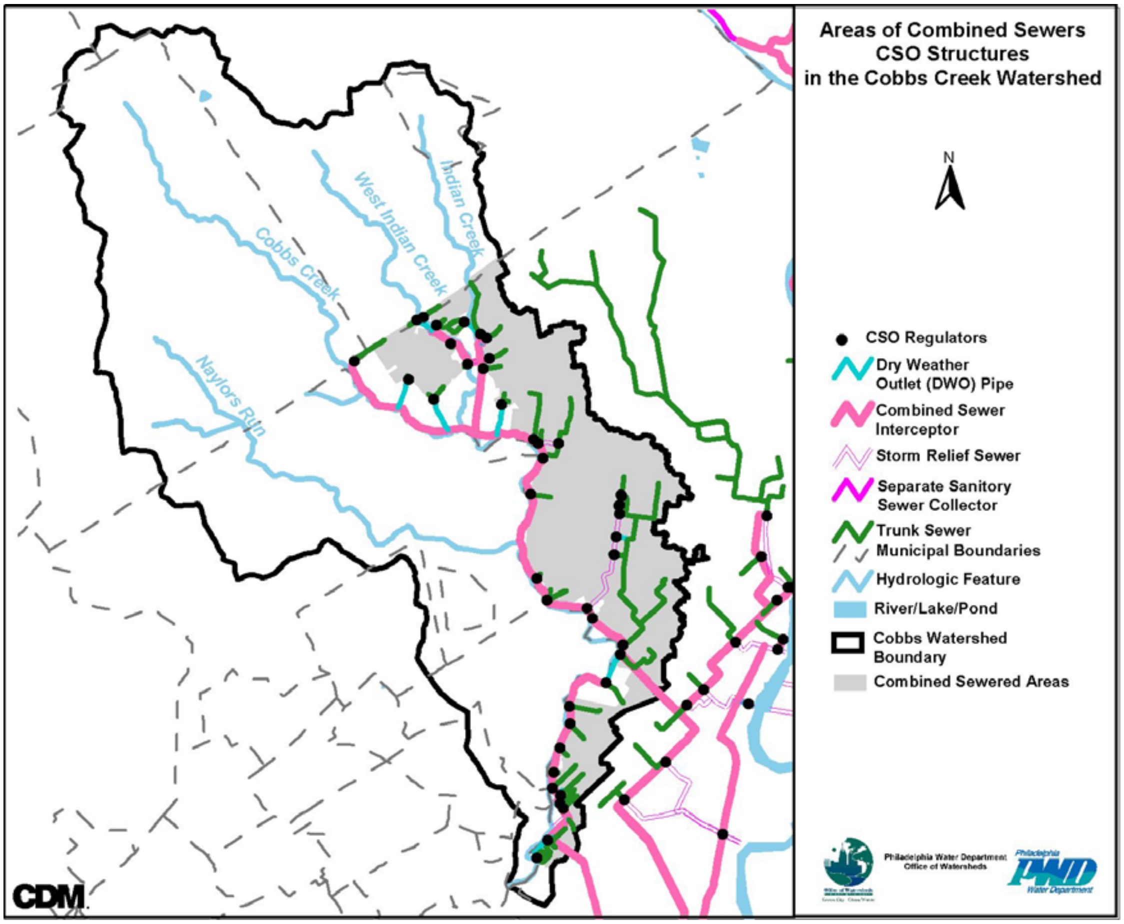

Figure 7-14 Areas of Combined Sewers and CSO Structures

The implementation of each of these control measures is discussed briefly below.

Nine Minimum Controls

In the first phase of the PWD's CSO strategy, and in compliance with its NPDES permits, the PWD submitted CSO Documentation: Implementation of Nine Minimum Controls to the Pennsylvania Department of Environmental Protection on September 27, 1995. The nine minimum controls are low-cost actions or measures that can reduce CSO discharges and their effect on receiving waters, do not require significant engineering studies or major construction, and can be implemented in a relatively short time frame. To provide information needed for the development of the Nine Minimum Controls (NMC) program, the PWD instituted a $6.5 million project to upgrade its comprehensive system flow monitoring network. This program provides information necessary to identify and eliminate dry weather overflows, monitor system performance and operation, and configure and calibrate computer hydraulic models needed to develop the NMCs and long-term CSO control plans. This information provided the basis for the System Hydraulic Characterization Report that was submitted to the PADEP in June 1995 and provided the technical basis for the development of the NMC plan.

Extensive data from the PWD's Geographic Information System (GIS), flow monitoring system, the U.S. Army Corps of Engineer's Storage, Treatment, Overflow, Runoff Model (STORM), and the EXTRAN and RUNOFF blocks of the EPA Stormwater Management Model (SWMM) were used to support each phase of the CSO program. These tools were developed to support concept engineering through implementation and post-construction monitoring. The monitoring system, models, and GIS will serve as the basis for planning improvements and enhancing operation of the sewerage system over the long-term.

Using the above tools, the PWD's NMC program includes comprehensive, aggressive measures to maximize water quality improvements through the following measures:

1. Review and improvement of on-going operation and maintenance programs

CSO Regulator Inspection & Maintenance Program

PWD has committed to demonstrating an improved follow-up response to sites experiencing a dry weather overflow. PWD has instituted a policy of next day follow-up inspection at sites that experience an overflow. PWD will conduct an evaluation of the effectiveness of twice-weekly inspections.

A database has been developed to document the maintenance performed on each CSO site. This system will ensure that proper regulator settings are maintained and system changes are documented. This database can also store scanned plan view and profile view drawings of CSO regulator and hydraulic control point chambers for inclusion in the filed inspection report forms.

Additional components of the O&M program include:

- Pumping Station Maintenance
- Sewer Cleaning Contracts
- Inflow Prevention Program
- Tide Gate Inspection and Maintenance Program
- Emergency Overflow Weir Modification

2. Measures to maximize the use of the collection system for storage

Use of the collection system for storage has long been recognized as a potentially cost-effective means to mitigate the occurrence and impacts of CSOs. PWD has been implementing in-system storage in Philadelphia's combined sewer system for nearly twenty years, using a variety of technologies.

- Reducing tidal inflows at regulators along the Southwest Main Gravity and the Lower Schuylkill West Side interceptors can reduce CSO overflows to Cobbs Creek by increasing available treatment capacity at the SWWPCP.

- A program to install tide gates or other backflow prevention structures at Cobbs Creek regulators to protect these regulators from potential inundation.

- Another approach that can be implemented to gain additional in-system storage is to raise the overflow elevation by physically modifying the overflow structure (e.g. raising an overflow weir). However, this approach must be implemented cautiously, since raising the overflow elevation also raises the hydraulic grade line in the combined trunk sewer during storm flows, and therefore increases the risk of basement and other structural flooding within the upstream sewer system due to backup or surcharge problems.

3. Review and modification of PWD's industrial pretreatment program

(also see the section from Regulatory Approaches: Industrial Pollution Prevention)

- Over the years, PWD has implemented a rigorous industrial pretreatment program. The effectiveness of this program has allowed the City to develop one of the largest and most successful biosolids beneficial reuse programs in the nation. As part of the nine minimum controls effort, the Department is committed to taking actions to encourage industries to better manage their process water discharges to the sewer collection system during wet weather periods.

4. Measures to maximize flow to the wastewater treatment facilities

As a minimum control, maximizing flow to the publicly owned treatment works (POTW) means making simple modifications to the sewer system and treatment plant to enable as much wet weather flow as possible to reach the treatment plant and receive treatment. The secondary capacity of the treatment plant should be maximized, and all flows exceeding the capacity of secondary treatment should receive a minimum of primary treatment (and disinfection, when necessary). The most effective way to determine the ability of the POTW to operate acceptably at incremental increases in wet weather flow, and to estimate the effect of the POTW's compliance with its permit requirement, is to perform stress testing to determine optimum flows, loads, and operations of the plant's unit processes.

5. Measures to detect and eliminate dry weather overflows

Relevant measures are discussed under the municipal measures of Target A.

6. Control of the discharge of solid and floatable materials

Solids are waterborne waste material and debris consisting of sand, gravel, silts, clay, and organic matter. Significant concentrations of solids are not only a visual nuisance, but can affect turbidity, dissolved oxygen, and carry pathogens in the receiving water. In addition, excessive amounts of solids can affect the combined sewer system by decreasing hydraulic capacity, thus increasing the frequency of overflows. Solids can enter the system through domestic and industrial wastewater, and debris washed from streets.

Floatables are waterborne waste material and debris (e.g., plastics, polystyrene, and paper) that float at or below the water surface. Floatables seen in significant quantities are aesthetically undesirable and can cause beach closings, interfere with navigation by fouling propellers and water intake systems, and impact wildlife through entanglement and ingestion.

Floatables and solids control measures consist of non structural and structural technologies.

Non structural technologies include combined sewer system maintenance procedures such as sewer flushing, street sweeping, and catch basin cleaning. Public education, land use planning and zoning, and ordinances are also considered non-structural technologies implemented to reduce solids and floatables entering the combined sewer system. These technologies are discussed under separate subsections and therefore will not be discussed further here.

Structural controls typically consist of abatement devices that would be constructed near the point of discharge. Technologies used for removing solids and floatables from CSOs include: Baffles, Booms, Catch Basin Modifications, Netting Systems, Swirl Concentrators, Screens, and Trash Racks. Modification of storm and combined sewer inlets for solids control, as well as catch basin and storm inlet maintenance are discussed under separate subsections.

Solids and floatables discharged from CSOs may represent a potentially significant impact to Cobbs Creek. PWD currently expends considerable effort to minimize the potential discharge of solids and floatables.

- PWD performs over 50,000 inlet cleanings each year preventing many tons of street surface-related materials from discharging to waterways through CSOs. The significant pipe cleaning and grit removal activities conducted by the department also remove a great deal of material that otherwise might discharge through CSO outlets during wet weather.

- The continued practice of regularly cleaning and maintaining grit pockets at critical locations in the trunk and interceptor system is an important part of the CSO control strategy. Grit buildup reduces the hydraulic capacity of the interceptor both by constricting its cross sectional area, and by increasing its frictional resistance. For example, quarterly cleaning of the 100-foot deep siphon grit pocket located at the Central Schuylkill wastewater pumping station is a major undertaking requiring specialized equipment and the commitment of significant labor resources. This practice has been shown to reduce the hydraulic grade surface at the siphon, increasing the wet weather flow capacity to the SWWPCP. Prior to the institution of this cleaning practice, the grit pit at this location had not been cleaned regularly in over 40 years.

- Inspections have revealed that grit has accumulated in the 30-inch Cobbs Creek Low-Level (CCLL) interceptor to a depth of approximately 12 inches. This project entails the removal of grit and debris along the entire 30-inch interceptor. This project will reduce the frequency and volume of overflows to Cobbs Creek by restoring the conveyance capacity of the 30-inch Cobbs Creek interceptor between the 75th and Gray's Avenue chamber and the SWWPCP low level pumping station. When grit is removed from this interceptor segment, the model indicates that the capacity nearly doubles from 5.9 mgd to 15 mgd. This project results in a 50 MG volume reduction on an average annual basis.

- Operation condition inspections of regulator chamber and backflow prevention devices are conducted for each structure approximately weekly, resulting in more than 10,000 inspections conducted each year. Additionally, comprehensive structural and preventative maintenance inspections are performed annually.

- Floatables will be monitored. If additional floatables control is warranted, then structural technologies will be considered. Structural technologies that would be considered first are catch basin modifications, including further enhancement of inlet grating and submerged outlet installations, netting systems, and static screens. More structurally intensive controls would be considered only if the application of the controls mentioned above proved not to be feasible under specific site requirements.

7. Implementation of programs to prevent generation and discharge of pollutants at the source

Most of the city ordinances related to this minimum control are housekeeping practices that help to prohibit litter and debris from actually being deposited on the streets and within the watershed area. These options are discussed under Target A, including litter ordinances and illegal dumping policies and enforcement. If these pollutants eventually accumulate within the watershed, practices such as street sweeping and regular maintenance of catch basins can help to reduce the amount of pollutants entering the combined system and ultimately, the receiving water.

8. Measures to ensure that the public is informed about the occurrence, location and impacts of CSOs

The Water Department has developed and will continue to develop a series of informational brochures and other materials about its CSO discharges and the potential affect on the receiving waters, in addition to information regarding dry weather flows from its stormwater outfalls. The brochures provide phone contacts for additional information. Also, the opportunity to recruit citizen volunteers to check or adopt CSO outfalls in their watersheds (i.e., notifying the PWD of dry weather overflows, etc.) will be explored through the watershed partnership framework. Brochures and other educational materials discuss the detrimental affects of these overflows and request that the public report these incidences to the department. In addition, the Water Department has enlisted watershed organizations to assist it with this endeavor. The department continued with this focus in 2002 to raise the level of awareness in its citizens about the function of combined and stormwater outfalls through a variety of educational mediums. The watershed partnerships are important for this kind of public/private effort to protect stream water quality. Lastly, the department's Clean Streams Team will investigate the feasibility of installing signs that can withstand nature and vandals at the department's outfalls

A more recent development in 2002/2003 was discussion among the state, PWD and the Delaware Estuary Program, to begin a marina best management practices education program that, in addition to alerting recreational users of the Delaware and Schuylkill Rivers regarding questionable water quality following rain storms, will also provide tips and information to marina operators to ensure their practices are environmentally sound. To complement this effort, the PWD has also been working with other city agencies to devise a "Recreational River Rating System" for the Schuylkill River due to the number of recreational activities that take place on the river year around. This system's educational message will be similar to that of the marina program as the advisories are based upon rainfall, CSOs and upstream influences on water quality.

9. Comprehensive inspection and monitoring programs to characterize and report overflows and other conditions in the combined sewer system.

Monitoring and characterization of CSO impacts from a combined wastewater collection and treatment system are necessary to document existing conditions and to identify water quality benefits achievable by CSO mitigation measures. Tables are compiled annually to represent average annual CSO overflow statistics as required in the NPDES Permit.

Long Term Control Plan Capital Projects

The second phase of the PWD's CSO strategy is focused on technology-based capital improvements to the City's sewerage system that will further increase its ability to store and treat combined sewer flow, reduce inflow to the system, eliminate flooding due to system surcharging, decrease CSO volumes and improve receiving water quality. The recommended capital improvement program is the result of a detailed analysis of a broad range of technology-based control alternatives.

Real Time Control

PWD has been evaluating and implementing computer controlled CSO outfall/regulator gate facilities that use level monitors to control the position of the dry-weather outlet (DWO) gate and tide gate at each location for maximizing the utilization of in-system storage in the combined sewer system. These computer controlled outfall facilities apply real-time control (RTC) mechanisms to maximize in-system storage. The use of RTC allows the capture and delivery to the treatment works of flow at the maximum rate at which it can be treated. This approach is attractive in terms of optimizing the use of the existing sewer system to capture combined wastewater and minimize CSOs.

- PWD is pursuing an opportunity to install an RTC system along the Lower Schuylkill combined sewer system, which takes the flow from the Cobbs Creek High Level (CCHL) interceptor. The modifications affect regulator structure C_17. The C_17 chamber regulates the capture of combined sewage from the largest combined-sewered area in the CCHL system. Due to its location and overflow elevation, C_17 controls the maximum head in the CCHL Cutoff Sewer and the conveyance capacity for the entire CCHL system. The proposed chamber modifications include raising the C_17 diversion dam and increasing its dry weather outlet (DWO) pipe diameter. The locations of C_17, the CCHL Cutoff Sewer and the SWWPCP are displayed on Figure 7-12.

Figure 7-15 Proposed RTC Sites

Cobbs Creek Low Level Interceptor Conveyance Improvements

Inspections have revealed that grit has accumulated in the 30-inch Cobbs Creek Low-Level (CCLL) interceptor to a depth of approximately 12 inches. Grit buildup reduces the hydraulic capacity of the interceptor both by constricting its cross sectional area, and by increasing its frictional resistance. This project entails the removal of grit and debris along the entire 30-inch interceptor. The estimated cost for the project is $440,000.

This project will reduce the frequency and volume of overflows to Cobbs Creek by restoring the conveyance capacity of the 30-inch Cobbs Creek interceptor between the 75th and Gray's Avenue chamber and the SWWPCP low level pumping station. When grit is removed from this interceptor segment, the model indicates that the capacity nearly doubles from 5.9 mgd to 15 mgd. This project results in a 50 MG volume reduction on an average annual basis.

Cobbs Creek Low Level (CCLL) Control Project

Control pipes, located in the CCLL interceptor near Glenmore Avenue, are two 18-inch orifice openings in an interceptor manhole bulkhead. The control pipes were installed to prevent chronic flooding occurring at the 75th and Grays Avenue chamber downstream. The 75th and Grays chamber is a former regulator (C-28), whose outfall to Cobbs Creek was sealed but still contained a 12-inch by 18-inch orifice opening to the interceptor. Grit accumulation has reduced the capacity of this orifice. The orifice opening at the 75th and Gray's chamber was the limiting hydraulic element in the interceptor. The opening restricted flow to the 30-inch interceptor that conveys flow from the 75th and Gray's Avenue chamber to the SWWPCP low level pumping station. The maximum flow through this opening was 11.8 mgd, assuming the 30- inch interceptor downstream of the 75th and Gray's Avenue has been cleaned (Cobbs Creek Low Level Interceptor Conveyance Improvements.) Flow was recently rerouted the flow past the orifice in the 75th and Gray's chamber with a new 30-inch pipe, increasing the capacity to 15 mgd. The hydraulic limit of the 30-inch CCLL interceptor can now be realized. This project was completed at a cost of $200,000. Additionally, the upstream interceptor will be cleaned and lined and a smooth transition between the brick sewer and the new 30-inch RCP bypass will be constructed. The two 18-inch orifices will be reconfigured in order to facilitate cleaning. While these orifices will control flooding problems at the 75th and Grays Avenue, they will not reduce the flow delivered to the interceptor below the interceptor capacity of 15 mgd. The projected cost for this project is $2,500,000.

These projects reduce the frequency and volume of overflows to Cobbs Creek, one of the smaller receiving streams. Interceptor capacity increases from 11.8 to 15 mgd due to the new 30-inch bypass line in conjunction with grit removal in the downstream interceptor (Cobbs Creek Low Level Interceptor Conveyance Improvements). The reduction in overflow volume is 10 MG on an average annual basis.

Watershed-Based Planning and Management

The third component of the City's CSO strategy involves a substantial commitment by the City to watershed planning to identify long term improvements throughout the watershed, including possibly additional CSO controls, which will result in further improvements in water quality and, ultimately, the attainment of water quality standards. The need for this watershed initiative is rooted in the fact that, prior to development of the Watershed Management Plan, insufficient physical, chemical and biological information existed on the nature and causes of water quality impairments, sources of pollution, and appropriate remedial measures. Because of this deficiency, it was impossible to determine what needed to be done for additional CSO control or control of other wet weather sources throughout the watershed. This deficiency, especially with respect to the effects of wet weather discharges and receiving water dynamics, is increasingly recognized nationwide and has led to a broader recognition of the need for watershed-based planning and management to properly define water quality standards and goals. The PWD believes that the National CSO Policy, state and federal permitting and water quality management authorities, cities, environmental groups, and industry, now recognize that effective long-term water quality management can be accomplished only through watershed-based planning. Completion of the Cobbs Creek Integrated Watershed Management Plan represents the realization of this commitment to watershed-based planning.

Catch Basin and Storm Inlet Maintenance (CM5) Related Goals: 4, 6, 8, 9, 10 Related Indicators: 11, 15, 16, 19, 20			
What	Who	Where	When
Regularly inspect catch basins (in combined areas) and storm inlets (in separate areas). Remove sediment as needed.	Sewer Owners (PWD and municipalities)	All inlets throughout watershed	Continue existing programs

Catchbasins and storm inlets that are part of the stormwater collection and conveyance system should be cleaned on a regular basis. Sediments, leaves, grass clippings, pet wastes, litter and other materials commonly accumulate in catchbasins. These materials can contain significant concentrations of nutrients, organics, bacteria, metals, hydrocarbons, and other pollutants. When a storm occurs, runoff entering the basin may dislodge and suspend some of this material. This debris can be conveyed along the storm sewer system and released to a surface water body. Catchbasin clean out should be scheduled for the fall and early spring in order to remove leaves and road salt and sand before the spring rains. In general, this is done with vacuum trucks, with disposal of the debris handled as solid waste.

In separate sewered areas of Cobbs Creek, each municipality is responsible for an effective storm sewer cleaning program. In Philadelphia, PWD has this responsibility.

Street Sweeping (CM6) Related Goals: 4, 6, 8, 9, 10 Related Indicators: 11, 15, 16, 19, 20			
What	Who	Where	When
Evaluate Existing Street Sweeping Programs Implement Enhanced Street Sweeping Practices	All Municipalities	Streets and Parking Lots in Commercial and Dense Residential Areas	Within next 5 years

Street and parking lot cleaning performed on a regular basis in urban and dense residential areas can be an effective measure for minimizing stormwater pollutant, sediment, and floatables loading to receiving waters.

Street sweeping programs had largely fallen out of favor as a pollutant removal practice following the 1983 NURP report. Recent improvements in street sweeper technology, however, have enhanced the ability of modern machines to pick up the fine grained sediment particles that carry a substantial portion of the storm water pollutant load, and have led to a recent reevaluation of their effectiveness. New studies show that conventional mechanical broom and vacuum-assisted wet sweepers reduce non-point pollution by 5 to 30 percent and nutrient content by 0 to 15 percent. However, newer dry vacuum sweepers can reduce non-point pollution by 35 to 80 percent and nutrients by 15 to 40 percent for those areas that can be swept (Runoff Report, 1998). A benefit of high-efficiency street sweeping is that by capturing pollutants before they are made soluble by rainwater, the need for structural storm water control measures might be reduced. Structural controls often require costly added measures, such as adding filters to remove some of these pollutants and requiring regular maintenance to change-out filters. Street sweepers that can show a significant level of sediment removal efficiency may prove to be more cost-effective than certain structural controls, especially in more urbanized areas with greater areas of pavement.

Computer modeling of pollutant removal in the Pacific Northwest suggests that the optimum sweeping frequency appears to be once every week or two (CWP, 1999). More frequent sweeping operations yielded only a small increment in additional removal (Bannerman, 1999; Claytor, 1999).

The following measures should be implemented toward achieving non-point source reductions in wet weather pollutant loads:

- Evaluate existing street and parking lot sweeping practices by municipalities with urban and dense residential areas contributing stormwater runoff to the watershed.
- Implement enhanced street and parking lot sweeping programs in urban and dense residential areas, prioritizing those not served by existing stormwater BMPs designed to reduce stormwater pollutant, sediment, or floatables loading to the receiving waters.

Responsible Landscaping on Public lands (CM7) Related Goals: 1, 6, 7, 8, 9, 10 Related Indicators: 1, 10, 11, 12, 13, 16, 19			
What	Who	Where	When
Incorporate integrated pest management (IPM) to reduce chemical use on public lands. Prevent clippings and cuttings from being transported by stormwater, and dispose of them through composting if possible.	Fairmount Park, municipalities PennDOT for vegetation along state roads	Parks, golf courses, school and institutional grounds, roadside vegetation	Short-term (within 5 years)

Common pesticides such as diazinon and chlorpyrifos (CWP, 1999 and Schueler, 1995) can be harmful to aquatic life even at very low levels. Proper use of these chemicals can be encouraged through public relations campaigns and demonstrated on public lands. Clippings and cuttings carried into the stormwater system and receiving streams can degrade water quality in a variety ways. A related problem exists with the illegal dumping of clippings and cuttings in or near drainage facilities. Recommended controls include:

- Consider an integrated pest management (IPM) program that encourages the use of alternatives to chemical pesticides. An IPM program incorporates preventative practices in combination with non-chemical and chemical pest controls to minimize the use of pesticides and promote natural control of pest species. In those instances when pesticides are required, programs encourage the use of less toxic products such as insecticidal soaps. The development of higher tolerance levels for certain weed species is a central concept of IPM programs for reducing herbicide use. This approach should be balanced with the invasive species control methods discussed under Target B.

- Collect clippings and cuttings on slopes and the bottom of stormwater control facilities and near stormwater inlets. Avoid mowing when significant rain events are predicted. Dispose of material through composting when possible.

Responsible Bridge and Roadway Maintenance (CM9) Related Goals: 1, 7, 9, 10 Related Indicators: 1, 19			
What	Who	Where	When
Incorporate BMPs into regular maintenance and repairs: Road and bridge resurfacing practices Deicing chemicals and practices Existing bridge drains	Bridge and roadway owners (municipalities and PennDOT)	Roadways and bridges (Figure 7-16)	Short-term (within 5 years)

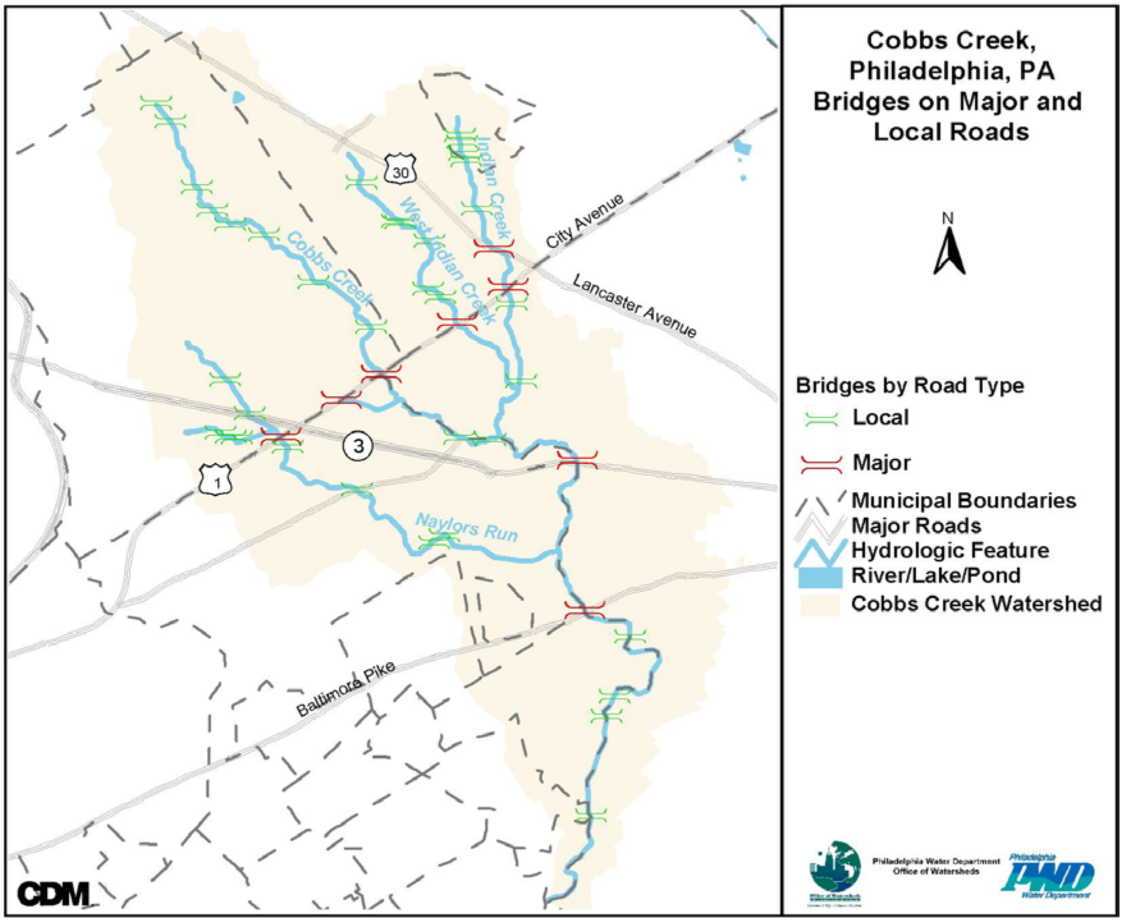

Figure 7-16 Major Roads and Bridges

Sediment and pollutants are generated during daily roadway and bridge use and scheduled repair operations, and these pollutants can impact local water quality by contributing heavy metals, hydrocarbons, sediment and debris to stormwater runoff. The use of road salt is a public safety as well as a water quality issue. Aside from contaminating surface and groundwater, high levels of sodium chloride from road salt can kill roadside vegetation, impair aquatic ecosystems, and corrode infrastructure such as bridges, roads, and stormwater management devices.

Recommended techniques are as follows:

- Consider alterations to road and bridge resurfacing practices near the creeks (Figure 7-16). Perform paving operations only under dry conditions. Cover storm drain inlets and manholes during paving operations, use erosion and sediment control measures, and use pollution prevention materials such as drip pans and absorbent material for all paving machines to limit leaks and spills of paving materials and fluids. Finally, consider employing porous asphalt for shoulder areas to reduce runoff.
- Consider alterations to the way deicing materials are used and applied as summarized in Table 7-17.

Table 7-17 Watershed Protection Techniques for Snow and Snowmelt Conditions

Use of De-icing Compounds

- Consider alternative de-icing compounds such as $CaCl_2$ and calcium magnesium acetate (CMA).
- Designate salt-free areas on roads adjacent to key streams, wetlands, and resource areas.
- Reduce use of de-icing compounds through better driver training, equipment calibration, and careful application.
- Sweep accumulated salt and grit from roads as soon as practical after surface clears.

Storage of De-icing Compounds

- Store compounds on sheltered, impervious pads.
- Locate at least 100 feet away from streams and floodplains.
- Direct internal flow to collection system and route external flow around shelters.

Dump Snow in Pervious Areas Where It Can Infiltrate

- Stockpile snow in flat areas at least 100 feet from stream or floodplain.
- Plant stockpile areas with salt-tolerant ground cover species.
- Remove sediments and debris from dump areas each spring.
- Choose areas with some soil-filtering capacity.

Blow Snow from Curbside to Pervious Areas

Operate Stormwater Ponds on a Seasonal Mode

Use Level Spreaders and Berms to Spread Melt water Over Vegetated Areas

Intensive Street Cleaning in Early Spring can Help Remove Particulates on Road Surfaces

- Consider alterations to existing bridge drains. Scupper drains can cause direct discharges to surface waters and have been found to carry relatively high concentrations of pollutants (CDM, 1993). At a minimum, routinely clean existing drains to avoid sediment and debris buildup, and consider retrofitting with catch basins or redirecting runoff to vegetated areas to provide treatment.

7.3.4 Stormwater Management

Source Control Measures

Reducing Effective Impervious Cover through Better Site Design (CS1)
Related Goals: 1, 7, 9, 10
Related Indicators: 1, 16, 19, 20

What	Who	Where	When
Reduce effective impervious cover by approximately 1% through: Downspout disconnection Pervious landscaping Sidewalk and driveway width reduction Vacant lands management	All municipalities require and/or encourage these measures using regulatory and/or public education options discussed elsewhere in this section.	All areas	Long term: 15+ years

Small changes in site design can lead to a gradual reduction in effective impervious cover that becomes significant over time. When applied consistently, the measures above can result in a 5-10% reduction in areas that are redeveloped. Assuming 10% of the watershed might be redeveloped over the planning horizon, a reduction in effective impervious area of 1% is a reasonable goal. Programs to require or encourage these practices are discussed under the regulatory approaches and public education options.

Downspout disconnection
In highly urbanized areas of the watershed, it is not always possible to direct runoff to pervious areas, and an informal inspection of lower density areas indicates that many properties are already disconnected. However, a further reduction in directly connected roof leaders from just 10% of residences will result in an effective impervious cover reduction of about 5%.

Pervious Landscaping
When repaving parking lots and loading areas, conversion of 10% of the area in half of parking lots to pervious landscaping (a measure required by municipalities including Portland, OR) will decrease watershed effective impervious cover by approximately 0.5%.

Sidewalk and Driveway Width Reduction
Reducing sidewalk and driveway widths by one foot will result in a watershed

effective impervious cover reduction of approximately 1%.

Vacant Lands Management

Vacant and abandoned lands in the City of Philadelphia account for approximately 2% of watershed effective impervious area. These sites are gradually being acquired and demolished by the City. Proper grading of these sites to encourage infiltration, or addition of small, inexpensive BMPs if needed, can eliminate runoff from these sites during all but the largest storms. Similar techniques can be followed for vacant and abandoned lands in the other counties.

Increasing Urban Tree Canopy (CS2) Related Goals: 1, 7, 8, 9, 10 Related Indicators: 1, 4, 13, 16, 17, 18, 19, 20			
What	Who	Where	When
Increase tree canopy in the watershed from 26% to 31%.	Municipalities (through ordinances, education, and incentive programs affecting land owners)	Private property Parking lots Streets Parks (riparian corridors under Target B)	Medium-term (5-15 years)

Tree planting and urban reforestation programs provide hydrologic benefits in addition to quality of life improvements. Leaf surfaces intercept some rainfall that might otherwise fall on impervious surfaces. The rainfall then either evaporates or is conveyed more slowly to the ground along plant stems and trunks. American Forests has assessed tree canopy in the Cobbs watershed at 26% (report "Urban Ecosystem Analysis, Delaware Valley Region" available at www.americanforests.org). American Forests recommends the following levels of tree canopy coverage for urban watersheds:

- 40% overall
- 50% in suburban residential zones
- 25% in urban residential zones
- 15% in central business districts

A goal of increasing tree canopy by 5% of the watershed over the medium term was selected as a feasible implementation level. Several regulatory and incentive-based strategies to achieve these goals include:

- Requirements to protect existing trees on private property, or creation of "tree banks" to offset loss (see regulatory/incentive approaches).
- Tree credits for redevelopers as part of impervious cover requirements or incentives (see regulatory/incentive approaches). The city of Portland, OR has given developers an impervious cover credit equal to 25% of tree canopy over impervious area.
- Parking lot landscaping or shade requirements (see regulatory/incentive approaches).
- Reforestation in parks and along the stream corridor (Target B).
- Increases in the number of trees along public streets and on vacant lots. The City of Philadelphia is taking this approach as part of its Green City Strategy.

Tree canopy over an additional 5% of impervious cover will result in an effective impervious cover reduction of approximately 1.5% over the watershed.

Municipalities with tree related ordinances are shown in Table 7-18.

Forming a tree commission is one way of implementing an urban forestry program in Pennsylvania. The powers and responsibilities of a tree commission are based on state statute and are assumed by local government. By forming and empowering a tree commission, a community can empower and motivate volunteers to run an effective urban forestry program. Tree commissions are either advisory or administrative and may have various responsibilities.

- Advise community leaders and staff on administering the community forest
- Stimulate and organize tree planting and maintenance
- Develop and implement urban forest inventories, management plans, and ordinances
- Lessen liability by arranging to remove hazardous trees and repair damage caused by trees

In Pennsylvania, a tree commission created by municipal ordinance as a decision-making body has exclusive control over a community's shade trees. No tree can be planted or removed within the public right-of-way except under the auspices of the tree commission. This includes public trees that may be planted or removed in conjunction with subdivisions or approved development plans. Tree commissions can be given additional power within a municipality by a council, including:

- Control over all public trees such as trees within community parks
- Review and approval of landscaping proposed in development plans

The formation and empowerment of a tree commission can be a crucial element in developing broad-based support for community trees and ensuring long-term success and continuance of a community forestry program. (For more information, contact the Extension Urban Forestry Program, School of Forest Resources. The Pennsylvania State University, 108 Ferguson, University Park, PA 16802; (814) 863-7941.)

Porous Pavement and Subsurface Storage (CS3) Related Goals: 1, 6, 7, 8, 9, 10 Related Indicators: 1, 10, 11, 16, 19, 20			
What	Who	Where	When
Install porous pavement and subsurface storage in 10-50% of parking lots; coverage to be chosen by municipality to meet a share of watershed-wide reduction targets. Route runoff from nearby impervious cover to storage when possible.	Public and private parking lot owners.	See Figure 7-17.	Long-term: 15+ years

As discussed in Section 5, subsurface storage under parking lots is the best way to create storage and promote infiltration in the highly urbanized environment. Porous pavement is an effective way of directing parking lot runoff to storage, but more conventional inlets or grates are also possibilities. The depth of storage is important. Whenever possible, runoff from nearby impervious areas should be routed into the storage under nearby parking lots. When this is not possible, only a few inches of gravel is needed to store a chosen design storm. Storage designs always include an overflow mechanism for very large storms.

The total parking lot area in the Cobbs watershed is estimated at 120 acres in the combined-sewered portion and 240 acres in the separate-sewered portion (Figure 7-17). Philadelphia has approximately 31% of parking lot area in the watershed. Other municipalities with large parking lot areas are Lower Merion (26%), Upper Darby (23%), and Haverford (12%). Other municipalities have smaller percentages as listed in Figure 7-18.

Because this BMP is believed to be the most important, an ambitious target of retrofitting 10-50% of parking lots over the long term is proposed. Begin with demonstration projects on public land. Over the long term, convert 10%-50% of parking lots watershed-wide to porous pavement with subsurface gravel storage.

The Partnership may choose among a variety of approaches to implementing porous pavement and other structural BMPs. Regulatory and incentive-based approaches were discussed in the low-impact redevelopment section. Distribution of structural BMPs may also be incorporated in a pollution trading program.

- Install demonstration projects in public parking lots.
- Require all parking lots to be retrofit with porous pavement (or other drainage mechanisms) and subsurface storage when they are redone. Private land owners

cannot be expected to bear the entire cost of this approach; municipalities should fund the additional cost of these changes either directly or through tax incentives.

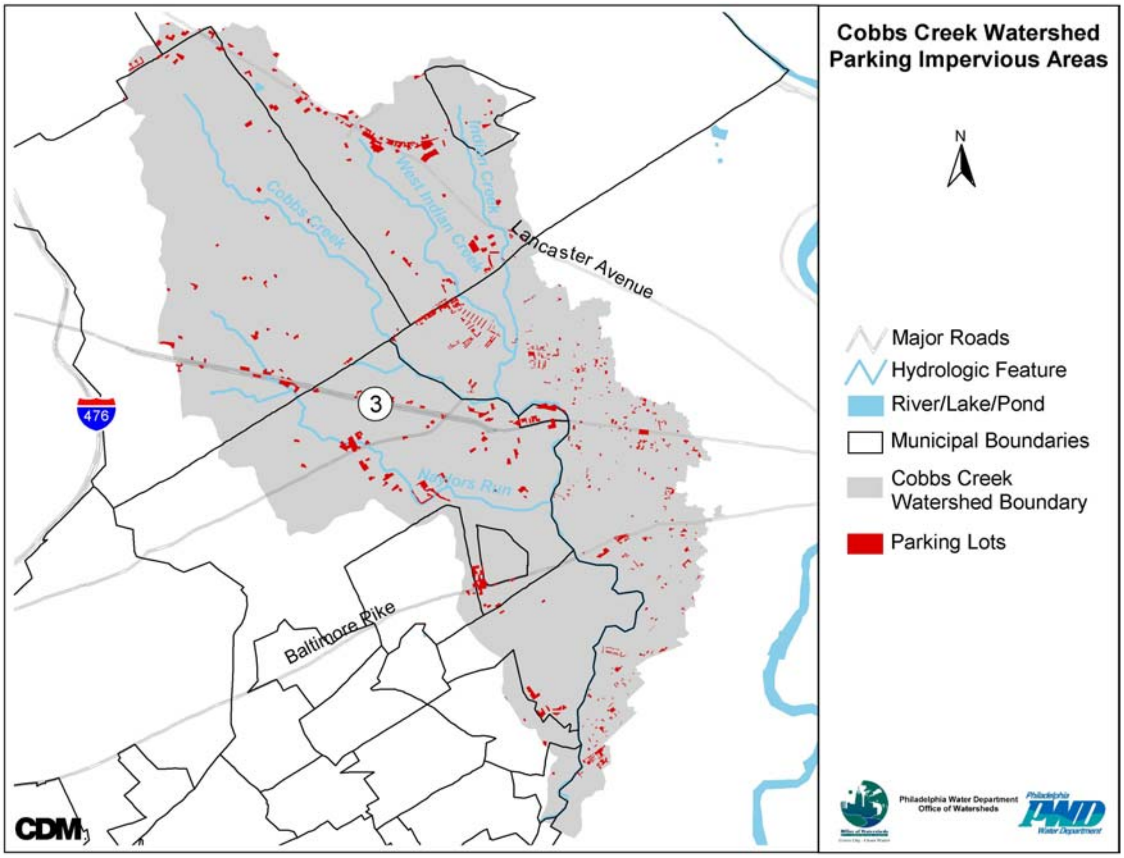

Figure 7-17 Parking Areas in Cobbs Creek Watershed

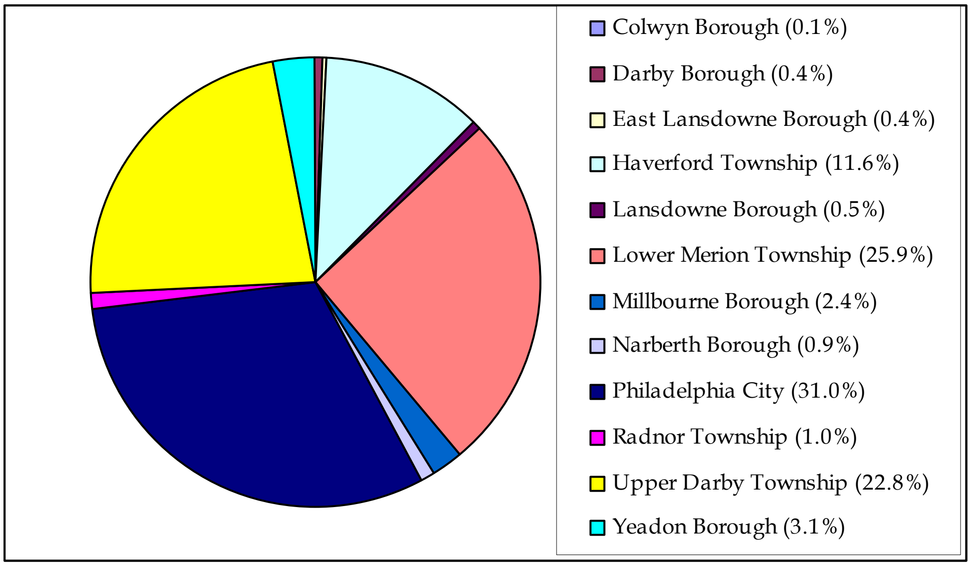

Figure 7-18 Percent of Total Parking Area by Municipality

Green Rooftops (CS4)
Related Goals: 1, 7, 8, 9, 10
Related Indicators: 1, 16, 18, 19, 20

What	Who	Where	When
Green rooftop demonstrations Targeted public information campaign on advantages of green roofs. Feasibility study and green roof implementation plan.	PWD	Appropriate public buildings chosen by PWD	Medium term: 5-15 years

The analyses in Sections 5 and 6 indicate that green rooftops, while highly effective at detaining and evaporating stormwater, are not currently a cost-effective option for the Cobbs. However, there is a potential for them to become more cost-effective in the future. As more successful demonstration projects are implemented in the United States, the materials and construction techniques will become more common and the economies of scale will improve. To facilitate this long-term change locally, this plan recommends that Philadelphia take the lead and implement one or more projects on public buildings in the City. Along with this project, we recommend a feasibility study of the potential for a larger-scale green roof program throughout the watershed. The feasibility study will form the basis for future recommendations when this plan is revised. In addition, we recommend a public relations campaign to change the perceptions of citizens, public officials, and contractors.

Capturing Roof Runoff in Rain Barrels or Cisterns (CS5)
Related Goals: 1, 7, 8, 9
Related Indicators: 1, 16, 18, 19

What	Who	Where	When
Install rain barrels on 5-25% of homes; coverage to be chosen by municipality to meet a share of watershed-wide reduction targets.	Homeowners through municipal incentive and education programs	Homes where dry wells are not feasible	Medium term: 5-15 years

As discussed in Section 5, rain barrels can be an effective stormwater management tool if they are properly designed and maintained. For detention of residential roof runoff, dry wells are the preferred technique because they have a larger capacity, require no maintenance, and allow more infiltration. Rain barrels are recommended as a secondary technique in areas where dry wells are infeasible. Proper design, including an appropriate slow release, is the responsibility of the municipality or nonprofit group leading the rain barrel program. Proper maintenance is accomplished through an intensive public education campaign and series of workshops. An ambitious target is to install rain barrels on 5-25% of homes throughout the watershed in the medium term. Adding barrels to 5% of homes will provide an estimated stormwater runoff reduction of 0.5%, a CSO reduction of 2%, and a pollutant (Total Suspended Solids) reduction of 2%.

Onsite and Regional Facilities

Maintain/Retrofit Existing Stormwater Structures (CS6)
Related Goals: 1, 4, 6, 7, 9, 10
Related Indicators: 4, 11, 15, 19

What	Who	Where	When
Inventory structures Assess potential for increased infiltration	Municipalities	Outside Philadelphia	Short term (within 5 years)

An inventory of existing detention and retention basins in Philadelphia indicates that there are none in the Cobbs portion. Other municipalities are asked to inventory and inspect existing stormwater control structures. Although this is not an explicit requirement of the Act 167 program, it is a reasonable task to include within the Act 167 framework. Older dry and wet detention basins may have been designed to reduce flood peaks but not to facilitate infiltration; this approach helps prevent property damage but may actually increase stream erosion. In some cases, it may be possible to retrofit these older basins to allow infiltration. Specific guidance on retention times and design recommendations will be included in the Act 167 plan.

Retrofitting Existing Sewer Inlets with Dry Wells (CS8) Related Goals: 4, 6, 9 Related Indicators: 11, 15, 19			
What	Who	Where	When
Retrofit 10-40% of existing stormwater catch basins in the combined sewered area to provide storage and allow infiltration	PWD	10-40% of existing inlets in combined-sewered areas	Long-term: 15+ years

As discussed in Section 5, retrofitting existing sewer inlets with dry wells is an expensive but effective measure in combined-sewered areas. Each inlet provides small amounts of storage and detention; distributed over a significant area, these measures reduce the number and duration of overflows.

There are approximately 2000 inlets in the combined-sewered portions of the Cobbs Creek watershed. It is proposed that at least 10% of these be retrofitted with dry wells. This measure will reduce CSO volume by approximately 0.4% and pollutant loads by approximately 0.4%.

During the first permit cycle this plan is in effect, inlets that are being repaired or replaced can be retrofitted at the same time. If, after the first 5 years, the program is not on track to affect the targeted number of inlets in 15 years, existing inlets in good condition may be retrofitted.

Residential Dry Wells, Seepage Trenches, and Water Gardens (CS9)
Related Goals: 1, 4, 6, 7, 8, 9, 10
Related Indicators: 1, 11, 15, 16, 17, 19

What	Who	Where	When
Install dry wells in 10-40% of residential yards; coverage to be chosen by municipality to meet a share of watershed-wide reduction targets. Install water gardens on school grounds	Municipalities School boards	Dry wells throughout watershed Water gardens in school yards with enough space	Long term: 15+ years

Routing residential roof runoff to dry wells is recommended as a priority control for the Cobbs watershed. Dry wells are cost-effective, can potentially affect a large portion of impervious cover, and require virtually no maintenance. They are clearly applicable in the lower-density residential areas but can be installed in some higher density areas; only a small lawn area is necessary. A properly sited and designed dry well will not cause basement flooding. Where soil conditions are insufficient to infiltrate all roof runoff, excess flows can be routed to a combined or sanitary sewer. Because dry wells are a priority control, they are recommended for implementation in the yards of 10%-40% of all homes in the watershed. At the 10% level, this measure could reduce CSO by approximately 3%, stormwater runoff by 0.3%, and pollutant loads (represented by TSS) by 5%.

Water gardens are recommended for implementation on school grounds, where they can both promote infiltration and educate students about stormwater management.

Bioretention Basins and Porous Media Filtration (CS12) Related Goals: 1, 4, 5, 7, 9, 10 Related Indicators: 1, 7, 8, 9, 15, 19, 20			
What	Who	Where	When
Install bioretention and/or sand filters in 10-50% of parking lots; coverage to be chosen by municipality to meet a share of watershed-wide reduction targets.	Public and private parking lot owners.	Everywhere in watershed	Long-term: 15+ Focus on redevelopment

The screening and modeling analyses in Section 5 targeted parking lot runoff for widespread implementation of BMPs. The preferred approach for parking lots is to route runoff to subsurface gravel storage through porous pavement, inlets, or grates. However, there will be cases where that approach is infeasible. The second preferred alternative is to direct parking lot runoff to a bioretention basin and/or a porous media filter. These systems infiltrate smaller storms completely, detain larger storms, and provide effective water quality treatment in separate sewered areas. 10-50% of parking lots are targeted for retrofit with bioretention. At the 10% level, this measure will reduce CSO by an estimated 1.3%, stormwater runoff by 0.1%, and pollutant loads by 2%. Over the long term, it is the goal to retrofit 50% of parking lots with either subsurface storage or bioretention. However, private land owners should not be expected to bear the entire cost of this approach; municipalities should fund the additional cost of these changes either directly or through tax incentives.

Treatment Wetlands: Onsite and Regional (CS13) Related Goals: 1, 5, 6, 7, 9, 10 Related Indicators: 1, 10, 11, 13, 19			
What	Who	Where	When
create and enhance wetlands for treatment	Municipalities	See Figure 7-11 in Target B.	Medium term: 5-15 years

Wetland creation and enhancement has benefits in terms of habitat, water quality, and water quantity. These benefits and proposed sites are discussed extensively under Target B.

Section 8: Cost and Institutional Analysis

8.1 Estimated Cost of Implementation

Planning-level costs have been developed for many of the options being recommended. Because costs are highly dependent on site specific conditions as well as the extent to which implementation occurs, costs are only approximate. These costs are useful, however, in providing order of magnitude funding needs, and also, as a comparison to potential costs associated with more traditional approaches to CSO control such as large scale storage tanks designed to reach the 85% capture goal.

Planning level costs are provided for each of the options discussed under the three Targets. "N/A" means that costs are not applicable because they are relatively small, or the option would be implemented by existing municipal staff. "N/A" can also mean that a cost estimate could not be developed based on existing information.

The combination of structural BMPs and implementation percentages in this section are suggested as a feasible plan that will equal or exceed the 20% discharge reduction target. The exact combination of BMPs implemented in each area of the watershed will be determined by local municipalities or by a government or institutional body to be chosen at a later time.

Order-of-magnitude, planning-level cost estimates are shown in Tables 8-1 through 8-5 for the two components of the plan:

1. A total cost for all options other than real time control and structural stormwater management BMPs.

2. A cost range for real time control and structural stormwater management BMPs. The cost for these measures varies depending on the combination chosen.

8.2 Distribution of Costs Among Communities

8.2.1 Comparison of Philadelphia to other Watershed Communities

In addition to total estimated costs associated with the CCIWMP, it is useful to express the costs on an annual basis and in the context of acreage and number of households affected. Presenting costs this way allows comparison to existing wastewater infrastructure-related costs supported by users and taxpayers.

Table 8-6 compares projected costs on a per-acre basis and per-household basis in the City of Philadelphia and outside the City of Philadelphia. Philadelphia pays approximately 40% of the total annual cost (line 3) while representing approximately 25% of the watershed area. On a per-acre basis, costs within Philadelphia are approximately double costs outside the City. This difference occurs because of the greater proportion of impervious cover in Philadelphia compared to the remaining aggregated communities; for a given land area, there is more impervious cover and water-related infrastructure requiring management. It is important to note that population density, degree of urbanization, and income vary greatly among the communities outside Philadelphia. An illustrative distribution of costs among municipalities in the watershed is shown in section 8.2.2.

In addition to showing costs per unit area, it is useful to express costs on a per-household basis. Line 7 in Table 8-6 expresses cost per household, assuming only householdes inside the watershed boundaries would be required to pay. This comparison is made because improvements occur, and citizens benefit, primarily within the watershed boundaries. Expressed in this manner, the cost is greater for households outside Philadelphia (line 7, outside parentheses); because of greater population density within the urban watershed, there are more households to distribute the cost among inside the City.

Line 8 of Table 8-6 expresses the per-household cost inside the watershed boundary as a percentage of mean household income (line 8, outside parentheses). Although the per-household cost in Philadelphia is lower, it represents a greater fraction of household income for a median family because of the generally lower mean household income of Philadelphia households when compared with the outside municipalities.

While expressing costs in terms of households inside the watershed boundary allows direct comparison between communities, it is also useful to express costs on the basis of all households within the boundaries of municipalities that intersect the watershed. Currently, most funding and institutional mechanisms occur on a municipal basis. For example, a given township may use a percentage of all water and sewer bills paid to finance improvements related to the CCIWMP, including bills paid by households outside the Cobbs watershed boundary.

The numbers in parentheses on lines 7 through 9 of Table 8-6 present the costs in terms of all residents of municipalities intersecting the watershed. These costs are lowest in Philadelphia because it has the greatest number of households; all households paying sewer bills will pay approximately 0.03% of household income to support the CCIWMP, compared to over 0.1% for the remaining communities. Compared to the other municipalities, Philadelphia has many more households to spread the cost of the CCIWMP over, but ultimately it has many more watersheds that will require management activities. Over time and on a regional basis, watershed management costs are expected to approach 0.3% to 0.5% of MHI within affected communities.

The costs associated with the CCIWMP are generally incremental to existing maintenance and management activities associated with water-related infrastructure. Therefore, it is useful to add the CCIWMP cost to current wastewater charges paid by households to obtain an approximate measure of the total annual cost of watershed and water-related infrastructure management. These costs, shown in the final line of Table 8-6, range from approximately 0.6% to 1.6% of MHI regionally.

Table 8-6 Affordability Impact on Philadelphia and Suburban Communities

		Philadelphia	Suburban Communities *(Combined)*
1	Capital:	$3,770,000	$5,820,000
2	Operating:	$2,000,000	$3,000,000
3	Total Annual Cost Associated with WMP	$5,770,000	$8,820,000
4	Cost per acre in watershed	$1,642	$826
5	2000 Median Household Income	$30,746	$61,962
6	Estimated Annual Sewer User Charge*	$343	$197
7	WMP cost per household in watershed (in entire municipalities)	$146.04 ($9.77)	$185.71 ($87.52)
8	WMP cost as % of MHI in watershed (in entire municipalities)	0.47% (0.03%)	0.30% (0.14%)
9	Existing sewer cost + WMP cost in watershed (entire municipalities)	1.59% (1.15%)	0.62% (0.46%)

* The sewer user charge in Philadelphia includes a stormwater collection and treatment fee. Stormwater-related charges outside Philadelphia were not investigated.

8.2.2 Distribution of Costs Among Communities Outside Philadelphia

Tables 8-7 and 8-8 provide data to assist communities outside Philadelphia in placing projected CCIWMP costs in a local context. Table 8-7 expresses estimated costs for communities per acre and per household inside the watershed boundaries; Table 8-8 presents costs within the boundaries of all municipalities that intersect the watershed. For the purposes of this illustrative example of cost distribution, general, watershed-related costs for communities outside of Philadelphia are apportioned according to the percentage of the watershed area within each municipality's jurisdiction.

These cost tables are but one illustration of a possible cost distribution, and are provided to aid municipalities in deciding what funding and institutional mechanisms may be most appropriate given local conditions.

8.3 Institutional Analysis

The primary purpose of Section 7 of this plan is to provide recommendations and guidance to stakeholders - primarily state, county and other government agencies, municipalities, non-government organizations, land owners, and individuals - on ways to better manage water resources of Cobbs Creek. Everyone in the watershed communities can contribute in numerous ways to the protection of water resources. Roles of primary stakeholders and participants in the plan are briefly described below, followed by the recommendation that a watershed-wide management organization be created to facilitate implementation.

8.3.1 Description of Roles

Both government and non-government organizations will play a role in the successful implementation of the Cobbs Creek Watershed Management Plan. The primary roles are outlined below.

PADEP Role

Two agencies of the Commonwealth of Pennsylvania are directly and indirectly involved in watershed planning in Cobbs Creek: the Pennsylvania Department of Environmental Protection (PADEP) and PA Department of Conservation and Natural Resources (PADCNR). Achievement of Watershed Plan goals and objectives through local implementation will require continued support through funding and integration of the various existing state level stormwater management and runoff related programs. Particular attention should be paid to the following programs:

- Act 167 Plans
- Phase II Stormwater permits
- Act 537 / CMOM Plans
- Construction Stormwater Pollution Prevention
- Industrial Stormwater Pollution Prevention
- Watershed monitoring and performance reporting
- Exploring Watershed Permitting Opportunities

A critical PADEP role will be activities required under Section 303(d) of the Clean Water Act (PADEP, 2004) and the EPA's Water Quality Planning and Management Regulations (40 CFR Part 130). PADEP will need to actively administer the water quality standards process for portions of Cobbs Creek in the near future. TMDLs should be integrated with the findings of this watershed plan, and the approaches recommended by this plan should be designed to meet the TMDL requirements as they arise. Most of the regulatory approaches will need to define guidelines and limits, including TMDLs, in order to create possibilities for pollution trading. PADEP would also need to support the review and revision of water quality standards and a

Use Attainability Analysis.

PWD Role

PWD, as the primary author of this plan, plays a central role in its implementation, as well as in continued monitoring to chart improvements to water quality and to provide the scientific foundation for eventual TMDLs and for a Use Review and Attainability Analysis. PWD will take a lead role in implementing a variety of the recommendations, including;

- Stream Restoration
- Improvement of Fish Passage
- CSO Control
- Green Rooftop Demonstrations
- Stormwater BMP installation
- Organization of Stakeholder Participation
- Monitoring

Municipal Role

Municipalities can play a key role in the implementation of recommendations through the incorporation of water resources strategies into their land use planning and governance functions. Because of the authorities contained in the Pennsylvania Municipalities Planning Code (MPC), municipalities are one of the two main foci of implementation efforts (PWD being the other). Enabled by the MPC, municipalities are the focal point to address runoff from redeveloped and existing developed lands, to address problems associated with sanitary sewer collection systems, to enhance recreational opportunities, and to protect natural resources from the effects of land disturbance.

The most fundamental roles recommended for municipalities are to consider undertaking a comprehensive review of their existing land use regulations, policies and requirements to identify where they may be unnecessarily causing impacts to water resources; and to undertake the necessary actions needed to eliminate SSOs and sanitary sewer leaks.

The primary actions recommended for municipalities include: encouraging connection of roof leaders to storm sewers, reduction of expansive paved (impervious) parking lot requirements and replacement of asphalt with porous paving surfaces, repair and maintenance of leaking sanitary sewers, instituting a urban tree planting and maintenance program through establishment of a Tree Commission, and the elimination of SSOs.

County Role

The primary role of Delaware County (and to a lesser extent, Montgomery County) is to conduct the necessary comprehensive stormwater management studies to:

- Complete an Act 167 stormwater plan that is consistent with and furthers the achievement of the goals and objectives of this plan.
- Work with municipalities to update Act 537 plans

In addition, the Delaware County Conservation District has several important responsibilities within the watershed, including:

- Chapter 102 Erosion Control: Administers of the State's program to control sediment pollution from earth disturbance activities.
- National Pollution Discharge Elimination System (NPDES): Processes applications and seeks compliance towards stormwater discharge permits for Construction Activities.
- Chapter 105 Waterways and Wetlands General Permitting: Assists applicants with permit information. Processes general permits for work within wetlands and streams.

These are important elements in coordinating Act 167 planning requirements with Phase II of the NPDES Stormwater Program.

Non-Government Organization Role

The Darby-Cobbs Partnership is an important organization within the watershed, and the partnership should continue to work with PWD through the implementation phase. A Tree Commission could be created within the watershed to manage the urban forest program recommendations. In Pennsylvania, a tree commission is created by municipal ordinance as a decision-making body, and once empowered, can have exclusive control over a community’s shade trees.

Land Owners’ Role

Voluntary watershed stewardship by all land owners can contribute significantly toward the protection and restoration of the Cobbs Creek watershed while simultaneously minimizing the need for additional regulatory controls. Recommended roles for land owners include:

- Implementing “watershed stewardship” practices in their landscape and outdoor housekeeping practices.
- Actively working to eliminate litter, trash, and illegal dumping through participation in cleanup activities and through heightened awareness.
- Disconnecting roof leaders and installing rain barrels or dry wells

- Considering pervious solutions for driveways
- Joining and supporting the activities of the watershed partnership.

8.3.2 Possible Organizational Structures

The above outlined roles can be, and often are, carried out within the existing regulatory structure without any real coordination or formal agreement to join and work through a watershed organization. In the absence of a central watershed organization, PWD would commit to implementation of recommended projects and programs within the City, and each of the major municipalities would respond to various regulatory requirements individually. Collectively, these activities would improve water quality and habitat in the watershed; however, there would be significant overlap, duplication of effort, and potential gaps in the implementation. This is far from ideal.

As an alternative, it is preferred that a Cobbs Creek Watershed Organization be created to coordinate activities. A Watershed Organization could be set up with a County or the City of Philadelphia as the primary organization running the program, with other organizations participating through stakeholder meetings. In this case, PWD could assume this role.

Alternatively, a separate, non-profit organization with member organizations bound by formal agreement could be established (perhaps as an expansion of the current Cobbs Creek Partnership). The Organization could be allowed to start modestly, and to grow as the need arises. Thus, the ultimate structure of the Organization and its responsibilities would evolve over time, but participants in the Organization would work together by formally adopting this plan, and providing funds for the completion of the major recommendations. Potential sources of funding could include member assessments, grants, in-kind and cash matches from implementing organizations, and in-kind services from member organizations.

An example of just such an organization was formed for the Rouge River in Michigan. Using the Rouge River Assembly as a guide, the Cobbs Creek Watershed Organization could have some or all of the following characteristics.

- Membership could be open to PWD, all the municipalities, and the two counties in the watershed. All members would either have a permit to discharge storm water into the creek, or are responsible for CSO into the creek.
- Membership could be expanded to include PADEP and EPA in an advisory capacity.
- For the City of Philadelphia, municipalities and the two counties, voting shares and costs could be apportioned based upon land and population in watershed.
- A General Assembly of participants could be set up to meet twice per year to focus on priorities, budget, and assessments.

- An Executive Committee with a representative from each major participating body could be set up to meet 6 times per year to provide management oversight.

- Standing Committees (e.g. Finance, Technical, and Public Involvement) could be established to provide day to day guidance and advice, with members drawn from the member organizations.

- An Organization Committee could be established to consider long term changes for the permanent organization to best meet needs.

Some of the primary functions of the newly formed organization could include:

- Seeking implementation plan approval. This approval includes obtaining signatures from municipalities followed by a letter of support from PADEP. The Organization would encourage PADEP to adopt the Plan as a governing document for the watershed. The existing Watershed Restoration Action Strategy (WRAS) program could provide a framework for implementation of the Plan.

- Instituting a program to hire watershed plan implementation specialists, similar to existing county conservation district specialists. A county would have several specialists, and each specialist would be assigned to several municipalities. The specialists would represent their assigned communities in Organization meetings and other regional meetings. The watershed Organization would apply to the Growing Greener program as a source of funding for these specialists.

- Overseeing the continued implementation of basic, essential services required of all municipalities by stormwater permits (e.g., sewer system maintenance).

- Overseeing continued monitoring, sampling, data analysis, and reporting on both the water quality and biology of the system using the established indicators.

- Providing public participation and public education.

- Exploring innovative solutions to long-term operation and maintenance of stormwater management facilities.

- Requiring that projects applying for state funding (Growing Greener, DCNR) must be reviewed and shown to be consistent with the Plan. The specialists, directed by the Organization, would review all submitted projects and apply a rating scale for consistency with the plan.

- Encouraging the idea of applying for federal funding for regional projects (e.g., stream restoration, regional wetlands); however, most smaller-scale projects would be funded locally. Public funding for major infrastructure projects on private land could be explored.

Appendix A: Glossary of Terms

Adaptive management	Process of continually monitoring progress and adjusting the approach
Bankfull flow	The high flow stage of a fluvial system distinguished by the highest stage elevation a stream can reach before spilling over.
Baseflow	The portion of streamflow contributed by groundwater.
Benthic	Used to describe aquatic organisms living at the bottom of a body of water
Benthic macroinvertebrates	Are mainly aquatic insect larvae that live on the stream bottom. Since they are short-lived and relatively immobile, they reflect the chemical and physical characteristics of a stream and chronic sources of pollution.
BMP -	*Best Management Practice* – Also called a "management option," BMP is a technique, measure, or structural control that addresses one or more objectives (e.g., a detention basin that gets built, an ordinance that gets passed, an educational program that gets implemented).
BOD	Biochemical Oxygen Demand
CCD	County Conservation District(s)
CCHL	Cobbs Creek High-Level Combined Sewer System
CCLL	Cobbs Creek Low-Level Combined Sewer System
CCTV	Closed Circuit Television
Clean Streams Law	
CSO	Combined Sewer Overflow
CSS	Combined Sewer System

CWA	*Clean Water Act* – The Federal Amendment that authorizes the EPA to implement pollution control programs and to set water quality standards for all contaminants in surface waters. "The Act made it unlawful for any person to discharge any pollutant from a point source into navigable waters, unless a permit was obtained under its provisions. It also funded the construction of sewage treatment plants under the construction grants program and recognized the need for planning to address the critical problems posed by nonpoint source pollution." (EPA website)
CWA Section 104(b)(3) Program	Promotes the coordination and acceleration of research, investigations, experiments, training, demonstrations, surveys, and studies relating to the causes, effects, extent, prevention, reduction and elimination of pollution.
CWA Section 208 Wastewater Planning	Intended to encourage and facilitate the development and implementation of area-wide waste treatment management plans.
CWA Section 319(b) Non-point Source Management Program	Designed to address mine drainage, agricultural runoff, construction/urban runoff, hydrologic and habitat modifications, on-lot wastewater systems, and silviculture.
DCIA	Directly Connected Impervious Area
DCVA	Darby Creek Valley Association
DO	Dissolved Oxygen
DRBC	Delaware River Basin Commission
DVRPC	Delaware Valley Regional Planning Commission
DWO	*Dry-Weather Outlet* - connector pipe between a CSO regulator and interceptor sewer.

IDD&E	*Illicit Discharge, Detection, and Elimination* – one of the six minimum control measures required of permittees under the Phase II NPDES Stormwater Regulations. Program steps include developing maps of municipal separate storm sewer system outfalls and receiving waterbodies; prohibiting illicit discharges via PADEP-approved ordinance; implementing an IDD&E Program that includes a field screening program and procedures, and elimination of illicit discharges; conducting public awareness and reporting program. A similar program is being followed by PWD in the Long Term Control Plan (LTCP) for CSOs.
EACs	Environmental Action Committees
Floatables	Waterborne waste material and debris (e.g., plastics, polystyrene, paper) that float at or below the water surface.
ET	*Evapotranspiration* – the sum of water vapor evaporation from the earth's surface and transpiration from plants.
EVAMIX	A multi-criteria evaluation program to help choose objectively between various alternatives
GIS	Geographic Information Systems
Handheld DO	Dissolved oxygen readings taken with a handheld meter.
HIS	Habitat Suitability Indices
IPM	Integrated Pest Management
LID	Low-Impact Development (similar to "better site design" and "conservation site design")
LTCP	*Long-Term CSO Control Plan* – part of the EPA's CSO Control Policy for regulation of CSOs under NPDES that guides municipalities, state, and federal permitting agencies in reaching full compliance with the CWA.
Macro invertebrates	Macroinvertebrates are invertebrate animals that are can be seen without the aid of a microscope.
MPC	Municipalities Planning Code

MS4	Municipal Separate Storm Sewer System
NLREEP	Natural Lands and Restoration and Environmental Education Program (a unit of Philadelphia's Fairmount Park Commission)
NOAA	National Oceanic and Atmospheric Administration
Non-point source pollution	Pollution that comes from a diffuse source such as atmospheric deposition, stormwater runoff from pasture and crop land, and individual on-lot domestic sewage systems discharging through shallow groundwater.
Non-structural BMPs	These BMPs will require no operation or maintenance. Examples are use of open space and vegetated buffers in development design, minimization of soil disturbance and compaction during construction, and minimization of directly-connected impervious areas.
NPDES	National Pollutant Discharge Elimination System
NPDES Phase I	The stormwater management component of the NPDES program, instituted in 1990, which addressed the storm runoff sources most threatening to water quality. Under this phase, sites with larger communities, industrial activity, and construction sites are required to obtain permits for the storm water leaving the site.
NPDES Phase II	Additional stormwater management regulations enacted in 1999, applying to smaller communities and construction sites.
OLDS	On-Lot sewage Disposal Systems
O&M	Operations and Maintenance
OOW	PWD's Office of Watersheds
PA Act 167	Stormwater Management Act
PA Act 537	Sewage Facilities Planning Act
PADCNR	Pennsylvania Department of Conservation and Natural Resources
PADEP	Pennsylvania Department of Environmental Protection

PADEP Greenways Program	An Action Plan for Creating Connections is designed to provide a coordinated and strategic approach to creating connections through the establishment of greenways in the State.
PEC	Pennsylvania Environmental Council
PENNVEST	*Pennsylvania State Revolving Fund Program* - Provides funding for sewer, stormwater, and water projects throughout the Commonwealth.
Point source	Pollution discharged from a single point, defined in the CWA as "any discernable, confined and discrete conveyance, including but not limited to any pipe, ditch, channel, tunnel, conduit, well, discrete fissure, container, rolling stock, concentrated animal feeding operation, vessel, or other floating craft from which pollutants are or may be discharged." (pg20 Section 7)
POTW	Publicly Owned Treatment Works
PRD	Planned Residential Development
PWD	Philadelphia Water Department
QA/QC	Quality Assurance/Quality Control
RBP	Rapid Bioassessment Protocol (developed by the EPA) a standard method to assess aquatic health through fish and macroinvertebrate diversity (EPA Website).
RBP III	Section of the RBP dealing benthic macroinvertebrates.
RCP	PADCNR's Rivers Conservation Program
Riparian corridor	The area of land along the bank or shoreline of a body of water (EPA website).
Riparian woodlands	Woodlands that grow within the riparian corridor.
RTC	*Real Time Control* - a dynamic system of hydraulic controls to provide additional storage and reduce overflows from a combined sewer system
SEO	Sewage Enforcement Officers (designated by PADEP)

Solids	Waterborne waste material and debris consisting of sand, gravel, silts, clay, and organic matter.
Sonde	Shallow depth continuous water quality monitor manufactured by YSI Inc.
SSA	Separate-Sewered Area stormwater runoff
SSET	Sewer Scanner and Evaluation Technology
SSMS	Sanitary Sewer Management System
SSO	Sanitary Sewer Overflow
STORET	USEPA's water quality database (STOrage and RETrieval)
Stormwater Management Program Protocol ("Protocol")	PADEP guidance for implementing the requirements of the NPDES Phase II stormwater regulations
Structural BMPs	These BMPS will require proper operation and maintenance. Examples include wet ponds, grassed swales, infiltration basins and bioretention areas.
SWMM	Storm Water Management Model
TDR	Transfer of Development Rights
TIGER	Topologically Integrated Geographic Encoding and Referencing (U.S. Census database)
TMDL program	*Total Maximum Daily Load program* - EPA/PADEP program for limiting and allocating discharges of a pollutant within a watershed.
Transpiration	The process by which water vapor passes through the membrane or pores of plants to the atmosphere.
TSS	Total Suspended Solids
UA	Urban Areas
UAA	Use Attainability Analysis
USGS	United States Geological Survey

Watershed	The area of land draining to a stream, river, or water body. Watershed boundaries are established where any precipitation falling inside the boundary will drain to that particular watershed water body. Precipitation falling outside the boundary will drain to a different watershed. Watershed boundaries are typically formed on high elevation ridges. The water bodies formed from the watershed drainage are usually at the lowest elevation in the watershed. Watersheds can also be called drainage basins.
WMP	Watershed Management Plan
WQS	Water Quality Standards
WRAS	PADEP's *Watershed Restoration Action Strategy*

COBBS CREEK

A GATEWAY
TO MANY PLACES AND TO CLEANER WATER

Darby-Cobbs Watershed Partnership,
Fairmount Park Commission,
Pennsylvania Environmental Council, and
Philadelphia Water Department

February 2009

DRAFT

The Darby-Cobbs Watershed Partnership

works to connect residents, businesses, and government as neighbors and stewards of the watershed. The Partnership has been active in developing this vision for the watershed and guiding and supporting subsequent planning activities within the watershed.

The Darby-Cobbs Watershed Partnership members and other organizations that have participated in partnership efforts:

Brother Rousseau Academy
Clean Air Council
Cobbs Creek Community Environmental Education Center
Cobbs Creek Golf Course
Cobbs Creek Recreation Center
Cobbs Creek West Community Association
Colwyn Borough
Darby Borough
Darby Creek Valley Association
Delaware County Anglers
Delaware County Concerned Citizens for Environmental Change
Delaware County Conservation District
Delaware County Environmental Network
Delaware County Intermediate Unit
Delaware County Planning Department
Delaware Valley Earth Force
Delaware Valley Regional Planning Commission
Delco Anglers
Department of Conservation and Recreation’s Southeast Regional Office
East Lansdowne Borough
Fairmount Park Commission
Friends of Cobbs Creek - Southside
Friends Central Middle School
Greater Lansdowne Civic Association
Haddington-Cobbs Creek CDC
Haverford Township
Haverford Township Environmental Advisory Council
Lansdowne Borough
Lansdowne Borough Environmental Committee
Lansdowne Tree Advisory Board
Lower Merion Conservancy
Lower Merion Township
Lower Merion Township Environmental Advisory Council
Men of Cobbs Creek
Merion East Golf Course
Millbourne Borough
Montgomery County Conservation District
Morris Park Restoration Association
Narberth Borough
Natural Resource Conservation Service
Northeast Treatment Center
Office of Congressman Joe Sestak (PA-7)
Operation Weed and Seed of Upper Darby Township
Overbrook Farms Club
PA Cleanways
Partnership CDC
Pennsylvania Department of Environmental Protection
Pennsylvania Environmental Council
Pennsylvania Horticultural Society
Pennsylvania Resources Council
Philadelphia Water Department
Radnor Conservancy
Royal Gardens Association
Saint Joseph’s University
Senior Environmental Corps
SEPTA
Streetz to Creeks, LLC
University of Pennsylvania
Upper Darby School District
Upper Darby Township
Upper Darby Weed and Seed
Ursinus College
Vision Quest
The Wagner Free Institute of Science
Wissahickon Friends Central School
Yeadon Borough

Planning and Design:

WRT

CDM

Cobbs Creek has the potential to be one of the major connective fibers of our region,

providing miles of needed trail links, connecting neighborhoods and amenities, and conveying and cleaning our waters before they reach the Delaware River. This vision has long been held by many who manage, live and play along "the Cobbs" and who over the past decade have collaborated to build this vision.

In 1997, funding from the William Penn Foundation allowed **Fairmount Park** to create a restoration master plan for the Cobbs and to more actively coordinate volunteer and partner activities. During the same period, the **Philadelphia Water Department** initiated the **Darby-Cobbs Watershed Partnership**, a consortium of proactive environmental stakeholders focused on achieving ecological and quality-of-life improvements in the watershed. Since then, Fairmount Park, the Philadelphia Water Department, and their partners have worked to further connect public and private stakeholders to the watershed through planning actions, improvements, and extensive volunteer activities.

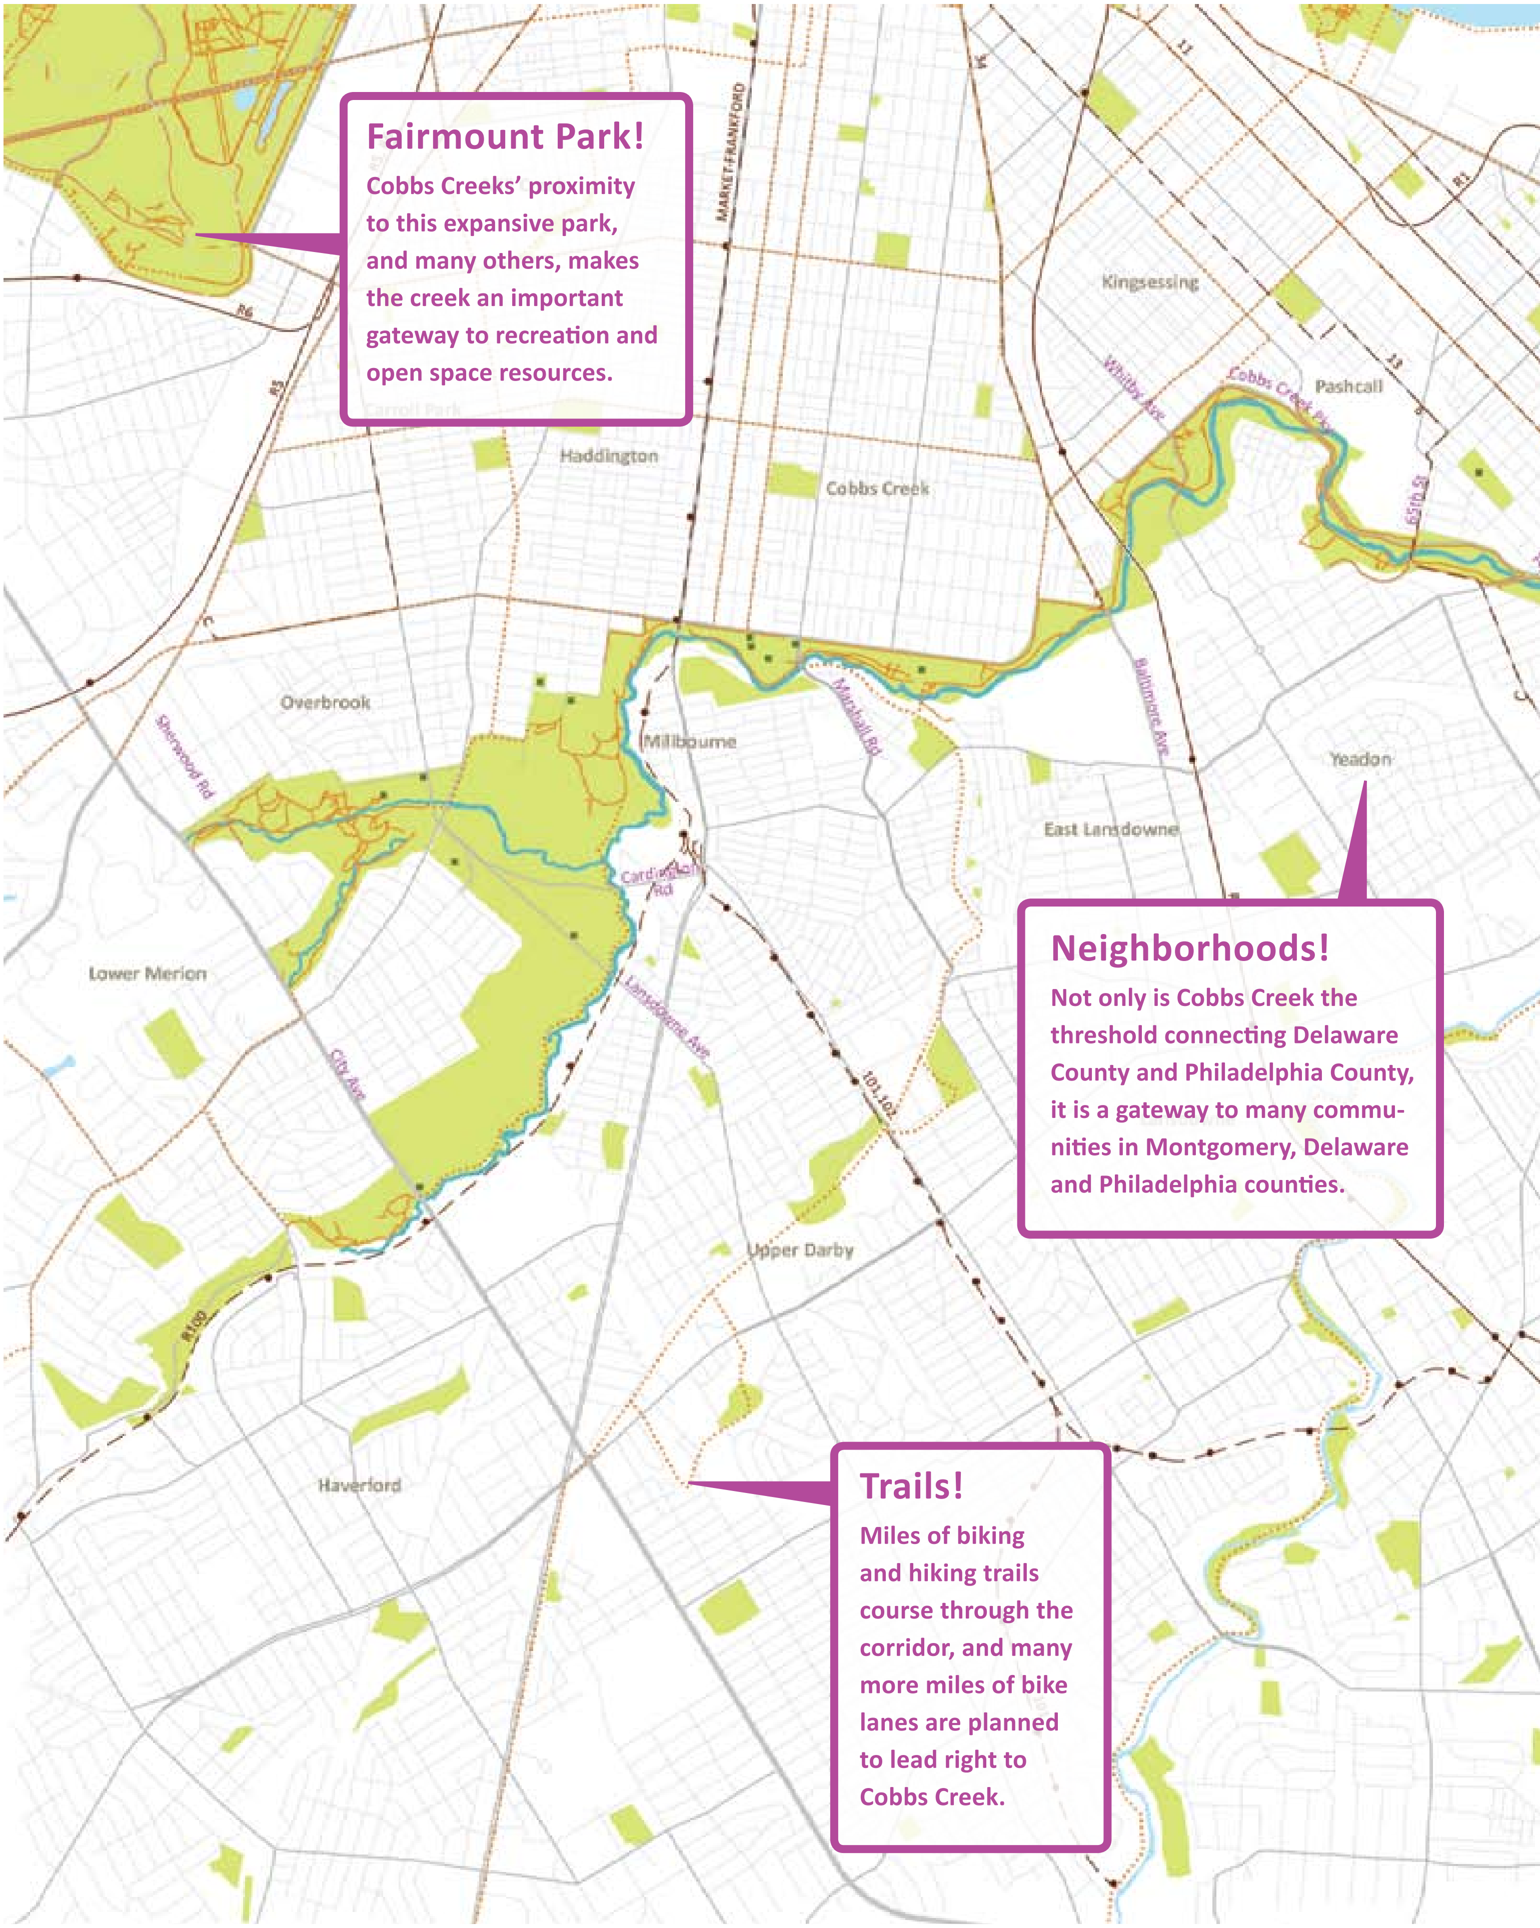
Over 20,000 volunteers are engaged in the management and improvement of the Darby-Cobbs watershed, for a total of almost 50,000 hours! Volunteerism continues to grow, as neighbors and groups come to realize the significance and potential of the creek and its lands. Public funders from the state and federal government such as DCNR and EPA continue to offer support. Knowledgeable partners such as the **Pennsylvania Environmental Council** continue to assist with watershed coordination. Now, ten years after the beginning of significant watershed planning, incipient ideas for Cobbs are being transformed by community participation into an enduring civic vision.

Much has been achieved by the watershed partners and volunteers over the past 10 years to make this vision real:

- A creek restoration and sewer relocation project near Marshall Road;
- 216 acres of restoration, including 1186 shrubs and 4017 trees planted (21 total acres); 9.5 acres of invasive plants removal; 2.4 acres of meadow creation; and 5 acres of stormwater management including wetland creation and stream restoration;
- Development of the Cobbs Creek Community Environmental Education Center; and
- Publicly vetted planning for upcoming trails and restoration projects.

The extensive parkland surrounding Cobbs Creek is public, presenting the opportunity for significant enhancement and public use, but also significant need for maintenance and event planning. The varied terrain and quality of the creek corridor keep people from experiencing or understanding the place in its entirety. It is understood as a composite of places. Its greatest potential can be realized only when it is appreciated as an integrated whole.

This vision statement brings together the many proposed improvements for Cobbs Creek by varied stakeholders, supporting the holistic approach Fairmount Park and the Philadelphia Water Department and their partners have long advocated.



Fairmount Park!

Cobbs Creeks' proximity to this expansive park, and many others, makes the creek an important gateway to recreation and open space resources.

Neighborhoods!

Not only is Cobbs Creek the threshold connecting Delaware County and Philadelphia County, it is a gateway to many communities in Montgomery, Delaware and Philadelphia counties.

Trails!

Miles of biking and hiking trails course through the corridor, and many more miles of bike lanes are planned to lead right to Cobbs Creek.

Recreation!

The Cobbs Creek corridor boasts a multitude of recreational facilities, including playgrounds, recreation centers, park and golf facilities, ice skating rinks, an environmental education center and trails!

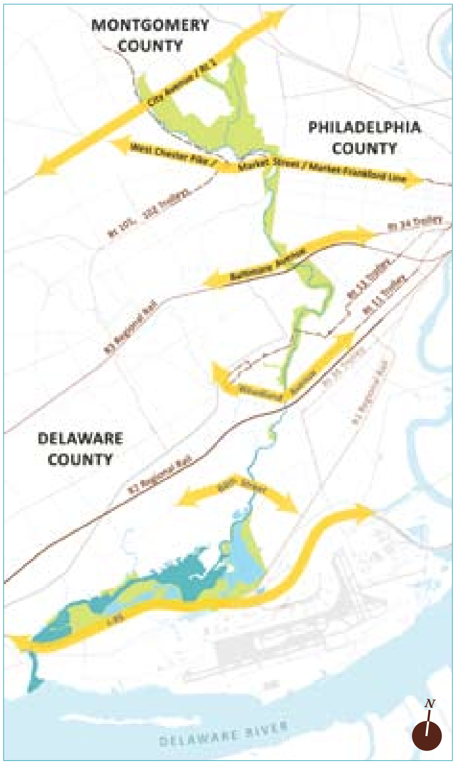
Transit!

Nine rail lines, including regional, subway, and trolley service, cross over or wind along the Cobbs Creek corridor.

Habitat!

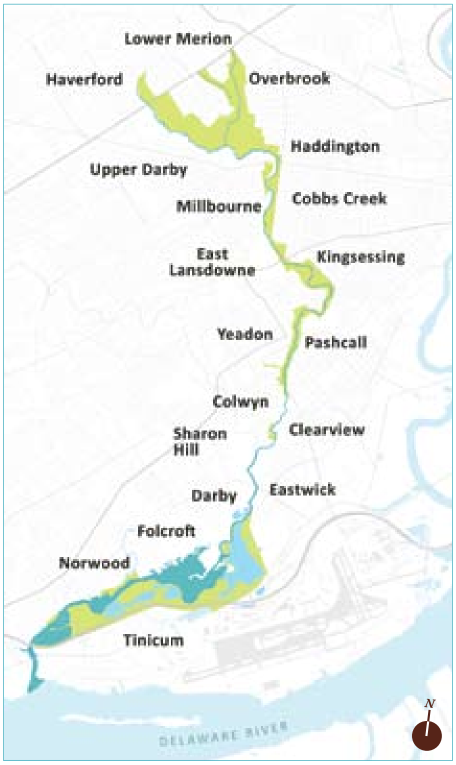
Cobbs Creek flows through the John Heinz National Wildlife Refuge at Tinicum, where marshes support diverse wildlife.

Cobbs Creek: A Gateway to Many Places and to Cleaner Water



A Gateway Across Regions

Cobbs Creek is the border between Philadelphia and Delaware Counties. The northern edge of Indian Creek at City Line Avenue defines the boundary between Montgomery and Philadelphia Counties. Although political borders can sometimes be abstract, Cobbs Creek plays a very real role as the gateway to communities on a regional scale.

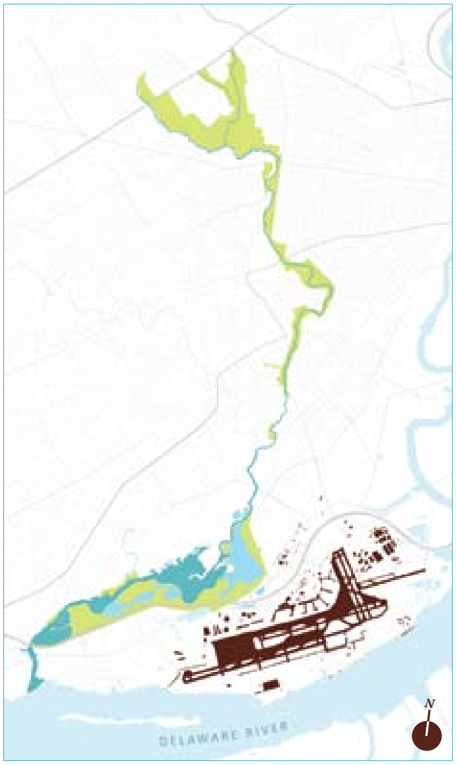


A Gateway to Communities

Cobbs Creek is the thread that unites diverse communities along and across its banks. Through roads, rail and the creek, these communities are stiched together.

A Gateway to Resources

Talk about proximity to cultural and natural resources: parks, including Fairmount Park and a plethora of neighborhood parks; the historic Blue Bell Tavern; the John Heinz National Wildlife Refuge at Tinicum; the Schuylkill and Delaware Rivers — among many others!

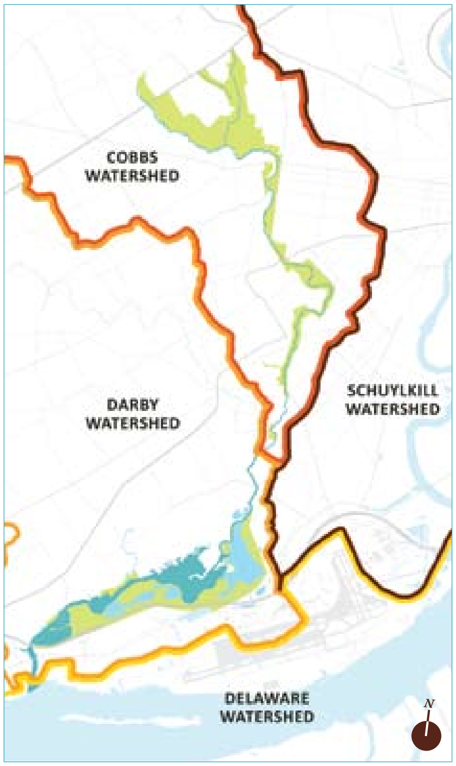


An Aerial Gateway

Viewed from an airplane, Cobbs Creek is a distinctive green ribbon, a connective environment that gracefully frames the approach to Philadelphia's International Airport. It provides a lush counterpoint to the nearby industrial lands of the Schuylkill and Delaware Rivers, enhancing the entry to our region.

A Gateway to Recreation

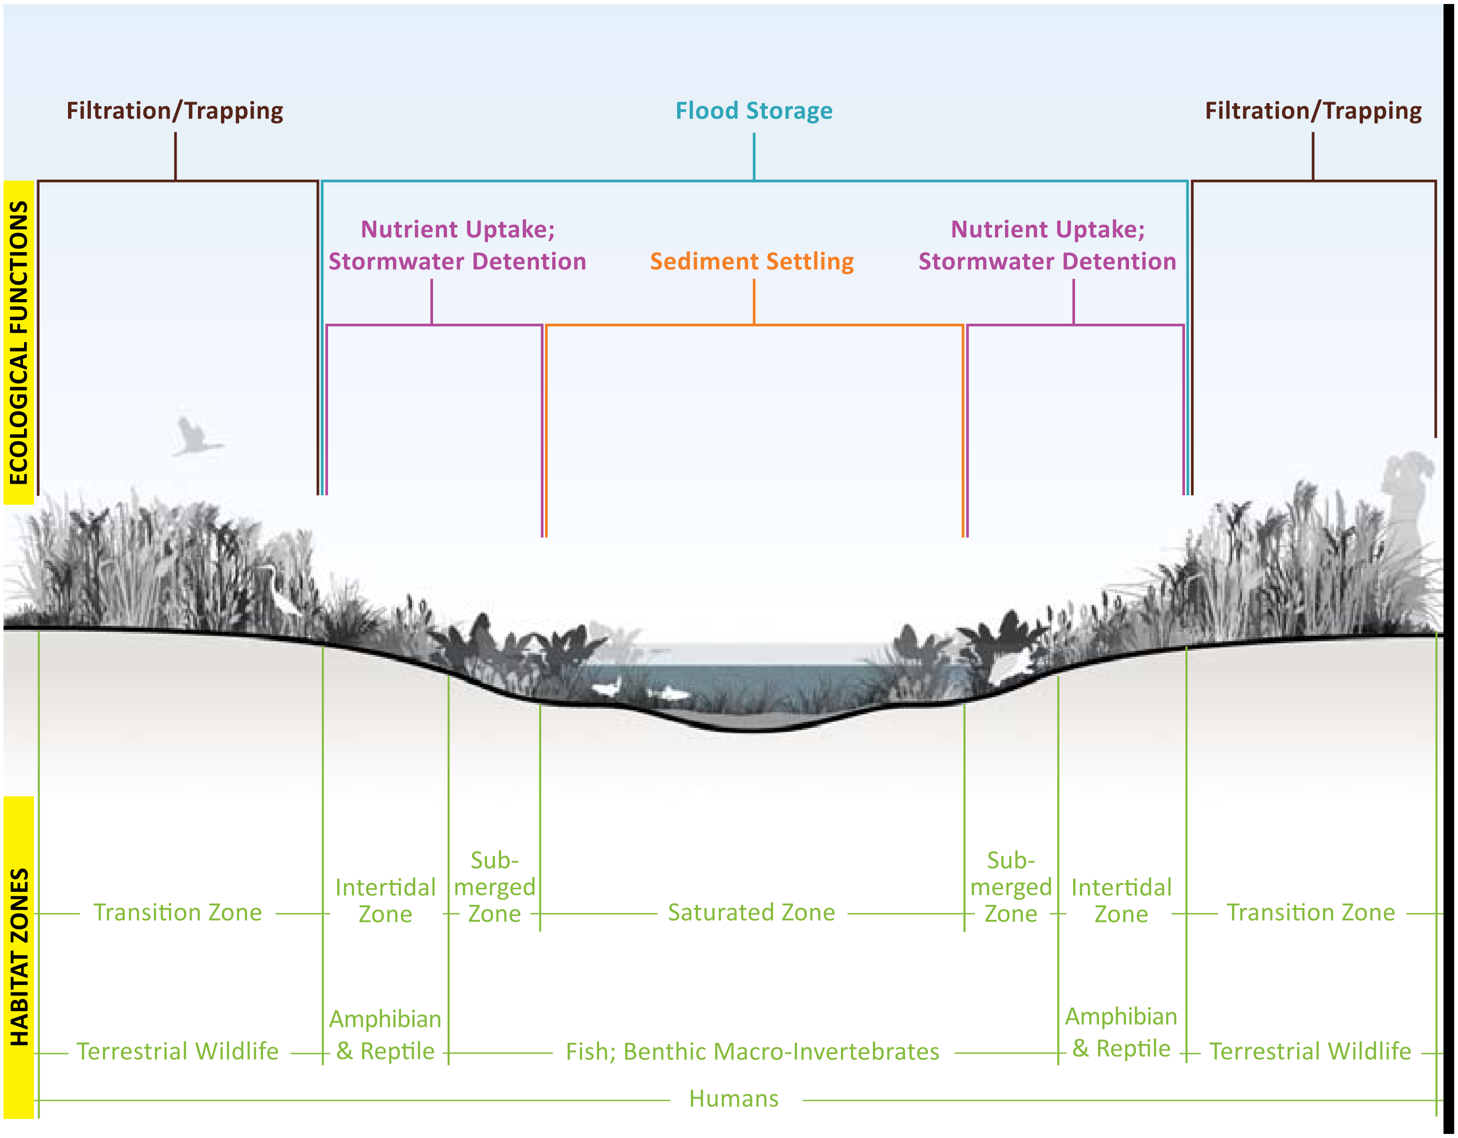
The Cobbs Creek corridor provides essential connective tissue to a network of great and varied recreational opportunities. It raises a series of resources, like golf courses, miles of trails, neighborhood parks, a stable, and acres of open water to kayak in, into a distinctive destination.

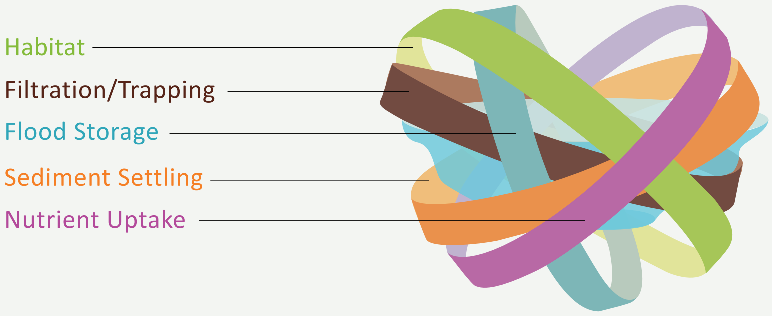


A Gateway to Cleaner Water

Like all of our few remaining creeks, the Cobbs Creek corridor offers us the opportunity to help steady the environmental imbalances caused by urban development. Restoring the natural environment along the stream corridor can improve water quality, habitats and environmental education opportunities.

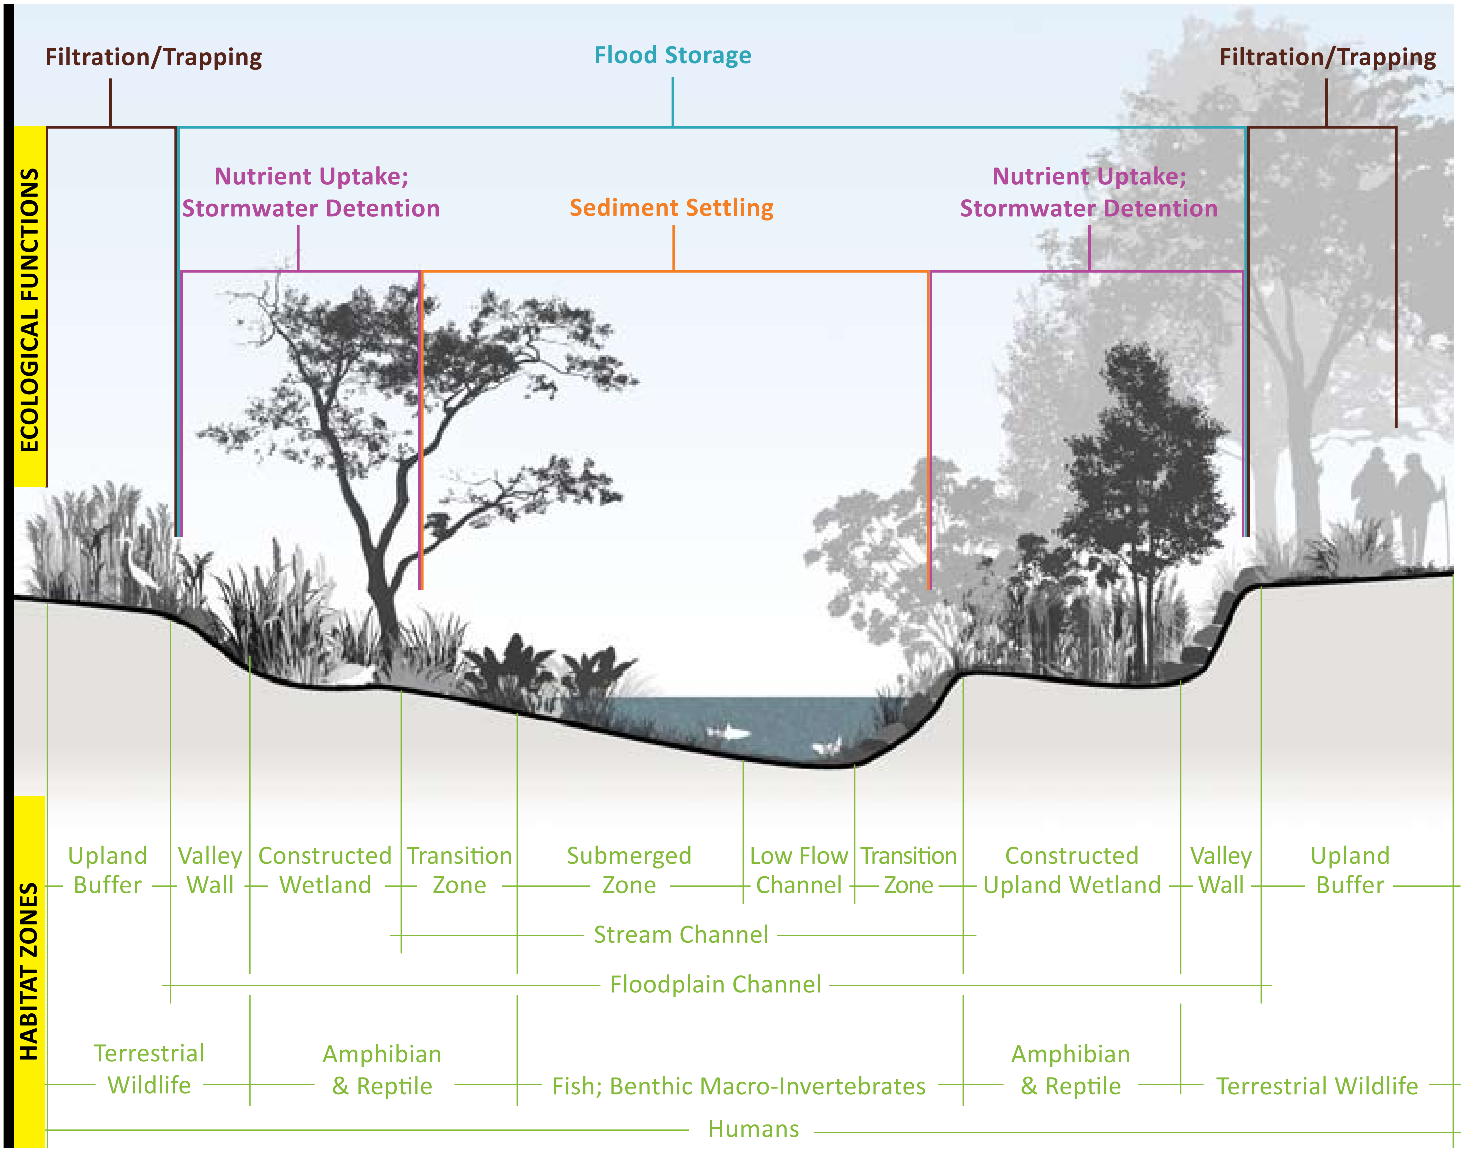
A typical WETLAND performs these kinds of ecological functions...





In a typical wetland, physical, chemical, and ecosystem constituents **cycle continuously** through the wetland.

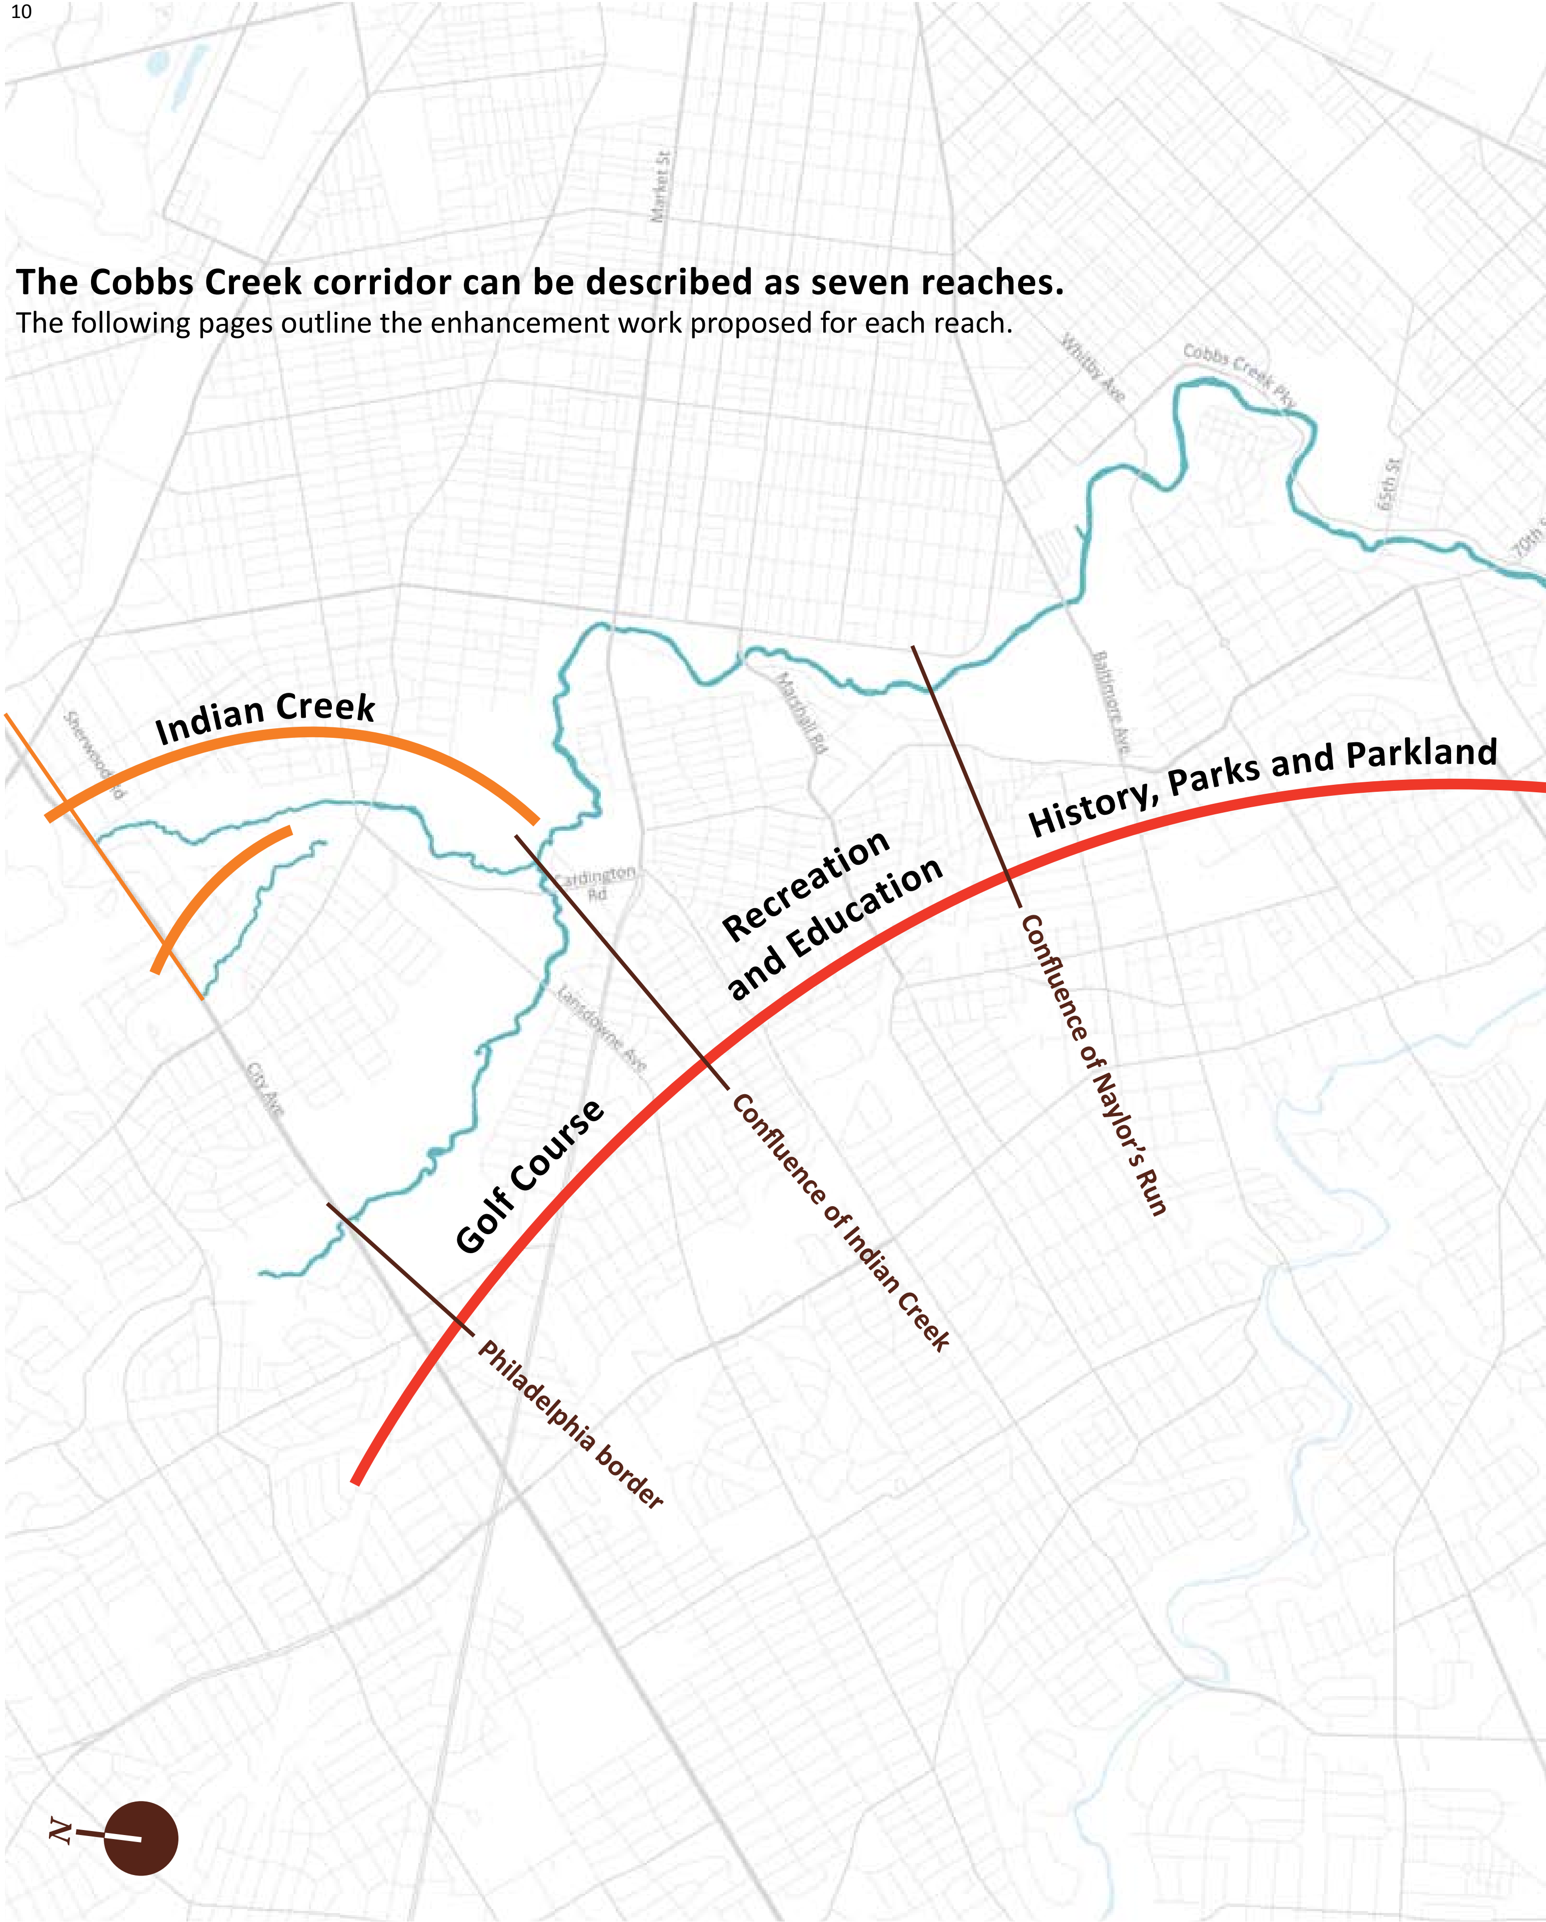
...but an enhanced STREAM CORRIDOR can perform the same functions, too.



The same physical, chemical, and ecological functions can be performed in a riparian corridor, but their spatial organization differs. In a riparian corridor, wetland functions may be more **spread out**, instead of layering over one another. Instead of cycling within a wetland, the functions may be understood as **spiraling** within the entire riparian corridor, with different ecological functions predominating in different areas.

The Cobbs Creek corridor can be described as seven reaches.

The following pages outline the enhancement work proposed for each reach.



Island Ave
84th St
Lower Cobbs
Darby
Tinicum
Woodland Avenue Dam
Confluence of Darby Creek
Confluence of Darby Lake
I-95
Wanamaker Ave
Essington Ave
Confluence of the Delaware River

Indian Creek Reach

The Indian Creek reach of Cobbs Creek represents the convergence of a remarkable number of signature places and recreation opportunities. It also offers some of the most dramatic opportunities for environmental enhancements anywhere in the the city. With 69th Street Terminal at its base, City Line Avenue defining its northern edge and the major streets of Haverford, Lansdowne, and Girard Avenues converging at its center, the site enjoys a remarkable degree of access. Surrounded by Lower Merion, Overbrook and Upper Darby, this reach could be a major community magnet, drawing support and stewardship from all edges.

In its current condition, this reach offers limited positive recreation and environmental education assets. The site does, however, offer a remarkable framework for enhancements. The potential palette of environmental enhancements include stream daylighting at the intersection of the west and east branches of Indian Creek; wetland creation in large, suitable sites; wetland restoration in several locations; and stream channel redefinition and plantings.

The Indian Creek reach offers a remarkable framework for environmental restoration. ***Above:*** *With stream daylighting, the east and west branches of Indian Creek may be brought together near this point.* ***Middle row:*** *This reach includes neighborhood parks, playgrounds, and trails.* ***Below:*** *This site in the upper reach is one of several opportunities for creation of large wetlands.*

A vision of the restoration of the natural watercourse of Indian Creek, upstream of Lansdowne Avenue.

existing conditions

Stream corridor improvements in the Indian Creek reach:

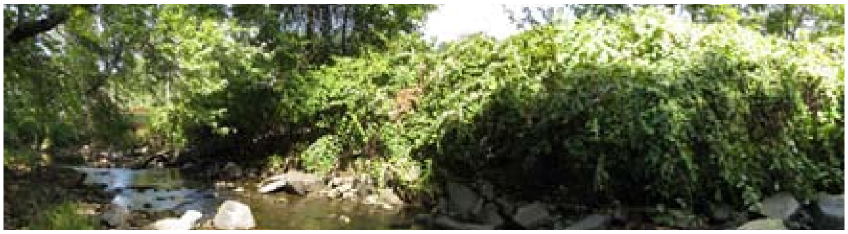
1.4 acres of wetland enhancement
0.5 acre of wetland creation
2.0 acres of stream daylighting

Golf Course Reach

Bordered by the R100 high speed line, with 69th Street Terminal near its base and City Line Avenue near its northern edge, the Golf Course reach is extremely well-connected by transit and roads. The thriving, compact neighborhoods of Parkview and Lower Merion border it and Overbrook neighborhood is close by. Currently, a lack of trails along this reach inhibits pedestrian connectivity between these neighborhoods and to the larger park network. Still, the reach's extensive public golfing facilities draw visitors from within and beyond the area.

In the Golf Course Reach, a pastoral setting and gently sloping banks frame Cobbs Creek. But typical golf course land management practices and application of fertilizers and other chemicals can threaten water quality and promote the spread of invasive vegetation. With stream bank enhancements, in-channel modifications, increased buffers and removal of invasive plants, this reach of the creek could become a true asset that brings many ecological benefits. With trail development, this reach could also provide tremendous educational and recreational benefits.

Top left: *Cloaked by invasives, the stretch near the golf driving range is a hidden jewel.* ***Top right:*** *The City Line Avenue bridge offers a glimpse into the potential and current problems.* ***Above:*** *The City Line Avenue driving range is a low-key, verdant place to spend an afternoon.* ***Below:*** *Managing stormwater from upstream and providing cleaner water will require the creation of more areas for water storage and infiltration.*



existing conditions

Stream corridor improvements in the Golf Course reach:

1.23 acres of wetland enhancement

5.66 acres of wetland creation

2.43 acres of streambank restoration

4.65 acres of in-channel streambank restoration

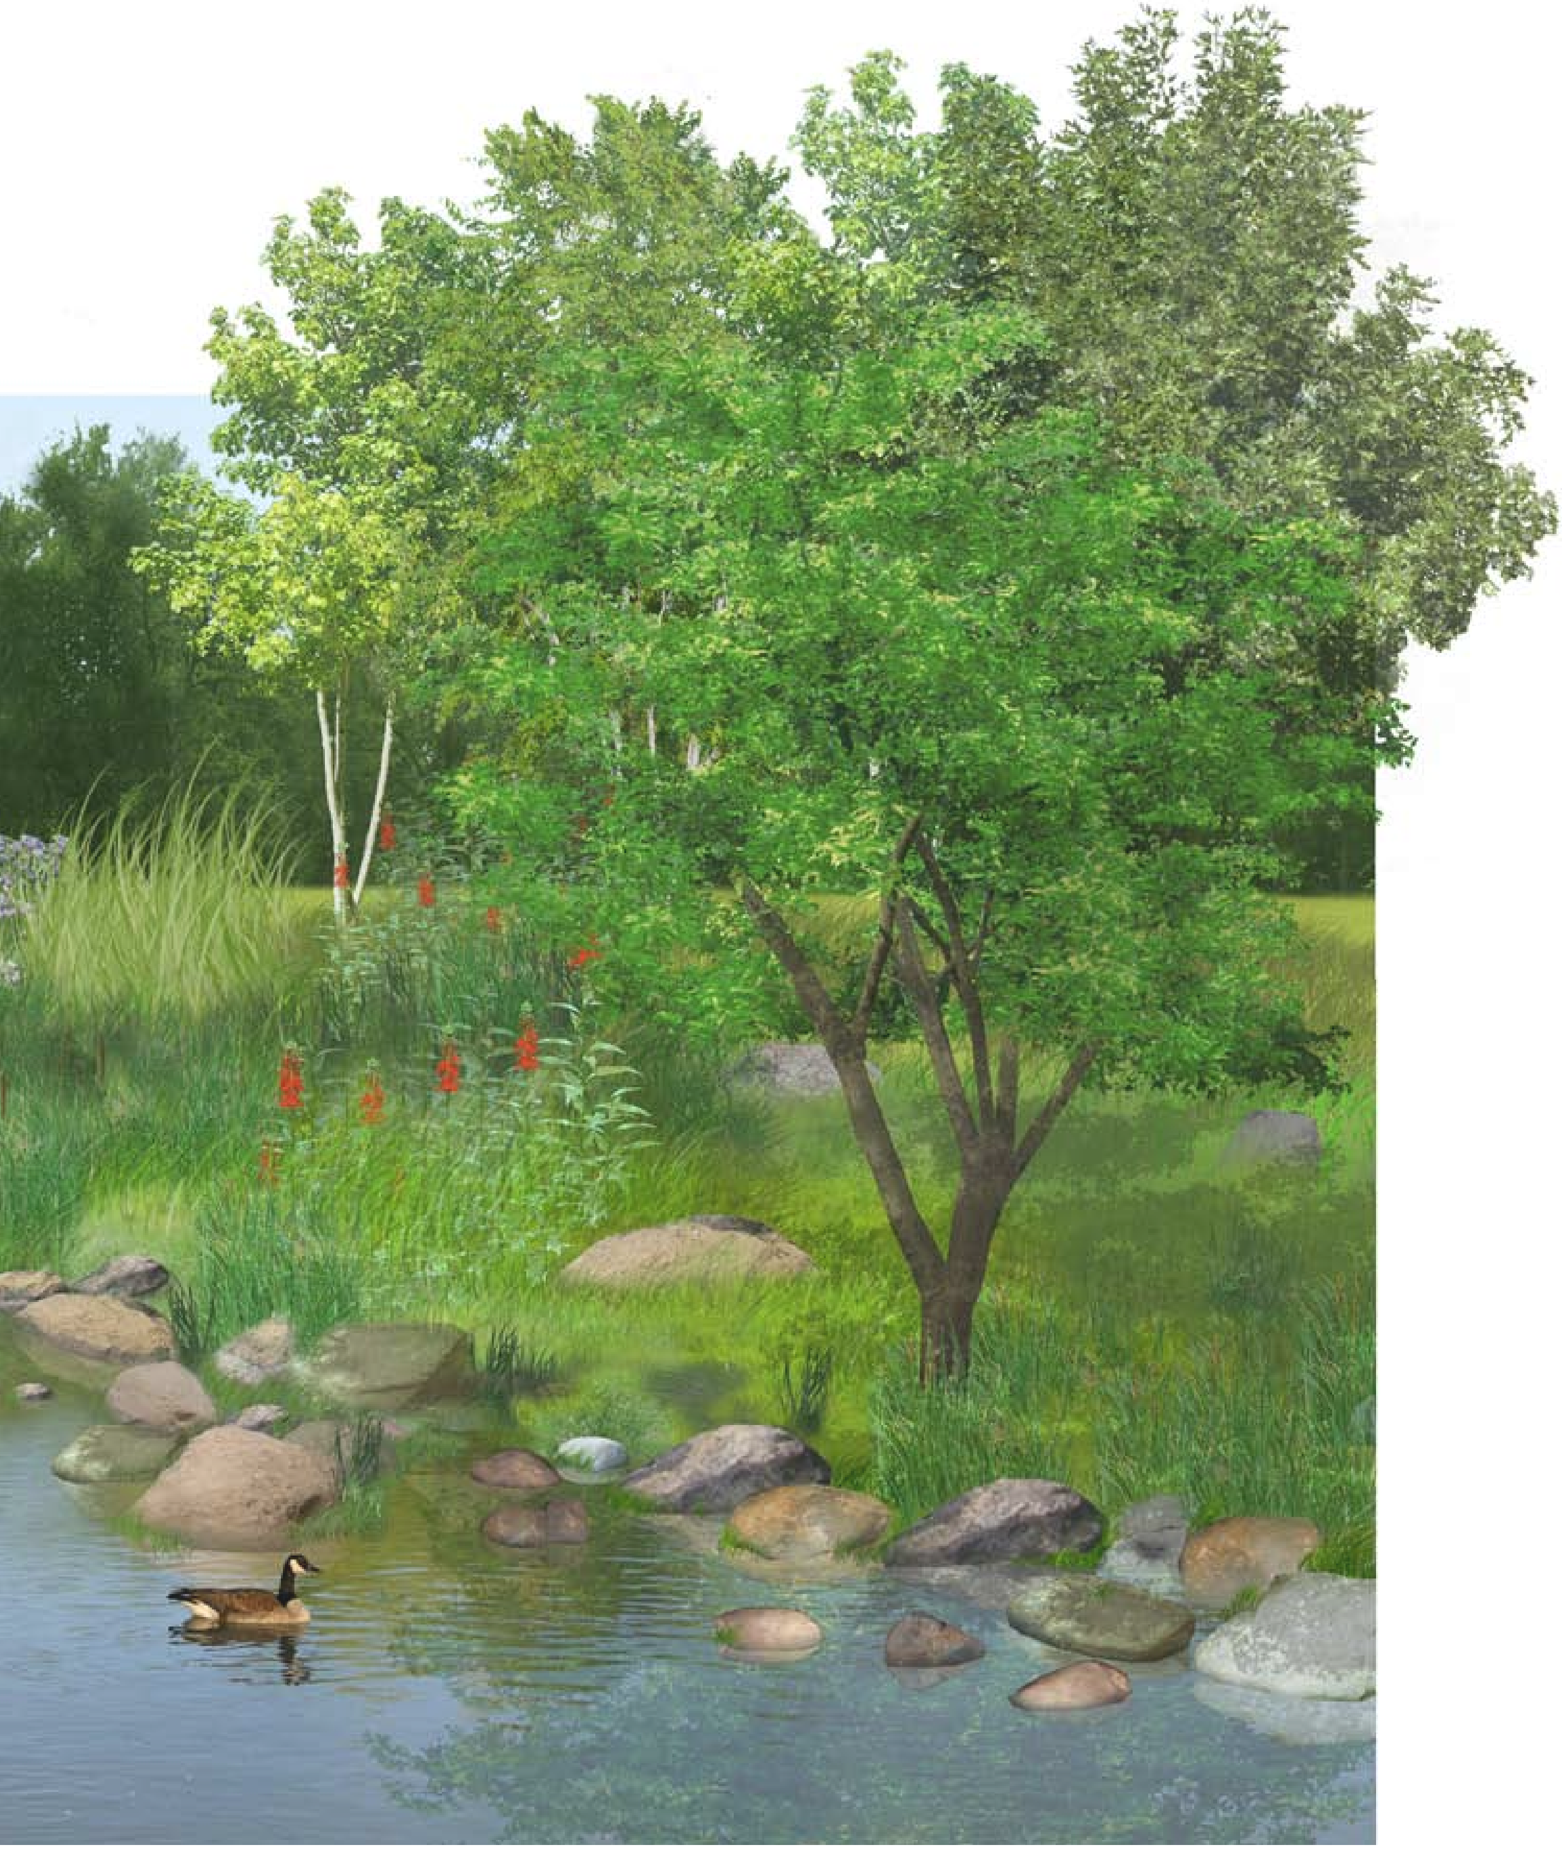
1.30 acres of additional tree canopy cover

1.71 acres of stormwater detention basins

0.19 acre of naturalized stormwater discharge

1.42 acres of new floodplain storage

0.15 acre of improved accessibility using trails



A vision of Cobbs Creek, looking north toward the golf driving range.

Recreation and Education Reach

The Recreation and Education Reach of Cobbs Creek beautifully demonstrates that even narrow corridor segments can provide a plethora of environmental benefits and community amenities. The reach begins at the Cobbs Creek confluence with Indian Creek and ends where it meets Naylor's Run. It is framed by the Cobbs Creek and Millbourne neighborhoods and includes a large range of facilities: an ice skating rink, a pool, a recreation center, and the jewel of the corridor, the Cobbs Creek Environmental Education Center.

The Cobbs Creek Environmental Education Center site's pastoral setting, historic bridge and buildings make it one of the most scenic places in the city. Its beautifully restored wetland and creek segment provide a model for high performing environmental enhancements. The Philadelphia Water Department has demonstrated through its work at the Center site that riparian corridor environmental enhancements can be ecologically high functioning and sustainable. There is still more work needed to bring the rest of this reach up to the standard set by the Cobbs Creek Environmental Education Center segment. Served by the Market-Frankford line, among other public transit routes, this reach is well positioned to become an important destination for education and recreation.

The Recreation and Education Reach provides many opportunities for environmental education and for recreation. ***Above:*** *A dam blocks fish passage in the upper portion of the reach.* ***Middle:*** *Children enjoying free playtime by exploring the Cobbs near the Cobbs Creek Environmental Education Center.* ***Right:*** *A view toward the Cobbs Creek Environmental Education Center building.* ***Bottom:*** *A successful enhancement project that provides a range of environmental and recreational benefits.*

Proposed stream corridor improvements in the Recreation and Education reach:

5.62 acres of wetland enhancement
14.41 acres of wetland creation
5.22 acres of streambank restoration
11.46 acres of in-channel streambank restoration
0.76 acre of additional tree canopy cover
2.60 acres of stormwater detention basins
0.84 acre of naturalized stormwater discharge
2.20 acres of new floodplain storage
2.64 acres of dam removal / new fish passages
0.28 acre of improved accessibility using trails

Stream corridor improvements are already at work in Cobbs Creek!

04/27/00

Years of streambank erosion led to exposure of a sewer pipe within Cobbs Creek near Marshall Road. This type of situation often occurs in streams receiving urban runoff and requires action to prevent damage to the pipe and to stabilize and restore the stream embankment.

10/22/04

In the fall of 2000, the Philadelphia Water Department (PWD) was awarded a PA Department of Conservation and Natural Resources Growing Greener Grant of $150,000 for natural channel restoration and habitat creation in this section of creek. PWD provided additional matching funds and the Marshall Road project has become a model of stream restoration, demonstrating the ecological, recreational and aesthetic value of stream improvement projects.

04/06/06

Design: Biohabitats, Inc.
Construction: Buckley & Company, Inc.

900 linear feet of streambank restoration

$51,000 for clearing and grubbing

170 feet of sewer rehabilitation

3412 cubic yards of excavation

2975 square yards of water course and erosion protection

$11,000 for invasive species management

4 vanes (artificial structures used to direct flows in a stream)

625 cubic yards of constructed riffle

1060 tons of boulder bank stabilization

366 trees planted

277 shrubs planted

492 linear feet of live branch layering

4391 square yards of native seeding and mulching

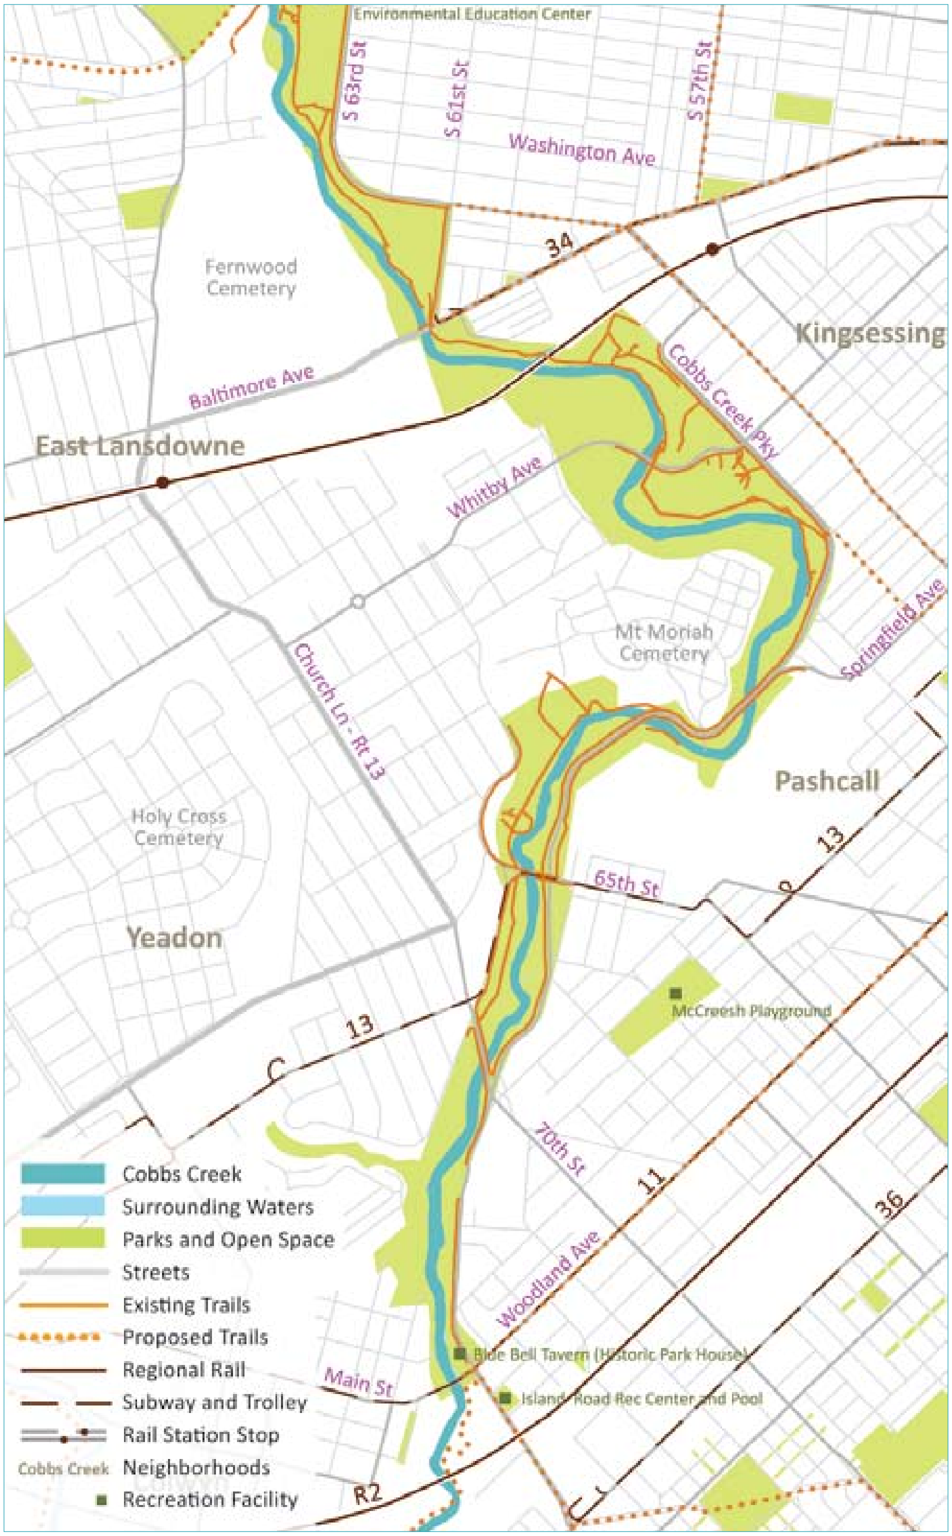
$768,737.80 total cost

09/29/06

History, Parks and Parkway Reach

The History, Parks and Parkway Reach truly imparts a feeling for the pace and setting of past periods. The gentle meanders of the verdant Cobbs Creek Parkway border the east side of the corridor; historic Woodland Avenue brings a visitor to the historic Blue Bell Tavern, the scene of a lethal Revolutionary War skirmish. Mt. Moriah Cemetery, built in the mid -19th Century within the “rural ideal” type, speaks of pastoral landscape style and ambitions of the time. These, and other, threads of the past come together in an area that faces contemporary environmental challenges and opportunities.

Significant opportunities for stream enhancements twine throughout this entire reach. Reconfigured banks can bring wetlands, stormwater storage, revitalized buffers and new trails. The dam near the Blue Bell Tavern currently prevents fish passage but with slight modification could allow for migration. Enhancements to the creek and creek landscape would re-frame the significant assets already in place in this reach, providing a new setting for the historic jewels. This combination of improved environmental, recreational and cultural assets would well serve the city and the densely developed adjacent neighborhoods of East Landsdowne, Yeadon, Kingsessing and Pashcall.



In the History, Parks and Parkway Reach, the strands of the past interweave with contemporary environmental challenges and opportunities. ***Top row, from left:*** *The historic Blue Bell Tavern; the beautiful Cobbs Creek Parkway; one of many quiet park areas.* ***Middle row, from left:*** *The C17 combined sewer outlet; Cobbs Creek near Mt. Moriah Cemetery in early autumn.* ***Bottom row:*** *The well-crafted stone Cobbs Creek Parkway Bridge crossing Cobbs Creek.*

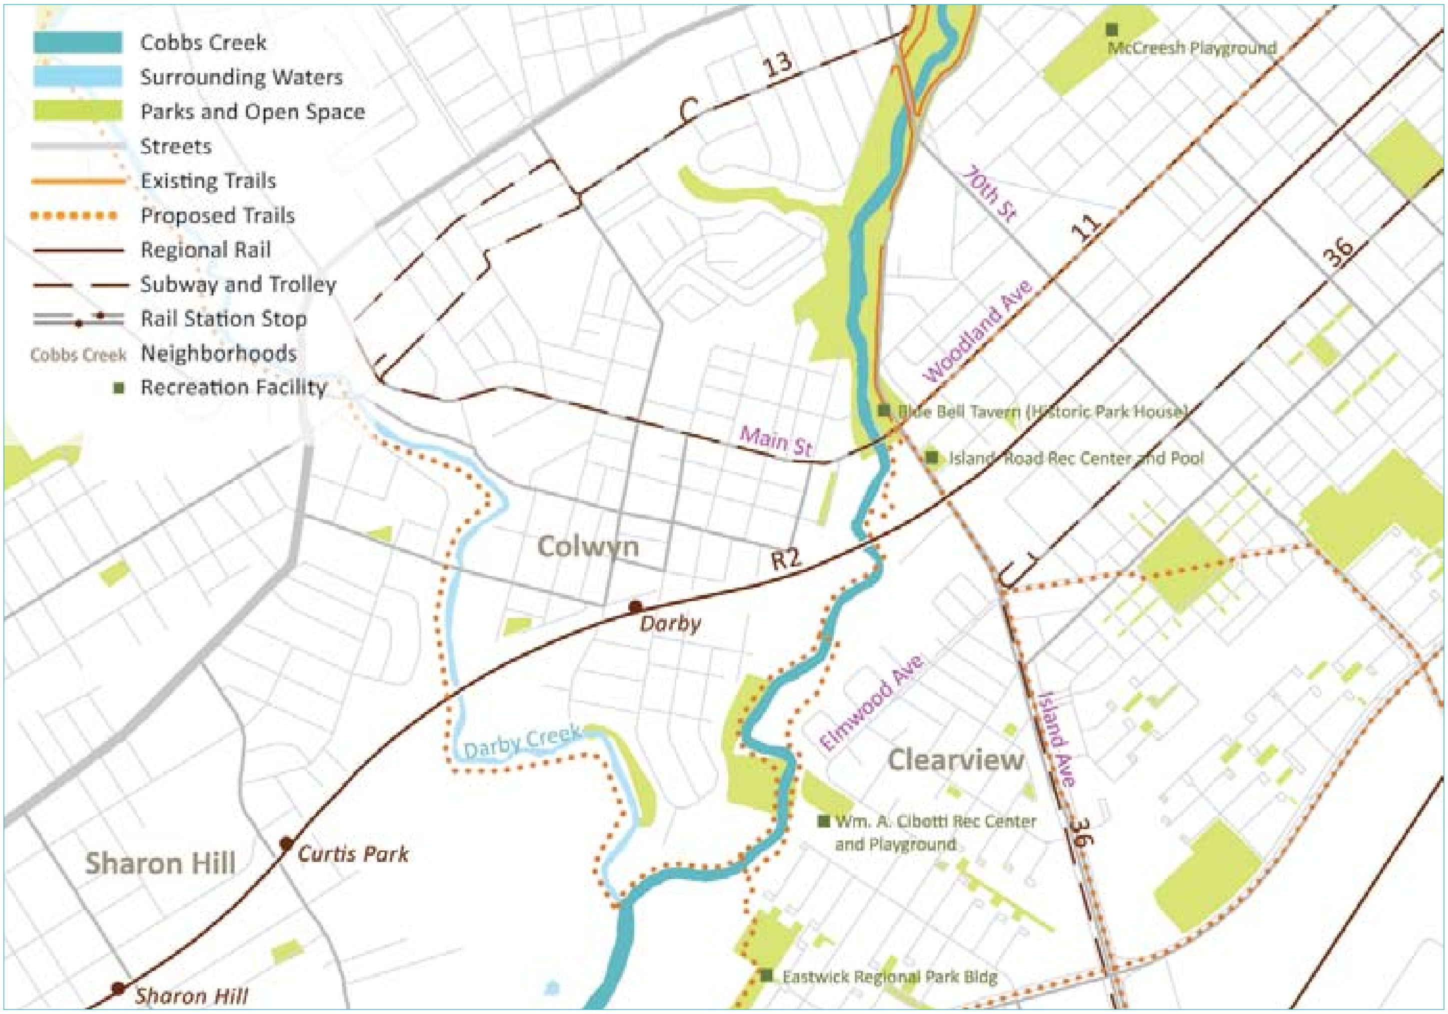
existing conditions

A vision of Cobbs Creek from Whitby Avenue Bridge.

Stream corridor improvements in the History, Parks and Parkland reach:

2.81 acres of wetland enhancement
10.20 acres of wetland creation
4.93 acres of streambank restoration
22.62 acres of in-channel streambank restoration
1.83 acres of additional tree canopy cover
3.53 acres of stormwater detention basins
2.74 acres of naturalized stormwater discharge
4.98 acres of new floodplain storage
2.64 acres of dam removal/ new fish passages
1.10 acres of improved accessibility using trails

Lower Cobbs Reach

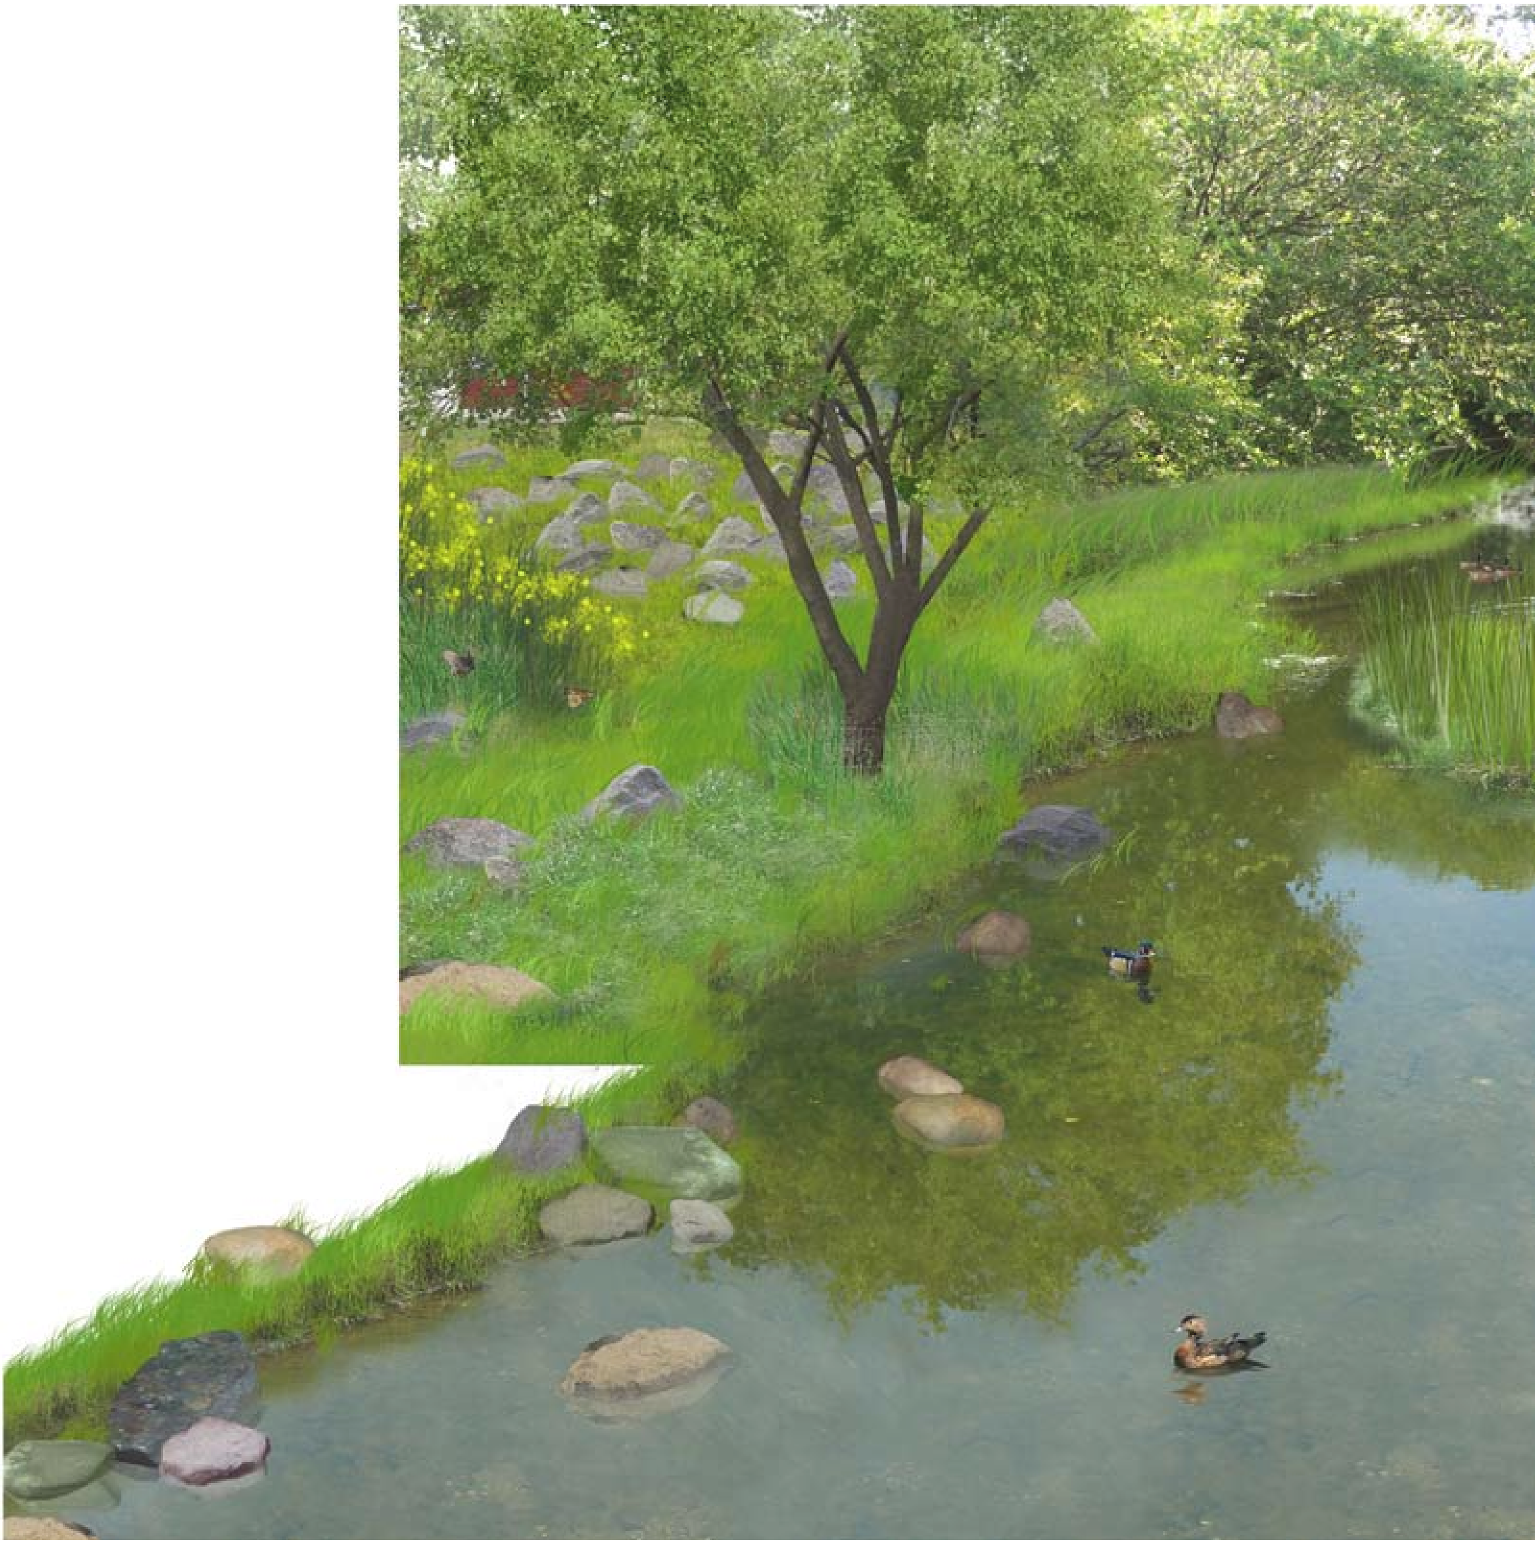


The Lower Cobbs Reach flows through the Colwyn and Clearview neighborhoods, ending at the confluence with Darby Creek. For a short and somewhat narrow reach, it offers green respites, great views and wonderful opportunities for environmental enhancement. Walking from the top of the reach to its end, a visitor would see the historic Blue Bell Tavern, the R2 line, the pastoral views of Saturn Park and the meeting of the the Darby and Cobbs Creeks. In its current state, one would also see stretches of bank erosion, invasive plants and limited tree buffers.

A wide range of improvements such as stream bank restoration, in-channel modifications and buffer enhancements could transform the functioning of this reach and the experiences it provides.

The Lower Cobbs Reach brings its adjacent neighborhoods in close contact with pastoral views and strolls. ***Top:*** *The Lower Cobbs with the Woodland Dam in the background. The photo-simulation on the following page addresses waterway restoration proposals for this area.* ***Lower right:*** *The Greensward of Saturn Park, near the confluence of Darby Creek, behind an Eastwick neighborhood.* ***Lower left:*** *Bank erosion and invasive plants near where Cobbs Creek meets Darby Creek.* ***Middle left:*** *One of the quiet Eastwick neighborhood streets.*

existing conditions



A vision of Cobbs Creek looking toward Woodland Avenue Dam, illustrating a new fish ladder that would promote fish passage.

Darby Reach

The neighborhoods bordering this reach, Sharon Hill, Darby, Clearview and Eastwick, know well the contrasts of their landscape. On one side of the Darby Reach are acres of “tank farm”, or oil tanks, and light industrial uses. On other side is the entry to The John Heinz National Wildlife Refuge at Tinium and the Cusano Environmental Education Center, and well-tended neighborhoods.

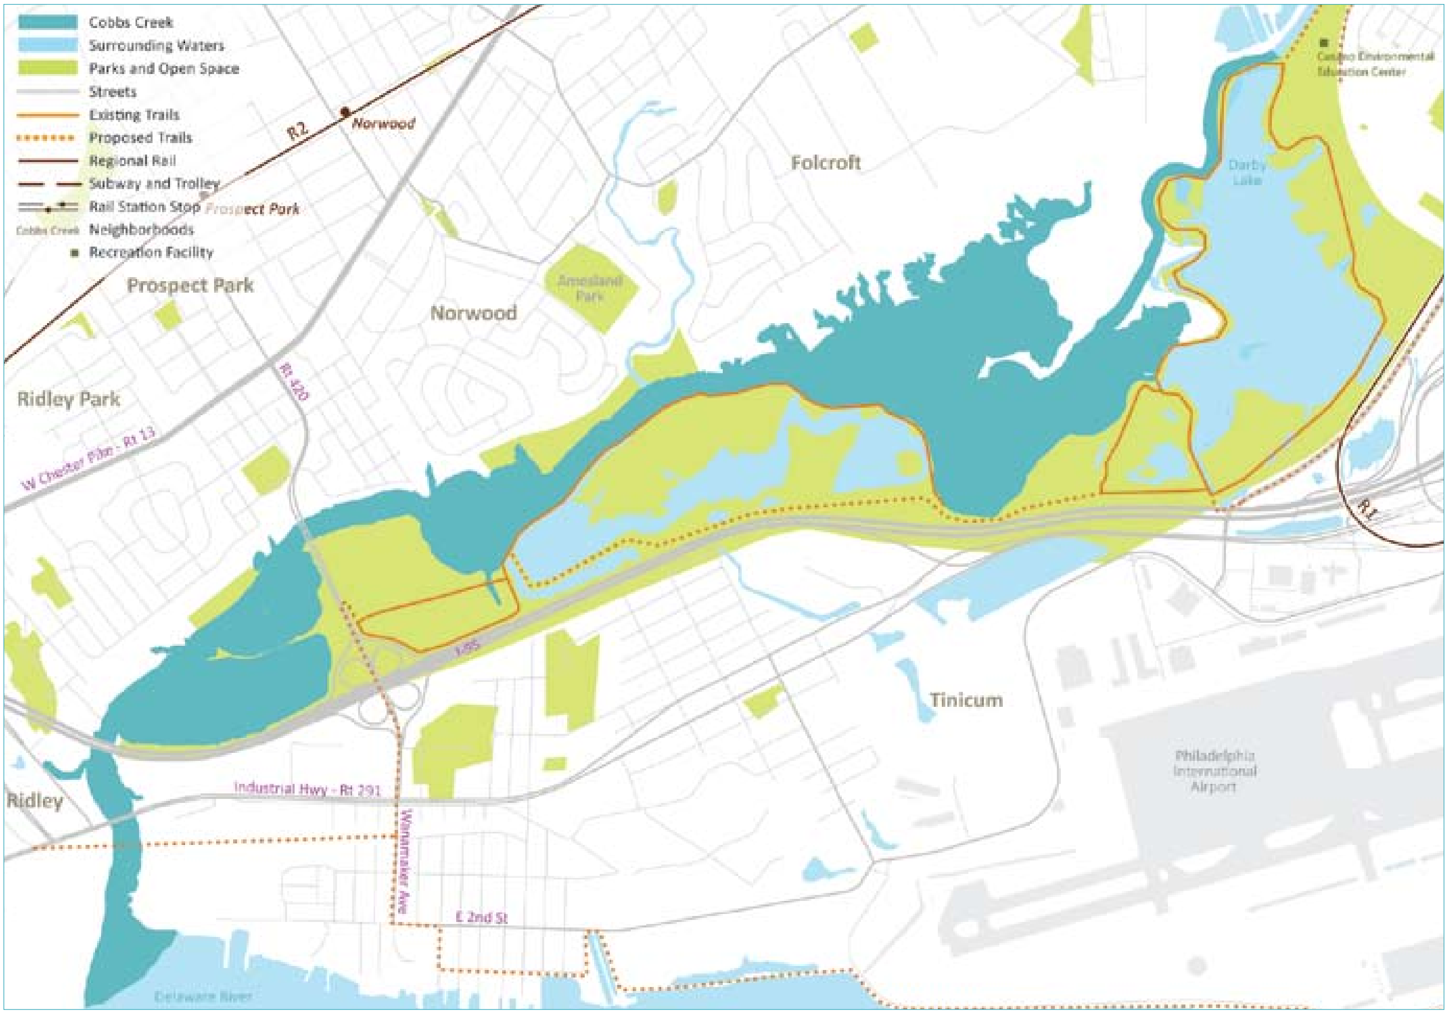
The presence of major circulation infrastructure including Interstate 95, two regional rail lines, trolley and even the airport, brings great opportunity to this area. But land use conflicts have tended to constrict those opportunities. With these conflicts and without a robust open space network to orient toward, some of the neighborhoods have developed frayed edges.

Currently, this reach is not a priority area for environmental restoration because of limited public ownership ouside of the wildlife refuge. With future land use changes, though, this reach will be well positioned for improvements.

The Darby reach is defined by a diverse blend of land uses. ***Below left:*** *The western banks of the Darby Reach are characterized by uses such as petroleum storage and warehousing, in addition to established neighborhoods within Darby (****left****). Opposite these banks is the Cusano Environmental Education Center (****below right****) whose mission is to "demonstrate within an urban setting, the importance of the natural world to the human quality of life and inspire visitors to become responsible stewards of the environment."*

www.phillysolar.com

Tinicum Reach



The first time visitor to the Tinicum Reach is almost always astounded by its vast and beautiful landscape. 1,200 acres of the site represent the largest freshwater tidal wetland in Pennsylvania - and yet, they are only a fraction of the original 6,000 acres of wetland. These wetlands perform amazing work but can cleanse only a portion of the Cobbs and Draby Creek waters that flow past them.

The pollutants those creek waters bring impact the health of plants and animals within the Tinicum Reach, the Delaware and even further. Managing our stormwater within the upper reaches of the Cobbs can bring positive benefits far beyond their boundaries.

With Fairmount Park to the north and the wildlife refuge at its base, with its prominent location within a multimodal circulation network - and someday, with much needed environmental enhancements - Cobbs Creek has the potential to become one of the region's most important riparian corridors. Its restoration could bring enormous benefits in ecological function, recreation, civic identity and quality of life.

Cobbs Creek Corridor Enhancements By Reach

Reach:

Length:

Compiled as of November 13, 2008

1 NOTE: The Indian Creek reach is not part of the "Main Stem" study area as designated by the PWD's February 2008 report. The values shown for Indian Creek in the above table are not included in the "Summary of Enhancements" shown at far right.

2 Project area, in acres.

3 Functional value of improvement, in acres.

STANDARD RIPARIAN CORRIDOR RESTORATION ACTIONS
Wetland enhancement
Wetland creation
Streambank restoration
In-channel stream restoration (below streambank)
Addition of tree canopy cover
Stormwater detention basin
Stream daylighting
Naturalize stormwater discharge
Create floodplain storage
Dam removal / create fish passageway
Improve accessibility using trail system

Total Functional Value:

Environmental restoration and improvement projects in the Cobbs Creek corridor might include new and restored wetlands, in-stream and streambank restoration projects, stormwater detention basins, stream daylighting, naturalizing stormwater discharge and increasing floodplain storage, and improving fish habitat and passage.

If these varied projects are to be used as mitigation for lost tidal wetlands or open water, the environmental values they restore must be determined using a functional value analysis. The area of wetlands lost or created (usually expressed in acres) is often used as the standard measure for determining wetland and waterway impacts, and to determine the required mitigation for wetlands and other aquatic resources. The measurement of area impacted or restored has been used in the past because functional assessment methods often have not been developed or calibrated for an area. This area-based comparison method, however, limits the types of projects that can be used to mitigate lost wetlands. Functional assessments are among the best tools available to characterize impact and compensation values, and open up a whole new range of mitigation projects to consider.

In order to assign values to the many possible restoration projects in the Cobbs corridor, and to help permitting authorities decide on the value of restoration and improvement actions, those actions must be organized around the environmental functions that each can provide.

Wetland or stream restoration functions and the values offered through mitigation can be categorized into hydrologic and physical, biological, habitat, and social groups. Each category has one or more measurable criteria that describe the value of the mitigation project. By determining how a wetland functions and the value it provides to the environment, and how those lost wetland

	10.27		44.62		104.71		118.68	

and open water functions can be replaced in an urban environment, compensatory mitigation requirements can be identified. Not only does this approach consider lost and restored functions and values, but it also considers the need to enhance valuable functions that may be scarce in the watershed. This functional value system was used to estimate the restoration value, or score, shown in the above table.

The goal of this riparian corridor restoration plan for Cobbs Creek is to illustrate the extensive benefit to the City's environment, its neighborhoods, its fish and wildlife, parks and recreation areas, and the health of our residents that would result from restoration of Cobbs Creek. Impacts to the Cobbs waterway, its water quality, and its wildlife are attendant to a long history of urbanization. This preliminary analysis illustrates the tremendous improvement in the quality of the City's natural environment and quality of life that can be achieved through a comprehensive restoration of the Cobbs Creek waterway.

- An **Act 167 Stormwater Management Plan** was completed for the Darby-Cobbs Watershed in 2004 under the leadership of the Delaware County Planning Department's Environmental Planning section. "The Pennsylvania General Assembly enacted Act 167 of 1978, the Pennsylvania Storm Water Management Act. This Act, which is the 'sister' legislation to Act 166, the Floodplain Management Act, recognizes the interrelationship between land development, accelerated runoff, and floodplain management. While Act 166 requires municipalities to regulate development in the floodplain, Act 167 requires municipalities to implement a stormwater management ordinance limiting stormwater runoff from new development."
  http://www.co.delaware.pa.us/planning/environmental/act167.html

- **The 58th Street Connector Greenway** is an initiative that is already underway to create a 1.2-mile recreational trail and green corridor. It will link Bartram's Garden and the Schuylkill River with southwest Philadelphia and Delaware County communities, multiple regional trail networks, and existing recreational facilities along 58th Street and Lindbergh Boulevard. Upon completion, it will be possible to bike, jog, blade, or walk from Center City to Delaware County, or loop around Southwest Philadelphia.

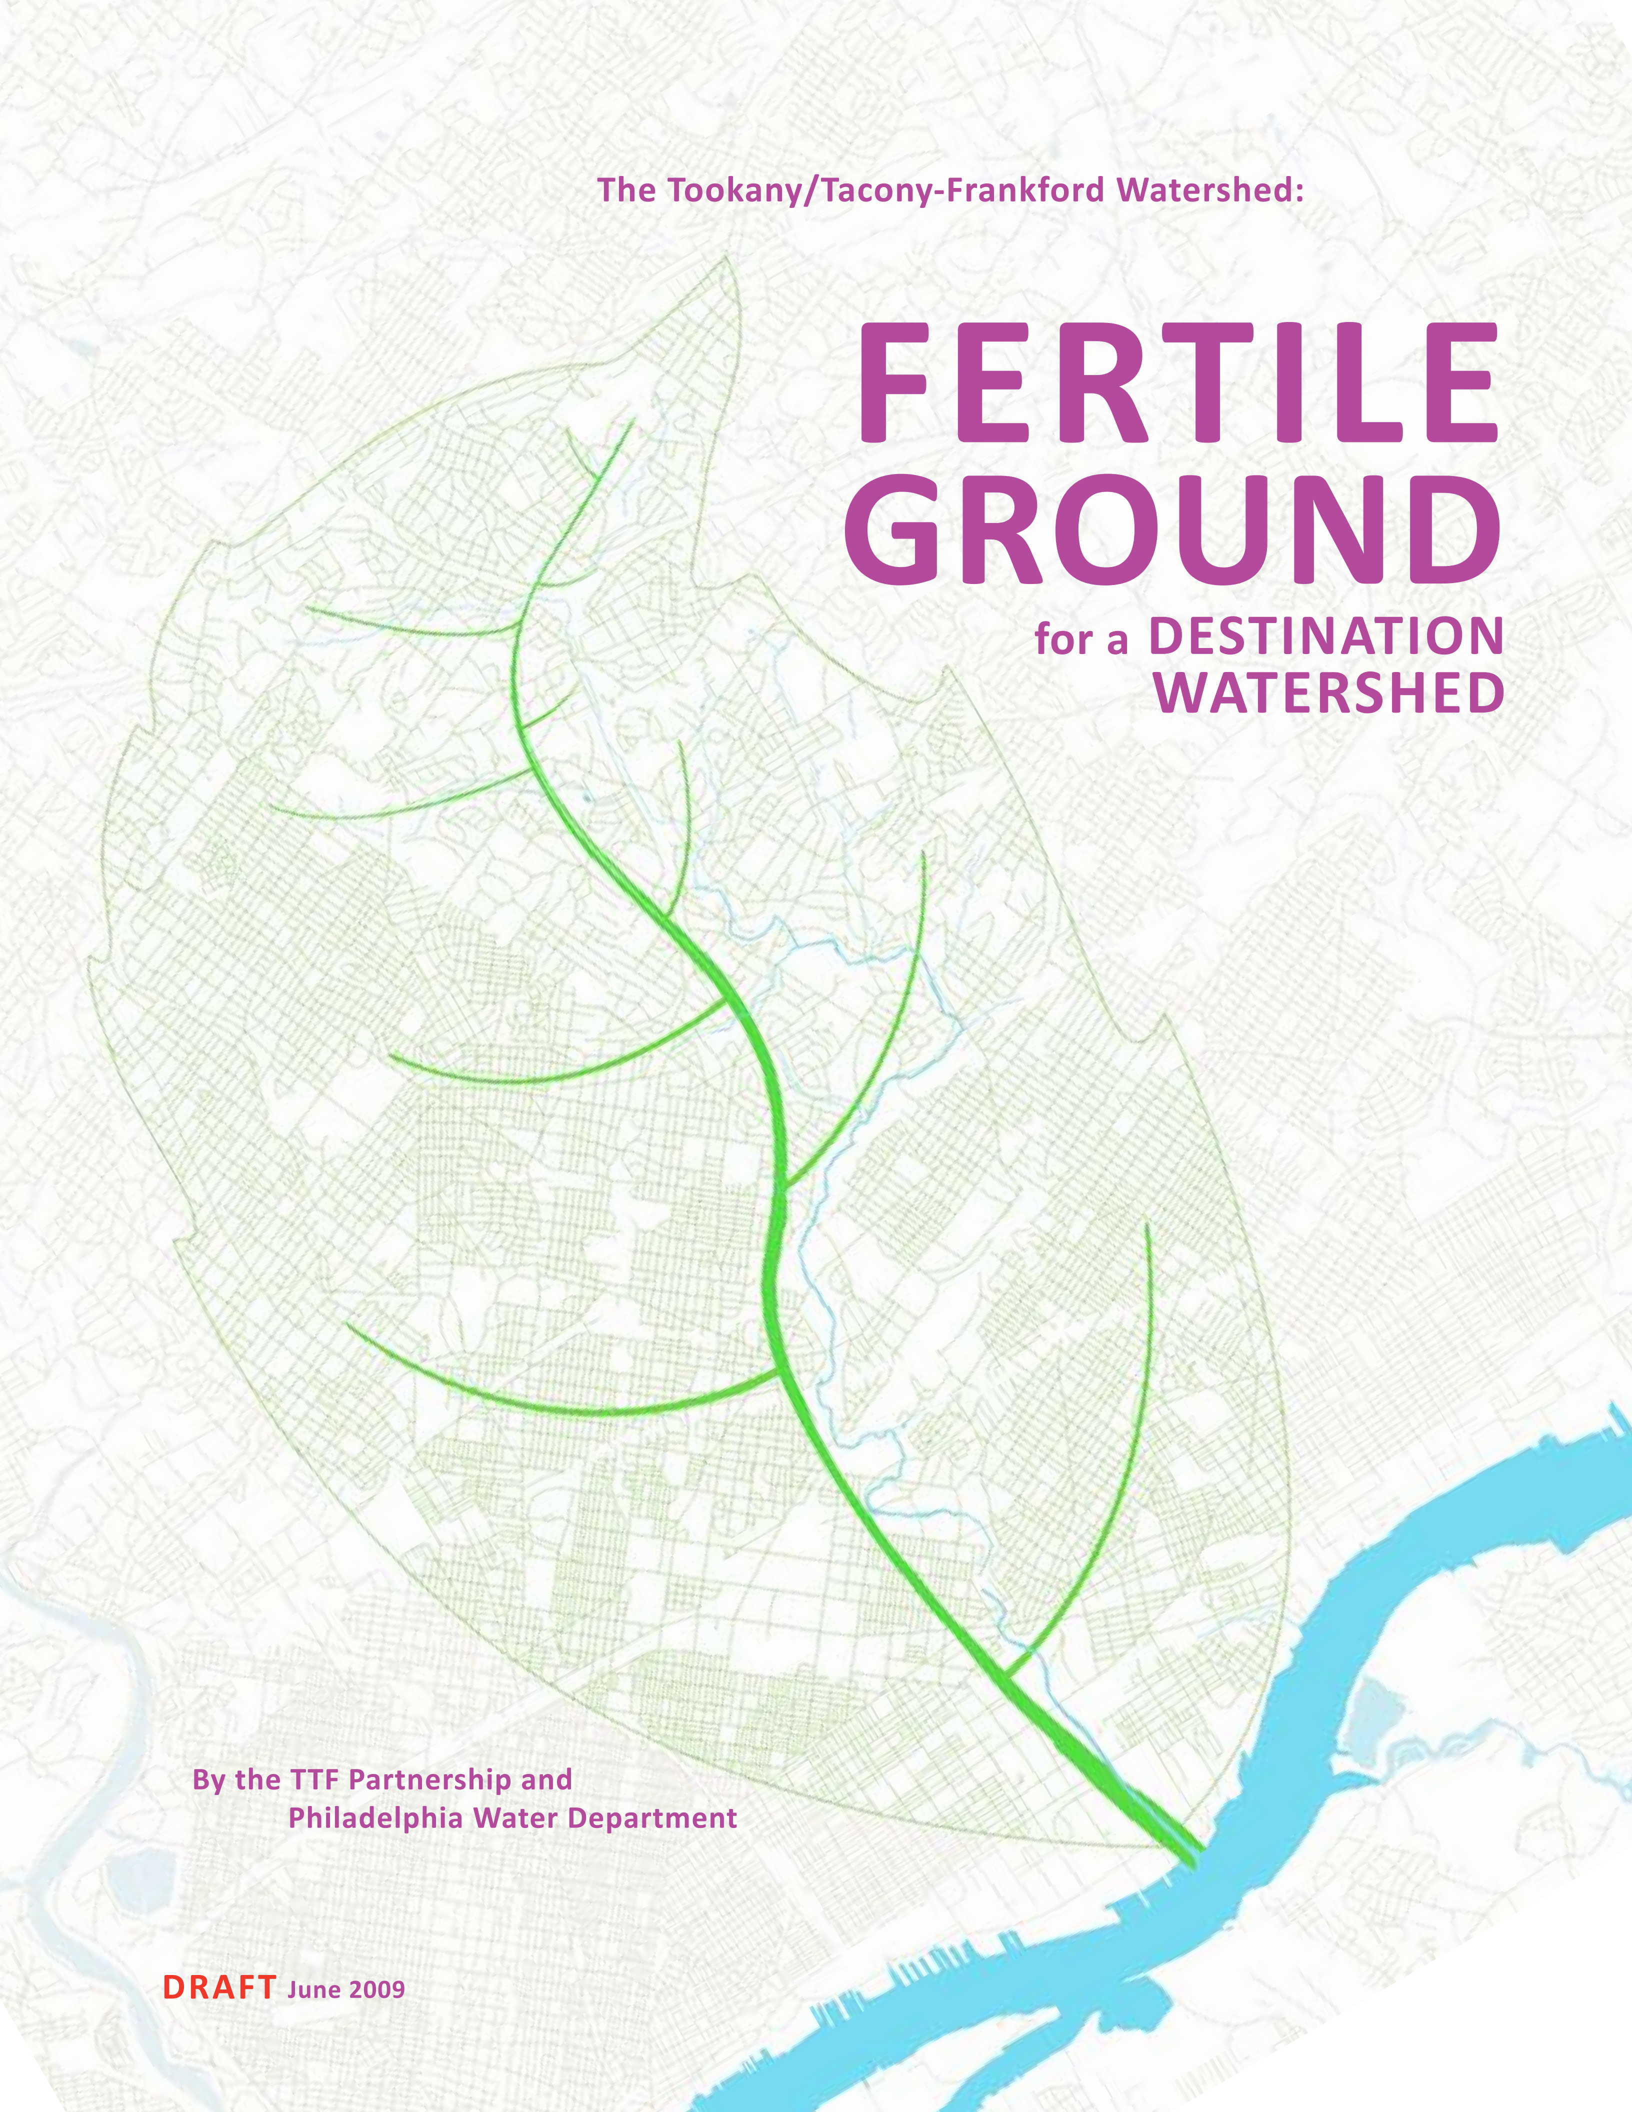
Cobbs Creek: A Gateway to Many Places and to Cleaner Water

February 2009

The Tookany/Tacony-Frankford Watershed:

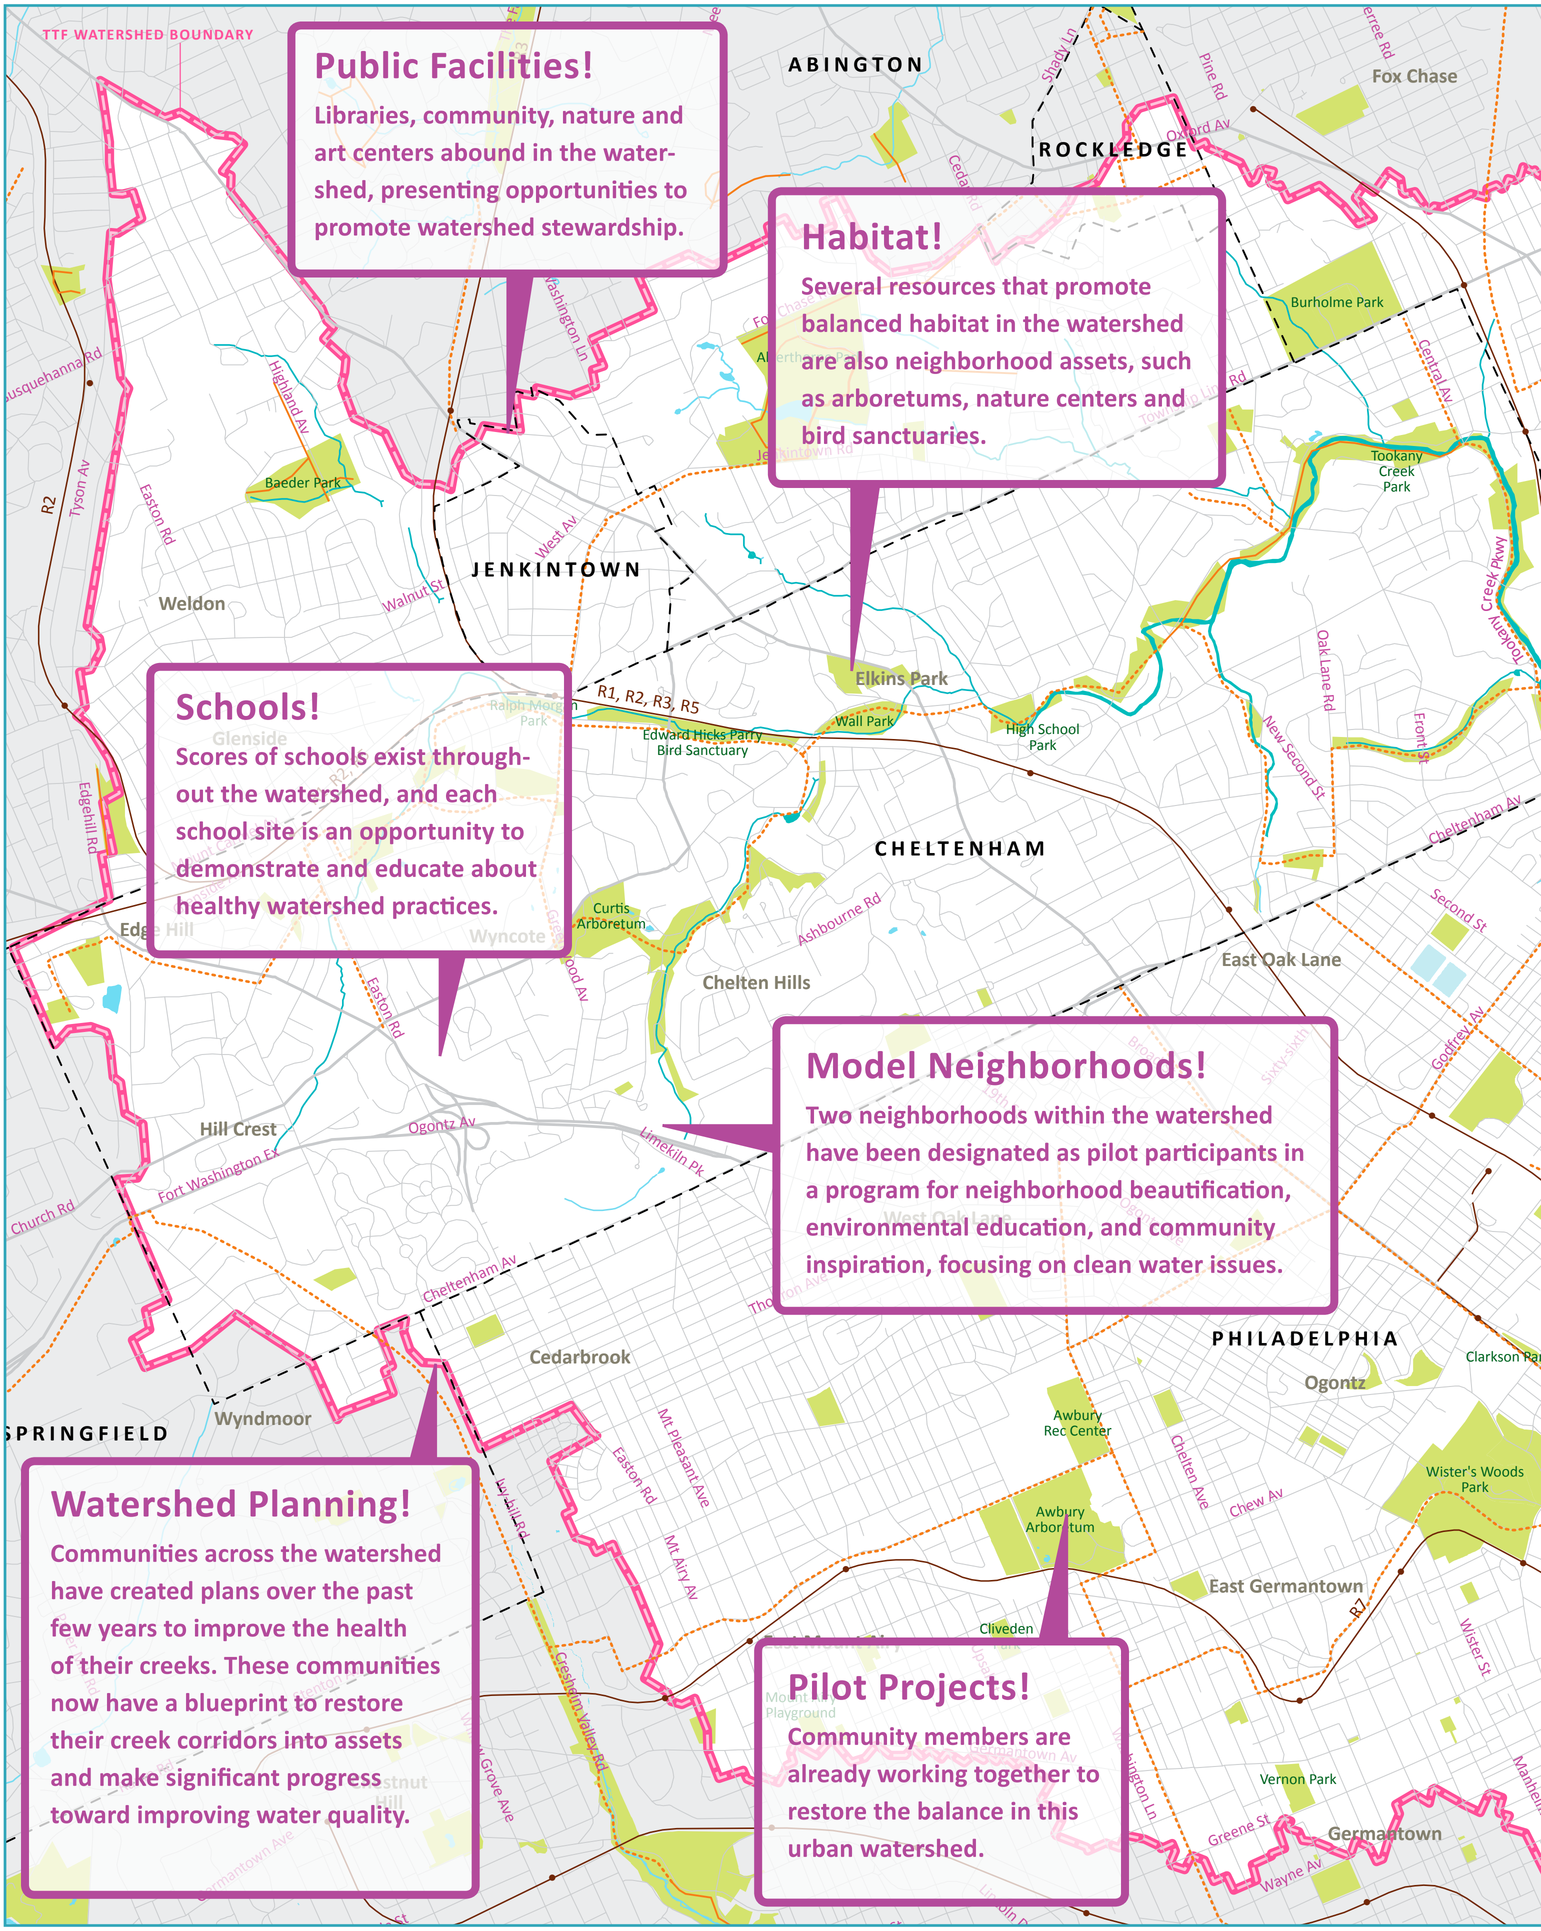
FERTILE GROUND

for a DESTINATION WATERSHED



By the TTF Partnership and
Philadelphia Water Department

DRAFT June 2009



Public Facilities!

Libraries, community, nature and art centers abound in the watershed, presenting opportunities to promote watershed stewardship.

Habitat!

Several resources that promote balanced habitat in the watershed are also neighborhood assets, such as arboretums, nature centers and bird sanctuaries.

Schools!

Scores of schools exist throughout the watershed, and each school site is an opportunity to demonstrate and educate about healthy watershed practices.

Model Neighborhoods!

Two neighborhoods within the watershed have been designated as pilot participants in a program for neighborhood beautification, environmental education, and community inspiration, focusing on clean water issues.

Watershed Planning!

Communities across the watershed have created plans over the past few years to improve the health of their creeks. These communities now have a blueprint to restore their creek corridors into assets and make significant progress toward improving water quality.

Pilot Projects!

Community members are already working together to restore the balance in this urban watershed.

Transit!

Multiple lines, including subway, regional rail, bus and trolley, link many communities within the watershed.

The Delaware!

The TTF watershed drains to the Delaware River. There is potential to tie into waterfront planning happening along the Delaware and to take advantage of the anticipated resources, by planning for open space, trails and greenways connecting back into the watershed.

Trails!

Miles of biking and hiking trails wind along the creeks and through the communities within the watershed. Many more miles of bike lanes and trails are planned.

Parks and Recreation!

Hundreds of acres of parks and fields cover this watershed, including playgrounds, recreation centers, golf courses, sports fields, ice rinks, dog parks, trails and more.

Neighborhoods!

The TTF watershed and its creeks thread together diverse and active communities with rich histories in Philadelphia and Montgomery Counties.

About the TTF Watershed Partnership

The mission of the the TTF Watershed Partnership is to enhance the health and vitality of the Tookany/Tacony-Frankford Creek and its watershed.

The Tookany/Tacony-Frankford Watershed Partnership. Inc. (TTF) acts as the crucial link connecting residents, businesses and government as neighbors and stewards of this impaired, but critically important watershed in the Philadelphia metro region. Through educational programming, community outreach, networking services, and project coordination, TTF facilitates, supports, and initiates efforts to restore the health of the watershed, and to mobilize its communities as watershed stewards.

Launched in 2000 by the Philadelphia Water Department, the Partnership was integral in developing the Tookany/Tacony-Frankford Integrated Watershed Management Plan, a blueprint for restoring this urban creek into a community asset while addressing the mandated requirements of the federal Clean Water Act and the federal Stormwater Permit Program (MS4). In 2005, the Partnership formally incorporated as an independent nonprofit with the recommendations of the Plan as its core vision.

TTF Watershed Partnership Board of Directors:

Abington Township
Arcadia University
Awbury Arboretum
Cheltenham Township
Fairmount Park Commission
Frankford Group Ministry
Friends of High School Park

Cheltenham Township (Springfield Township)
Jenkintown Borough (Springfield Township)
Montgomery County
Philadelphia County
Rockledge Borough (Springfield Township)

Fertile Ground

For A Destination Watershed

There is no metaphor like water itself to describe the cumulative effects of our practices, with every upstream action having an impact downstream. Too often when we seek out respite along our creeks, we find degraded areas filled with trash, silt, weeds and dilapidated structures at the margins. We blame others for dumping trash or our city for not attending to the weeds, but the condition of the creeks is directly related to how we manage stormwater on our own properties and streets. The effects of flooding affect how we can invest and recreate in waterfronts – often thwarting our natural impulses to be next to water.

This document attempts to describe the dynamic, reciprocal relationship between practices throughout a watershed and its waterfront environments. This document also presents a vision for what the Tookany Tacony Frankford watershed could be if we make small changes on our public and private properties. This plan presents a vision of healthy vegetation that supports a diverse range of birds and other animals, where Frankford Creek's water is safe enough to wade in on a hot day and where lasting investments in parks and adjacent development can be realized.

If we can significantly change the amount of stormwater and debris that flood into our creeks, an expansive range of benefits become possible – clean water, places to gather and play, places to invest safely, habitat – the list goes on. The benefits of stormwater management can be immediate and direct as well. Planting trees and installing rain barrels and green roofs saves property owners money and makes buildings and neighborhoods more comfortable and valuable. Wetlands, meadows and woodlands filter our air and water, give respite from compact urban neighborhoods and offer home and food to animals. All of those measures, and other such as pervious pavings, help to replenish the underlying water table, securing our future drinking water.

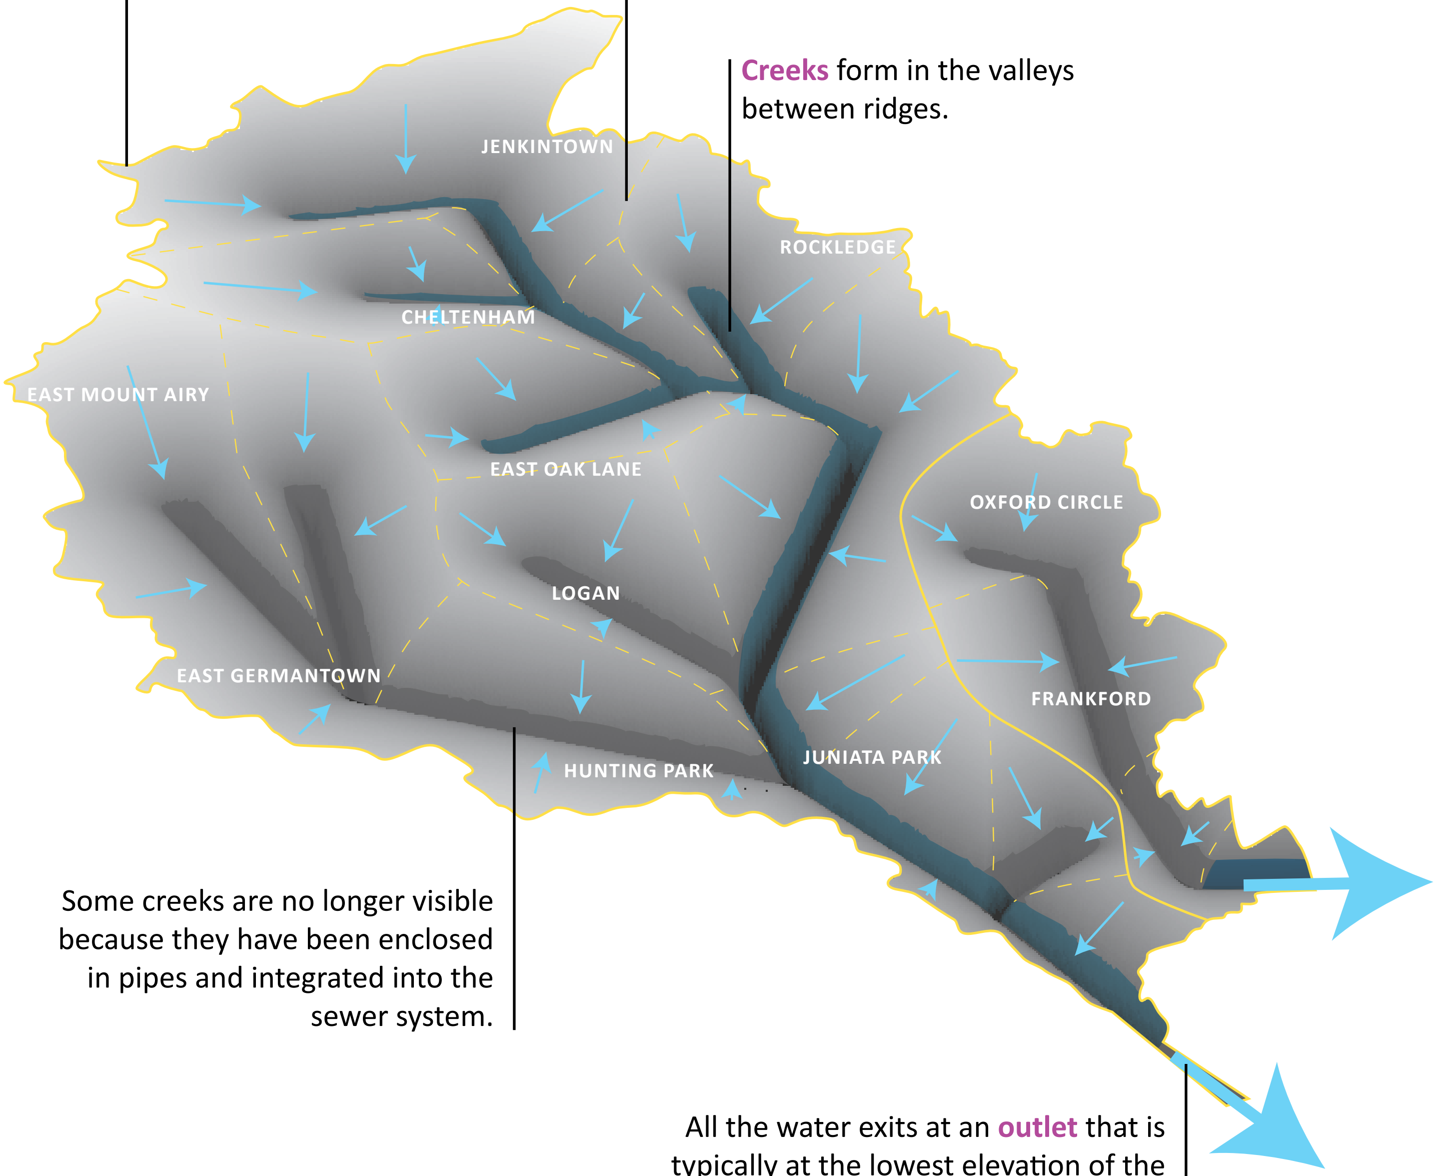
The Tookany Tacony Frankford watershed is an exciting place, full of vibrant neighborhoods and vast potential. Through stormwater investments throughout the watershed and strategic changes along Frankford Creek, we can realize that potential.

What exactly is a watershed?

A watershed is a **drainage basin**, within which all water flows to a single location.

Water flows in opposite directions on each side of a **ridge**.

Creeks form in the valleys between ridges.



Some creeks are no longer visible because they have been enclosed in pipes and integrated into the sewer system.

All the water exits at an **outlet** that is typically at the lowest elevation of the watershed into another body of water.

Fertile Ground

For A Destination Watershed

Laying the groundwork for restoring the Tookany/Tacony-Frankford Creek corridor toward a vision of creek health and community wealth.

FERTILE GROUND FOR STORMWATER INNOVATION

The waters of the TTF watershed and its underground infrastructure stitch together many diverse communities in Montgomery and Philadelphia Counties. Although some communities feel disconnected from their local creek because of limited access or because it has been enclosed by the sewer system, all neighborhoods in this watershed drain to the creek and must share responsibility for its health. It is therefore important for neighborhoods in the watershed to work together to manage stormwater.

The TTF watershed is already home to a number of demonstration projects that exhibit best practices in stormwater management. These projects have become sources of community pride and examples for using green infrastructure to reduce stormwater volume in the city's sanitary system.

FERTILE GROUND FOR DISTINCTIVE RECREATION

The TTF watershed is home to about 357,000 people with a range of income levels and backgrounds, and a variety of community strengths and struggles. One could imagine the creek would serve as a meeting place for relaxation, recreation, inspiration, and community connection.

Because of the area's topography, much of the parkland within the creek corridor is below street level, creating secluded oases within a highly urbanized area. However, the frequent flooding and widespread invasive species reduce the quality of these parks.

A number of core trails exist within the watershed and along the creek, and plans show the intentions of all the municipalities to connect these trails into a cohesive network.

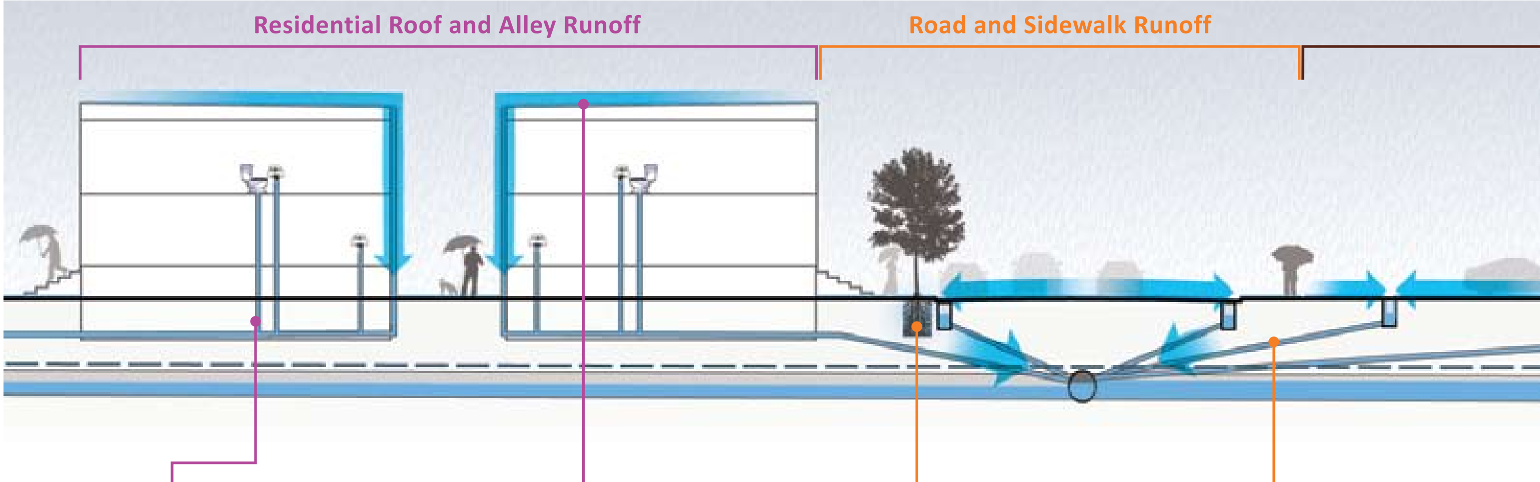
FERTILE GROUND FOR HEALTHY CREEKS

The watershed hosts several creeks, wetlands, and uplands that support diverse communities of wildlife and fish. Like all of our urban creeks, the waters within the TTF watershed have been compromised by intense development.

Today, many areas along and within the creek suffer from frequent flooding, invasive species, litter and illegal dumping that compromises the creek's health, beauty, and habitat value, and this deters residents from enjoying the many benefits healthy creeks offer.

Restoring the creek environment to a more natural state wherever possible and committing to responsible stewardship of the watershed will improve water quality, generate healthier habitats, and create environmental education opportunities.

A TYPICAL urban watershed has negative effects on its creeks:



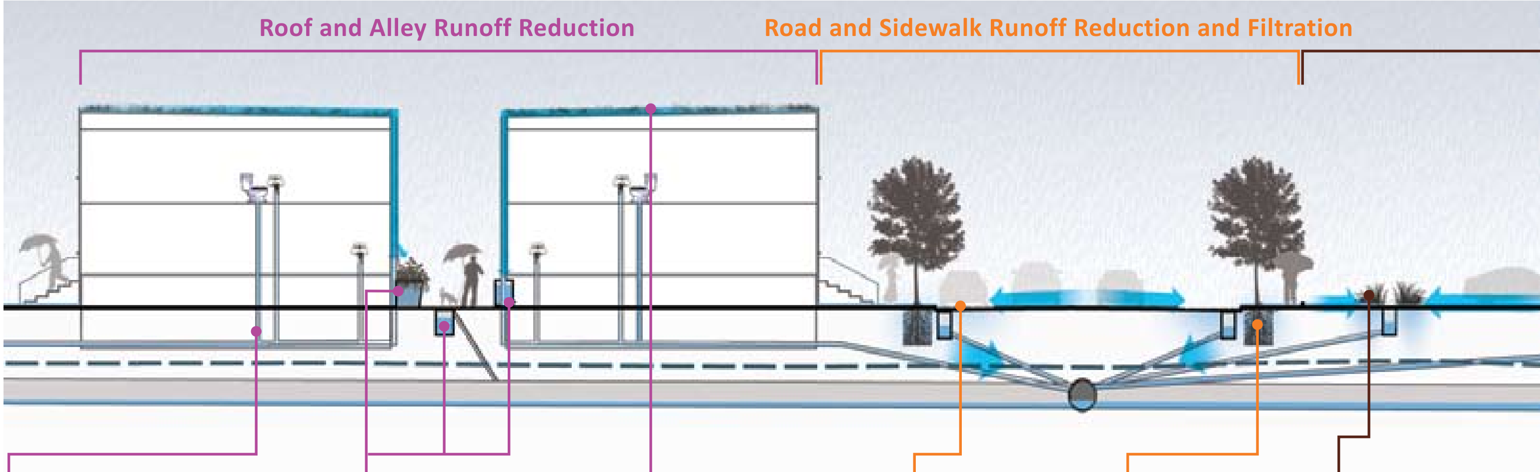
Overuse of water for household and personal needs adds additional stress on the municipal water system.

Roof runoff goes into roof leaders and pipes; it does not absorb into the ground.

Too few street trees to retain stormwater through canopy and root system intercept.

Stormwater drains quickly; does not absorb into the ground.

A more SUSTAINABLE approach to stormwater will positively affect the watershed:



More efficient household water use reduces stress on the municipal water and sewer systems.

Planters, rain barrels and cisterns retain stormwater, provide gardening water.

Green roofs collect and divert runoff from the municipal water system.

Permeable paving in parking lanes reduces road runoff.

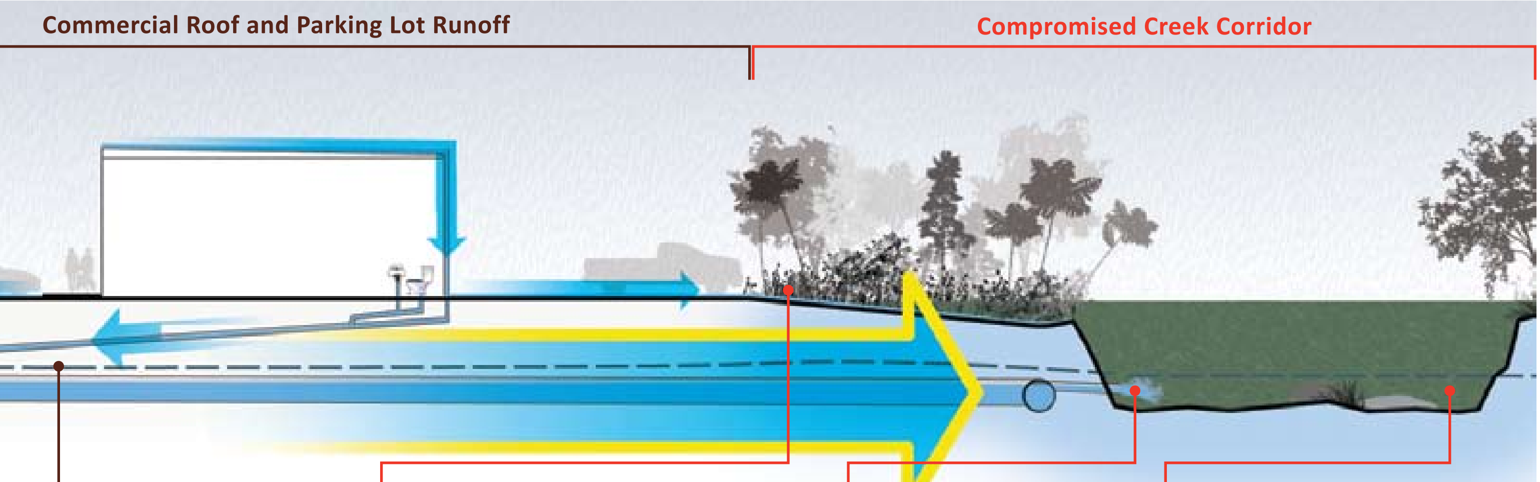
Larger, enhanced street tree networks filter and store runoff.

Groves and swales in parking lots filter and slow runoff.

Fertile Ground

For Stormwater Innovation

Stormwater management is vital to improving creek health in areas near creeks and in areas distant from creeks.

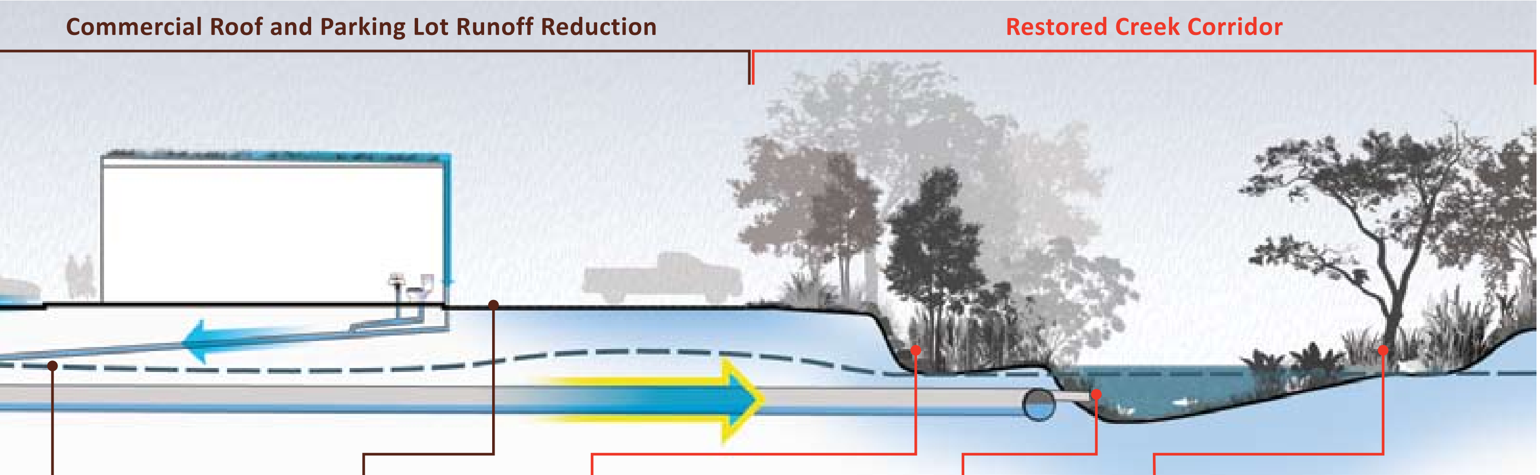


Water table/creek base flow level is lower due to reduced infiltration of stormwater.

Creek banks degrade and lose native plants due to runoff and frequent flooding; become overwhelmed with agressive invasive plants.

Frequent overflows release untreated sewage and unfiltered stormwater into creek.

High flow velocities erode and widen the creek and make it less habitable for fish, wildlife, plants and people.



Water table/creek base flow level is higher, ensuring drinking water supply.

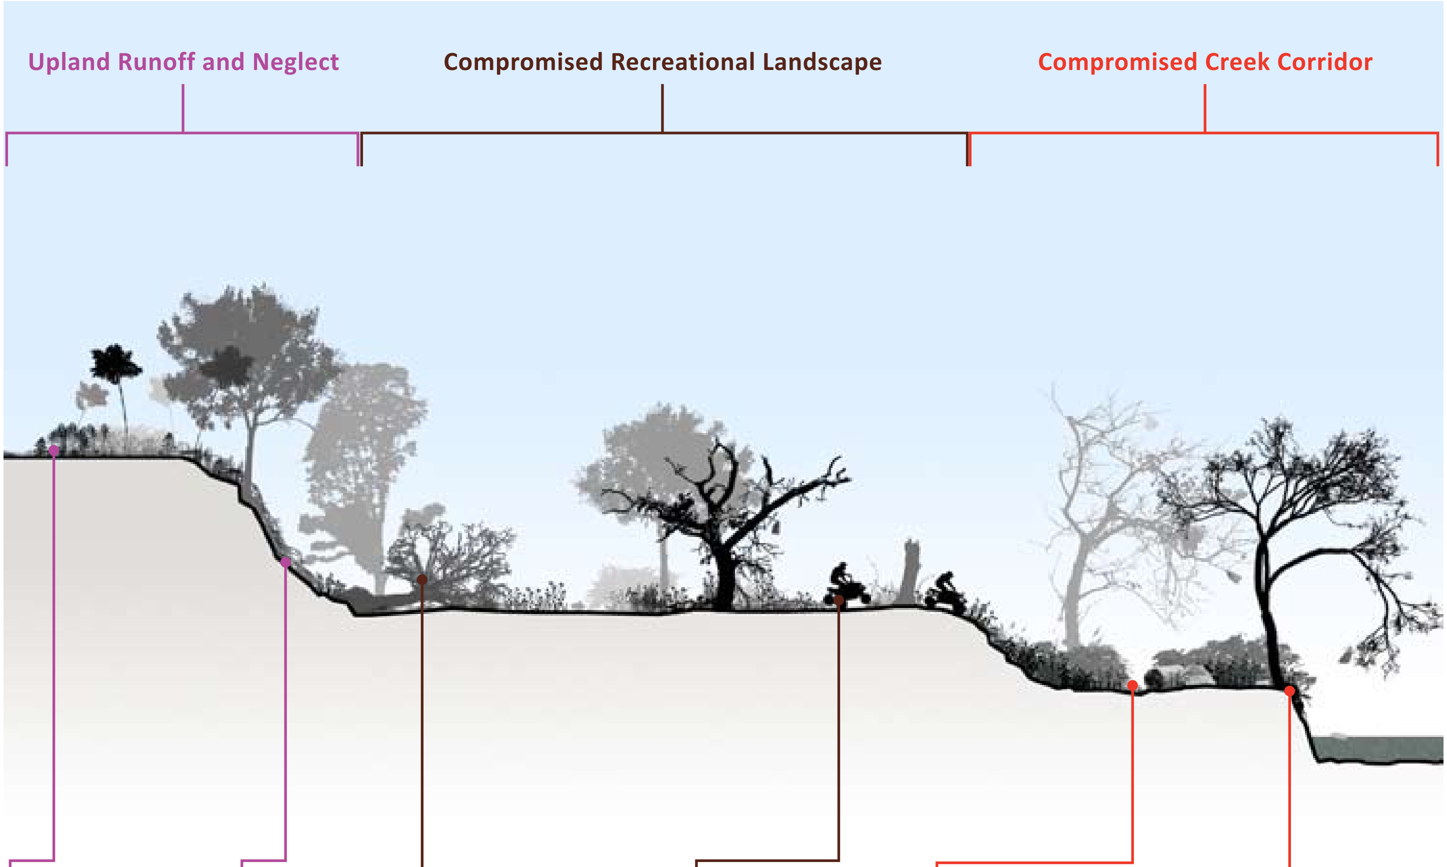
Pervious parking surfaces near the creek reduce runoff.

Reduced runoff and contamination and fewer flood events allow banks to host native plants and wildlife.

Fewer combined sewer overflow events.

Reduced runoff permits slower creek flows, more naturalized channels, and a healthier creek environment.

Frequent flooding degrades landscapes and makes investment in development and maintenance difficult.



Adjacent upland parcels have little investment value.

Slopes are undermined by runoff.

The landscape is unhealthy and suffers from illegal dumping and invasive vegetation.

Neglected public lands encourage illegal recreation.

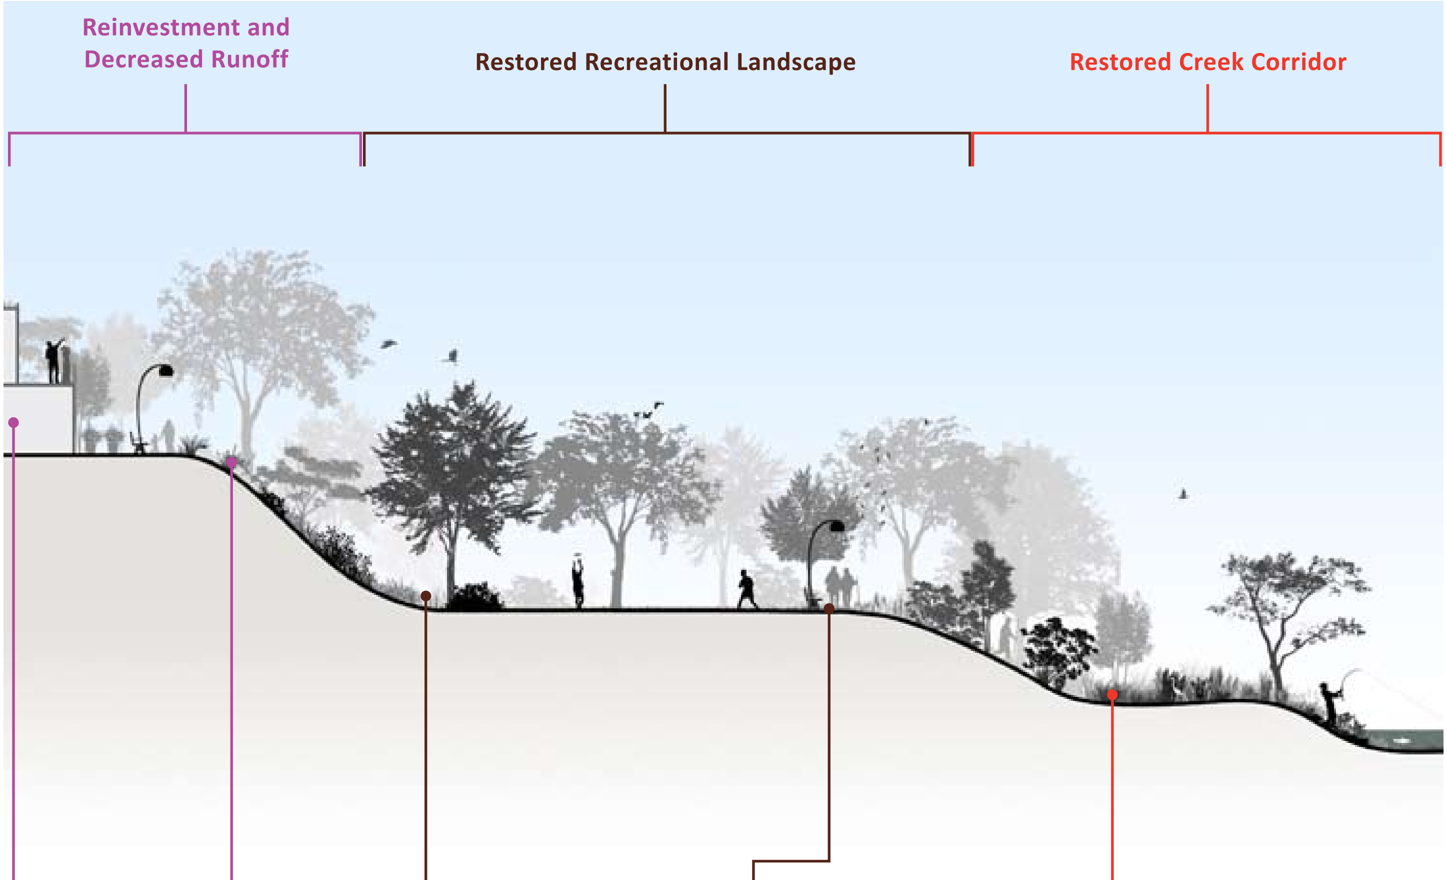
Frequent floods strip floodplains of native vegetation, encourage invasives, deposit debris and compromise the recreational and ecological value of adjacent lands.

Creek banks are steeply eroded.

Fertile Ground
For Distinctive Recreation

Restoration of the floodplain creates spaces for recreation and development sites, enhanced by proximity to the creek.

Watershed-wide stormwater management halts cycles of damage and allows for sustainable investment.



A restored creek landscape can increase its value to the community and encourage nearby investments.

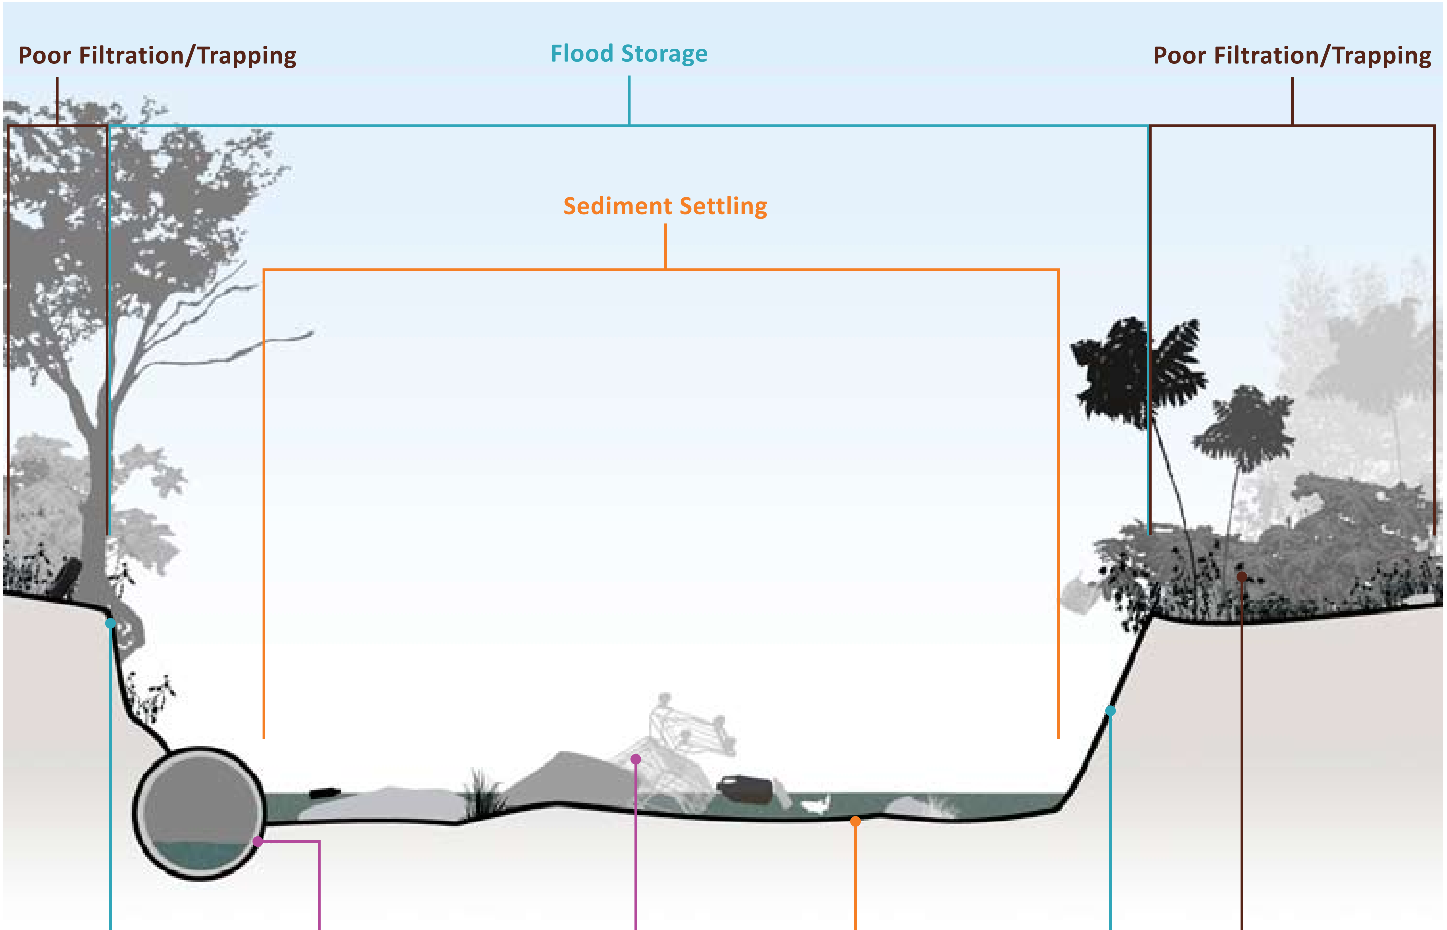
Decreased runoff allows for rehabilitation of upland slopes with native plants.

Reduced flooding and runoff allows for reclaimed parkland that is healthier and more valuable.

Investments in landscape features and park maintenance support diverse and enhanced recreation.

Restored floodplains and creek channels increase flood storage capacity, improve habitat, and encourage community access.

An UNHEALTHY creek corridor cannot perform essential ecological functions.



Flood waters erode creek banks, washing away valuable soil and native vegetation. Banks are left bare or are overcome by aggressive invasive plants.

Bank erosion exposes the sewer system infrastructure, leaving pipes and manholes susceptible to damage.

Trash and debris overwhelm the landscape.

Fast-moving flood waters wash away sediment, which is critical to the health of the creek habitat. Without sediment, fish habitat and food wash away.

Creek banks become steeply eroded after floods, creating a wide, shallow creek during dry weather.

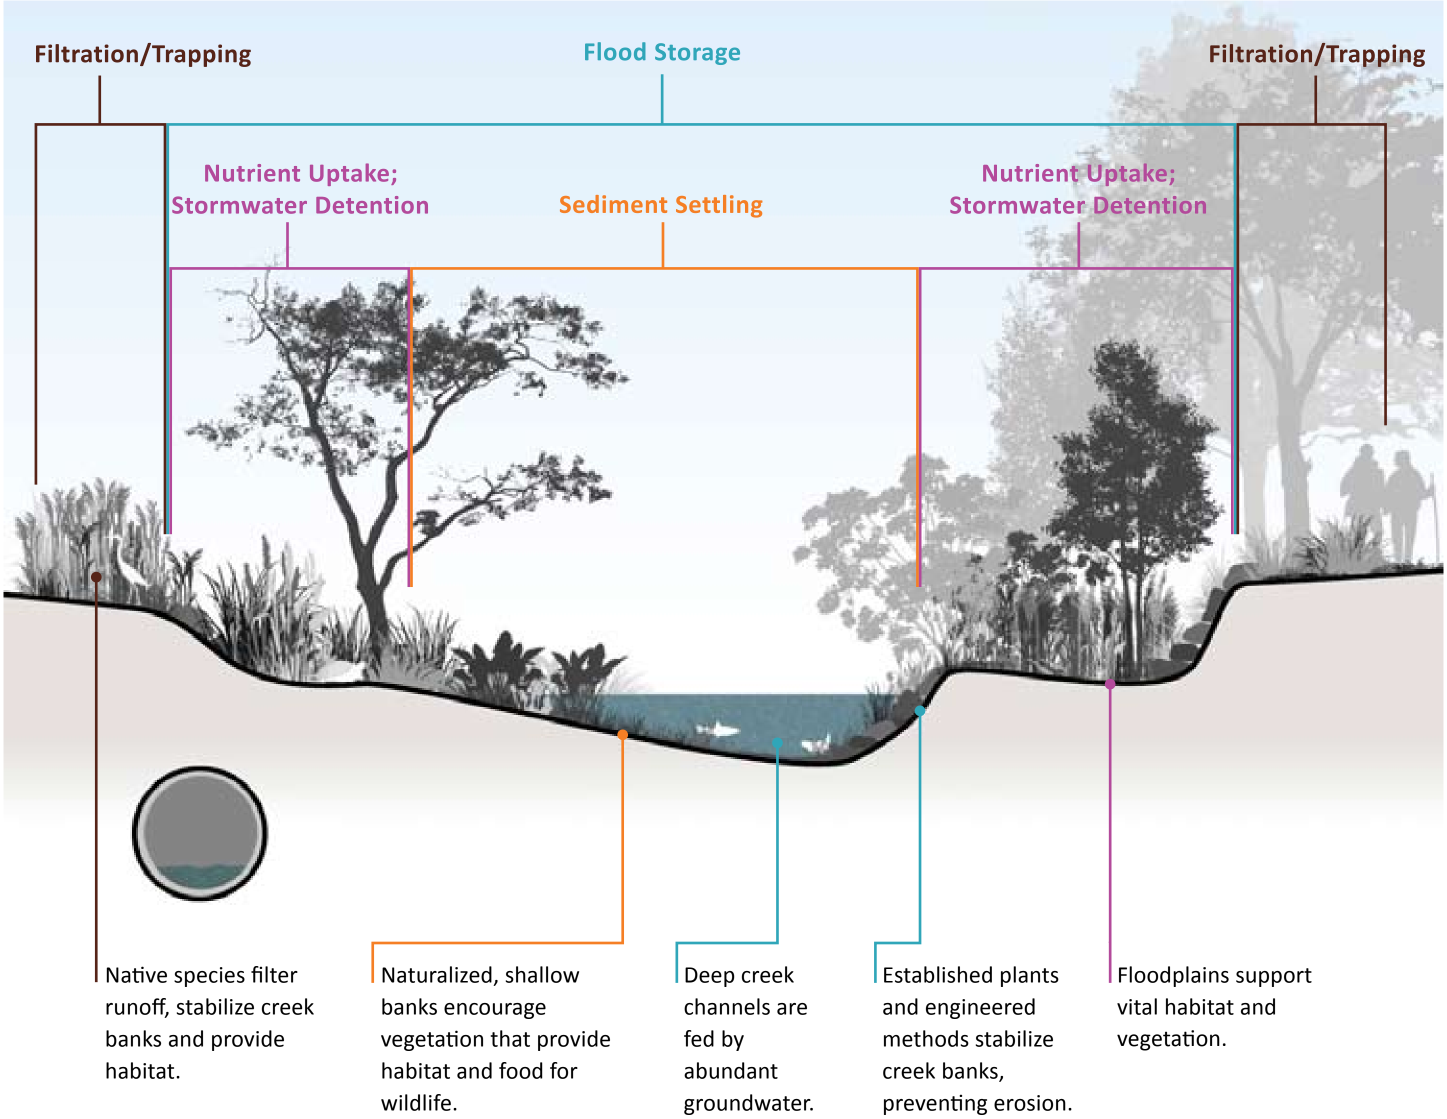
Invasive species overtake compromised creek banks, decreasing its habitat value and increasing maintenance costs.

Fertile Ground

For Healthy Creeks

Creek restoration repairs scoured and littered creek beds, improves water quality and allows native plants and animals to flourish.

A HEALTHY creek corridor performs critical ecological functions.



Native species filter runoff, stabilize creek banks and provide habitat.

Naturalized, shallow banks encourage vegetation that provide habitat and food for wildlife.

Deep creek channels are fed by abundant groundwater.

Established plants and engineered methods stabilize creek banks, preventing erosion.

Floodplains support vital habitat and vegetation.

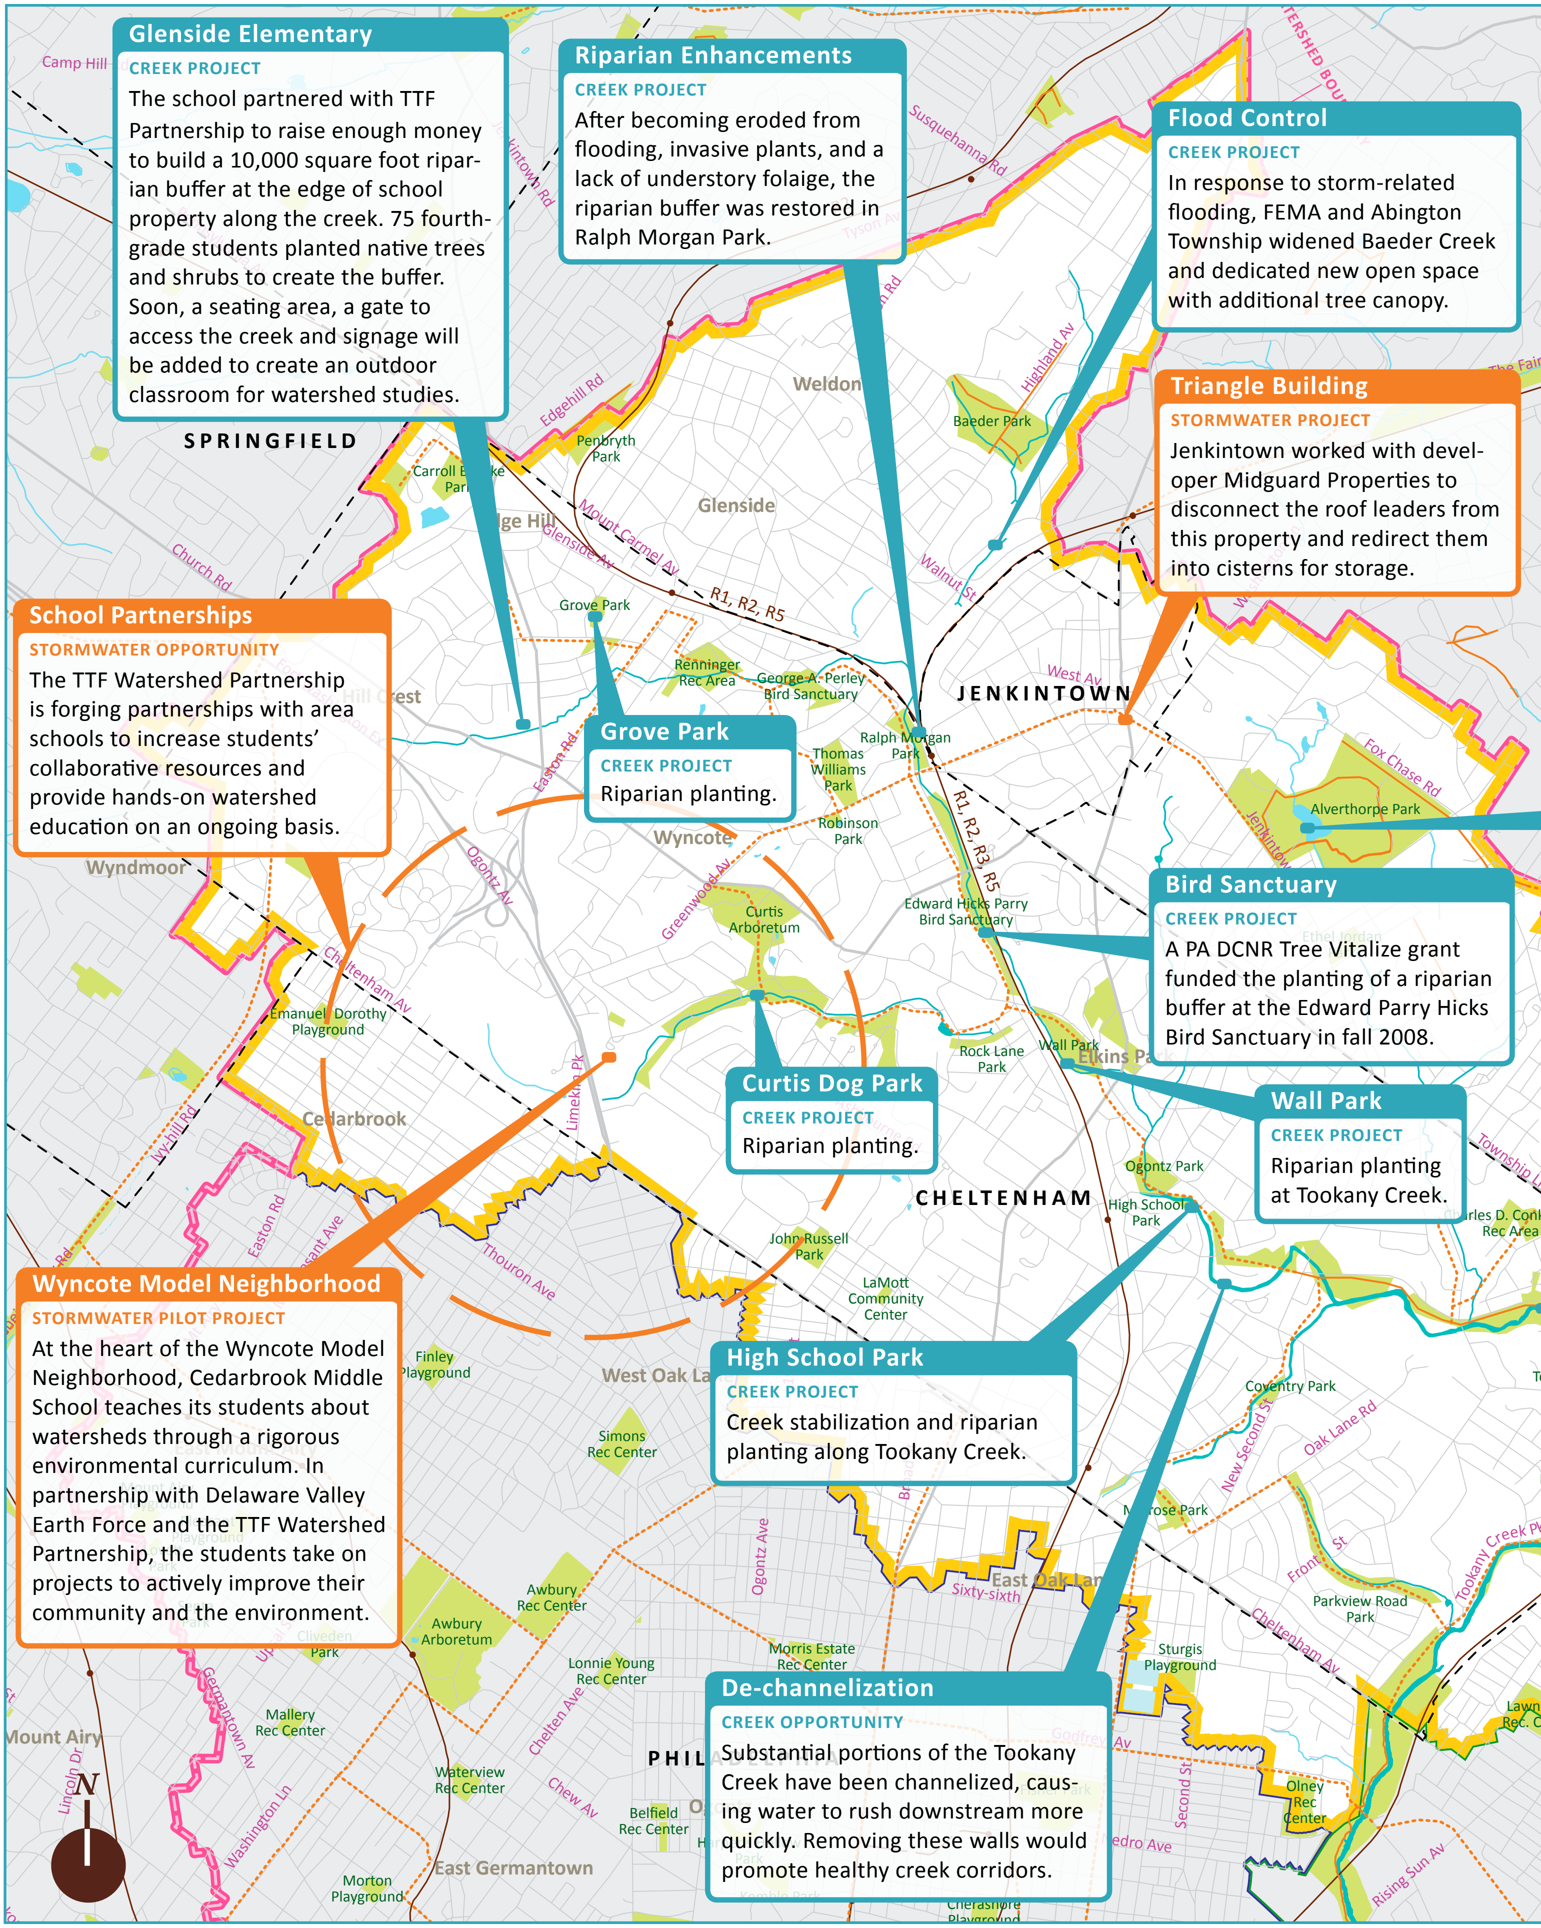
The Tookany/Tacony-Frankford watershed can be divided into five sub-watersheds.

The following pages outline the current conditions and vision for each.



Glenside Elementary

CREEK PROJECT

The school partnered with TTF Partnership to raise enough money to build a 10,000 square foot riparian buffer at the edge of school property along the creek. 75 fourth-grade students planted native trees and shrubs to create the buffer. Soon, a seating area, a gate to access the creek and signage will be added to create an outdoor classroom for watershed studies.

Riparian Enhancements

CREEK PROJECT

After becoming eroded from flooding, invasive plants, and a lack of understory folaige, the riparian buffer was restored in Ralph Morgan Park.

Flood Control

CREEK PROJECT

In response to storm-related flooding, FEMA and Abington Township widened Baeder Creek and dedicated new open space with additional tree canopy.

Triangle Building

STORMWATER PROJECT

Jenkintown worked with developer Midguard Properties to disconnect the roof leaders from this property and redirect them into cisterns for storage.

School Partnerships

STORMWATER OPPORTUNITY

The TTF Watershed Partnership is forging partnerships with area schools to increase students' collaborative resources and provide hands-on watershed education on an ongoing basis.

Grove Park

CREEK PROJECT

Riparian planting.

Bird Sanctuary

CREEK PROJECT

A PA DCNR Tree Vitalize grant funded the planting of a riparian buffer at the Edward Parry Hicks Bird Sanctuary in fall 2008.

Curtis Dog Park

CREEK PROJECT

Riparian planting.

Wall Park

CREEK PROJECT

Riparian planting at Tookany Creek.

Wyncote Model Neighborhood

STORMWATER PILOT PROJECT

At the heart of the Wyncote Model Neighborhood, Cedarbrook Middle School teaches its students about watersheds through a rigorous environmental curriculum. In partnership with Delaware Valley Earth Force and the TTF Watershed Partnership, the students take on projects to actively improve their community and the environment.

High School Park

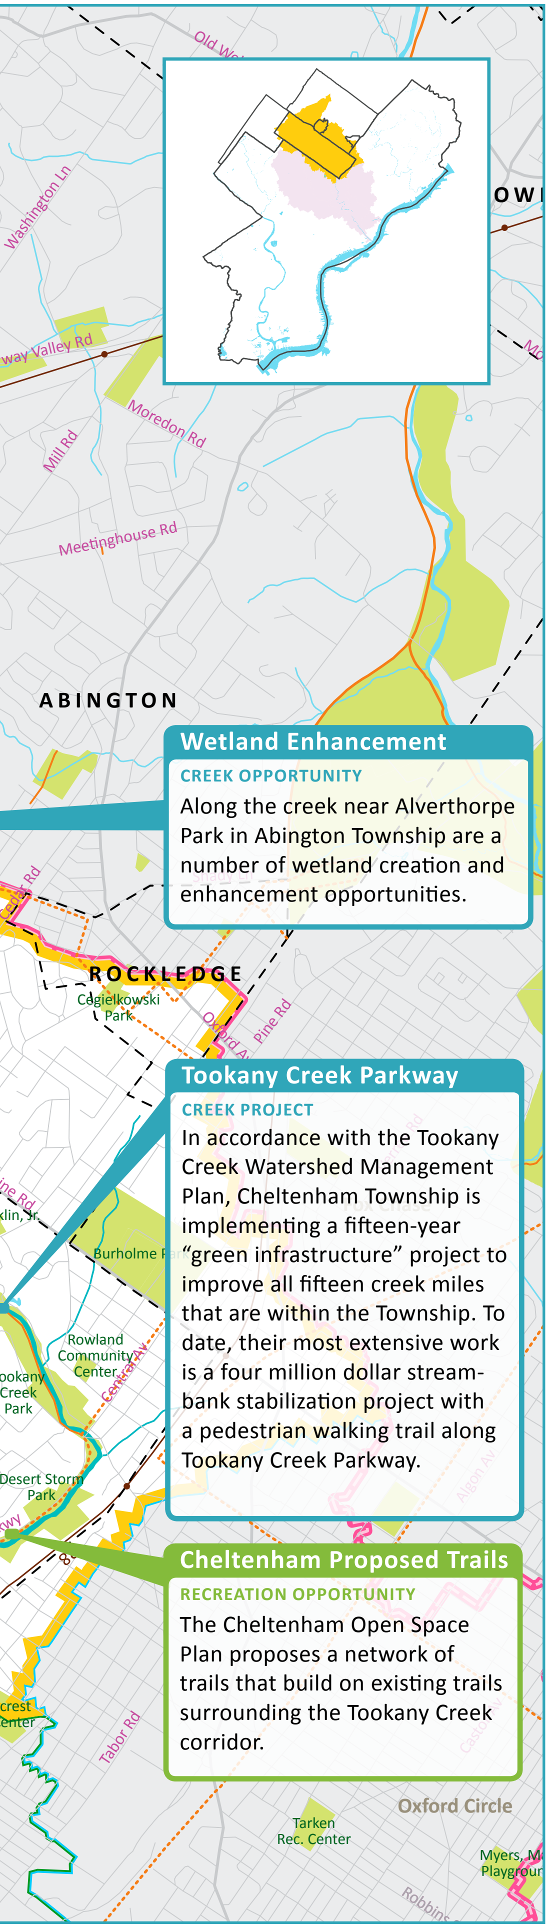
CREEK PROJECT

Creek stabilization and riparian planting along Tookany Creek.

De-channelization

CREEK OPPORTUNITY

Substantial portions of the Tookany Creek have been channelized, causing water to rush downstream more quickly. Removing these walls would promote healthy creek corridors.



Wetland Enhancement

CREEK OPPORTUNITY

Along the creek near Alverthorpe Park in Abington Township are a number of wetland creation and enhancement opportunities.

Tookany Creek Parkway

CREEK PROJECT

In accordance with the Tookany Creek Watershed Management Plan, Cheltenham Township is implementing a fifteen-year “green infrastructure” project to improve all fifteen creek miles that are within the Township. To date, their most extensive work is a four million dollar streambank stabilization project with a pedestrian walking trail along Tookany Creek Parkway.

Cheltenham Proposed Trails

RECREATION OPPORTUNITY

The Cheltenham Open Space Plan proposes a network of trails that build on existing trails surrounding the Tookany Creek corridor.

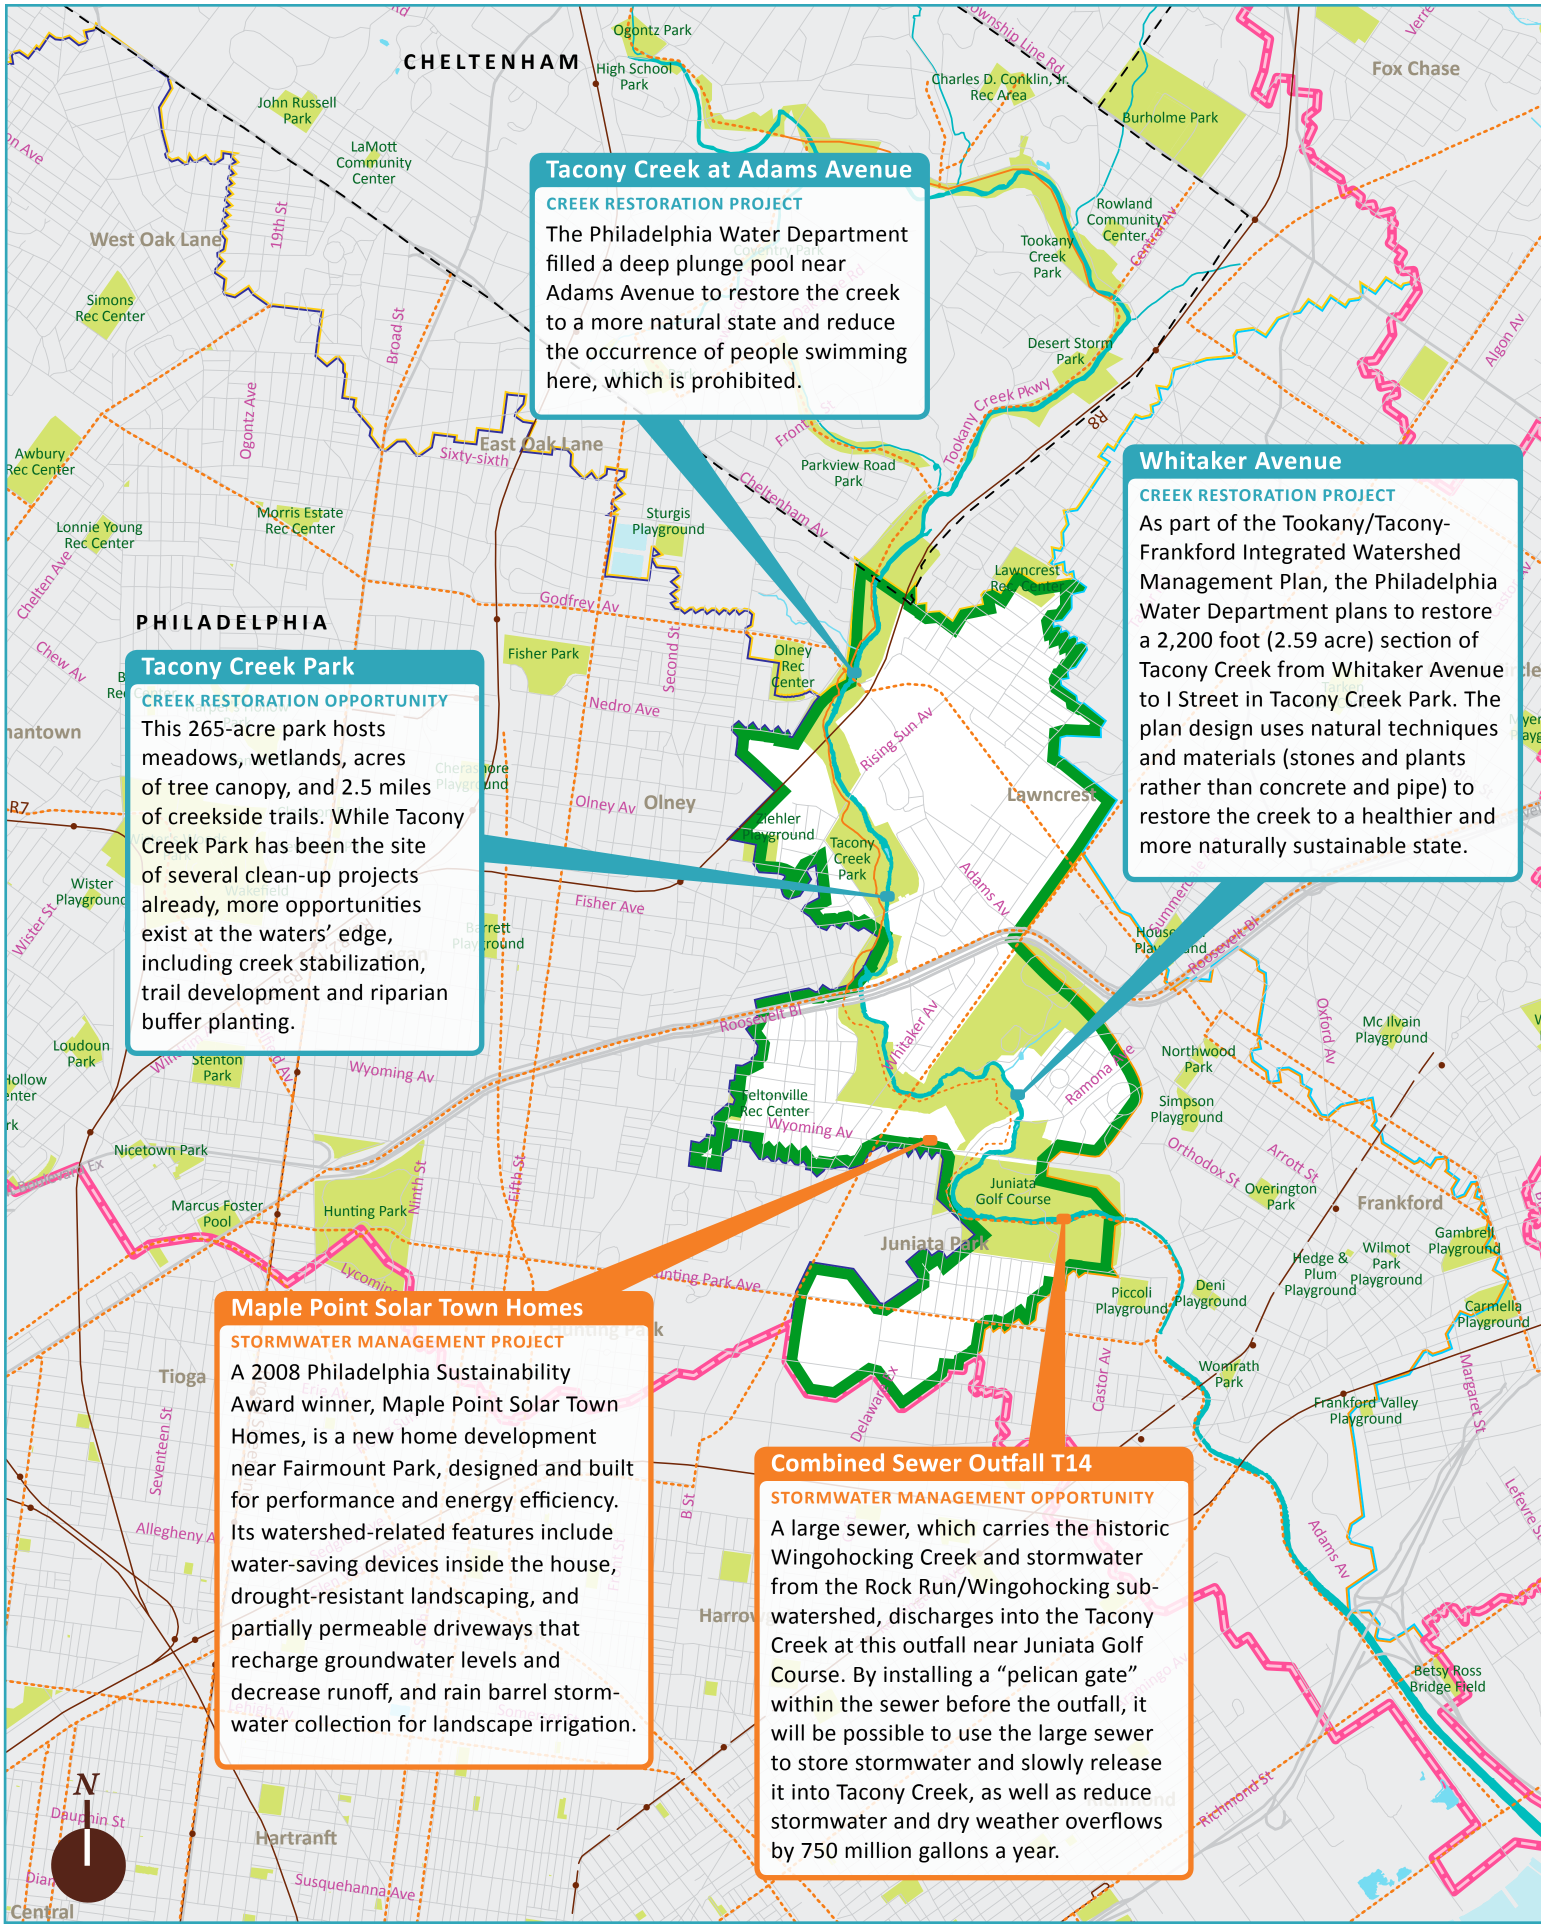
Tookany
sub-watershed

The Tookany sub-watershed exists mostly in Cheltenham and Jenkintown Townships. Tookany Creek flows through a mostly suburban landscape, and, unlike its urban environs downstream, benefits from a lower density of buildings on its banks, as well as open space, trails and greenways. Also, the communities around the creek have sponsored creek enhancements and community programs that focus on watershed health. This sub-watershed also hosts a developing “model neighborhood” described at left.

Despite these measures, the creek suffers the impacts of development, including clear-cutting of its banks, short dumping and litter, invasive species, stormwater surcharges, creek channelization, and incompatible land uses along its banks, like impervious parking lots.

Top: *Tookany Creek at Cedarbrook Middle School, where the creek acts as a classroom and forum for watershed education. Philadelphia Water Department’s T1 interceptor releases overflow just upstream of this site.* ***Middle***: *At Wall Park, there is evidence of the plights of the creek common to this reach: parking lots and surface impermeability at the edge of creek banks, invasive plants, litter and creek channelization (beyond the footbridge).* ***Bottom***: *While de-channelization was not an option at several points along the Tookany in Tookany Creek Park, other bank rehabilitation treatments were employed, including riparian buffers and invasives management. Additionally, the trail at right is a community resource and its upstream expansion is planned.*

Photosim showing potential improvements within the Tookany subwatershed to be developed.



Tacony Creek at Adams Avenue

CREEK RESTORATION PROJECT

The Philadelphia Water Department filled a deep plunge pool near Adams Avenue to restore the creek to a more natural state and reduce the occurrence of people swimming here, which is prohibited.

Whitaker Avenue

CREEK RESTORATION PROJECT

As part of the Tookany/Tacony-Frankford Integrated Watershed Management Plan, the Philadelphia Water Department plans to restore a 2,200 foot (2.59 acre) section of Tacony Creek from Whitaker Avenue to I Street in Tacony Creek Park. The plan design uses natural techniques and materials (stones and plants rather than concrete and pipe) to restore the creek to a healthier and more naturally sustainable state.

Tacony Creek Park

CREEK RESTORATION OPPORTUNITY

This 265-acre park hosts meadows, wetlands, acres of tree canopy, and 2.5 miles of creekside trails. While Tacony Creek Park has been the site of several clean-up projects already, more opportunities exist at the waters' edge, including creek stabilization, trail development and riparian buffer planting.

Maple Point Solar Town Homes

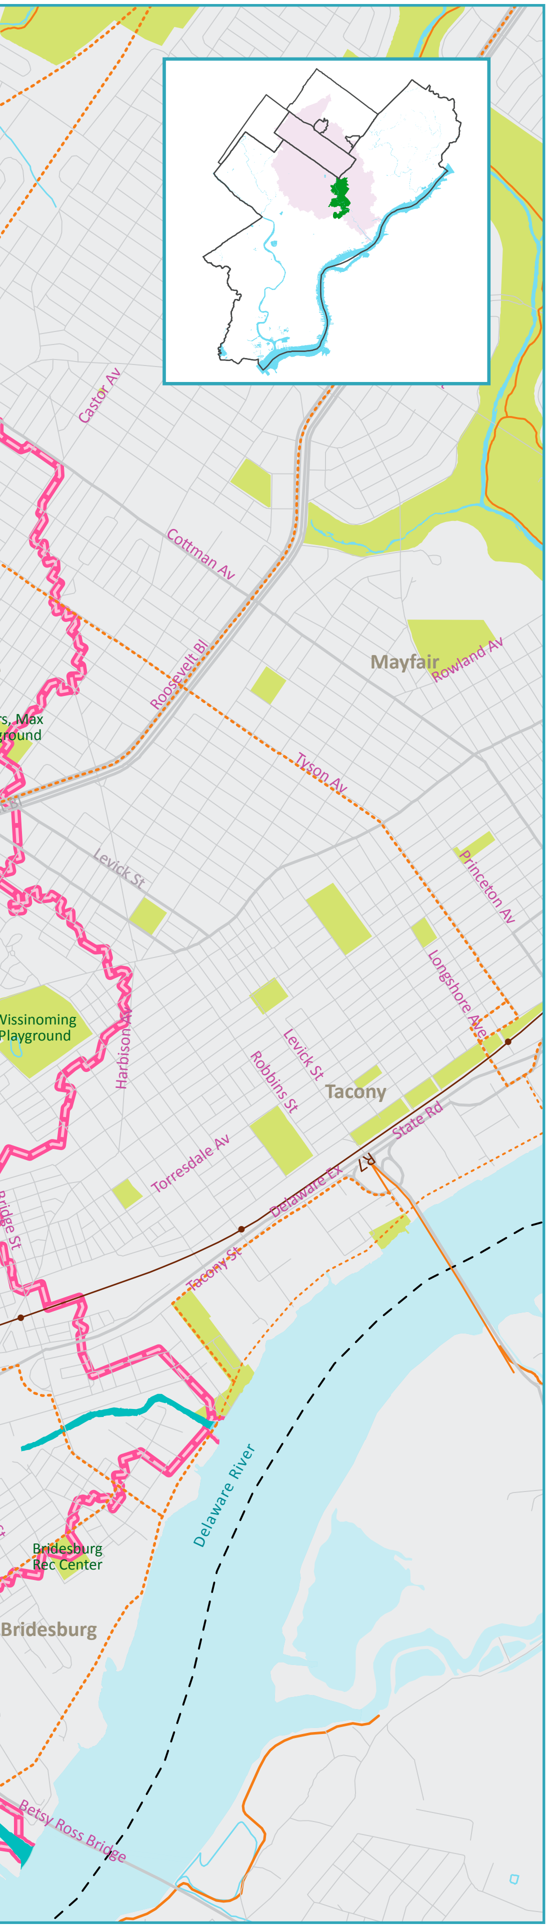
STORMWATER MANAGEMENT PROJECT

A 2008 Philadelphia Sustainability Award winner, Maple Point Solar Town Homes, is a new home development near Fairmount Park, designed and built for performance and energy efficiency. Its watershed-related features include water-saving devices inside the house, drought-resistant landscaping, and partially permeable driveways that recharge groundwater levels and decrease runoff, and rain barrel stormwater collection for landscape irrigation.

Combined Sewer Outfall T14

STORMWATER MANAGEMENT OPPORTUNITY

A large sewer, which carries the historic Wingohocking Creek and stormwater from the Rock Run/Wingohocking sub-watershed, discharges into the Tacony Creek at this outfall near Juniata Golf Course. By installing a "pelican gate" within the sewer before the outfall, it will be possible to use the large sewer to store stormwater and slowly release it into Tacony Creek, as well as reduce stormwater and dry weather overflows by 750 million gallons a year.



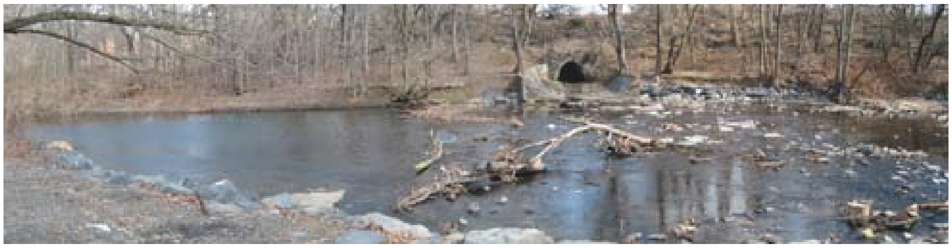
Tacony
sub-watershed

With its northern edge at the Philadelphia border, and its southern edge at the outfall that drains the entire Wingohocking sub-watershed, the Tacony sub-watershed not only performs myriad functions within the larger watershed but also reflects some of its biggest issues. 3 miles of creek banks are enveloped by Tacony Creek Park and other large open spaces like Juniata Golf Course. The functions of these open spaces represent an incredible opportunity to not only restore watershed functions, but also to regenerate valuable community open space and recreational programs for the Olney, Juniata Park and Lawncrest neighborhoods — and beyond.

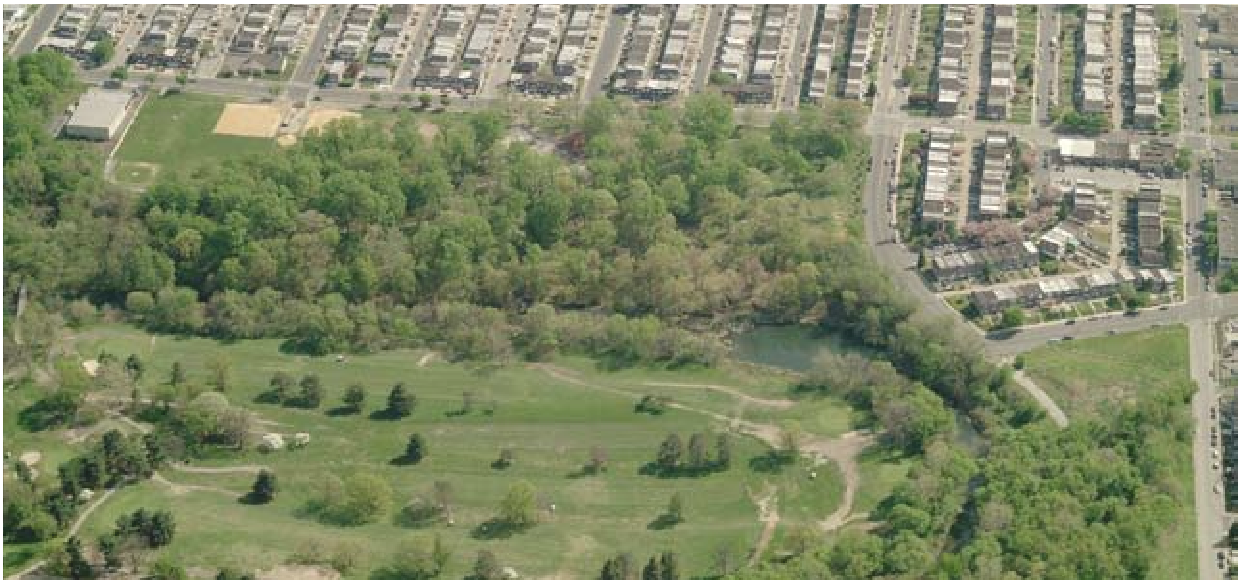
Top*: A trail meanders through a largely unmanaged floodplain landscape in Tacony Creek Park. Utilizing neglected floodplains for open recreational use is a characteristic opportunity within this sub-watershed.*

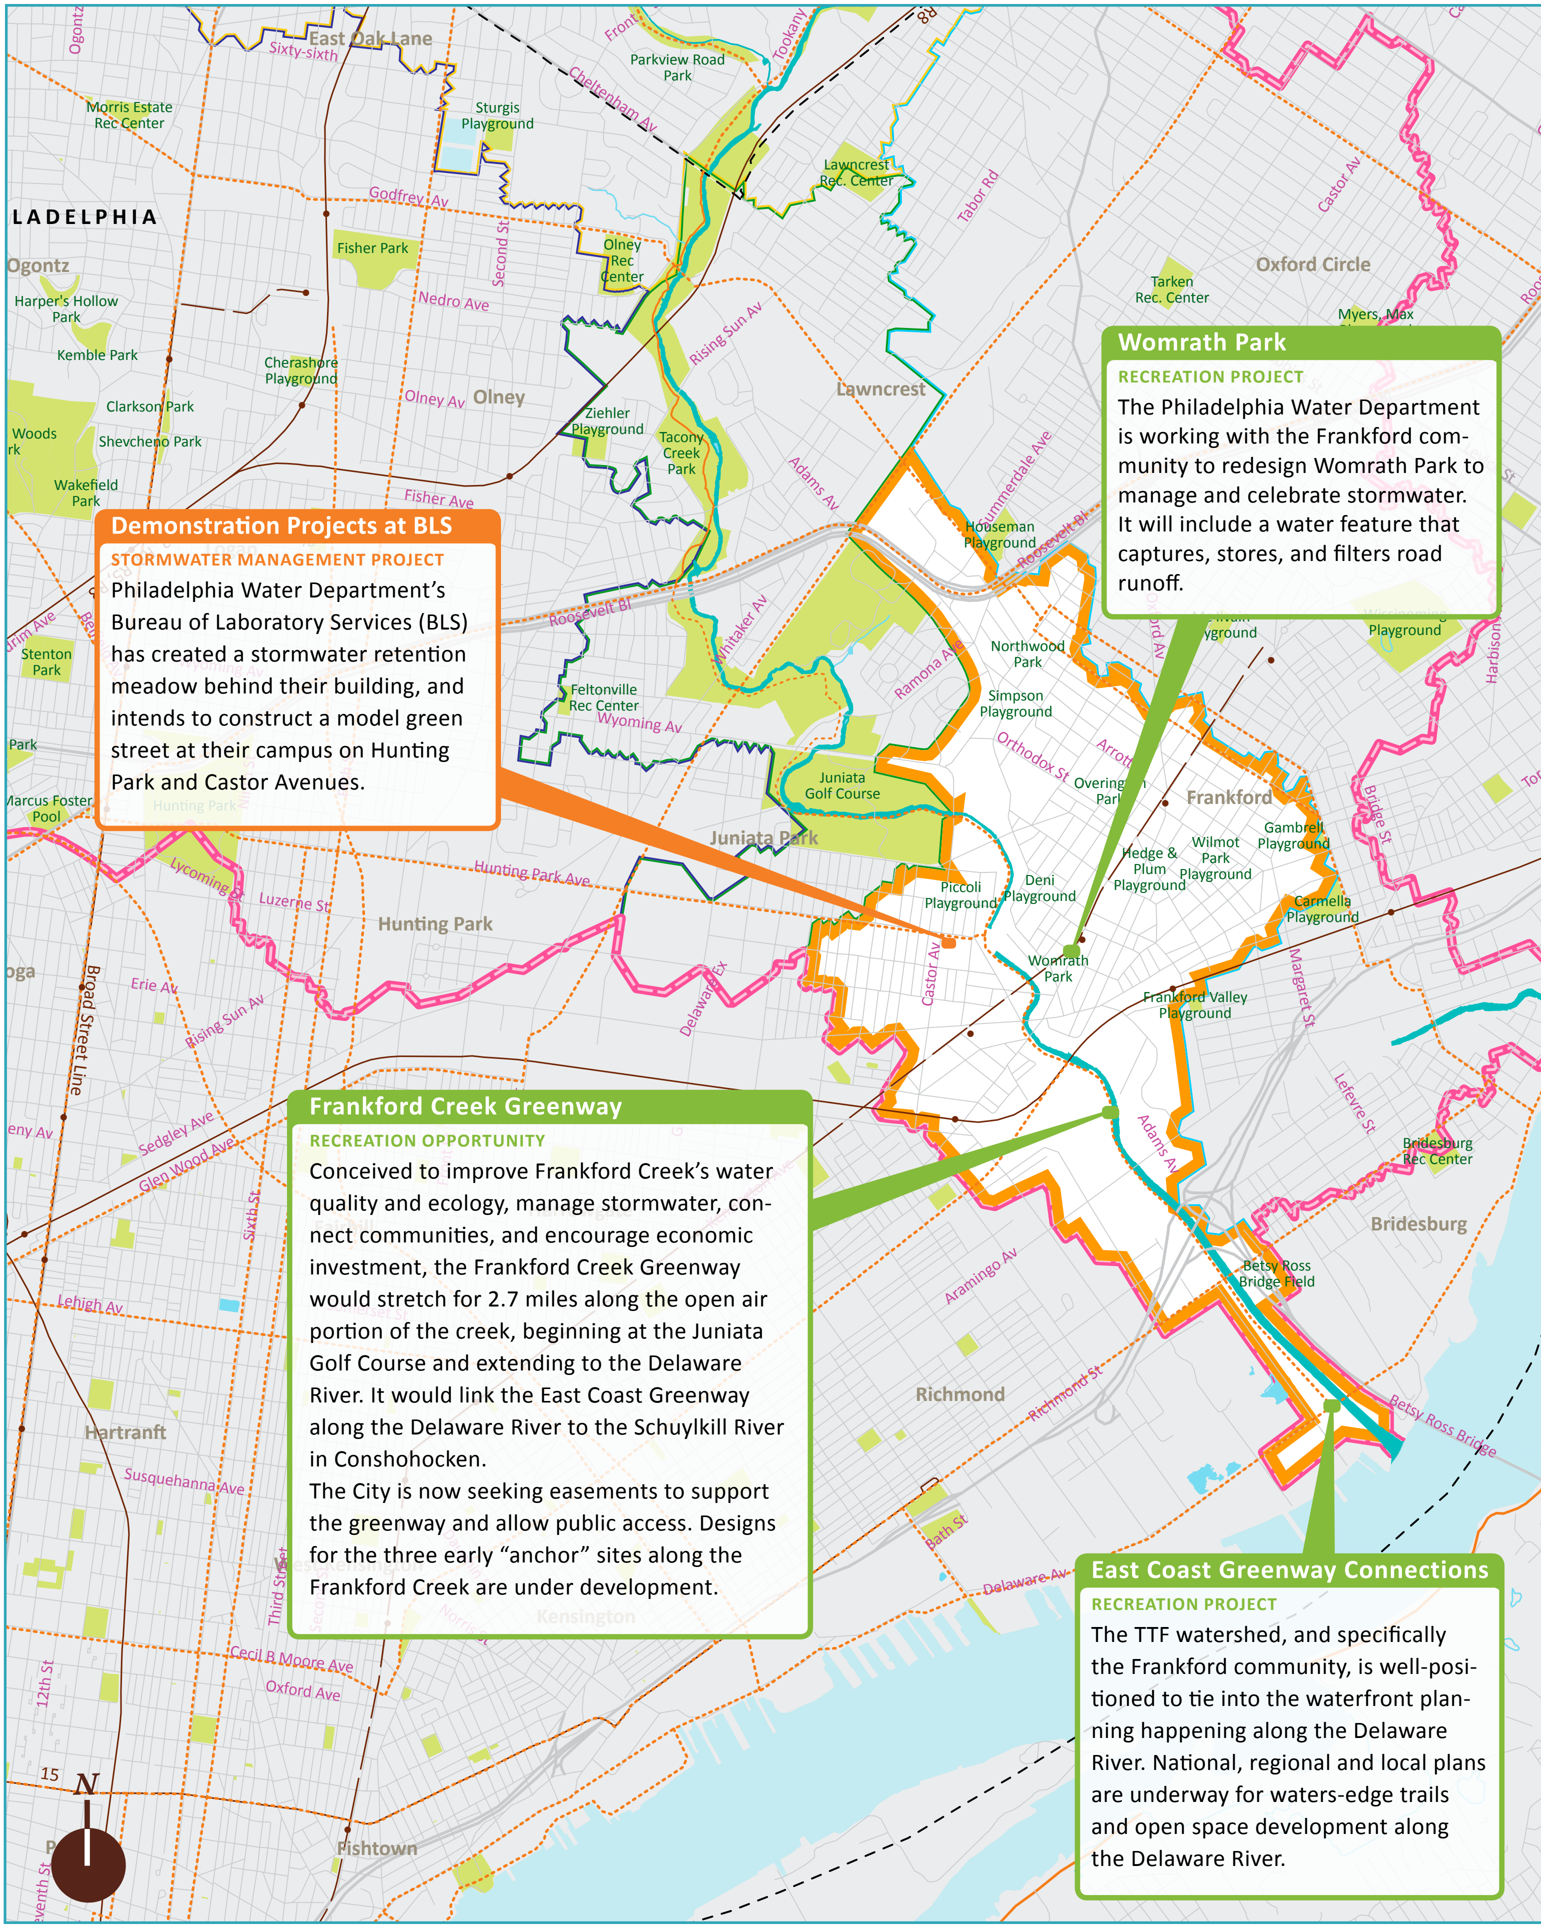
Middle*: The effects of overflow events on the creek are clearly evident at the confluence with the T6 outfall. Forceful water flows during storms have widened the creek creating low base flow, and debris and litter abound. PWD’s Waterways Restoration Team has shored up the banks (foreground) to prevent further erosion. Looking upstream, to the left, reveals the character of the creek before the outfall.*

Bottom*: Just north of Roosevelt Boulevard, the 17-foot wide T8 outfall drains into the creek. Years of overflows have altered the creek’s meander, which now flows under the furthest arch in the bridge instead of through the middle. Major work is needed to restore the integrity of the creek and its surroundings and permit a trail crossing under the bridge.*



The Tacony Creek winds through Juniata Golf Course, and many acres of the course lie within the natural floodplain of the creek. Carefully designed wetlands that can handle the seasonal stormwater floods will reduce downstream impacts, creating a place of both functional and aesthetic value, while upland interventions like green roofs, cisterns, and green streets will reduce overflow events.





Demonstration Projects at BLS

STORMWATER MANAGEMENT PROJECT

Philadelphia Water Department's Bureau of Laboratory Services (BLS) has created a stormwater retention meadow behind their building, and intends to construct a model green street at their campus on Hunting Park and Castor Avenues.

Womrath Park

RECREATION PROJECT

The Philadelphia Water Department is working with the Frankford community to redesign Womrath Park to manage and celebrate stormwater. It will include a water feature that captures, stores, and filters road runoff.

Frankford Creek Greenway

RECREATION OPPORTUNITY

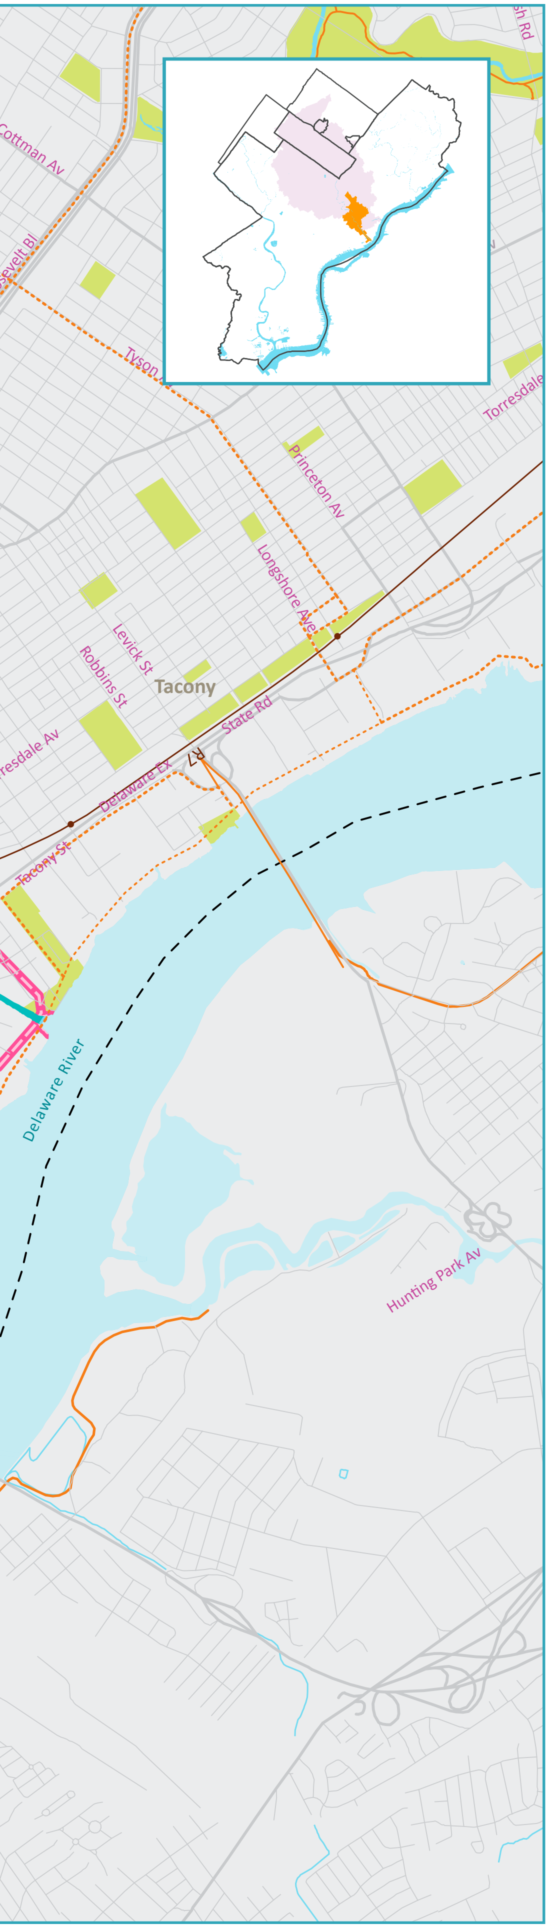
Conceived to improve Frankford Creek's water quality and ecology, manage stormwater, connect communities, and encourage economic investment, the Frankford Creek Greenway would stretch for 2.7 miles along the open air portion of the creek, beginning at the Juniata Golf Course and extending to the Delaware River. It would link the East Coast Greenway along the Delaware River to the Schuylkill River in Conshohocken.

The City is now seeking easements to support the greenway and allow public access. Designs for the three early "anchor" sites along the Frankford Creek are under development.

East Coast Greenway Connections

RECREATION PROJECT

The TTF watershed, and specifically the Frankford community, is well-positioned to tie into the waterfront planning happening along the Delaware River. National, regional and local plans are underway for waters-edge trails and open space development along the Delaware River.



Frankford
sub-watershed

The Frankford sub-watershed hosts a creek channel surrounded by one the most dense urban areas in the watershed. Much of the creek is channelized, and its health has historically been compromised by upstream impacts. It also has a unique characteristic: it includes the creek's confluence with the Delaware River. This confluence, however, is man-made, created as a flood control measure from 1948-1956.

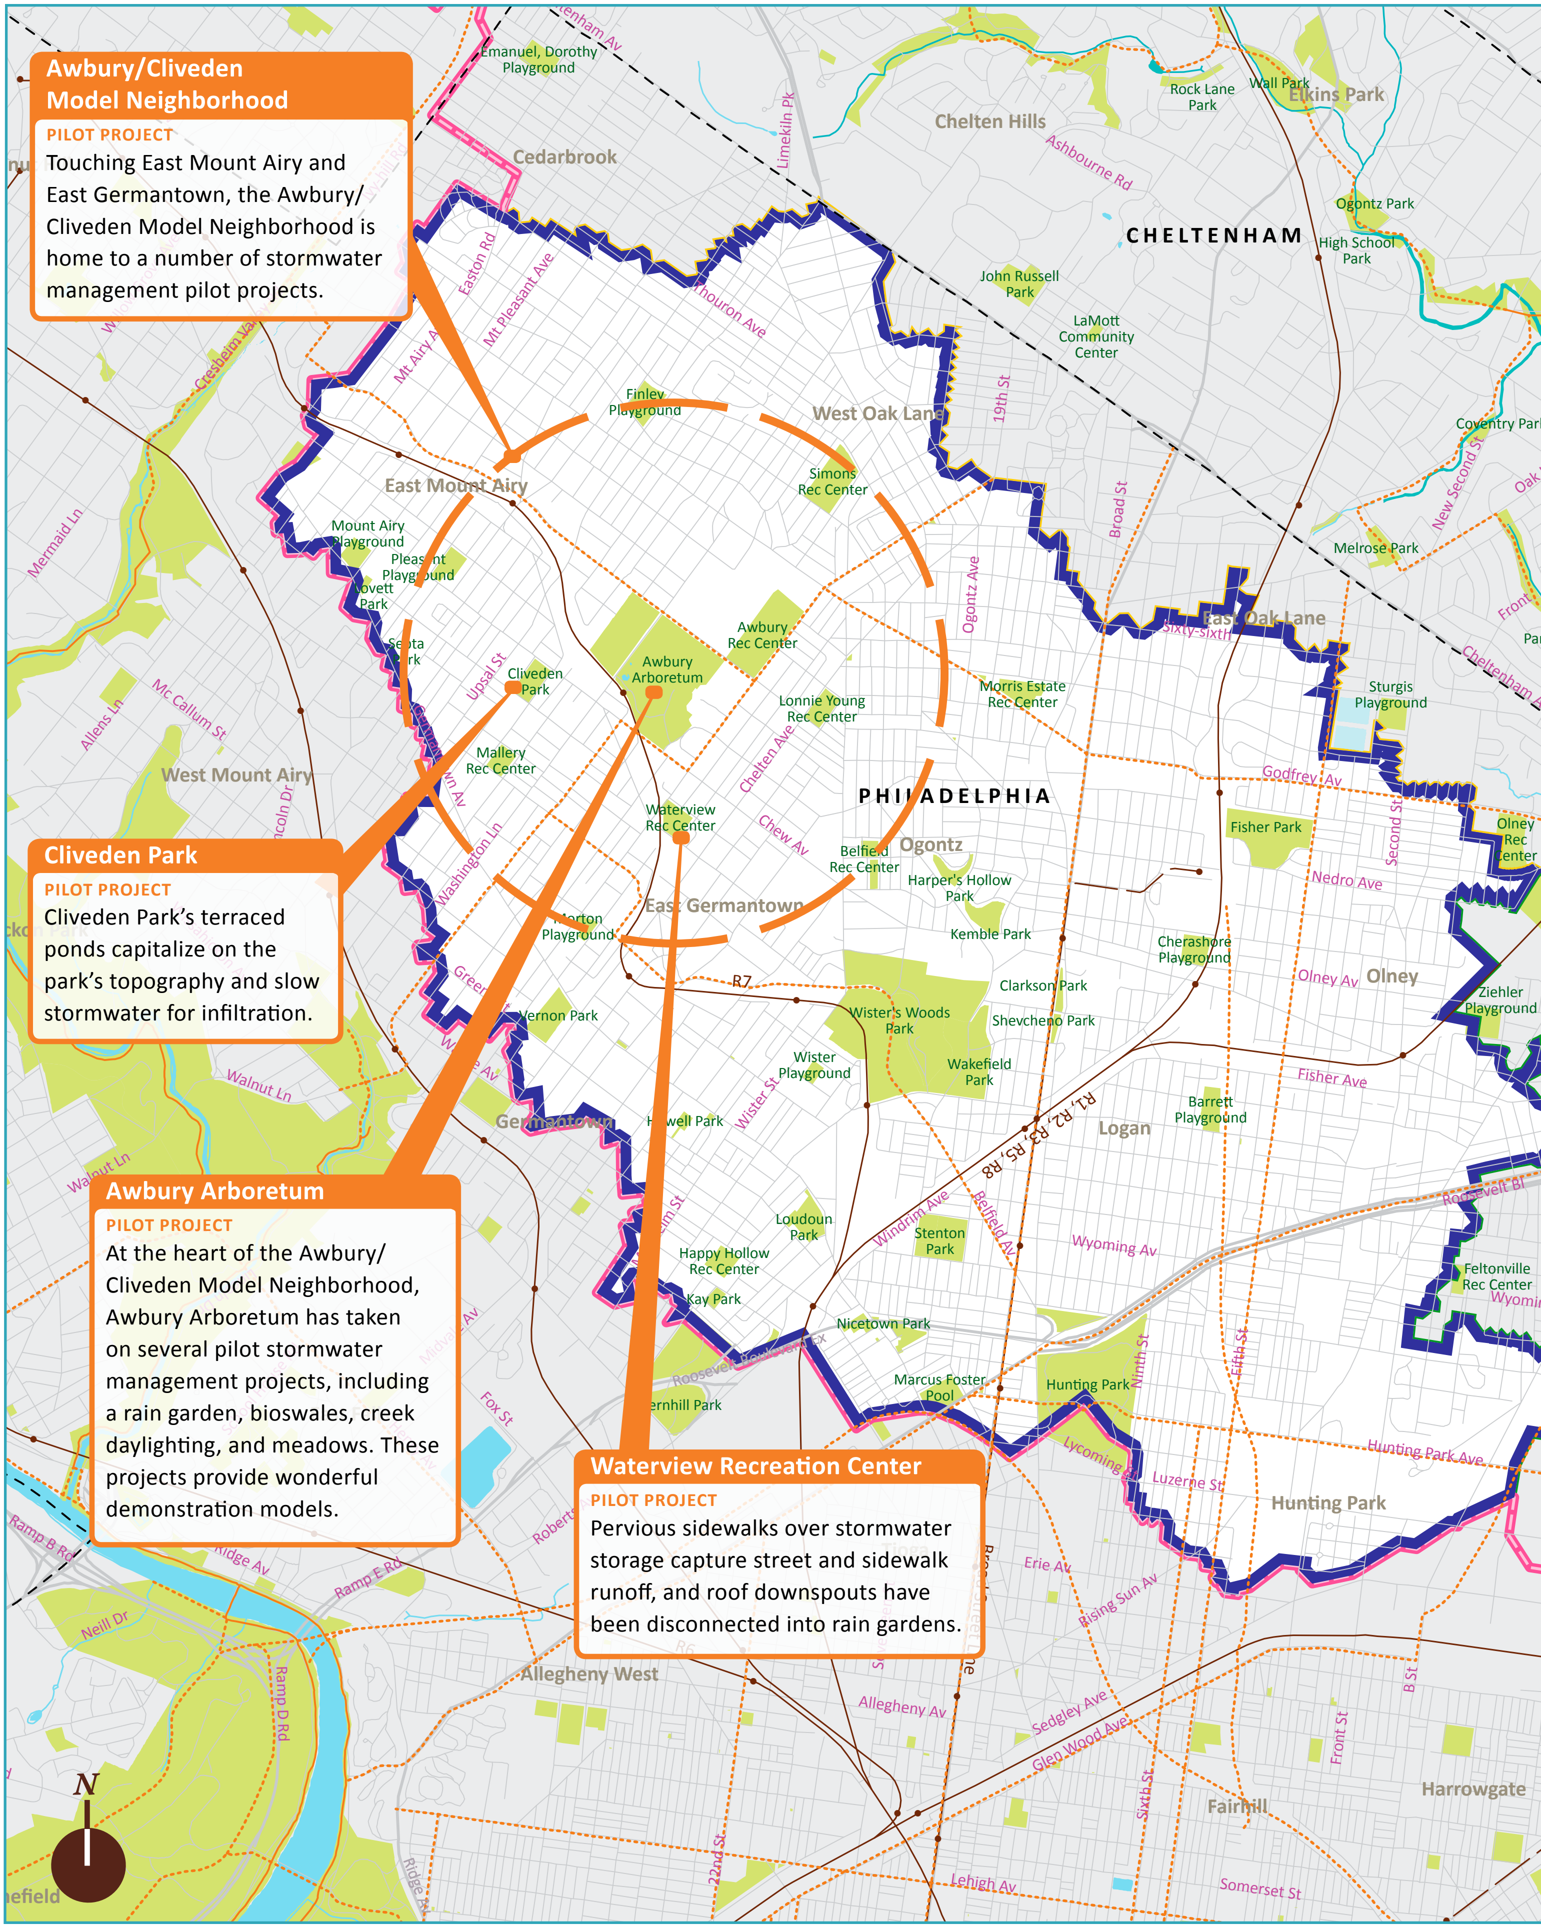
Due to the area's density and the creek's high degree of channelization, opportunities to contribute to the health of the watershed include upland interventions and programs such as green roofs and streets, pervious paving and pocket parks to slow and filter stormwater before entering the creek. There is also the chance to create a greenway along a major portion of the creek, creating much-needed open space and a renewed connection to the creek for the community.

Top left*: Frankford Creek's – and the watershed's – confluence with the Delaware River. The Creek flows into the River just south of the Betsy Ross Bridge fully channelized and through a large industrial area.*

Top right*: Looking upstream at Frankford Creek near the Delaware River, its concrete channelization is revealed, as are the diverse land uses around the creek. They range from light industry to dense residential – all rather impervious – to scrubby fields. Permeable landscapes here could both provide much-needed open space for the community and assist the functions of the watershed.*

Bottom*: Where it is not fully channelized with concrete walls, Frankford Creek is characterized by wide, shallow base flows and severely degraded creek banks due to the erosive forces of floodwaters from further upstream.*

While riparian improvements would be limited in this channelized reach of Frankford Creek, permeability-boosting enhancements to the urban upland, like parks, green roofs, greener streets, pervious paving and even a creek-side greenway would provide much needed open space and vegetation for the community.



Awbury/Cliveden Model Neighborhood

PILOT PROJECT

Touching East Mount Airy and East Germantown, the Awbury/Cliveden Model Neighborhood is home to a number of stormwater management pilot projects.

Cliveden Park

PILOT PROJECT

Cliveden Park's terraced ponds capitalize on the park's topography and slow stormwater for infiltration.

Awbury Arboretum

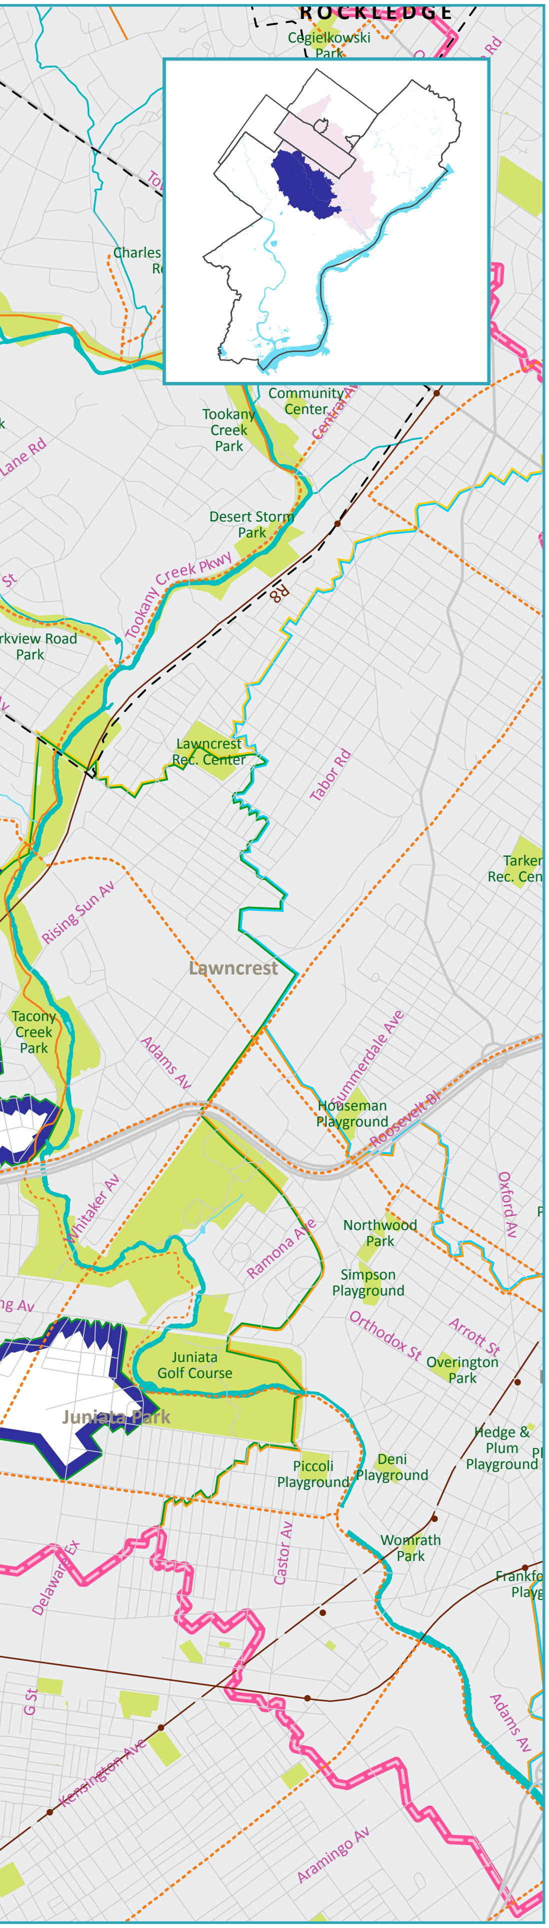
PILOT PROJECT

At the heart of the Awbury/Cliveden Model Neighborhood, Awbury Arboretum has taken on several pilot stormwater management projects, including a rain garden, bioswales, creek daylighting, and meadows. These projects provide wonderful demonstration models.

Waterview Recreation Center

PILOT PROJECT

Pervious sidewalks over stormwater storage capture street and sidewalk runoff, and roof downspouts have been disconnected into rain gardens.



Rock Run/ Wingohocking

sub-watershed

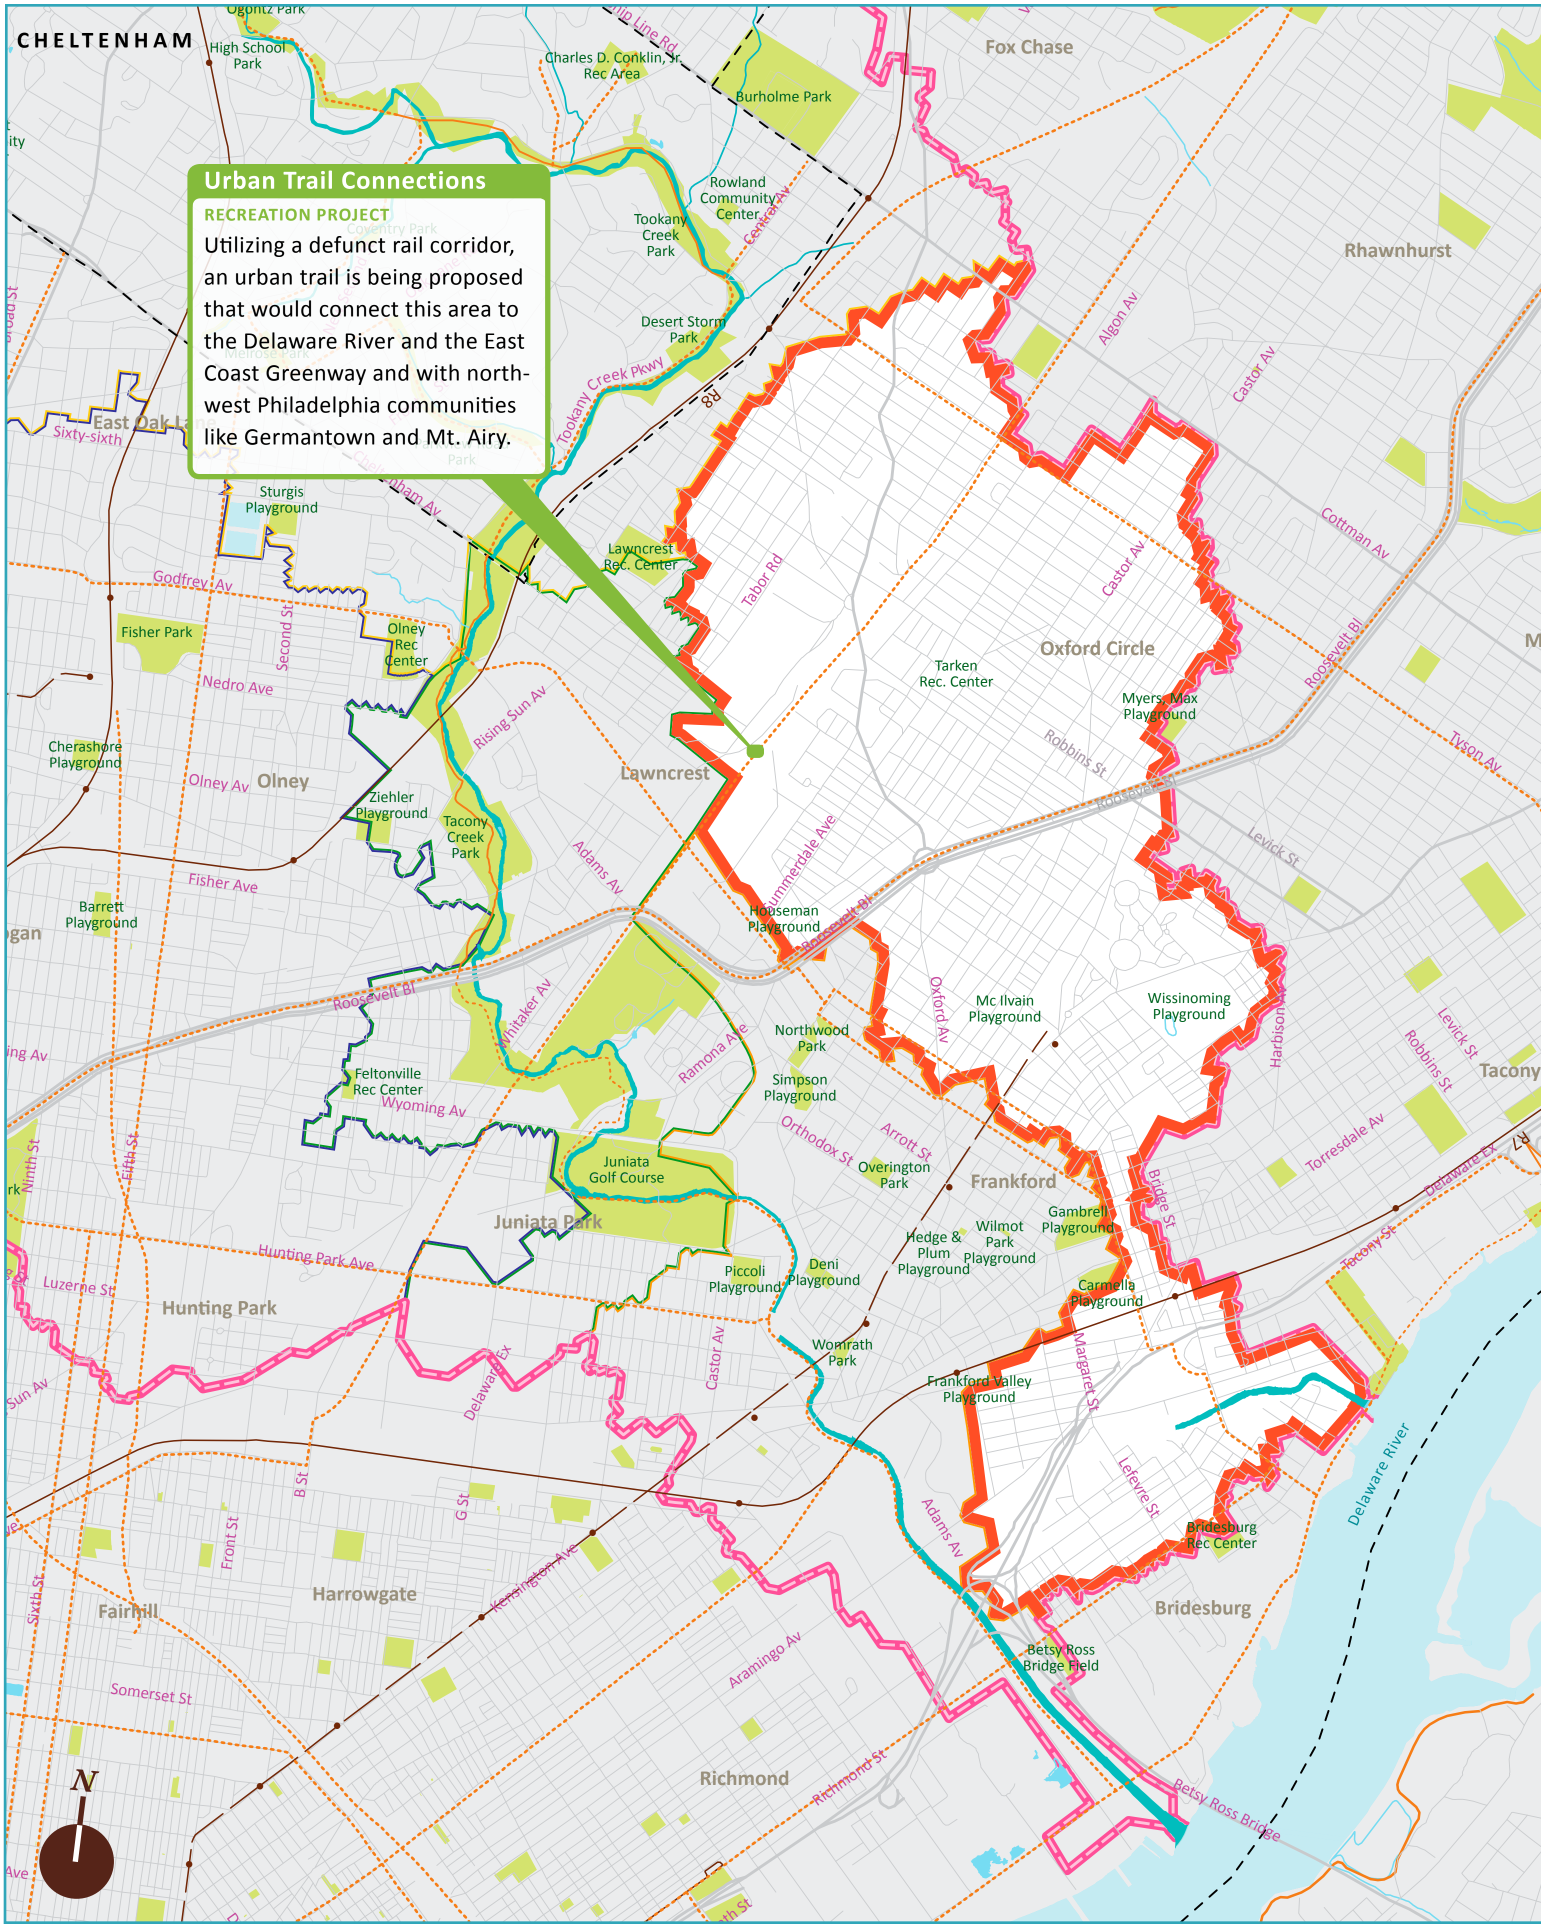
A map of the historic Battle of Germantown in 1777 shows the Wingohocking Creek threading through East Mt. Airy and Germantown. By the 1890s, the historic creek was buried in sewers and streets and houses were built on top of it. It was the largest creek system in the city to be put underground. All of the watershed's piped stormwater (that mixes with wastewater during heavy rains) now drains to a single outfall into the creek near Juniata Golf Course. This sub-watershed exhibits a full gradient of land use, from dense urban neighborhoods near Center City to densely vegetated valleys outside of the city. Parts of this sub-watershed average more tree cover than any other area in Philadelphia. It also boasts plenty of parks, but it still could do better at supporting a healthier watershed by slowing and filtering runoff before it drains away. Steps are being taken to get there: projects and opportunities have been identified in the map shown at left.

*The land use here is diverse, ranging from flat-roofed twin houses with small yards, gardens and mature trees near neighborhood parks (**top left**), to sprawling short-term commercial development with acres of impervious paving (**top right**). Each type of land use has opportunities to positively affect the health of the watershed, from homeowner practices to commercial building guidelines.*

***Bottom left**: Miles of bike trails are planned for this sub-watershed. The green swath running through the photo is a retired rail line near the Juniata Golf Course, which could become a trail that would connect the Tacony Creek with the Schuylkill River.*

***Bottom right**: Using the natural bowl shape of the landscape, this terraced rain garden in Cliveden Park makes an event of rain storms. In warmer months, the three terraced depressions are colonized with plants that slow runoff from the street above.*

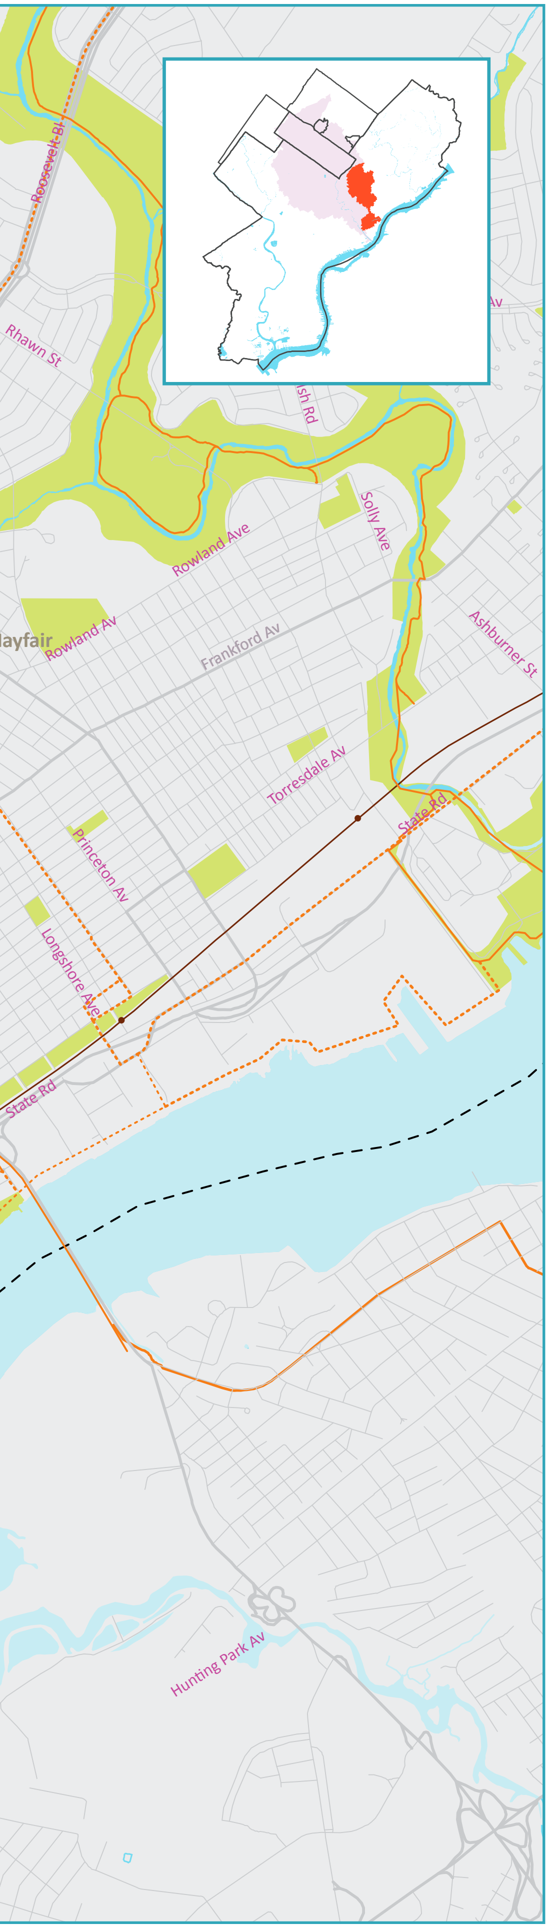
MLK High School becomes a center of activity for environmental education. Stormwater wetlands reveal the original Wingohocking Creek floodplain after rain events. Pervious pavement, street trees and green roofs divert rainfall from the sewers and make for a lush, walkable neighborhood.



Urban Trail Connections

RECREATION PROJECT

Utilizing a defunct rail corridor, an urban trail is being proposed that would connect this area to the Delaware River and the East Coast Greenway and with northwest Philadelphia communities like Germantown and Mt. Airy.



Wakeling/ Old Frankford

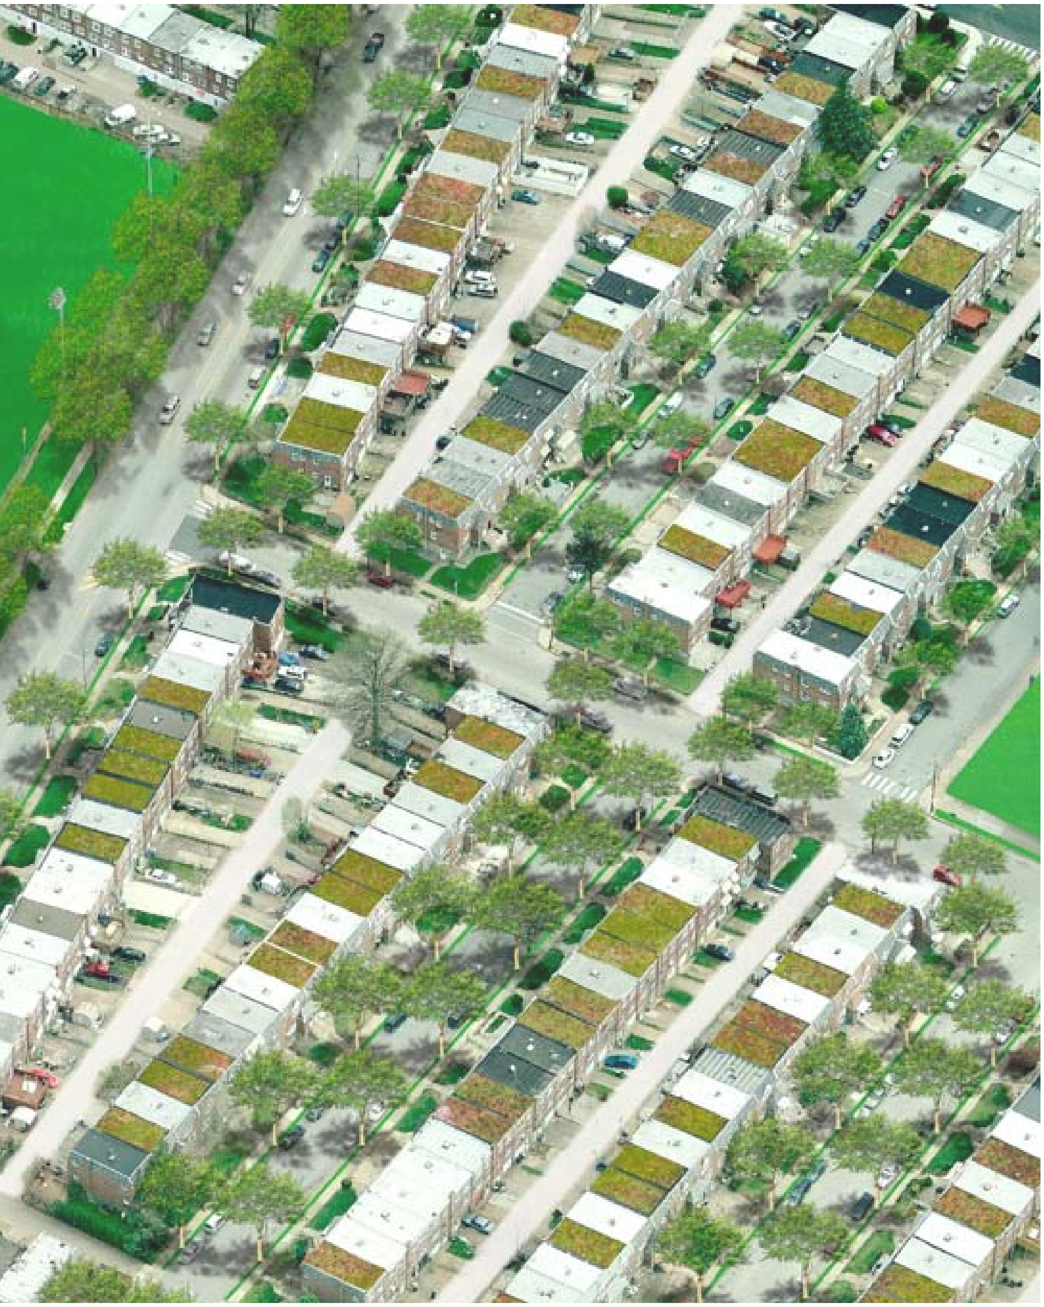
sub-watershed

The Wakeling/Old Frankford sub-watershed, historically connected to the TTF watershed, once contained Wakeling Creek, a tributary to Frankford Creek. This tributary has since been converted into a sewer, and the stormwater that used to slowly absorb into the watershed now drains away quickly over pavement and through sewer mains to the remnant of Frankford Creek where it meets the Delaware River. Today, the acres of impervious surfaces covering this area—buildings, streets and pavement—in addition to too few trees and large open spaces, not only keeps water from infiltrating locally to support a healthy watershed, but also demonstrates the visual impact of poor watershed practices. Here, the focus will need to be on promoting healthier practices, such as green roofs and cisterns, green streets, more pervious cover, less water use and less litter.

Top left*: Sprawling and paved commercial development abuts dense residential neighborhoods near Roosevelt Boulevard. Just behind the Home Depot in the photo, a trail is proposed that would connect the Delaware River—and the East Coast Greenway—with northwest Philadelphia.*

Top right*: The sub-watershed is characterized by dense residential neighborhoods with little access to community parks and open space and not enough tree cover.*

Bottom*: The confluence of the historic Frankford Creek with the Delaware River. Here, the entire TTF watershed used to drain into the Delaware. Now, this channelized remnant is surrounded by acres of paving and mostly industrial uses (and the historic Frankford Arsenal, at right) and drains only the Wakeling sub watershed.*



In dense urban sub-watersheds like the Wakeling/Old Frankford community, efforts to maintain a healthy watershed will focus on upland practices like green roofs, green streets and increased permeability. Community open spaces and parks like Tarken Playground can also manage large amounts of stormwater and further increase their value to the community with stormwater gardens.
